Combinatorial maps are defined in any dimension. A 0D combinatorial map is a set of isolated darts describing isolated vertices. A 1D combinatorial map describes paths or cycles of darts corresponding to paths or cycles of edges, and equivalent to double linked lists. The most useful cases are 2D and 3D combinatorial maps. Since 2D combinatorial maps are equivalent to halfedge data structure, notions are illustrated in 3D in the following examples to help the reader understand this specific case. But it is important to keep in mind that one main interest of combinatorial maps is their generic definition in any dimension, and that everything presented in this manual is valid in any dimension.

A *d*D combinatorial map is useful when you want to describe *d*D objects and the adjacency relations between these objects, and you want to be able to efficiency traverse these objects by using the different relations. For example, we can use a 3D combinatorial map to describe a 3D segmented image: each 3-cell corresponds to a region in the image and each 2-cell corresponds to a contact area between two regions.

A combinatorial map does not contain any geometrical information. However, this package allows to associate any information to the cells of the combinatorial map. A specific information, which is often used in practice, consists in adding linear geometry to a combinatorial map by associating a point to each vertex of the map[2]: this is the object of the *Linear_cell_complex* package. This package can for example be useful to describe 3D buildings as set of walls, rooms, doors and windows (both combinatorial and geometrical descriptions) and all the adjacency relations between these elements allowing for example to move a camera in a given building from rooms to rooms by traversing doors.

[2]When an object has a point associated to each vertex, each edge is thus a straight line segment, which explains the name ”linear geometry”.

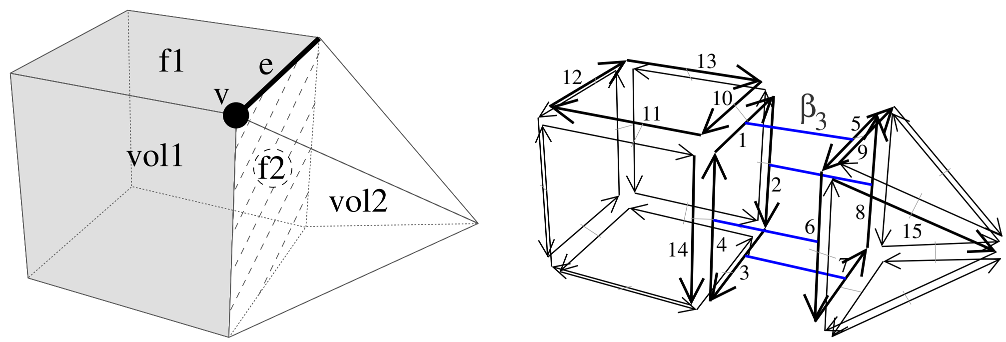

Figure 27.4: Example of a 3D combinatorial map. **Left**: A 3D object made of two volumes adjacent along facet *f2*. **Right**: The corresponding 3D combinatorial map. Darts are drawn with arrows, sometimes numbered. Two darts linked by β_1 are drawn consecutively (for example $\beta_1(10)$=11), and two darts linked by β_2 are drawn parallel, in reverse orientations, with a little gray segment joining them (for example $\beta_2(1)$=10). β_3 pointers are represented by blue segments (for example $\beta_3(1)$=5).

27.2 Data Structure Presentation

In this section, we describe *d*D combinatorial maps in terms of data structure and operations. Mathematical definitions are provided in Section 27.7, and a package description is given in Section 27.3.

27.2.1 Combinatorial Map and Darts

A *d*D combinatorial map is a set of darts *D*. A dart *d0* is an element that can be *linked* with *d*+1 darts by pointers called β_i, with $0 \leq i \leq d$. Dart *d0* is said *i-free* when $\beta_i(d0)=\varnothing$. Each β_i, for $2 \leq i \leq d$, is its own inverse, i.e., if dart *d0* is not *i*-free, then $\beta_i(\beta_i(d0))=d0$. This is different for β_0 and β_1: β_0 is the inverse of β_1, i.e., if darts *d1* and *d2* are such that $\beta_1(d1)=d2$, then $\beta_0(d2)=d1$. Given dart *d1*, if there is no dart *d2* such that $\beta_1(d2)=d1$, then $\beta_0(d1)=\varnothing$. $\varnothing$ is a constant, which does not belong to the set of darts *D* of the combinatorial map. However, by definition $\varnothing$ is linked with itself for all β_is: $\forall i$, $0 \leq i \leq d$, $\beta_i(\varnothing)=\varnothing$.

A combinatorial map is *without i-boundary* if there is no *i*-free dart, and it is *without boundary* if it is without *i*-boundary for all dimensions $1 \leq i \leq d$.

We show in Figure 27.4 a 3D object and the corresponding 3D combinatorial map. This map has 40 darts represented by arrows, some darts being numbered. In this combinatorial map, we have for example $\beta_1(1)$=2, $\beta_2(1)$=10, and $\beta_3(1)$=5. This combinatorial map is without 1-boundary and 2-boundary, but has some 3-boundary, because some darts are 3-free, for example $\beta_3(10)=\varnothing$ and $\beta_3(12)=\varnothing$.

27.2.2 Cells as Sets of Darts

A cell in a *d*D combinatorial map is implicitly represented by a subset of darts. In this section, we will see how to retrieve all cells containing a given dart, how to retrieve all darts belonging to a cell containing a given dart, and how incidence and adjacency relations are defined in terms of darts.

The first important property of a combinatorial map is that each dart belongs to an *i*-cell, $\forall i$, $0 \leq i \leq d$. For example in 3D, a dart belongs to a vertex, an edge, a facet, and a volume. This means that a 3D combinatorial map containing an isolated dart contains exactly one vertex, one edge, one facet and one volume.

The second important property is that cells of a combinatorial map correspond to specific *orbits*. Given a set $S \subseteq \{\beta_1,\ldots,\beta_d\}$ and a dart *d0*, the *orbit* $\langle S\rangle(d0)$ is the set of darts that can be reached from *d0* by following any combination of any β_i's in S and their inverses (to simplify notations, we can use for example $\langle\beta_1,\beta_4\rangle(d0)$ to denote $\langle S\rangle(d0)$ with $S=\{\beta_1,\beta_4\}$).

Given a dart *d0*, in general, $\beta_i(d0)$ (with $1\leq i\leq$d) belongs to the same cells as *d0*, only the *i*-cell and 0-cell are different. There are two exceptions: (1) if *d0* is *i*-free, then $\beta_i(d0)=\varnothing$; (2) if $\beta_i(d0)$ belongs to the same *i*-cell as *d0* (case of multi-incidence). For example if an edge is an isolated loop, it is incident twice to the same vertex, then given a dart *d0* belonging to this edge, $\beta_1(d0)$ goes to the next edge, which is in fact the same edge.

Since $\beta_i(d0)$ (with $1\leq i\leq d$) allows to change the current *i*-cell, all the darts that can be reached from *d0* by using any combination of β_j's, $\forall j$, $1\leq j\leq d$ and $j\neq i$ and their inverse are contained in the same *i*-cell as *d0*. The *i*-cell containing *d0* is defined in terms of orbit by $\langle\beta_1,\ldots,\beta_{i-1},\beta_{i+1},\ldots,\beta_d\rangle(d0)$.

There is a special case for vertices. Given a dart *d0*, the set of darts contained in the same vertex as *d0* are the darts that can be reached from *d0* by using any combination of $\beta_i\circ\beta_j$, $\forall i,j$, $1\leq i<j\leq d$, and their inverse. The 0-cell containing *d0* is defined in terms of orbit by $\langle\{\beta_i\circ\beta_j|\forall i,j\text{: } 1\leq i<j\leq d\}\rangle(d0)$.

Orbit $\langle\beta_1,\ldots,\beta_d\rangle(d0)$ is the *connected component* containing dart *d0*. A combinatorial map is *connected* if this set is equal to the set of all the darts of the combinatorial map.

A last important property of cells is that for all dimensions *i* the set of *i*-cells forms a partition of the set of darts *D*, i.e. for any *i*, the union of the sets of darts of all the *i*-cells is equal to *D*, and the sets of darts of two different *i*-cells are disjoint.

Let us give some examples of cells in 3D, for the 3D combinatorial map of Figure 27.4:

- All the darts belonging to the same edge can be obtained by any combination of β_2 and β_3: for example edge *e* of the object corresponds in the combinatorial map to the set of darts {1,5,9,10}. Given any dart belonging to this edge, we retrieve all the other darts by, for example, a breadth-first traversal. In terms of orbits, this 1-cell corresponds to $\langle\beta_2,\beta_3\rangle(1)$.
- All the darts belonging to the same facet can be obtained by any combination of β_1 and β_3: for example facet *f2* corresponds in the combinatorial map to the set of darts {1,2,3,4,5,6,7,8}. Facet *f1* corresponds to the set of darts {10,11,12,13}. Note that these last darts are 3-free since there is no other volume sharing this facet. In terms of orbits, *f2* corresponds to $\langle\beta_1,\beta_3\rangle(1)$ and *f1* corresponds to $\langle\beta_1,\beta_3\rangle(10)$.
- All the darts belonging to the same volume can be obtained by any combination of β_1 and β_2: for example volume *vol1* corresponds in the combinatorial map to the set of the twenty-four darts representing the cube. In terms of orbits, *vol1* corresponds to $\langle\beta_1,\beta_2\rangle(1)$.
- All the darts belonging to the same vertex can be obtained by any combination of $\beta_1\circ\beta_2$, $\beta_1\circ\beta_3$ and $\beta_2\circ\beta_3$ and their inverse functions. In our example, vertex *v* of the object corresponds in the combinatorial map to the set of darts {1,6,9,11,14,15}. Starting from dart 1, we obtain for example dart $14=(\beta_1\circ\beta_2)^{-1}(1)=\beta_2\circ\beta_0(1)$, dart $11=\beta_1\circ\beta_2(1)$, and dart $9=\beta_2\circ\beta_3(1)$. Intuitively, the set of darts corresponding to a vertex contains all the darts represented by arrows starting from this vertex. In terms of orbits, *v* corresponds to $\langle\beta_1\circ\beta_2,\ \beta_1\circ\beta_3,\ \beta_2\circ\beta_3\rangle(1)$.

Using this definition of cells as sets of darts, we can retrieve all the incidence and adjacency relations between the cells of the subdivision in a combinatorial map. Two cells are *incident* if the intersection of their two sets of darts is non empty (whatever the dimension of the two cells). Two *i*-cells *c1* and *c2*, $1\leq i\leq d$, are *adjacent* if there is $d1\in c1$ and $d2\in c2$ such that $d1=\beta_i(d2)$ (or $d2=\beta_i(d1)$ for i=1).

In the example of Figure 27.4, vertex *v* and edge *e* are incident since the intersection of the two corresponding sets of darts is $\{1,9\}\neq\emptyset$. Vertex *v* is incident to facet *f2* since the intersection of the two corresponding sets of darts is $\{1,6\}\neq\emptyset$. Edge e and facet $f1$ are incident since the intersection of the two corresponding sets of darts is $\{10\}\neq\emptyset$. Finally, facets $f1$ and $f2$ are adjacent because $10\in f1$, $1\in f2$ and $10=\beta_2(1)$.

We can consider i-cells in a dimension d' with $i\leq d'\leq d$. The idea is to consider the i-cells as if the combinatorial map was in d' dimension. For that, we only take into account the β_js for $j\leq d'$. The i-cell containing $d0$ in dimension d' is the orbit $\langle\beta_1,\ldots,\beta_{i-1},\beta_{i+1},\ldots,\beta_{d'}\rangle(d0)$, and the 0-cell is the orbit $\langle\{\beta_i\circ\beta_j|\forall i,j\colon 2\leq i<j\leq d'\}\rangle(d0)$. By default, i-cells are considered in dimension d, the dimension of the combinatorial map.

In the example of Figure 27.4, the 2-cell containing dart 1 is facet $f2$ which is the set of darts $\{1,2,3,4,5,6,7,8\}$. If we consider the same 2-cell in dimension 2, we obtain the set of darts $\{1,2,3,4\}$. Intuitively we "forget" β_3 and we obtain the set of darts of the facet containing dart 1 restricted to the volume containing this dart.

27.2.3 How to Associate Information to Cells

Combinatorial maps only describe the cells of the subdvision, and all the incidence and adjacency relations between these cells. This is not enough for many applications which need to associate *information* to cells. This can be geometric or non-geometric information, such as 3D points associated to vertices, the edge length associated to edges, or a color or normal to a facet.

To answer this need, a combinatorial map allows to create *attributes* which are able to store any information, and to associate attributes to cells of the combinatorial map. We denote i-attributes for the attributes associated with i-cells. Attributes may exist for only some of the dimensions, and if they exist for dimension i, they do not necessarily exist for each of the i-cells. More precisely, i-attributes are associated to i-cells by an injection:

- two different i-cells are associated to two different i-attributes;
- an i-cell may have no associated i-attribute.

Since i-cells are not explicitely represented in combinatorial maps, the association between i-cells and i-attributes is transferred to darts: if attribute a is associated to i-cell c, all the darts belonging to c are associated to a.

We can see two examples of combinatorial maps having some attributes in Figure 27.5. In the first example (Left), a 2D combinatorial map has 1-attributes containing a float, for example corresponding to the length of the associated 1-cell, and 2-attributes containing a color in RGB format. In the second example (Right), a 3D combinatorial map has 2-attributes containing a color in RGB format.

27.2.4 Combinatorial Map Properties

There are some conditions that a combinatorial map must satisfy to be valid. Some of them have already been given about the β pointers (see Section 27.2.1) and about the association between darts and attributes (see Section 27.2.3).

There is an additional condition related to the type of represented objects, which are *quasi-manifold* orientable dD objects. A dD quasi-manifold is an object obtained by taking some isolated d-cells, and allowing to glue d-cells along *(d-1)*-cells. It is orientable if it is possible to embed it in the Euclidean space and to define a global "left" and "right" direction in each point of the embedded object. In 2D, quasi-manifolds are manifolds, but this is no longer true in higher dimension as we can see in the example presented in Figure 27.6. In this example, the object to the right is not a manifold since the neighborhood of the point p in the object is not homeomorphic[3] to a 3D ball.

[3]Intuitively, two objects are homeomorphic if each object can be continuously deformed into the second one. In such a case, the two objects have exactly the same topological properties.

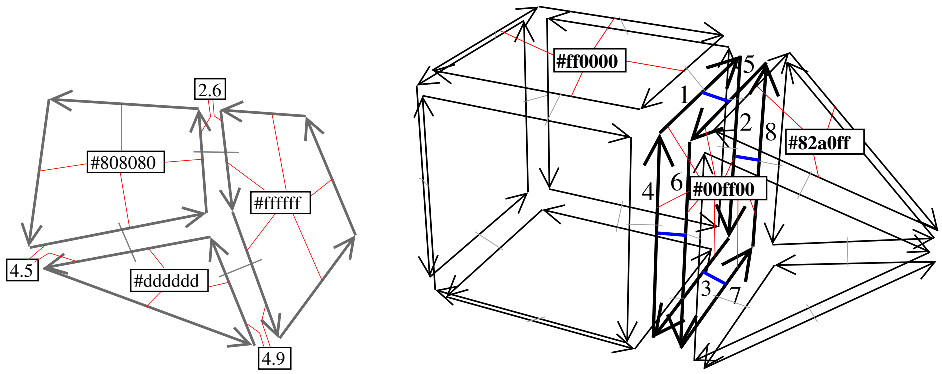

Figure 27.5: Example of combinatorial maps with attributes. Attributes are represented by black rectangles containing an information, and association between darts and attributes are represented by small lines. **Left**: A 2D combinatorial map with 1-attributes containing a double, for example corresponding to the length of the 1-cell, and 2-attributes containing a color in RGB format. Only three edges of the combinatorial map, among the nine, are associated to a 1-attribute. All the 2-cells are associated to a 2-attribute. **Right**: A 3D combinatorial map with 2-attributes containing a color in RGB format. Only three 2-cells of the combinatorial map, among the ten, are associated to a 2-attribute.

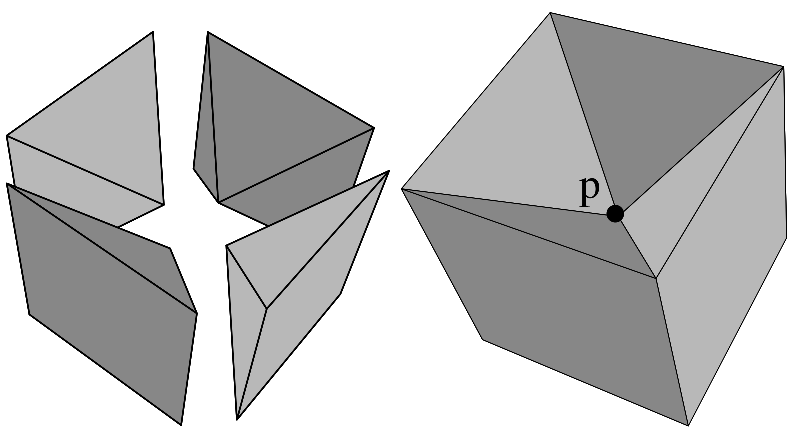

Figure 27.6: Example of a 3D quasi-manifold which is not a manifold. The object to the right is made of the four pyramids (shown to the left) glued together along facets, thus it is a quasi-manifold.

Combinatorial maps can only represent quasi-manifolds due to the definition of β pointers. As we have seen in Section 27.2.2, $\beta_i(d0)$ (with $1 \le i \le d$) belongs to the same cells as *d0*, only the *i*-cell and 0-cell are different. In other words, β_i links two *i*-cells that share a common *(i-1)*-cell: it is not possible to link more than two *i*-cells along a same *(i-1)*-cell. For this reason, it is not possible to describe non quasi-manifold objects as those shown in Figure 27.7 by combinatorial maps.

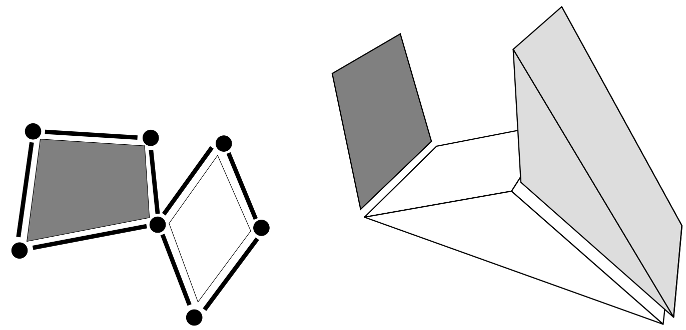

Figure 27.7: Three examples of non quasi-manifold objects. **Left**: A 2D object which is not a quasi-manifold since the two 2-cells share a common vertex but no common 1-cell. **Middle**: A 3D object which is not a quasi-manifold since is it not only composed by 3D cells glued together (there is an isolated 2-cell in dark gray). **Right**: A 3D object which is not a quasi-manifold since the two 3-cells share a common edge but no common 2-cell.

Due to this additional condition, any objects can not be represented by a combinatorial map but only orientable quasi-manifolds. We need to study now the inverse relation. Does any set of darts linked together by β_i's, with $0 \le i \le d$ correspond to a quasi-manifold? As we can see in Figure 27.8, the answer is no.

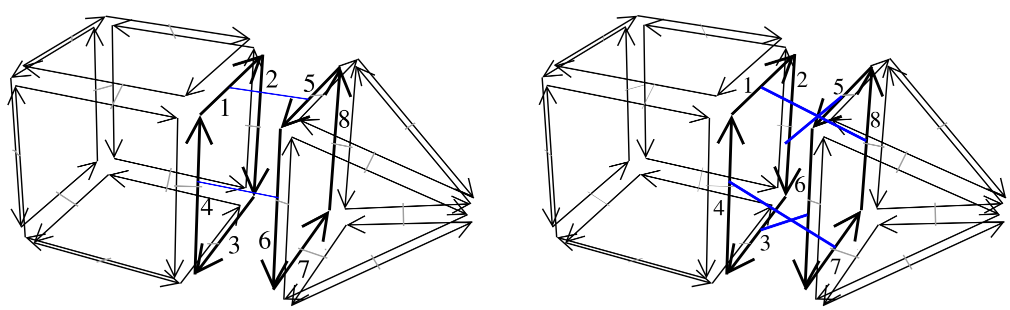

Figure 27.8: Two examples of darts linked together by some β_0, β_1, β_2 and β_3 which does not represent a 3D quasi-manifold, and thus which are not 3D combinatorial map. **Left**: In this example, all the darts are 3-free except $\beta_3(1)=5$ and $\beta_3(4)=6$ (and vice-versa). **Right**: In this example, darts linked by β_3 are not in the same order in both 3-cells.

In the first example (Left), there are two 3-cells (one to the left for the cube, a second to the right for the pyramid) which are "partially adjacent" along one 2-cell. Indeed, only two darts of the 2-cell are linked by β_3. We have $\beta_3(1)=5$ and $\beta_3(4)=6$ (and reciprocally). This configuration is not possible in a quasi-manifold: two *d*-cells are always glue along an "entire" *(d-1)*-cells.

But as we can see in the second example (Right), the condition that all the darts of the cell are linked in not sufficient. Indeed, in this example, all the darts of the 2-cell between the cube and the pyramid are linked together by β_3. However, this configuration does not correspond to an orientable 3D quasi-manifold. Indeed, the operation of gluing two *d*-cells along one *(d-1)*-cell must preserve the initial *(d-1)*-cell.

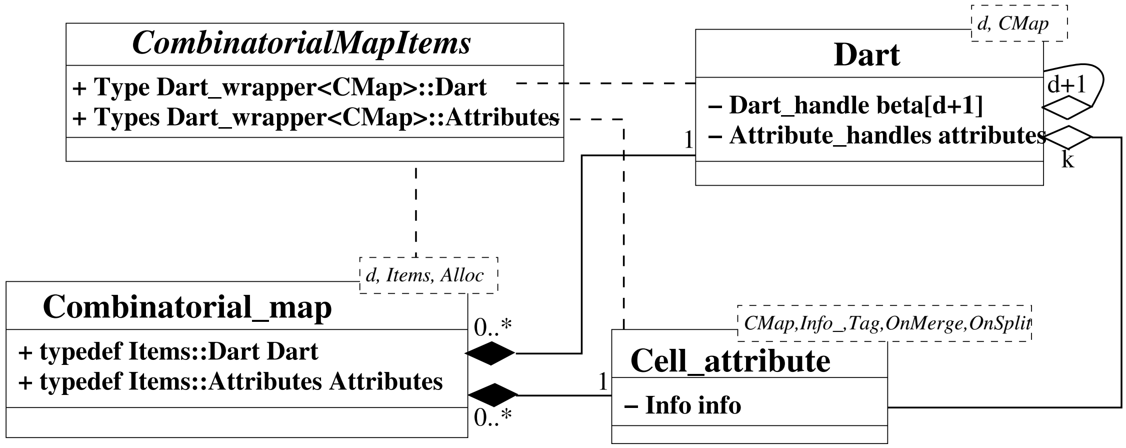

Figure 27.9: UML diagram of the main classes of the package. k is the number of non void attributes.

To avoid these two kinds of configurations, conditions are added on β pointers compositions (see Section 27.7, condition (4) of the definition of combinatorial maps). Intuitively these conditions say that if two darts are linked by β_i, then all the required darts are linked by β_i two by two in such a way that neighborhood relations are preserved.

We say that a combinatorial map is *valid* if it satisfies all the conditions on β pointers and on association between darts and attributes. High level operations provided on combinatorial maps ensure that these conditions are always satisfied. Sometimes, it can be useful to use low level operations in a specific algorithm, for example to modify locally a combinatorial map in a really fast way. In such a case, additional operations may be needed to restore these validity conditions.

27.3 Software Design

The diagram in Figure 27.9 shows the different classes of the package. *Combinatorial_map* is the main class (see Section 27.3.1). It allows to manage darts (see Section 27.3.3) and attributes (see Section 27.3.4). Users can customize a combinatorial map thanks to an items class (see Section 27.3.2), which defines the dart type and the attribute types. These types may be different for different dimensions, and they may also be void. The darts and attributes are accessed through *handles*. A handle is a model of the *Handle* concept, thus supporting the two dereference operators *operator** and *operator->*.

27.3.1 Combinatorial Maps

The class *Combinatorial_map<d,Items,Alloc>* is a model of the *CombinatorialMap* concept. It has three template parameters standing for the dimension of the combinatorial map (an *unsigned int*), an items class (a model of the *CombinatorialMapItems* concept), and an allocator which must be a model of the allocator concept of the STL. Default classes are provided for the items and the allocator classes.

The main role of the class *Combinatorial_map* is the storage and the management of darts. It allows to create or remove an isolated dart from the combinatorial map. The *Dart_handle* type defines a handle to the type of used darts (given in the items class). *Combinatorial_map* provides several *ranges* which allow to iterate over specific subsets of darts of the combinatorial map (see Section 27.4.1). It also defines several methods to link and to unlink darts by β_is (see Section 27.5.1). We said that a dart *d0* is *i*-free if $\beta_i(d0)=\varnothing$. The ∅

constant is represented in the class *Combinatorial_map* through a *static const Dart_handle* called *null_dart_handle*. Finally, some high level operations are defined as global functions taking a *Combinatorial_map* as argument (see Section 27.5.2)

The second role of the class *Combinatorial_map* is the storage and the management of attributes. It allows to create or remove an attribute, and provides methods to associate attributes and cells. A range is defined for each *i*-attribute allowing to iterate over all the *i*-attributes of the combinatorial map. Finally, *Combinatorial_map* defines several types allowing to manage the attributes. We can use *Combinatorial_map::Attribute_handle<i>::type* for a handle to the *i*-attributes (and the const version *Combinatorial_map::Attribute_const_handle<i>::type*) and *Combinatorial_map::Attribute_type<i>::type* for the type of the *i*-attributes.

27.3.2 Combinatorial Map Items

The *CombinatorialMapItems* concept defines dart and attribute types of a combinatorial map. It contains one inner class named *Dart_wrapper*, having one template parameter, *CMap*, a model of *CombinatorialMap* concept. The *Dart_wrapper<CMap>* class provides two local types: *Dart* which must be a model of the *Dart* concept, and *Attributes* which defines the attributes and their types.

The *Attributes* tuple must contain at most d+1 types (one for each possible cell dimension of the combinatorial map). Each type of the tuple must be either a model of the *CellAttribute* concept or *void*. The first type corresponds to 0-attributes, the second to 1-attributes and so on. If the i^{th} type in the tuple is *void*, *(i-1)*-attributes are disabled: we say that *(i-1)*-attributes are *void*. Otherwise, *(i-1)*-attributes are enabled and have the given type: we say *(i-1)*-attributes are *non void*. If the size of the tuple is k, with $k<dimension+1$, $\forall i$: $k \leq i \leq$dimension, i-attributes are void.

The class *Combinatorial_map_min_items<d>* is a model of the *CombinatorialMapItems* concept which can be used for default behaviors. It defines *CGAL::Dart<d,CMap>* as type of dart, and *Attributes* as empty tuple.

27.3.3 Darts

The class *Dart<d,CMap>*, a model of the *Dart* concept, defines a dD dart. It has two template parameters standing for the dimension of the combinatorial map, and a model of the *CombinatorialMap* concept, which provides the two types *Dart_handle* and *Dart_const_handle*.

Each instance *d0* of *Dart<d,CMap>* stores the β_i pointers in an array of d+1 *Dart_handle* (because we describe also the β_0 pointer). It also stores the attributes associated to this dart in a tuple of *CMap::Attribute_handle<i>::type*, one for each non void *i*-attribute.

Methods are defined allowing to retrieve each β_i and each associated *i*-attribute of *d0*, and allowing to test if *d0* dart is *i*-free.

Note that the use of the *Dart* class is not hard wired in the combinatorial map class. Users can provide their own model of the *Dart* concept, and pass it to the combinatorial map with the help of a custom item class.

27.3.4 Cell Attributes

The class *Cell_attribute<CMap,Info_,Tag,OnMerge,OnSplit>*, a model of the *CellAttribute* concept, represents an attribute associated with a cell of a combinatorial map. The template parameter *CMap* must be a model of the *CombinatorialMap* concept. The attribute stores a handle to one dart of its associated cell when the template parameter *Tag* is *Tag_true*. *Info_* is the type of information stored in the attribute. It may be *void*. *OnMerge* and *OnSplit* must be either *Null_functor*, or models of the *Binary Function* concept having two references to a model of *CellAttribute* as type of both parameters and *void* as return type. There are two default parameters for *OnMerge* and *OnSplit*, which are *Null_functor*, a default parameter for *Tag* which is *Tag_true*, and a default parameter for *Info_* which is *void*.

If *Info_* is different from *void*, the class *Cell_attribute* contains two methods *info()* returning the information contained in the attribute (const and non const version). The information is returned by reference, thus the non const version allows the modification of the information.

Two attributes are merged when their corresponding cells are merged into one cell during some operation. In this case, the functor *OnMerge* is called, unless it is equal to *Null_functor*. This functor allows the user to define its own custom behavior when two attributes are merged (for example if the information is a color, we can compute the average color of the two initial attributes, and affect this value to the first attribute, see example in Section 27.6.4). Similarly, the functor *OnSplit* is called when one attribute is split in two, because its corresponding cell is split in two during some operation, unless it is equal to *Null_functor*. In any high level operation, *OnMerge* is called before to start the operation (i.e. before modifying the combinatorial map), and *OnSplit* is called when the operation is finished (i.e. after all the modifications were made).

What we said for the dart also holds for the cell attribute. The combinatorial map can be used with any user defined model of the *CellAttribute* concept.

27.3.5 Example of Combinatorial Map Definition

Here comes an example of two combinatorial map definitions. The first case *Example_cmap4* defines a 4D combinatorial map which uses all the default values (*Dart* and *Combinatorial_map_min_items*). The second example *Example_custom_cmap3* uses its own model of the *CombinatorialMapItems* concept. In this model, the type of dart is *Dart<3,CMap>*, thus a dart is in 3D, and an attribute containing an integer is associated to edges.

```
typedef CGAL::Combinatorial_map<4> Example_cmap4;

struct Example_items_3
{
   template <class CMap>
   struct Dart_wrapper
   {
     typedef CGAL::Dart<3, CMap> Dart;
     typedef CGAL::Cell_attribute<CMap, int> Edge_attrib;
     typedef CGAL::cpp0x::tuple<void,Edge_attrib> Attributes;
   };
};
typedef CGAL::Combinatorial_map<3, Example_items_3> Example_custom_cmap3;
```

27.4 Iteration and Creation Operations

An important operation in combinatorial maps consists in iterating over specific subsets of darts or over attributes. For that, several *ranges* are offered (see Section 27.4.1). A range is a model of the *Range* concept, thus supporting the two methods *begin()* and *end()* allowing to iterate over all the elements in the range. Several global functions allow to create specific configurations of darts into a combinatorial map (see Section 27.4.2). Darts can be marked during operations, for example when performing a breadth-first search traversal, thanks to

Boolean marks (see Sections 27.4.3). In the following, we denote by *dh0*, *dh1*, *dh2* the dart handles for the darts *d0*, *d1*, *d2*, respectively. That is *d0 == *dh0*.

27.4.1 Iterating over Orbits, Cells, and Attributes

The combinatorial map offers iterators to traverse the darts of a specific orbit, to traverse all darts of one cell, or one dart per cell, and to traverse all *i*-attributes.

Instead of the *begin()/end()* member function pair as we know it from STL containers, and from most CGAL data structures, the combinatorial map defines range classes which are all models of the *Range* concept.

There are three different categories of dart range classes:

- *Dart_range*: range of all the darts of a combinatorial map;
- *Dart_of_orbit_range<Beta...>*: range of all the darts of the orbit $\langle$*Beta...*$\rangle$(*d0*) for a given *d0*. *Beta...* is a sequence of integers $i_1,\ldots,i_k$, each $i_j \in \{0,\ldots,d\}$. These integers must satisfy: $i_1 < i_2 < \ldots < i_k$, and ($i_1 \neq 0$ or $i_2 \neq 1$) (for example *Dart_of_orbit_range<1,2>* for the orbit $\langle\beta_1,\beta_2\rangle$(*d0*));
- *Dart_of_cell_range<i,dim>*: range of all the darts of the *i*-cell containing a given dart. The *i*-cell is considered in dimension *dim* (with $0 \leq dim \leq d$, *dim*=*d* by default), with $0 \leq i \leq dim+1$. If *i=dim+1*, *Dart_of_cell_range<i,dim>* is the range of all the darts of the connected component containing a given dart.

There are also two different classes of ranges containing one dart per *i*-cell. Note that in these classes, the dart of each *i*-cell can be any dart of the cell. Moreover, each *i*-cell (and *j*-cell in the second case) is considered in dimension *dim* (with $0 \leq dim \leq d$, *dim*=*d* by default).

- *One_dart_per_cell_range<i,dim>*: range containing one dart of each *i*-cell of the combinatorial map, $0 \leq i \leq dim+1$ (for example *One_dart_per_cell_range<2>* for the range of one dart per 2-cell of the combinatorial map);
- *One_dart_per_incident_cell_range<i,j,dim>*: range containing one dart of each *i*-cell incident to the *j*-cell containing a given dart, with $0 \leq i \leq dim+1$ and $0 \leq j \leq dim+1$ (for example *One_dart_per_incident_cell_range<0,3>* for the range of one dart per vertex of the volume incident to the starting dart). If *i=j*, the range contains only the given dart.

The iterators of the *Dart_range* are bidirectional iterators, while the iterators of the other four ranges are forward iterators. The value type of all these iterators is *Dart* thus all these iterators can be directly used as *Dart_handle*.

Additionally, there is a range over non void *i*-attributes: *Attribute_range<i>::type*, having a bidirectional iterator with value type *Attribute_type<i>::type*.

For each range, there is an associated const range, a model of the *ConstRange* concept. You can find some examples of ranges in Section 27.6.1.

27.4.2 Construction Operations

Several global functions allow to create specific configurations of darts into a combinatorial map. Existing darts in the combinatorial map are not modified. Note that the dimension of the combinatorial map must be large enough: darts must contain all the β pointers used by the operation. All these functions take an instance of *CombinatorialMap* as first parameter (called *cm*) and return a *Dart_handle* to a new dart created during the operation.

- *make_edge<CMap>(cm)*: creates an isolated edge (two darts linked by β_2); dimension must be greater or equal than two;
- *make_combinatorial_polygon<CMap>(cm,lg)*: creates an isolated combinatorial polygon of length *lg* (*lg* darts linked by β_1), for *lg>0*; dimension must be greater or equal than one;
- *make_combinatorial_tetrahedron<CMap>(cm)*: creates an isolated combinatorial tetrahedron (four combinatorial triangles linked together by β_2); dimension must be greater or equal than two;
- *make_combinatorial_hexahedron<CMap>(cm)*: creates an isolated combinatorial hexahedron (six combinatorial quadrangles linked together by β_2); dimension must be greater or equal than two.

advanced

27.4.3 Boolean Marks

It is often necessary to mark darts, for example to retrieve in *O(1)* if a given dart was already processed during a specific algorithm, for example, iteration over a given range. Users can also mark specific parts of a combinatorial map (for example mark all the darts belonging to objects having specific semantics). To answer these needs, a *CombinatorialMap* has a certain number of Boolean marks (fixed by the constant *NB_MARKS*). When one wants to use a Boolean mark, the following methods are available (with *cm* an instance of a combinatorial map):

- get a new free mark: *int m = cm.get_new_mark()* (return -1 if no mark is available);
- set mark *m* for a given dart *d0*: *cm.mark(dh0,m)*;
- unset mark *m* for a given dart *d0*: *cm.unmark(dh0,m)*;
- test if a given dart *d0* is marked for *m*: *cm.is_marked(dh0,m)*;
- unmark all the darts of *cm* for *m*: *cm.unmark_all(m)*;
- negate mark *m* of all the darts of *cm*: *cm.negate_mark(m)*. All the marked darts become unmarked and all the unmarked darts become marked;
- free mark *m*: *cm.free_mark(m)*. This method unmarks all the darts of *cm* for *m* before freeing it.

It is important to free a mark when it is no longer needed, otherwise you may at some point run out of marks.

The following example illustrates how to use marks. Two combinatorial tetrahedra are created and 3-sewn (see Section 27.5.1 for a detailed description of the sew operation). Then a mark is reserved and used to mark all the darts belonging to the first combinatorial tetrahedron. Finally, these tetrahedron are merged. The marks allow us to know which darts come from the first and second tetrahedron.

```
#include <CGAL/Combinatorial_map.h>
#include <CGAL/Combinatorial_map_constructors.h>
#include <CGAL/Combinatorial_map_operations.h>
#include <iostream>
#include <cstdlib>

typedef CGAL::Combinatorial_map<3> CMap_3;
typedef CMap_3::Dart_handle Dart_handle;

int main()
```

```
{
  CMap_3 cm;

  // 1) Reserve a mark.
  int mark = cm.get_new_mark();
  if ( mark==-1 )
    {
      std::cerr<<"No more free mark, exit."<<std::endl;
      exit(-1);
    }

  // 2) Create two tetrahedra.
  Dart_handle dh1 = make_combinatorial_tetrahedron(cm);
  Dart_handle dh2 = make_combinatorial_tetrahedron(cm);

  // 3) 3-sew them.
  cm.sew<3>(dh1, dh2);

  // 4) Mark the darts belonging to the first tetrahedron.
  for  (CMap_3::Dart_of_cell_range<3>::iterator
          it(cm.darts_of_cell<3>(dh1).begin()),
          itend(cm.darts_of_cell<3>(dh1).end()); it!=itend; ++it)
    cm.mark(it, mark);

  // 4) Remove the common 2-cell between the two cubes:
  // the two tetrahedra are merged.
  CGAL::remove_cell<CMap_3, 2>(cm, dh1);

  // 5) Thanks to the mark, we know which darts come from the first
   tetrahedron.
  unsigned int res=0;
  for (CMap_3::Dart_range::iterator it(cm.darts().begin()),
         itend(cm.darts().end()); it!=itend; ++it)
    {
      if ( cm.is_marked(it, mark) )
        ++res;
    }

  std::cout<<"Number of darts from the first tetrahedron:
   "<<res<<std::endl;
  cm.free_mark(mark);

  return EXIT_SUCCESS;
}
```

advanced

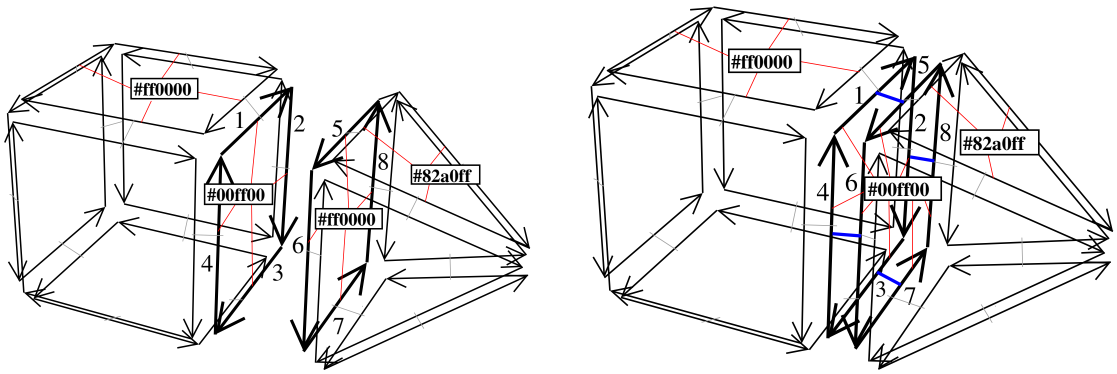

Figure 27.10: Example of 3-sew operation. **Left**: A 3D combinatorial map containing two volumes that are not connected, with 2-attributes. Each attribute contains a color in RGB format, and there are four 2-cells associated with attributes. Associations between darts and attributes are drawn with red segments. **Right**: The 3D combinatorial map obtained as result of *sew<3>(1,5)* (or *sew<3>(2,8)*, or *sew<3>(3,7)*, or *sew<3>(4,6)*). Darts (1,5), (2,8), (3,7) and (4,6) are linked together by β_3. The two 2-cells *c1*={1,2,3,4} and *c2*={5,6,7,8} are merged after the sew into the 2-cell {1,2,3,4,5,6,7,8}. We are in the case where the two attributes are non NULL, thus the first one is kept, and all the darts of *c2* are associated with the first attribute.

27.5 Modification Operations

Several operations allow to modify a given combinatorial map. There are two main categories of modification operations:

- Sew, link, unsew and unlink which modify some existing β pointers, without creating or removing darts (see Section 27.5.1);
- Removal and insertion of cells which modify both darts and β pointers (see Section 27.5.2).

27.5.1 Sewing Orbits and Linking Darts

The *CombinatorialMap* defines two groups of methods to modify the β pointers of existing darts.

- The *sew* and *unsew* methods iterate over two orbits in order to link or unlink specific darts two by two. Intuitively, a *sew<i>* operation glues two *i*-cells by identifying two of their *(i-1)*-cells (see example in Figure 27.10 where *sew<3>* is used to glue two 3-cells along one 2-cell). Reciprocally, a *unsew<i>* operation un-glues two *i*-cells which were glued along one of their *(i-1)*-cells. These methods guarantee that given a valid combinatorial map and a possible operation we obtain a valid combinatorial map as result of the operation.
- *advanced*

  The *link_beta* and *unlink_beta* methods only modify the pointer of two darts: the obtained combinatorial maps may be not valid. These operations can be useful to use low level operations in a specific algorithm, for example to modify locally a combinatorial map in a really fast way. In such a case, additional operations may be needed to restore the validity conditions.

  advanced

Linking two darts *d1* and *d2* by β_i, with $2 \leq i \leq d$ and $d1 \neq d2$, consists in modifying two β_i pointers such that $\beta_i(d1)=d2$ and $\beta_i(d2)=d1$. For i=1, the modification is $\beta_1(d1)=d2$ (and thus $\beta_0(d2)=d1$ by definition of β_0); in this case we can have $d1=d2$ (a dart linked with itself corresponds to an edge which is a loop).

Reciprocally, unlinking a given dart *d0* by β_i, with $2 \leq i \leq d$, consists in modifying two β_i pointers such that $\beta_i(\beta_i(d0))=\varnothing$ and $\beta_i(d0)=\varnothing$. For $i=1$, the modification is $\beta_1(d0)=\varnothing$ (and thus $\beta_0(\beta_1(d0))=\varnothing$ by definition of β_0). Note that is it possible to unlink a given dart for β_i only if it is not *i*-free.

The *sew<i>(dh1,dh2)* method consists mainly to link two by two several darts by β_i. This operation is possible only if there is a bijection f between all the darts of the orbit $D1=\langle\beta_1,\ldots,\beta_{i-2},\beta_{i+2},\ldots,\beta_d\rangle(d1)$ and $D2=\langle\beta_1,\ldots,\beta_{i-2},\beta_{i+2},\ldots,\beta_d\rangle(d2)$ satisfying: $f(d1)=d2$, and for all $e \in D1$, for all $j \in \{1,\ldots,i\text{-}2,i\text{+}2,\ldots,d\}$, $f(\beta_j(e))=\beta_j^{-1}(f(e))$. Intuitively, this condition ensures the validity of the combinatorial map by verifying that condition discussed in Section 27.2.4 will be satisfied after the operation. This condition can be tested by using the method *is_sewable<i>(dh1,dh2)*. For example, the function *is_sewable<i>* would return *false* if we tried to sew a triangular facet with a quad facet. Note that given two darts *d1* and *d2*, if there is such a bijection, it is uniquely defined. So giving the two darts as arguments of the *sew<i>* is enough to retrieve all the pairs of darts to link. If such a bijection exists, the *sew<i>(dh1,dh2)* operation consists only in linking by β_i each couple of darts *d3* and *d4* such that $d3=f(d4)$.

In addition, the sew operation updates the associations between darts and non void attributes in order to guarantee that all the darts belonging to a given cell are associated with the same attribute (which is a condition of combinatorial map validity). For each couple of *j*-cells *c1* and *c2* that are merged into one *j*-cell during the sew, we have to update the two associated attributes *attr1* and *attr2*. If both are NULL, there is nothing to do. If one is NULL and the other not, we only associate the non NULL attribute to all the darts of the resulting cell. When the two attributes are non NULL, we first apply functor *On_merge* on the two attributes *attr1* and *attr2* (see Section 27.3.4). Then, we associate the attribute *attr1* to all darts of the resulting *j*-cell. Finally, attribute *attr2* is removed from the combinatorial map.

Note that when the two attributes are non NULL, the first one is kept. But user can customize this behavior in order to update the information contained in the attributes according to its needs. For that, we can define a specific functor, and use it as template argument for *OnMerge* parameter of the *Cell_attribute* definition. This functor can for example copy the information of the second attribute in the information of the first one to make as if the second attribute is kept.

For example, in Figure 27.10, we want to 3-sew the two initial volumes. *sew<3>(1,5)* links by β_3 the pairs of darts (1,5), (2,8), (3,7) and (4,6), thus the combinatorial map obtained is valid. 2-attributes are updated so that all the darts belonging to the 2-cell containing dart 1 become associated to the same 2-attribute after the operation.

Similarly, *unsew<i>(dh0)* operation unlinks β_i for all the darts in the orbit $\langle\beta_1,\ldots,\beta_{i-2},\beta_{i+2},\ldots,\beta_d\rangle(d0)$, and thus guarantees to obtain a valid combinatorial map. This operation is possible for any non *i*-free dart.

As for the sew operations, attributes are updated to guarantee that two darts belonging to two different *j*-cells are associated to two different *j*-attributes. If the unsew operation splits a *j*-cell *c* in two *j*-cells *c1* and *c2*, and if *c* is associated to a *j*-attribute *attr1*, then this attribute is duplicated into *attr2*, and all the darts belonging to *c2* are associated with this new attribute. Finally, we call the functor *On_split* on the two attributes *attr1* and *attr2* (see Section 27.3.4).

Let us consider the combinatorial map given in Figure 27.10 (Right). If we call *unsew<3>(2)*, we obtain the combinatorial map in Figure 27.10 (Left) (except for the color of the attribute associated to the 2-cell {5,6,7,8} which would be `#00ff00`). The *unsew<3>* operation has duplicated the 2-attribute associated to the 2-cell {1,2,3,4,5,6,7,8} since this 2-cell is split in two after the unsew operation.

advanced

If one wants to modify a combinatorial map *manually*, it is possible to switch off the updating between darts and attributes by passing *false* as last argument of *sew<i>(dh1,dh2,update_attributes=true)* and *unsew<i>(dh0,update_attributes=true)*. In these cases, the combinatorial map obtained may be no longer valid due to incorrect associations between darts and attributes.

In Figure 27.10 (Left), if we call *sew<3>(1,5,false)*, the resulting combinatorial map is similar to the combinatorial map of Figure 27.10 (Right) (we have linked by β_3 the pairs of darts (1,5), (2,8), (3,7) and (4,6)), but associations between darts and attributes are not valid. Indeed, we have kept the four initial attributes and all the associations between darts and attributes, thus two darts belonging to the same 2-cell (for example darts 1 and 5) are associated with two different attributes.

We can also use the *link_beta<i>(dh1,dh2,update_attributes=true)* which links *d1* and *d2* by β_i without modifying the other links. Association between darts and attributes are only modified for darts *d1* and *d2*, and similarly as for *sew<i>*, this updating can be avoided by passing *false* as last argument of *link_beta<i>(dh1,dh2,update_attributes)*. Lastly, we can use *unlink_beta<i>(dh0)* to unlink *d0* for β_i. In this last case, there is no modification of association between darts and attributes.

In Figure 27.10 (Left), if we call *link_beta<3>(1,5)*, in the resulting combinatorial map we have now $\beta_3(1)$=5 and $\beta_3(5)$=1. This combinatorial map is no longer valid (for example dart 2 is 3-free and we should have $\beta_3(2)$=8).

advanced

27.5.2 Removal and Insertion Operations

The following high level operations are defined as global functions taking an instance *cm* of *CombinatorialMap* as first argument. All these methods ensure that given a valid combinatorial map and a possible operation, the modified combinatorial map is also valid.

The first one is *remove_cell<CMap,i>(cm,dh0)* which modifies the combinatorial map to remove the *i*-cell containing dart *d0*, with $0 \leq i \leq d$. This operation is possible if *i=d* or if the given *i*-cell is incident to at most two *(i+1)*-cells which can be tested thanks to *is_removable<CMap,i>(cm,dh0)*. If the removed *i*-cell was incident to two different *(i+1)*-cells, these two cells are merged into one *(i+1)*-cell. In this case, the *On_merge* functor is called if two *(i+1)*-attributes are associated to the two *(i+1)*-cells. If the *i*-cell is associated with a non void attribute, it is removed from the combinatorial map (see three examples on Figures 27.11, 27.13 and 27.14).

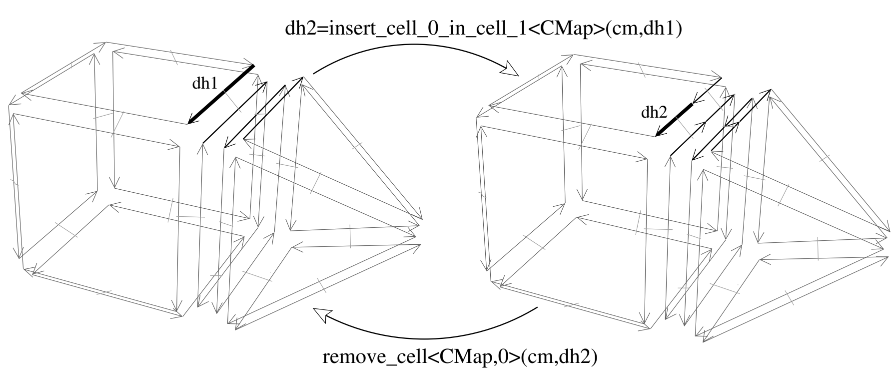

Figure 27.11: Example of *insert_cell_0_in_cell_1* and *remove_cell<0>* operations. **Left**: Initial combinatorial map. **Right**: After the insertion of a 0-cell in the 1-cell containing dart *d1*. Now if we remove the 0-cell containing dart *d2*, we obtain the initial combinatorial map.

The inverse operation of the removal is the insertion operation. Several versions exist, sharing a common principle. They consist in adding a new *i*-cell "inside" an existing *j*-cell, $i<j$, by splitting the *j*-cell into several *j*-cells. Contrary to *remove_cell<CMap,i>*, is it not possible to define a unique *insert_cell_i_in_cell_j<CMap,i,j>* function because parameters are different depending on *i* and *j*.

insert_cell_0_in_cell_1<CMap>(cm,dh0) adds a 0-cell in the 1-cell containing dart *d0*. The 1-cell is split in two. This operation is possible if *d0*$\in$*cm.darts()* (see example on Figure 27.11).

insert_cell_0_in_cell_2<CMap>(cm,dh0) adds a 0-cell in the 2-cell containing dart *d0*. The 2-cell is split in triangles, one for each initial edge of the facet. This operation is possible if *d0*$\in$*cm.darts()* (see example on Figure 27.12).

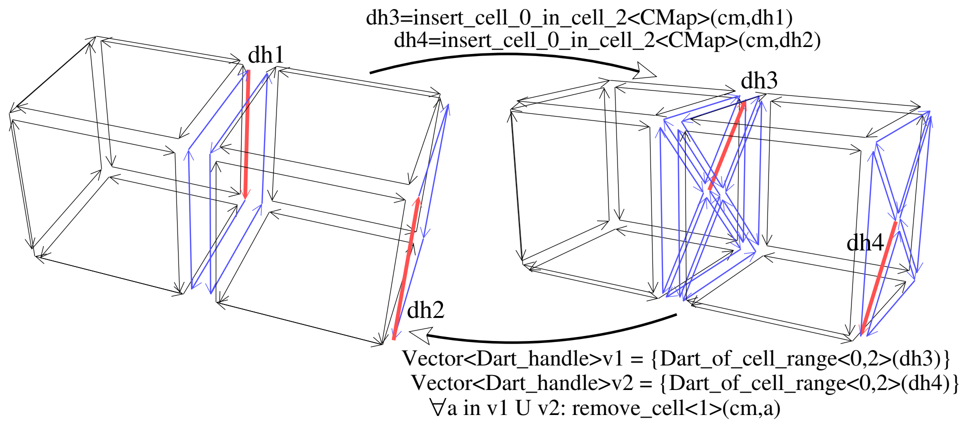

Figure 27.12: Example of *insert_cell_0_in_cell_2* operation.

insert_cell_1_in_cell_2<CMap>(cm,dh1,dh2) adds a 1-cell in the 2-cell containing darts *d1* and *d2*, between the two 0-cells containing darts *d1* and *d2*. The 2-cell is split in two. This operation is possible if $d1 \in \langle \beta_1 \rangle (d2)$ which can be tested thanks to *is_insertable_cell_1_in_cell_2(cm,dh1,dh2)*. In the example on Figure 27.13, it is possible to insert an edge between darts *d2* and *d3*, but it is not possible to insert an edge between *d1* and *d3*.

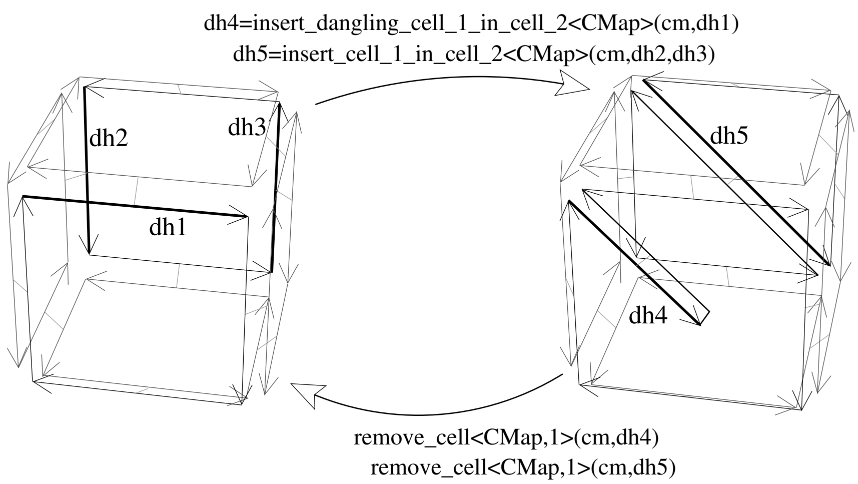

Figure 27.13: Example of *insert_cell_1_in_cell_2* and *remove_cell<1>* operations. **Left**: Initial combinatorial map. **Right**: After the insertion of two 1-cells: a first one between the two 0-cells containing darts *d2* and *d3*, and a second one incident to the 0-cell containing dart *d1*. Now if we remove the two 1-cells containing darts *d4* and *d5*, we obtain the initial combinatorial map.

insert_dangling_cell_1_in_cell_2<CMap>(cm,dh0) adds a 1-cell in the 2-cell containing dart *d0*, the 1-cell being attached by only one of its vertex to the 0-cell containing dart *d0*. This operation is possible if *d0∈cm.darts()*.

insert_cell_2_in_cell_3<CMap>(cm,itbegin,itend) adds a 2-cell in the 3-cell containing all the darts between *itbegin* and *itend*, along the path of 1-cells containing darts in [*itbegin*,*itend*). The 3-cell is split in two. This operation is possible if all the darts in [*itbegin*,*itend*) form a closed path inside a same 3-cell which can be tested thanks to *is_insertable_cell_2_in_cell_3(cm,itbegin,itend)* (see example on Figure 27.14).

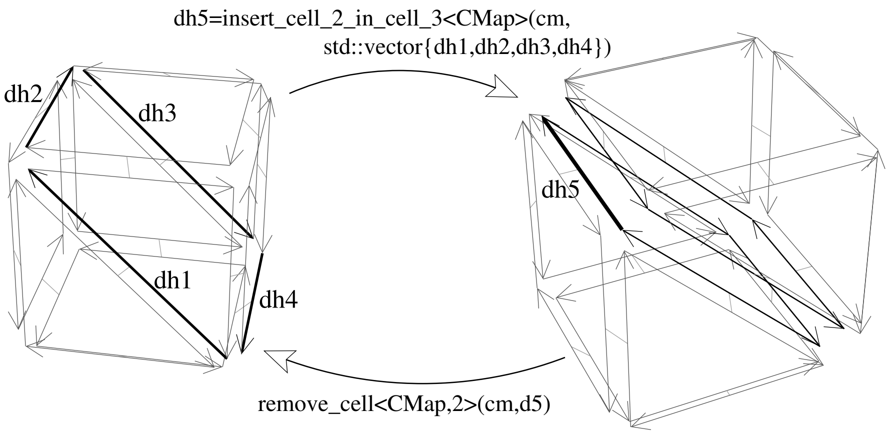

Figure 27.14: Example of *insert_cell_2_in_cell_3* and *remove_cell<2>* operations. **Left**: Initial combinatorial map. **Right**: After the insertion of a 2-cell along the path of 1-cells containing respectively *d1,d2,d3,d4*. Now if we remove the 2-cell containing dart *d5*, we obtain the initial combinatorial map.

Some examples of use of these operations are given in Section 27.6.2.

27.6 Examples

27.6.1 A 3D Combinatorial Map

In this example, a 3-dimensional combinatorial map is constructed. Two combinatorial tetrahedra are created, then the numbers of cells of the combinatorial map are displayed, and the validity of the combinatorial map is checked. Then, we illustrate the use of ranges to iterate over specific darts. The first loop enumerates all the darts of the first tetrahedron by using the range *Dart_of_orbit_range<1,2>*, and the second loop enumerates all the darts of the facet containing dart *dh2* by using the range *Dart_of_orbit_range<1>*.

```
#include <CGAL/Combinatorial_map.h>
#include <CGAL/Combinatorial_map_constructors.h>
#include <iostream>
#include <cstdlib>

typedef CGAL::Combinatorial_map<3> CMap_3;
typedef CMap_3::Dart_const_handle Dart_const_handle;

  int main()
  {
    CMap_3 cm;

    // Create two tetrahedra.
```

```
  Dart_const_handle dh1 = CGAL::make_combinatorial_tetrahedron(cm);
  Dart_const_handle dh2 = CGAL::make_combinatorial_tetrahedron(cm);

  // Display the combinatorial map characteristics.
  cm.display_characteristics(std::cout);
  std::cout<<", valid="<<cm.is_valid()<<std::endl;

  unsigned int res = 0;
  // Iterate over all the darts of the first tetrahedron.
  // Note that CMap_3::Dart_of_orbit_range<1,2> in 3D is equivalent to
  // CMap_3::Dart_of_cell_range<3>.
  for  (CMap_3::Dart_of_orbit_range<1,2>::const_iterator
          it(cm.darts_of_orbit<1,2>(dh1).begin()),
          itend(cm.darts_of_orbit<1,2>(dh1).end()); it!=itend; ++it)
    ++res;

  std::cout<<"Number of darts of the first tetrahedron: "
           <<res<<std::endl;

  res = 0;
  // Iterate over all the darts of the facet containing dh2.
  for (CMap_3::Dart_of_orbit_range<1>::const_iterator
         it(cm.darts_of_orbit<1>(dh2).begin()),
         itend(cm.darts_of_orbit<1>(dh2).end()); it!=itend; ++it)
    ++res;

  std::cout<<"Number of darts of the facet containing dh2: "
           <<res<<std::endl;

  return EXIT_SUCCESS;
}
```

File: examples/Combinatorial_map/map_3_simple_example.cpp

The output is:

```
#Darts=24, #0-cells=8, #1-cells=12, #2-cells=8, #3-cells=2, #ccs=2, valid=1
Number of darts of the first tetrahedron: 12
Number of darts of the facet containing dh2: 3
```

which gives the number of darts of the combinatorial map, the numbers of different cells, the number of connected components, and finally a Boolean showing the validity of the combinatorial map (a tetrahedron is made up of 12 darts because there are 3 darts per facet and there are 4 facets).

Note the creation in the for loops of the two instances of *Dart_of_orbit_range::const_iterator*: *it* is the current iterator, and *itend* an iterator to the end of the range. Having *itend* avoids calling *cm.darts_of_orbit<1,2> (dh1).end()* again and again as in the following example (which is a bad solution):

```
for (CMap_3::Dart_of_orbit_range<1,2>::const_iterator
       it(cm.darts_of_orbit<1,2>(dh1).begin());
       it!=cm.darts_of_orbit<1,2>(dh1).end(); ++it)
{...}
```

27.6.2 High Level Operations

This example shows some uses of high level operations. First we create a combinatorial hexahedron, the combinatorial map obtained is shown in Figure 27.15 (Left). Then we insert two 1-cells along two opposite 2-cells of the hexahedron. The combinatorial map obtained is shown in Figure 27.15 (Middle). Finally, we insert a 2-cell in the diagonal of the hexahedron in order to split it into two parts. We obtain the combinatorial map shown in Figure 27.15 (Right). We display the characteristics of the combinatorial map and check its validity.

The second part of this example removes the inserted elements. First we remove the inserted 2-cell, then the two inserted 1-cells. We get back the initial combinatorial hexahedron, which is verified by displaying once again the characteristics of the combinatorial map.

```
#include <CGAL/Combinatorial_map.h>
#include <CGAL/Combinatorial_map_constructors.h>
#include <CGAL/Combinatorial_map_operations.h>
#include <iostream>
#include <cstdlib>

typedef CGAL::Combinatorial_map<3> CMap_3;
typedef CMap_3::Dart_handle        Dart_handle;

int main()
{
  CMap_3 cm;

  // Create one combinatorial hexahedron.
  Dart_handle dh1 = CGAL::make_combinatorial_hexahedron(cm);

  // Add two edges along two opposite facets.
  CGAL_assertion( CGAL::is_insertable_cell_1_in_cell_2
                        (cm,dh1->beta(1),dh1->beta(0)) );

  CGAL::insert_cell_1_in_cell_2(cm,dh1->beta(1),dh1->beta(0));
  CGAL_assertion( cm.is_valid() );

  Dart_handle dh2=dh1->beta(2)->beta(1)->beta(1)->beta(2);

  CGAL_assertion( CGAL::is_insertable_cell_1_in_cell_2
                        (cm,dh2,dh2->beta(1)->beta(1)) );

  CGAL::insert_cell_1_in_cell_2(cm,dh2,dh2->beta(1)->beta(1));
  CGAL_assertion( cm.is_valid() );

  // Insert a facet along these two new edges plus two initial edges
  // of the hexahedron.
  std::vector<Dart_handle> path;
  path.push_back(dh1->beta(1));
  path.push_back(dh1->beta(0)->beta(2)->beta(1));
  path.push_back(dh2->beta(0));
  path.push_back(dh2->beta(2)->beta(1));

  CGAL_assertion( (CGAL::is_insertable_cell_2_in_cell_3
                   (cm,path.begin(),path.end())) );
```

```
  Dart_handle
   dh3=CGAL::insert_cell_2_in_cell_3(cm,path.begin(),path.end());
  CGAL_assertion( cm.is_valid() );

  // Display the combinatorial map characteristics.
  cm.display_characteristics(std::cout) << ", valid=" <<
    cm.is_valid() << std::endl;

  // We use the removal operations to get back to the initial hexahedron.
  CGAL_assertion( (CGAL::is_removable<CMap_3, 2>(cm,dh3)) );
  CGAL::remove_cell<CMap_3,2>(cm,dh3);
  CGAL_assertion( cm.is_valid() );

  CGAL_assertion( (CGAL::is_removable<CMap_3, 1>(cm,dh1->beta(1))) );
  CGAL::remove_cell<CMap_3,1>(cm,dh1->beta(1));
  CGAL_assertion( cm.is_valid() );

  CGAL_assertion( (CGAL::is_removable<CMap_3, 1>(cm,dh2->beta(0))) );
  CGAL::remove_cell<CMap_3,1>(cm,dh2->beta(0));
  CGAL_assertion( cm.is_valid() );

  // Display the combinatorial map characteristics.
  cm.display_characteristics(std::cout) << ", valid="
                                        << cm.is_valid() << std::endl;

  return EXIT_SUCCESS;
}
```

File: examples/Combinatorial_map/map_3_operations.cpp

The output is:

```
#Darts=36, #0-cells=8, #1-cells=14, #2-cells=9, #3-cells=2, #ccs=1, valid=1
#Darts=24, #0-cells=8, #1-cells=12, #2-cells=6, #3-cells=1, #ccs=1, valid=1
```

The first line gives the characteristics of the combinatorial map after all the insertions (the combinatorial map drawn in Figure 27.15 (Right)). There are two 3-cells (since the combinatorial hexahedron was split in two by the 2-cell insertion), nine 2-cells (since two 2-cells of the original hexahedron were split in two by the two 1-cell insertions, and a new 2-cell was created during the 2-cell insertion), fourteen 1-cells (since there are two new 1-cells created by the 1-cell insertion) while the number of 0-cells remains unchanged.

The second line is the result after the removal operations. We retrieve the original combinatorial hexahedron since we have removed all the inserted elements.

27.6.3 A 4D Combinatorial Map

In this example, a 4-dimensional combinatorial map is used. Two tetrahedral cells are created and sewn by β_4. Then the numbers of cells of the combinatorial map are displayed, and its validity is checked.

By looking at these numbers of cells, we can see that the 4D combinatorial map contains only one 3-cell. Indeed, the *sew<4>* operation has identified by pairs all the darts of the two 3-cells by definition of the sew operation

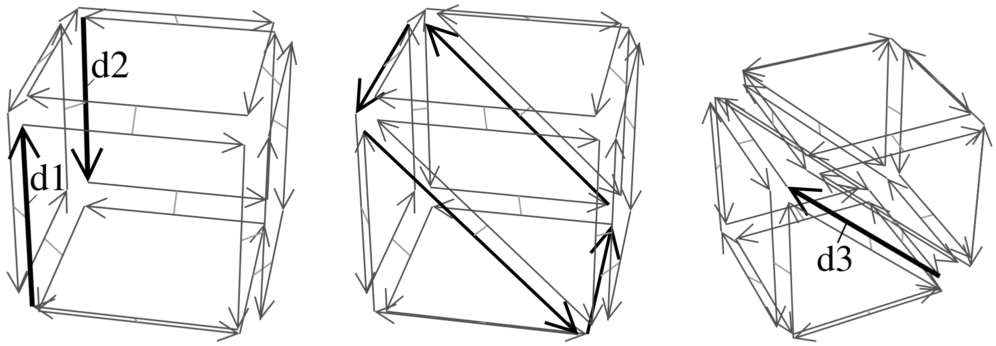

Figure 27.15: Example of high level operations. **Left**: Initial 3D combinatorial map after the creation of the combinatorial hexahedron. **Middle**: Combinatorial map obtained after the two 1-cell insertions. The two 2-cells were split in two. **Right**: Combinatorial map obtained after the 2-cell insertion. The 3-cell was split in two.

(see Section 27.5.1) which, in 4D, links by β_3 all the darts in $\langle\beta_1,\beta_2\rangle(d1)$ and in $\langle\beta_1,\beta_2\rangle(d2)$. The situation is similar (but in higher dimension) to the configuration where we have two triangles in a 3D combinatorial map, and you use *sew<3>* between these two triangles. The two triangles are identified since all their darts are linked by β_3, thus we obtain a 3D combinatorial map containing only one 3-cell. Note that this 3-cell is unbounded since the darts of the two triangles are all 2-free. In the 4D case, the 4-cell is unbounded since all its darts are 3-free.

In this example, we also illustrate how to use the basic methods to build "by hand" some specific configuration in a combinatorial map. In fact, these functions are already present in the package: function *make_triangle(cm)* is equivalent to *CGAL::make_combinatorial_polygon(cm,3)* and *make_tetrahedron(cm)* is equivalent to *CGAL::make_combinatorial_tetrahedron(cm)*. If we want to create a 4D simplex, we must create five 3D simplexes, and sew them correctly two by two by β_3 (and so on if you want to create higher dimensional combinatorial map).

```
#include <CGAL/Combinatorial_map.h>
#include <CGAL/Combinatorial_map_constructors.h>
#include <iostream>
#include <cstdlib>

typedef CGAL::Combinatorial_map<4> CMap_4;
typedef CMap_4::Dart_handle Dart_handle;

Dart_handle make_triangle(CMap_4& amap)
{
 Dart_handle d1 = amap.create_dart();
 Dart_handle d2 = amap.create_dart();
 Dart_handle d3 = amap.create_dart();
 amap.link_beta<1>(d1,d2);
 amap.link_beta<1>(d2,d3);
 amap.link_beta<1>(d3,d1);
 return d1;
}

Dart_handle make_tetrahedral(CMap_4& amap)
{
  Dart_handle d1 = make_triangle(amap);
  Dart_handle d2 = make_triangle(amap);
  Dart_handle d3 = make_triangle(amap);
```

```
  Dart_handle d4 = make_triangle(amap);
  amap.link_beta<2>(d1, d2);
  amap.link_beta<2>(d3, d2->beta(0));
  amap.link_beta<2>(d1->beta(1), d3->beta(0));
  amap.link_beta<2>(d4, d2->beta(1));
  amap.link_beta<2>(d4->beta(0), d3->beta(1));
  amap.link_beta<2>(d4->beta(1), d1->beta(0));
  return d1;
}

int main()
{
  CMap_4 cm;
  Dart_handle d1 = make_tetrahedral(cm);
  Dart_handle d2 = make_tetrahedral(cm);

  cm.sew<4>(d1,d2);

  cm.display_characteristics(std::cout);
  std::cout<<", valid="<<cm.is_valid()<<std::endl;

  return EXIT_SUCCESS;
}
```

File: examples/Combinatorial_map/map_4_simple_example.cpp

The output is:

```
#Darts=24, #0-cells=4, #1-cells=6, #2-cells=4, #3-cells=1, #4-cells=2, #ccs=1, valid=1
```

27.6.4 Combinatorial Map With Attributes

In the following example, we illustrate how to specify the 2-attributes in a 3D combinatorial map. For that, we define our own item class using *CGAL::Dart<3,CMap>* as type of dart, and *CGAL::Cell_attribute< CMap,int,CGAL::Tag_true,Sum_functor,Divide_by_two_functor>* as attributes which contain an *int* and which are associated to 2-cells of the combinatorial map.

Functors *Sum_functor* and *Divide_by_two_functor* define a custom behavior: when two attributes *ca1* and *ca2* are merged into *ca1*, the value of *ca1* is the sum of the two initial values. When an attribute *ca1* is split in the two attributes *ca1* and *ca2*, the value of each attribute is half of the first value.

```
#include <CGAL/Combinatorial_map.h>
#include <CGAL/Combinatorial_map_constructors.h>
#include <CGAL/Combinatorial_map_operations.h>
#include <CGAL/Cell_attribute.h>
#include <iostream>
#include <algorithm>
#include <cstdlib>

struct Sum_functor
{
```

```
  template<class Cell_attribute>
  void operator()(Cell_attribute& ca1,Cell_attribute& ca2)
  { ca1.info()=ca1.info()+ca2.info(); }
};
struct Divide_by_two_functor
{
  template<class Cell_attribute>
  void operator()(Cell_attribute& ca1,Cell_attribute& ca2)
  {
    ca1.info()=(ca1.info()/2);
    ca2.info()=(ca1.info());
  }
};

struct Myitem
{
  template<class CMap>
  struct Dart_wrapper
  {
    typedef CGAL::Dart<3, CMap> Dart;
    typedef CGAL::Cell_attribute<CMap, int, CGAL::Tag_true,
                                 Sum_functor, Divide_by_two_functor>
    Facet_attribute;
    typedef CGAL::cpp0x::tuple<void,void,Facet_attribute> Attributes;
  };
};

typedef CGAL::Combinatorial_map<3,Myitem> CMap_3;
typedef CMap_3::Dart_handle               Dart_handle;

int main()
{
  CMap_3 cm;

  // Create 2 hexahedra.
  Dart_handle dh1 = make_combinatorial_hexahedron(cm);
  Dart_handle dh2 = make_combinatorial_hexahedron(cm);

  // 1) Create all 2-attributes and associated them to darts.
  for (CMap_3::Dart_range::iterator
         it=cm.darts().begin(), itend=cm.darts().end();
         it!=itend; ++it)
    {
      if ( it->attribute<2>()==NULL )
        cm.set_attribute<2>(it, cm.create_attribute<2>());
    }

  // 2) Set the color of all facets of the first hexahedron to 7.
  for (CMap_3::One_dart_per_incident_cell_range<2, 3>::iterator
         it=cm.one_dart_per_incident_cell<2,3>(dh1).begin(),
         itend=cm.one_dart_per_incident_cell<2,3>(dh1).end(); it!=itend;
   ++it)
    { it->attribute<2>()->info()=7; }
```

```
  // 3) Set the color of all facets of the second hexahedron to 13.
  for (CMap_3::One_dart_per_incident_cell_range<2, 3>::iterator it=
         cm.one_dart_per_incident_cell<2,3>(dh2).begin(),
         itend=cm.one_dart_per_incident_cell<2,3>(dh2).end(); it!=itend;
   ++it)
    { it->attribute<2>()->info()=13; }

  // 4) 3-Sew the two hexahedra along one facet.
  cm.sew<3>(dh1, dh2);

  // 5) Display all the values of 2-attributes.
  for (CMap_3::Attribute_range<2>::type::iterator
         it=cm.attributes<2>().begin(), itend=cm.attributes<2>().end();
       it!=itend; ++it)
    {
      std::cout<<it->info()<<"; ";
    }
  std::cout<<std::endl;

  // 6) Insert a vertex in the facet between the two hexahedra.
  CGAL::insert_cell_0_in_cell_2(cm, dh2);

  // 7) Display all the values of 2-attributes.
  for (CMap_3::Attribute_range<2>::type::iterator
         it=cm.attributes<2>().begin(), itend=cm.attributes<2>().end();
       it!=itend; ++it)
    {
      std::cout<<it->info()<<"; ";
    }
  std::cout<<std::endl;
  cm.display_characteristics(std::cout);
  std::cout<<", valid="<<cm.is_valid()<<std::endl;

  return EXIT_SUCCESS;
}
```

File: examples/Combinatorial_map/map_3_with_colored_facets.cpp

The output is:

```
20; 7; 7; 7; 7; 7; 13; 13; 13; 13; 13;
2; 7; 7; 7; 7; 7; 2; 13; 13; 13; 13; 13; 5; 10;
#Darts=64, #0-cells=13, #1-cells=24, #2-cells=14, #3-cells=2, #ccs=1, valid=1
```

Before the *cm.sew<3>*, each 2-cell of the first cube is associated with an attribute having 7 as value, and each 2-cell of the second cube with an attribute having 13 as value. During the *cm.sew<3>*, two 2-cells are merged, thus the functor *Sum_functor* is called on the two associated 2-attributes, and the value of the new 2-cell is the sum of the two previous one: 20.

Then we call *CGAL::insert_cell_0_in_cell_2* on a dart which belong to this 2-cell. This method splits the existing 2-cell in *k* 2-cells, *k* being the number of 1-cells of the initial 2-cell (4 in this example). These splits are made consecutively, thus for the first split, we create a new attribute as copy of the initial one and call functor *Divide_by_two_functor* on these two attributes: the value of each attribute is thus 20/2=10. For the second split, the value of each attribute is thus 10/2=5, and for the last split the value of each attribute is thus 5/2=2 (remember that information contained in 2-attributes in an *int*). At the end, we obtain five 2-attributes with 7 as value, five 2-attributes with 13 as value, and four 2-attributes having respectively 2, 2, 5 and 10 as values.

27.7 Mathematical Definitions

The initial definition of combinatorial map in any dimension is given in [Lie91, Lie94]. But it allows only to represent objects without boundaries. This definition was extended [PABL07, Dam10] in order to allow to represent objects with boundaries, based on the notions of partial permutations and partial involutions.

Intuitively, a *partial permutation* on a finite set E is a mapping from $E \cup \{\varnothing\}$ to $E \cup \{\varnothing\}$ which is injective on the subset of the domain that does not map to $\varnothing$. More precisely, a mapping p: $E \cup \{\varnothing\} \rightarrow E \cup \{\varnothing\}$ is a *partial permutation* defined on E if:

1. $p(\varnothing)=\varnothing$;
2. $\forall e1 \in E$, $\forall e2 \in E$, $p(e1)=p(e2) \neq \varnothing \Rightarrow e1=e2$.

The inverse p^{-1} of this partial permutation is also a partial permutation and is defined by:

1. $p^{-1}(\varnothing)=\varnothing$;
2. $\forall e \in E$, if it exists $a \in E$ such that $p(a)=e$, then $p^{-1}(e)$=a, otherwise $p^{-1}(e)=\varnothing$.

Let E be a set, and p a partial permutation on E. An element e is called a *fixed point* for p if $p(e)=e$. p is a *partial involution* if $\forall e \in E$: $p(e) \neq \varnothing \Rightarrow p(p(e))=e$.

Now we can give the definition of a combinatorial map in any dimension. Let $d \geq 0$. A d-dimensional combinatorial map (or d-map) is a (d+1)-tuple $M=(D,\beta_1,\ldots,\beta_d)$ where:

1. D is a finite set of darts;
2. β_1 is a partial permutation on D;
3. $\forall i$, $2 \leq i \leq d$, β_i is a partial involution on D without fixed point;
4. $\forall i$: $0 \leq i \leq d$-2, $\forall j$: $3 \leq j \leq d$, $i+2 \leq j$, $\beta_i \circ \beta_j$ is a partial involution.

A d-dimensional combinatorial map represents a subdivision of an orientable d-dimensional quasi-manifold. A dart is an abstract element which is only required to define partial permutations. The last line of the definition fixes constraints which guarantee the topological validity of the represented object, i.e., the fact that it is a quasi-manifold. This definition allows us to verify the validity of a given combinatorial map by checking if each item of the definition is satisfied.

Given a set of partial permutations $S=\{f_1,\ldots,f_k\}$, we denote by $\langle S \rangle$ the *permutation group* generated by $\{f_1,\ldots,f_k\}$ and whose group operation is the composition of partial permutations. The orbit $\langle f_1,\ldots,f_k \rangle(a)$ is the set of darts which can be obtained from a by elements of $\langle S \rangle$: $\langle f_1,\ldots,f_k \rangle(a)=\{\phi(a) | \phi \in \langle S \rangle\} \setminus \{\varnothing\}$.

Let $d0 \in D$ be a dart. Given i, $1 \leq i \leq d$, the i-cell containing $d0$ is $\langle \beta_1,\ldots,\beta_{i-1},\beta_{i+1},\ldots,\beta_d \rangle(d0)$. The 0-cell containing $d0$ is $\langle \{\beta_i \circ \beta_j | \forall i,j$: $1 \leq i < j \leq d\} \rangle(d0)$.

27.8 Design and Implementation History

The code of this package is inspired by Moka, a 3D topological modeler mainly developed by Frédéric Vidil and Guillaume Damiand (http://moka-modeller.sourceforge.net/). However, Moka was based on Generalized maps (and not Combinatorial maps), and the design was not CGAL "compatible". Thus, Guillaume Damiand started to develop a totally new package by mixing ideas taken from Moka with the design of the Halfedge data structure package of CGAL. Andreas Fabri and Sébastien Loriot contributed to the design, the coding, and to the documentation of the package, and Laurent Rineau helped for the design. Emma Michel contributed to the manual. Monique Teillaud and Bernd Gärtner contributed to the manual by giving useful remarks, really numerous and detailed for Monique.

CombinatorialMap

Definition

The concept CombinatorialMap defines a d-dimensional combinatorial map.

Creation

CombinatorialMap cm;	Default constructor.

Types

CombinatorialMap:: Dart	Dart type, a model of the *Dart* concept.
CombinatorialMap:: Dart_handle	Dart handle type, equal to *Dart::Dart_handle*.
CombinatorialMap:: Dart_const_handle	Dart const handle type, equal to *Dart::Dart_const_handle*.
CombinatorialMap:: size_type	Size type (an unsigned integral type).

Constants

static unsigned int	*dimension;*	The dimension d of *cm*, equal to *Dart::dimension.*
static size_type	*NB_MARKS;*	The number of available Boolean marks of *cm*.
static Dart_handle	*null_dart_handle;*	The null dart handle constant: a dart *d0* is *i*-free if *d0.beta(i)==null_dart_handle*. Note that **null_dart_handle*$\notin$*cm.darts()*.

Types for attributes

CombinatorialMap:: Attributes

The tuple of attributes, containing at most *dimension+1* types (one for each possible cell of the combinatorial map). Each type of the tuple must be either a model of the *CellAttribute* concept or *void*. The first type corresponds to 0-attributes, the second to 1-attributes and so on. If the i^{th} type in the tuple is *void*, *(i-1)*-attributes are disabled. Otherwise, *(i-1)*-attributes are enabled and have the given type. If the size of the tuple is k, with k<*dimension+1*, $\forall i$: $k \leq i \leq$ *dimension*, i-attributes are disabled.

CombinatorialMap:: template<unsigned int i> Attribute_type<i>::type

Type of i-attributes, a model of *CellAttribute* concept. *Attribute_type<i>::type::Dart_handle* is equal to *Dart_handle*, and *Attribute_type<i>::type::Dart_const_handle* is equal to *Dart_const_handle*.
Precondition: $0 \leq i \leq$ *dimension* and i-attributes are non void.

CombinatorialMap:: template<unsigned int i> Attribute_handle<i>::type

Handle to i-attributes, equal to *Dart::Attribute_handle<i>::type*.
Precondition: $0 \leq i \leq$ *dimension* and i-attributes are non void.

CombinatorialMap:: template<unsigned int i> Attribute_const_handle<i>::type

Const handle to i-attributes, equal to *Dart::Attribute_const_handle<i>::type*.
Precondition: $0 \leq i \leq dimension$ and i-attributes are non void.

Range types

CombinatorialMap:: Dart_range

Range of all the darts of *cm*. This type is a model of *Range* concept, its iterator type is bidirectional and its value type is *Dart*.

CombinatorialMap:: Dart_const_range

Const range of all the darts of *cm*. This type is a model of *ConstRange* concept, its iterator type is bidirectional and its value type is *Dart*.

CombinatorialMap:: template<unsigned int i> Attribute_range<i>::type

Range of all the i-attributes (which must be non void), with $0 \leq i \leq dimension$. This type is a model of *Range* concept, its iterator type is bidirectional and its value type is *Attribute_type<i>::type*.

CombinatorialMap:: template<unsigned int i> Attribute_const_range<i>::type

Const range of all the i-attributes (which must be non void), with $0 \leq i \leq dimension$. This type is a model of *ConstRange* concept, its iterator type is bidirectional and its value type is *Attribute_type<i>::type*.

CombinatorialMap:: template<unsigned int ... Beta> Dart_of_orbit_range

Range of all the darts of the <*Beta...*> orbit. This type is a model of *Range* concept, its iterator type is forward and its value type is *Dart*.

CombinatorialMap:: template<unsigned int ... Beta> Dart_of_orbit_const_range

Const range of all the darts of the <*Beta...*> orbit. This type is a model of *ConstRange* concept, its iterator type is forward and its value type is *Dart*.

CombinatorialMap:: template<unsigned int i,unsigned int dim=dimension> Dart_of_cell_range

Range of all the darts of an i-cell in *dim* dimension (with $0 \leq i \leq dim+1$ and $0 \leq dim \leq dimension$). If $i==dim+1$, range of all the darts of a connected component. This type is a model of *Range* concept, its iterator type is forward and its value type is *Dart*.

CombinatorialMap:: template<unsigned int i,unsigned int dim=dimension> Dart_of_cell_const_range

Const range of all the darts of the i-cell in *dim* dimension (with $0 \leq i \leq dim+1$ and $0 \leq dim \leq dimension$). If $i==dim+1$, range of all the darts of a connected component. This type is a model of *ConstRange* concept, its iterator type is forward and its value type is *Dart*.

CombinatorialMap:: template<unsigned int i,unsigned int j,unsigned int dim=dimension> One_dart_per_incident_cell_range

Range of one dart of each *i*-cell incident to one *j*-cell. Cells are considered in *dim* dimension (with $0 \leq i \leq dim+1$, $0 \leq j \leq dim+1$ and $0 \leq dim \leq dimension$). If *i==dim+1*, consider each connected component instead of each *i*-cell. If *j==dim+1*, consider one connected component instead of one *j*-cell. This type is a model of *Range* concept, its iterator type is forward and its value type is *Dart*.

CombinatorialMap:: template<unsigned int i,unsigned int j,unsigned int dim=dimension> One_dart_per_incident_cell_const_range

Const range of one dart of each *i*-cell incident to one *j*-cell. Cells are considered in *dim* dimension (with $0 \leq i \leq dim+1$, $0 \leq j \leq dim+1$ and $0 \leq dim \leq dimension$). If *i==dim+1*, consider each connected component instead of each *i*-cell. If *j==dim+1*, consider one connected component instead of one *j*-cell. This type is a model of *ConstRange* concept, its iterator type is forward and its value type is *Dart*.

CombinatorialMap:: template<unsigned int i,unsigned int dim=dimension> One_dart_per_cell_range

Range of one dart of each *i*-cell of *cm*. Cells are considered in *dim* dimension (with $0 \leq i \leq dim+1$ and $0 \leq dim \leq dimension$). If *i==dim+1*, consider each connected component instead of each *i*-cell. This type is a model of *Range* concept, its iterator type is forward and its value type is *Dart*.

CombinatorialMap:: template<unsigned int i,unsigned int dim=dimension> One_dart_per_cell_const_range

Const range of one dart of each *i*-cell of *cm*. Cells are considered in *dim* dimension (with $0 \leq i \leq dim+1$ and $0 \leq dim \leq dimension$). If *i==dim+1*, consider each connected component instead of each *i*-cell. This type is a model of *ConstRange* concept, its iterator type is forward and its value type is *Dart*.

Access Member Functions

bool	*cm.is_empty() const*	Returns true iff *cm* is empty, i.e. it contains no dart.
bool	*cm.is_valid() const*	Returns true iff *cm* is valid.

A combinatorial map *cm* is valid (see Sections 27.2.1 and 27.2.4) if for all dart handle *dh* such that **dh∈cm.darts()*:

- *dh->is_free(0)*, or *dh->beta(0)->beta(1)==dh*;
- *dh->is_free(1)*, or *dh->beta(1)->beta(0)==dh*;

- $\forall i$, $2 \leq i \leq dimension$: *dh->is_free(i)*, or *dh->beta(i)->beta(i)==dh*;
- $\forall i,j$, $0 \leq i < i+2 \leq j \leq dimension$ such that $j \geq 3$: *dh->beta(i)->beta(j)==null_dart_handle* or *dh->beta(i)->beta(j)->beta(i)->beta(j)==dh*;
- $\forall i$, $0 \leq i \leq dimension$ such that *i*-attributes are non void: $\forall$*dh2* such that **dh2* belong to the same *i*-cell than **dh*: *dh2->attribute<i>()==dh->attribute<i>()*.

bool *cm.is_without_boundary(unsigned int i) const*

Returns true iff *cm* is wihout *i*-boundary (i.e. there is no *i*-free dart).
Precondition: $1 \leq i \leq dimension$.

bool *cm.is_without_boundary() const*

Returns true iff *cm* is without boundary in all dimensions.

size_type *cm.number_of_darts() const*

Returns the number of darts in *cm*.

template <unsigned int i>
size_type *cm.number_of_attributes() const*

Returns the number of *i*-attributes in *cm*.
Precondition: $0 \leq i \leq dimension$, and *i*-attributes are non void.

Dart_handle *cm.dart_handle(Dart& adart)*

Returns the dart handle of *adart*.
Precondition: *adart*$\in$*cm.darts()*.

Dart_const_handle *cm.dart_handle(Dart adart) const*

Returns the dart const handle of *adart*.
Precondition: *adart*$\in$*cm.darts()*.

Dart_handle *cm.beta(Dart_handle dh, int i, int j) const*

Returns $\beta_j(\beta_i(dh))$. Overloads of this member function are defined that take from one to nine integer as arguments. For each function, betas are applied in the same order as their indices are given as parameters. For example *beta(dh,1)*=$\beta_1(dh)$, and *beta(dh,1,2,3,0)*=$\beta_0(\beta_3(\beta_2(\beta_1(dh))))$.
Precondition: $0 \leq i \leq dimension$, $0 \leq j \leq dimension$ and **dh*$\in$*cm.darts()*.

Dart_const_handle *cm.beta(Dart_const_handle dh, int i, int j) const*

Returns $\beta_j(\beta_i(dh))$. Overloads of this member function are defined that take from one to nine integer as arguments.
Precondition: $0 \leq i \leq dimension$, $0 \leq j \leq dimension$ and **dh*$\in$*cm.darts()*.

template <unsigned int i>
bool *cm.is_sewable(Dart_const_handle dh1, Dart_const_handle dh2) const*

Returns true iff *dh1* can be *i*-sewn with *dh2* by keeping *cm* valid, i.e. if there is a bijection f between all the darts of the orbit $D1=\langle\beta_1,\ldots,\beta_{i-2},\beta_{i+2},\ldots,\beta_d\rangle(dh1)$ and $D2=\langle\beta_1,\ldots,\beta_{i-2},\beta_{i+2},\ldots,\beta_d\rangle(dh2)$ satisfying: $f(dh1)=dh2$, and for all $e\in D1$, for all $j\in\{1,\ldots,i\text{-}2,i\text{+}2,\ldots,d\}$, $f(\beta_j(e))=\beta_j^{-1}(f(e))$.
Precondition: $0\leq i\leq dimension$, $*dh1\in cm.darts()$, and $*dh2\in cm.darts()$.

std::ostream& *cm.display_characteristics(std::ostream & os) const*

Displays on *os* the characteristics of *cm*: its number of darts, its number of *i*-cells, for each *i*, $0\leq i\leq$CMap::*dimension*, and its number of connected components.

Example of output for a 3D combinatorial map containing two disjoint combinatorial tetrahedra:
`#Darts=24, #0-cells=8, #1-cells=12, #2-cells=8, #3-cells=2, #ccs=2`

Range Access Member Functions

Dart_range& *cm.darts()* Returns a range of all the darts in *cm*.
Dart_const_range& *cm.darts() const* Returns a const range of all the darts in *cm*.

template<unsigned int i>
Attribute_range<i>::type&

cm.attributes() Returns a range of all the *i*-attributes in *cm*.
Precondition: $0\leq i\leq dimension$, and *i*-attributes are non void.

template<unsigned int i>
Attribute_const_range<i>::type&

cm.attributes() const Returns a const range of all the *i*-attributes in *cm*.
Precondition: $0\leq i\leq dimension$, and *i*-attributes are non void.

template<unsigned int ... Beta>
Dart_of_orbit_range *cm.darts_of_orbit(Dart_handle dh)*

Returns a range of all the darts of the orbit *<Beta...>(dh)*.
Precondition: **dh*$\in$*cm.darts()* and *Beta...* is a sequence of integers $i_1,\ldots,i_k$, such that $0\leq i_1<i_2<\ldots<i_k\leq dimension$, and ($i_1\neq 0$ or $i_2\neq 1$).

template<unsigned int ... Beta>
Dart_of_orbit_const_range

cm.darts_of_orbit(Dart_const_handle dh) const

Returns a const range of all the darts of the orbit *<Beta...> (dh)*.
Precondition: Same as for the non const version.

template<unsigned int i,unsigned int dim=dimension>
Dart_of_cell_range *cm.darts_of_cell(Dart_handle dh)*

Returns a range of all the darts of the *i*-cell containing *dh*. *i*-cells are considered in *dim* dimension. If *i==dim+1*, range of all the darts of the connected component containing *dh*.
Precondition: **dh*$\in$*cm.darts()*, $0 \leq i \leq dim+1$ and $0 \leq dim \leq dimension$.

template<unsigned int i,unsigned int dim=dimension>
Dart_of_cell_const_range

cm.darts_of_cell(Dart_const_handle dh) const

Returns a const range of all the darts of the *i*-cell containing *dh*. *i*-cells are considered in *dim* dimension. If *i==dim+1*, const range of all the darts of the connected component containing *dh*.
Precondition: Same as for the non const version.

template<unsigned int i,unsigned int j,unsigned int dim=dimension>
One_dart_per_incident_cell_range

cm.one_dart_per_incident_cell(Dart_handle dh)

Returns a range of one dart of each *i*-cell incident to the *j*-cell containing *dh*. Cells are considered in *dim* dimension. If *i==dim+1*, consider each connected component instead of each *i*-cell. If *j==dim+1*, consider the connected component containing *dh* instead of the *j*-cell.
Precondition: **dh*$\in$*cm.darts()*, $0 \leq i \leq dim+1$, $0 \leq j \leq dim+1$ and $0 \leq dim \leq dimension$.

template<unsigned int i,unsigned int j,unsigned int dim=dimension>
One_dart_per_incident_cell_const_range

cm.one_dart_per_incident_cell(Dart_const_handle dh) const

Returns a const range of one dart of each *i*-cell incident to the *j*-cell containing *dh*. Cells are considered in *dim* dimension. If *i==dim+1*, consider each connected component instead of each *i*-cell. If *j==dim+1*, consider the connected component containing *dh* instead of the *j*-cell.
Precondition: Same as for the non const version.

template<unsigned int i,unsigned int dim=dimension>
One_dart_per_cell_range

cm.one_dart_per_cell()

Returns a range of one dart of each *i*-cell in *cm*. Cells are considered in *dim* dimension. If *i==dim+1*, range of one dart of each connected component in *cm*.
Precondition: $0 \leq i \leq dim+1$ and $0 \leq dim \leq dimension$.

template<unsigned int i,unsigned int dim=dimension>

One_dart_per_cell_const_range

cm.one_dart_per_cell() const

Returns a const range of one dart of each *i*-cell in *cm*. Cells are considered in *dim* dimension. If *i==dim+1*, const range of one dart of each connected component in *cm*.
Precondition: Same as for the non const version.

Modifiers

template<typename T1>
Dart_handle *cm.create_dart(T1 t1)*

Creates a new dart in *cm*, and returns the corresponding handle. Calls the constructor of dart having *T1* as parameter. A new dart is initialized to be *i*-free, $\forall i$: $0 \leq i \leq dimension$, and to have no associated attribute for each non void attribute. Overloads of this member function are defined that take from zero to nine arguments. With zero argument, *create_dart()* creates a new dart by using the default constructor.

void *cm.erase_dart(Dart_handle dh)*

Removes **dh* from *cm*.
Precondition: **dh*$\in$*cm.darts()*.

template<unsigned int i,typename T1>
Attribute_handle<i>::type

cm.create_attribute(T1 t1)

Creates a new *i*-attribute in *cm*, and returns the corresponding handle. Calls the constructor of *i*-attribute having *T1* as parameter. Overloads of this member function are defined that take from zero to nine arguments. With zero argument, *create_attribute<i>()* creates a new *i*-attribute by using the default constructor.
Precondition: $0 \leq i \leq dimension$, and *i*-attributes are non void.

template <unsigned int i>
void *cm.erase_attribute(Attribute_handle<i>::type ah)*

Removes the *i*-attribute **ah* from *cm*.
Precondition: $0 \leq i \leq dimension$, *i*-attributes are non void, and **ah*$\in$*cm.attributes<i>()*.

template <unsigned int i>

void *cm.set_attribute(Dart_handle dh, Attribute_handle<i>::type ah)*

Associates the i-attribute of all the darts of the i-cell containing *dh* to *ah*.
Precondition: **dh*$\in$*cm.darts()*, $0 \leq i \leq$ *dimension*, i-attributes are non void, and **ah*$\in$*cm.attributes<i>()*.

void *cm.clear()* Deletes all the darts and all the attributes of *cm*.

Operations

template <unsigned int i>
void *cm.sew(Dart_handle dh1, Dart_handle dh2, bool update_attributes=true)*

Links by β_i two by two all the darts of the orbit $D1=\langle\beta_1,\ldots,\beta_{i-2},\beta_{i+2},\ldots,\beta_d\rangle(dh1)$ and $D2=\langle\beta_0,\beta_2,\ldots,\beta_{i-2},\beta_{i+2},\ldots,\beta_d\rangle\ (dh2)$ such that $d2=f(d1)$, f being the bijection between $D1$ and $D2$ satisfying: $f(dh1)=dh2$, and for all $e \in D1$, for all $j \in \{1,\ldots,i\text{-}2,i\text{+}2,\ldots,d\}$, $f(\beta_j(e))=\beta_j^{-1}(f(e))$.
If *update_attributes* is *true*, when necessary, non void attributes are updated to ensure the validity of *cm*: for each j-cells *c1* and *c2* which are merged into one j-cell during the sew, the two associated attributes *attr1* and *attr2* are considered. If one attribute is NULL and the other not, the non NULL attribute is associated to all the darts of the resulting cell. When the two attributes are non NULL, functor *Attribute_type<i>::type::On_merge* is called on the two attributes *attr1* and *attr2*. Then, the attribute *attr1* is associated to all darts of the resulting j-cell. Finally, attribute *attr2* is removed from *cm*.
Precondition: *cm.is_sewable<i>(dh1,dh2)*.

advanced

If *update_attributes* is *false*, non void attributes are not updated; thus *cm* can be no more valid after this modification.

advanced

template <unsigned int i>

void *cm.unsew(Dart_handle dh, bool update_attributes=true)*

Unlinks by β_i all the darts in the orbit $\langle\beta_1,\ldots,\beta_{i-2},\beta_{i+2},\ldots,\beta_d\rangle(dh)$. If *update_attributes* is *true*, when necessary, non void attributes are updated to ensure the validity of *cm*: for each *j*-cell *c* split in two *j*-cells *c1* and *c2* by the operation, if *c* is associated to a *j*-attribute *attr1*, then this attribute is duplicated into *attr2*, and all the darts belonging to *c2* are associated with this new attribute. Finally, the functor *Attribute_type<i>::type::On_split* is called on the two attributes *attr1* and *attr2*.
Precondition: $0 \leq i \leq dimension$, $*dh \in cm.darts()$ and *dh* is not *i*-free.

advanced

If *update_attributes* is *false*, non void attributes are not updated thus *cm* can be no more valid after this modification.

advanced

advanced

template <unsigned int i>
void *cm.link_beta(Dart_handle dh1, Dart_handle dh2, bool update_attributes=true)*

Links *dh1* and *dh2* by β_i. *cm* can be no more valid after this modification. If *update_attributes* is true, non void attributes of *dh1* and *dh2* are updated: if one dart has an attribute and the second dart not, the non null attribute is associated to the dart having a null attribute. If both darts have an attribute, the attribute of *dh1* is associated to *dh2*.
Precondition: $0 \leq i \leq dimension$, $*dh1 \in cm.darts()$, $*dh2 \in cm.darts()$ and ($i<2$ or $dh1 \neq dh2$).

template <unsigned int i>
void *cm.unlink_beta(Dart_handle dh)*

Unlinks *dh* and $\beta_i(dh)$ by β_i. *cm* can be no more valid after this modification. Attributes of *dh* and $\beta_i(dh)$ are not modified.
Precondition: $0 \leq i \leq dimension$, $*dh \in cm.darts()$, and *dh* is not *i*-free.

advanced

advanced

Boolean marks

int *cm.get_new_mark() const*

Reserves a new mark. Returns its index. Returns -1 if there is no more available free mark.

bool	*cm.is_reserved(int amark) const*	
		Returns true iff *amark* is a reserved mark of *cm*. *Precondition*: 0≤*amark*<*NB_MARKS*.
bool	*cm.is_marked(Dart_const_handle dh, int amark) const*	
		Returns true iff *dh* is marked for *amark*. *Precondition*: *is_reserved(amark)* and **dh*∈*cm.darts()*.
void	*cm.mark(Dart_const_handle dh, int amark) const*	
		Marks *dh* for *amark*. *Precondition*: *is_reserved(amark)* and **dh*∈*cm.darts()*.
void	*cm.unmark(Dart_const_handle dh, int amark) const*	
		Unmarks *dh* for the mark *amark*. *Precondition*: *is_reserved(amark)* and **dh*∈*cm.darts()*.
void	*cm.negate_mark(int amark) const*	
		Inverse the mark *amark* for all the darts of *cm*. All the marked darts become unmarked and all the unmarked darts become marked. *Precondition*: *is_reserved(amark)*.
void	*cm.unmark_all(int amark) const*	
		Unmarks all the darts of *cm* for *amark*. *Precondition*: *is_reserved(amark)*.
size_type	*cm.number_of_marked_darts(int amark) const*	
		Returns the number of marked darts for *amark*. *Precondition*: *is_reserved(amark)*.
size_type	*cm.number_of_unmarked_darts(int amark) const*	
		Return the number of unmarked darts for *amark*. *Precondition*: *is_reserved(amark)*.
void	*cm.free_mark(int amark) const*	
		Frees *amark*. *Precondition*: *is_reserved(amark)*.

advanced

Has Models

CGAL::Combinatorial_map<d,Items,Alloc> . . . . page 1936

Concept

Dart

Definition

The concept Dart defines a d-dimensional dart. A dart mainly stores handles to the darts linked with itself by β_i, $\forall i$, $0 \leq i \leq d$. Moreover, it stores also handles to each non void attribute associated with itself.

Creation

A dart *d0* is never constructed directly, but always created within a combinatorial map *cm* by using the method *cm.create_dart();* A new dart is initialized to be i-free, $\forall i$: $0 \leq i \leq dimension$, and having all its attribute handles initialized to NULL, for each non void attribute.

Constants

static unsigned int *dimension;* The dimension of *d0*.

Types

Dart:: Dart_handle Dart handle type.
Dart:: Dart_const_handle Dart const handle type.

Dart:: template<unsigned int i> Attribute_handle<i>::type

Handle to i-attributes, with $0 \leq i \leq dimension$.

Dart:: template<unsigned int i> Attribute_const_handle<i>::type

Const handle to i-attributes, with $0 \leq i \leq dimension$.

Access Member Functions

Dart_handle *d0.beta(unsigned int i)* Returns $\beta_i(d0)$.
Precondition: $0 \leq i \leq dimension$.

Dart_const_handle *d0.beta(unsigned int i) const*

Returns $\beta_i(d0)$ when *d0* is const.
Precondition: $0 \leq i \leq dimension$.

Dart_handle *d0.beta_inv(unsigned int i)*

Returns $\beta_i^{-1}(d0)$.
Precondition: $0 \leq i \leq dimension$.

Dart_const_handle *d0.beta_inv(unsigned int i) const*

Returns $\beta_i^{-1}(d0)$ when *d0* is const.
Precondition: $0 \leq i \leq dimension$.

bool	*d0.is_free(unsigned int i) const*	
		Returns true iff *d0* is *i*-free. *Precondition*: $0 \leq i \leq dimension$.
int	*d0.highest_nonfree_dimension() const*	
		Returns the highest dimension *i* such that *d0* is not *i*-free. -1 if *d0* is free for any dimension.
Dart_handle	*d0.opposite()*	Returns a handle to a dart belonging to the same edge than *d0*, and not to the same vertex. NULL if such a dart does not exist.
Dart_const_handle	*d0.opposite() const*	Returns a handle to a dart belonging to the same edge than *d0*, and not to the same vertex, when *d0* is const. NULL if such a dart does not exist.
Dart_handle	*d0.other_extremity()*	Returns a handle to a dart belonging to the other vertex of the edge containing *d0* (but contrary to *opposite()* not necessarily to the same edge). NULL if such a dart does not exist.
Dart_const_handle	*d0.other_extremity() const*	
		Returns a *Dart_const_handle* to a dart belonging to the other vertex of the edge containing *d0*, when *d0* is const (but contrary to *opposite()* not necessarily to the same edge). NULL if such a dart does not exist.
template <unsigned int i> Attribute_handle<i>::type		
	d0.attribute()	Returns the *i*-attribute associated to *d0*. *Precondition*: $0 \leq i \leq dimension$, and *i*-attributes are non void.
template <unsigned int i> Attribute_const_handle<i>::type		
	d0.attribute() const	Returns the *i*-attribute associated to *d0*, when *d0* is const. *Precondition*: $0 \leq i \leq dimension$, and *i*-attributes are non void.

CellAttribute

Definition

The concept CellAttribute represents a non void attribute associated with a cell of a combinatorial map. It can keep a handle to one dart of its associated cell, and can contain any information.

Types

CellAttribute:: Dart_handle	Dart handle type.
CellAttribute:: Dart_const_handle	Dart const handle type.
CellAttribute:: Info	Type of the information contained in the attribute. If *void*, the cell attribute does not have any information.
CellAttribute:: Supports_cell_dart	Equals to *Tag_true* to enable the storage of a *Dart_handle* of the associated cell, *Tag_false* otherwise.
CellAttribute:: On_merge	Functor called before merging two attributes. Must be a model of the *Binary Function* concept having two references to a model of *CellAttribute* as type of both arguments and *void* as return type.
CellAttribute:: On_split	Functor called after an attribute was split in two. Must be a model of the *Binary Function* concept having two references to a model of *CellAttribute* as type of both arguments and *void* as return type.

Creation

CellAttribute ca;

CellAttribute ca(Info info);	Constructor initializing the information of *ca* by the copy contructor *Info(info)*. Defined only if *Info* is different from *void*.

Access Member Functions

Dart_handle	*ca.dart()*	Returns one dart of the cell associated to attribute *ca*. NULL if *Supports_cell_dart* is equal to *Tag_false*.
Dart_const_handle	*ca.dart() const*	Returns one dart of the cell associated to attribute *ca*, when *ca* is const. NULL if *Supports_cell_dart* is equal to *Tag_false*.
void	*ca.set_dart(Dart_handle ahandle)*	
		Sets the dart of the cell associated to attribute *ca* to *ahandle*, if *Supports_cell_dart* is equal to *Tag_true*. Otherwise, this method does nothing. *Precondition*: *ahandle* belongs to the cell associated to *ca*.

Info&	*ca.info()*	Returns the information of *ca*. Defined only if *Info* is different from *void*.
Info	*ca.info() const*	Returns the information of *ca*, when *ca* is const. Defined only if *Info* is different from *void*.

CombinatorialMapItems

Definition

The concept CombinatorialMapItems allows to customize a *d*D combinatorial map by choosing the type of darts, and by enabling and disabling some attributes. For that, it defines an inner class template named *Dart_wrapper*, with one template parameter, *CMap*, a model of the *CombinatorialMap* concept. This inner class must define two types: *Dart* and *Attributes*.

Types in *CombinatorialMapItems::Dart_wrapper<CMap>*

CombinatorialMapItems::Dart_wrapper<CMap>:: Dart

The type of dart, a model of the *Dart* concept.

CombinatorialMapItems::Dart_wrapper<CMap>:: Attributes

The tuple of attributes, containing at most *dimension+1* types (one for each possible cell of the combinatorial map). Each type of the tuple must be either a model of the *CellAttribute* concept or *void*. The first type corresponds to 0-attributes, the second to 1-attributes and so on. If the i^{th} type in the tuple is *void*, (i-1)-attributes are disabled. Otherwise, (i-1)-attributes are enabled and have the given type. If the size of the tuple is k, with *k*¡*dimension+1*, $\forall i$: $k \leq i \leq dimension$, i-attributes are disabled.

Example

The following examples show two possible models of the *CombinatorialMapItems* concept: the first one for a 4D combinatorial map without enabled attributes, the second one for a 3D combinatorial map with edge attributes enabled, and associated with a *Cell_attribute* containing an *int*.

```
struct Exemple_Item_4
{
   template < class CMap >
   struct Dart_wrapper
   {
     typedef CGAL::Dart<4, CMap> Dart;
     typedef CGAL::cpp0x::tuple<> Attributes;
   };
};
```

```
struct Exemple_Item_3
{
   template < class CMap >
   struct Dart_wrapper
   {
```

```
      typedef CGAL::Dart<3, CMap> Dart;
      typedef Cell_attribute<CMap, int> Edge_attrib;
      typedef CGAL::cpp0x::tuple<void,Edge_attrib> Attributes;
    };
};
```

Has Models

CGAL::Combinatorial_map_min_items<d> .... page 1940

See Also

CombinatorialMap .... page 1919
Dart .... page 1930

Class

CGAL::Combinatorial_map<d,Items,Alloc>

#include <CGAL/Combinatorial_map.h>

Definition

The class *Combinatorial_map<d,Items,Alloc>* represents a dD combinatorial map.

Darts and non void attributes are stored in memory using *CGAL::Compact_container*, using *Alloc* as allocator.

Is Model for the Concepts

CombinatorialMap . . . . page 1919

Parameters

d an integer for the dimension of the map.
Items must be a model of the *CombinatorialMapItems* concept.
Alloc has to match the standard allocator requirements. The *rebind* mechanism from *Alloc* will be used to create appropriate allocators internally with value type *Dart*.

There are two default template arguments: *Combinatorial_map_min_items<d>* for *Items* and *CGAL_ALLOCATOR(int)* from the *<CGAL/memory.h>* header file for *Alloc*.

Types

typedef Combinatorial_map<d,Items,Alloc>	*Self;*
typedef Items::Dart_wrapper<Self>::Dart	*Dart;*

Complexity

The complexity of *sew* and *unsew* is in $O(|S| \times |c|)$, S being the set of darts of the orbit $\langle \beta_1,\ldots,\beta_{i-2},\beta_{i+2},\ldots,\beta_d \rangle$ for the considered dart, and c the biggest j-cell merged or split during the sew such that j-attributes are non void. The complexity of *is_sewable* is in $O(|S|)$.

The complexity of *set_attribute* is in $O(|c|)$, c being the i-cell containing the considered dart.

The complexity of *is_without_boundary(unsigned int i)* is in $O(|D|)$, D being the set of darts of the combinatorial map, and the complexity of *is_without_boundary()* is in $O(|D| \times d)$.

The complexity of *unmark_all* and *free_mark* is in $O(1)$ if all the darts of the combinatorial map have the same mark, and in $O(|D|)$ otherwise.

The complexity of *is_valid* is in $O(|D| \times d^2)$.

The complexity of *clear* is in $O(|D| \times d)$.

Other methods have all a constant time complexity.

See Also

CombinatorialMapItems . . . . page 1934
Dart . . . . page 1930

Class

CGAL::Dart<d,CMap>

#include <CGAL/Dart.h>

Definition

The class *Dart<d,CMap>* represents a *d*D dart.

β_i pointers are coded in a array of *d+1 Dart_handle* (because we describe also the β_0 link). Attributes are associated to each dart by *Attribute_handle<i>*, one for each non void *i*-attribute.

Is Model for the Concepts

Dart . . . . page 1930

Parameters

d an integer for the dimension of the dart.
CMap must be a model of the *CombinatorialMap* concept.

Types

typedef CMap::Dart_handle	*Dart_handle;*
typedef CMap::Dart_const_handle	*Dart_const_handle;*
typedef CMap::Attribute_handle<i>::type	*Attribute_handle<i>::type;*
typedef CMap::Attribute_const_handle<i>::type	*Attribute_const_handle<i>::type;*

Complexity

Each β_i link is initialized to *CMap::null_dart_handle*, and each attribute handle of non void *i*-attribute is initialized to *NULL* at the creation of the dart, thus the complexity of the creation is in $O(d+1)$.

The complexity of *opposite* and *other_extremity* methods is in $O(d+1)$.

Other methods have all a constant time complexity.

See Also

CombinatorialMap . . . . page 1919

CGAL::Cell_attribute<CMap,Info_,Tag,OnMerge,OnSplit>

Class

#include <CGAL/Cell_attribute.h>

Definition

The class *Cell_attribute<CMap,Info_,Tag,OnMerge,OnSplit>* represents an attribute containing (or not) an information.

Is Model for the Concepts

CellAttribute . . . . page 1932

Parameters

CMap must be a model of the *CombinatorialMap*.
*Info_* is the type of the information contained in the attribute.
Tag is *Tag_true* to enable the storage of a *Dart_handle* of the associated cell, *Tag_false* otherwise.
OnMerge is the type of the functor called before two attributes are merged.
OnSplit is the type of the functor called after one attribute is split in two.

By default, *OnMerge* and *OnSplit* are equal to *Null_functor*; *Tag* is equal to *Tag_true*; and *Info_* is equal to *void*.

Types

*typedef Info_*	*Info;*
typedef Tag	*Supports_cell_dart;*
typedef OnMerge	*On_merge;*
typedef OnSplit	*On_split;*
typedef CMap::Dart_handle	*Dart_handle;*
typedef CMap::Dart_const_handle	*Dart_const_handle;*

CGAL::Combinatorial_map<d,Items,Alloc> . . . . page 1936

Class

CGAL::Combinatorial_map_min_items<d>

#include <CGAL/Combinatorial_map_min_items.h>

Definition

The class *Combinatorial_map_min_items<d>* is a model of the *CombinatorialMapItems* concept. It defines the type of darts which is a *CGAL::Dart<d,CMap>*. The *Combinatorial_map_min_items<d>* has a template argument for the dimension of the combinatorial map. In this class, no attribute is enabled.

Is Model for the Concepts

CombinatorialMapItems . . . . page 1934

Example

The following example shows the implementation of the *CGAL::Combinatorial_map_min_items* class.

```
template <unsigned int d>
struct Combinatorial_map_min_items
{
   template <class CMap>
   struct Dart_wrapper
   {
     typedef CGAL::Dart<d, CMap> Dart;
     typedef CGAL::cpp0x::tuple<> Attributes;
   };
};
```

Function

CGAL::is_insertable_cell_2_in_cell_3<CMap,InputIterator>

#include <CGAL/Combinatorial_map_operations.h>

template <class CMap, class InputIterator>
bool *is_insertable_cell_2_in_cell_3(CMap cm, InputIterator afirst, InputIterator alast)*

Returns true iff it is possible to insert a 2-cell in *cm* along the path of darts given by the range *[afirst,alast)*. The 2-cell can be inserted iff each couple of consecutive darts of the path *a1* and *a2* belong to the same vertex and the same volume, and if the path is closed.
Precondition: *CMap::dimension*$\geq$3.

CGAL::insert_cell_0_in_cell_1<CMap>

#include <CGAL/Combinatorial_map_operations.h>

template < class CMap >
typename CMap::Dart_handle

insert_cell_0_in_cell_1(CMap& cm, typename CMap::Dart_handle dh)

Inserts a 0-cell in the 1-cell containing *dh*. Returns a handle on one dart belonging to the new 0-cell.
Precondition: *CMap::dimension*$\geq$1 and **dh*$\in$*cm.darts()*.
See example in Figure 27.11.
If 1-attributes are non void, *Attribute_type<1>::type::On_split*(*a*,*a'*) is called, with *a* the original 1-attribute associated with *dh* and *a'* the new 1-attribute created during the operation.

#include <CGAL/Combinatorial_map_operations.h>

template <class CMap>
typename CMap::Dart_handle

insert_cell_0_in_cell_2(CMap & cm, typename CMap::Dart_handle dh)

Inserts a 0-cell in the 2-cell containing *dh*. The 2-cell is split in triangles, one for each initial edge of the facet. Returns a handle on one dart belonging to the new 0-cell.
Precondition: *CMap::dimension*$\geq$2 and **dh*$\in$*cm.darts()*.
See example in Figure 27.12.
If 2-attributes are non void, *Attribute_type<2>::type::On_split*(*a*,*a'*) is called, with *a* the original 2-attribute associated with *dh* and *a'* each new 2-attribute created during the operation.

Chapter 28

Linear Cell Complex

Guillaume Damiand

Contents

28.1 Introduction

A *d*D linear cell complex allows to represent an orientable subdivided *d*D object having linear geometry: each vertex of the subdivision is associated with a point. The geometry of each edge is a segment whose end points are associated with the two vertices of the edge, the geometry of each 2-cell is obtained from all the segments associated to the edges describing the boundary of the 2-cell and so on.

The combinatorial part of a linear cell complex is described by a *d*D combinatorial map (it is strongly recommended to first read the combinatorial maps chapter (Page 1887) for definitions). To add the linear geometrical embedding, a point (a model of *CGAL::Point_2* or *CGAL::Point_3* or *CGAL::Point_d*) is associated to each vertex of the combinatorial map.

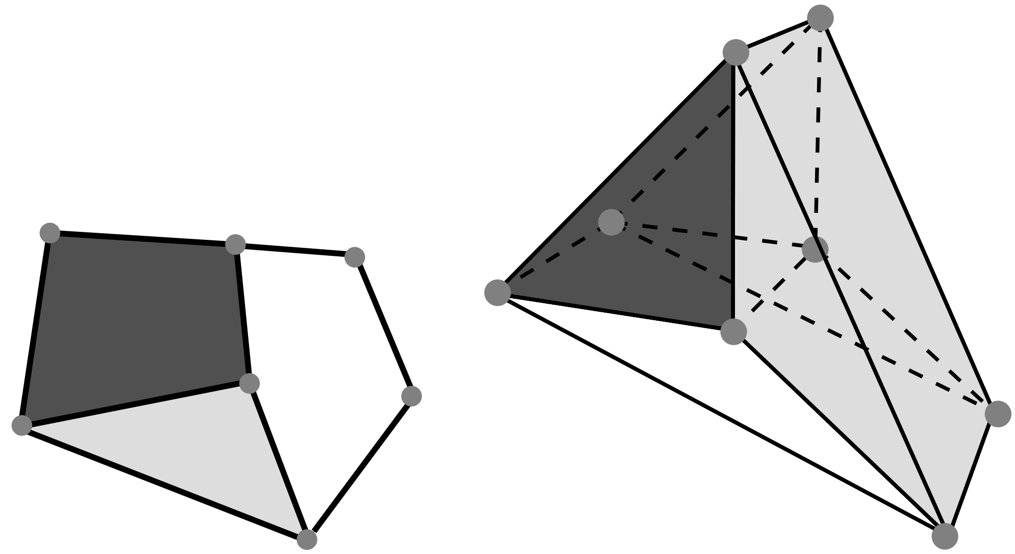

Figure 28.1: Examples of objects with linear geometry. **Left**: A 2D object composed of three 2-cells, nine 1-cells and seven points associated to the seven 0-cells . **Right**: A 3D object composed of three 3-cells, twelve 2-cells, sixteen 1-cells and eight points associated to the eight 0-cells.

If we reconsider the example introduced in the combinatorial map package, recalled in Figure 28.1 (Right), the combinatorial part of the 3D object is described by a 3D combinatorial map. As illustrated in Figure 28.2, the geometrical part of the object is described by associating a point to each vertex of the map.

Note that the dimension of the combinatorial map *d* is not necessarily equal to the dimension of the ambient space *d2*. Indeed, we can use for example a 2D combinatorial map in a 2D ambient space to describe a planar graph (*d*=*d2*=*2*), or a 2D combinatorial map in a 3D ambient space to describe a surface in 3D space (*d*=2, *d2*=3) (case of the *Polyhedron_3* package), or a 3D combinatorial map in a 3D ambient space (*d*=*d2*=3) and so on.

28.2 Software Design

The diagram in Figure 28.3 shows the main classes of the package. *CGAL::Linear_cell_complex* is the main class (see Section 28.2.1), which inherits from the *CGAL::Combinatorial_map* class. Attributes can be associated to some cells of the linear cell complex thanks to an items class (see Section 28.2.4), which defines the dart type and the attributes types. These types may be different for different dimensions of cells, and they may also be void. In the class *CGAL::Linear_cell_complex*, it is required that specific attributes are associated to all vertices of the combinatorial map. These attributes must contain a point (a model of *CGAL::Point_2* or *CGAL::Point_3* or *CGAL::Point_d*), and can be represented by instances of class *CGAL::Cell_attribute_with_point* (see Section 28.2.2).

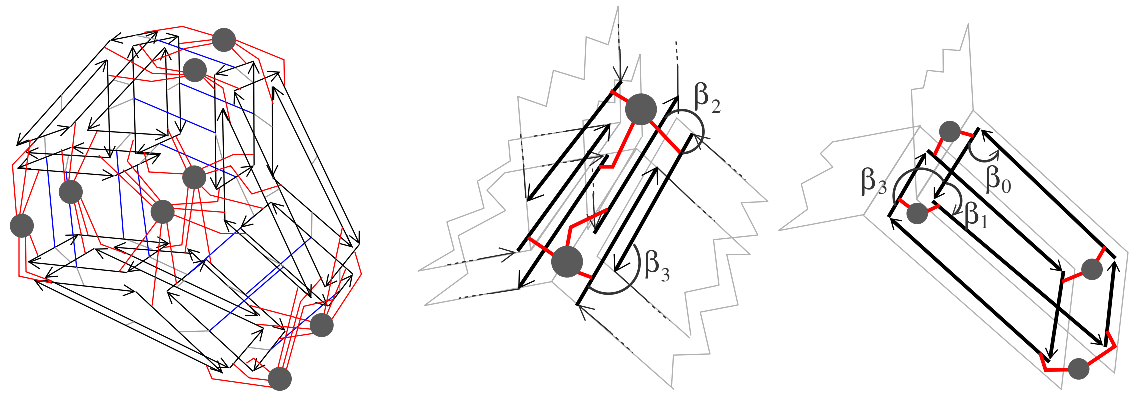

Figure 28.2: Example of 3D linear cell complex describing the object given in Figure 28.1 (Right). **Left**: The 3D linear cell complex which contains 54 darts (18 for each 3-cell) where each vertex is associated with a point, here a *CGAL::Point_3*. Blue segments represent β_3 relations. **Middle**: Zoom around the central edge which details the six darts belonging to the edge and the associations between darts and points. **Right**: Zoom around the facet between light gray and white 3-cells, which details the eight darts belonging to the facet and the associations between darts and points (given by red segments).

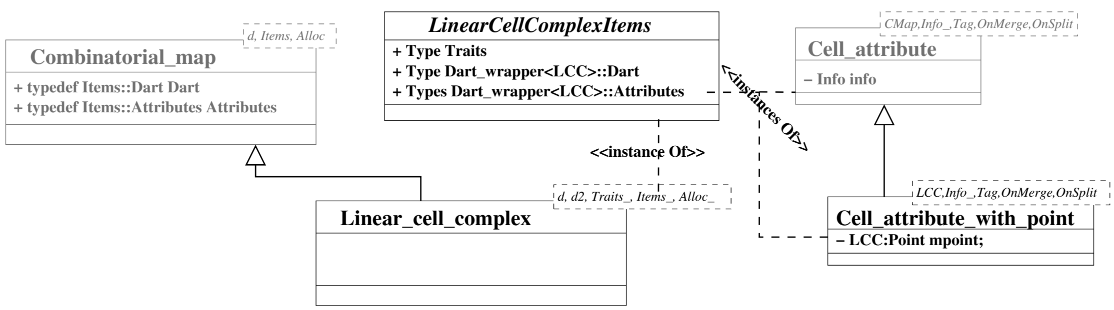

Figure 28.3: UML diagram of the main classes of the package. Gray elements come from the combinatorial map package (Page 1887).

28.2.1 Linear Cell Complex

The *CGAL::Linear_cell_complex<d,d2,LCCTraits,Items,Alloc>* class is a model of the *CombinatorialMap* concept. It guarantees that each vertex of the combinatorial map is associated with an attribute containing a point. This class can be used in geometric algorithms (it plays the same role as *Polyhedron_3* for *HalfedgeDS*).

This class has five template parameters standing for the dimension of the combinatorial map, the dimension of the ambient space, a traits class (a model of the *LinearCellComplexTraits* concept, see Section 28.2.3), an items class (a model of the *LinearCellComplexItems* concept, see Section 28.2.4), and an allocator which must be a model of the allocator concept of STL. Default classes are provided for the traits, items, and for the allocator classes, and by default *d2=d*.

A linear cell complex is valid, if it is a valid combinatorial map where each dart is associated with an attribute containing a point (i.e. an instance of a model of the *CellAttributeWithPoint* concept). Note that there are no validity constraints on the geometry (test on self intersection, planarity of 2-cells...). We can see two examples of *CGAL::Linear_cell_complex* in Figure 28.4.

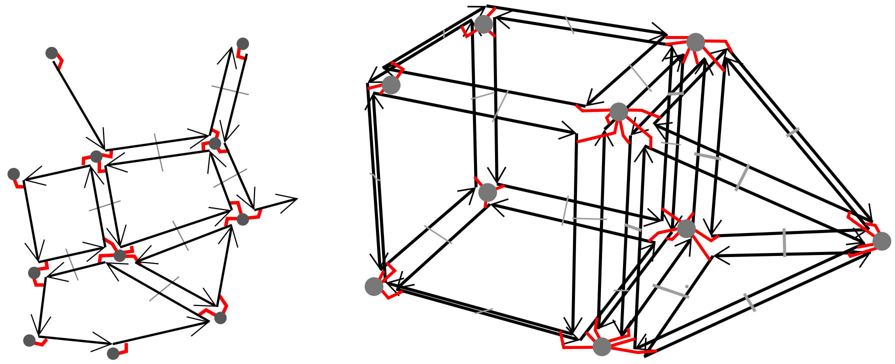

Figure 28.4: Examples of *CGAL::Linear_cell_complex*. Gray disks show the attributes associated to vertices. Associations between darts and attributes are drawn by small lines between darts and disks. **Left:** Example of *CGAL::Linear_cell_complex<2,2>*. **Right:** Example of *CGAL::Linear_cell_complex<3,3>*.

28.2.2 Cell Attributes

The *CGAL::Cell_attribute_with_point<LCC,Info_,Tag,OnMerge,OnSplit>* class is a model of the *CellAttributeWithPoint* concept, which is a refinement of the *CellAttribute* concept. It represents an attribute associated with a cell, which can contain an information (depending on whether *Info_==void* or not), but which always contains a point, an instance of *LCC::Point*.

28.2.3 Linear Cell Complex Traits

The *LinearCellComplexTraits* geometric traits concept defines the required types and functors used in the *Linear_cell_complex* class. For example it defines *Point*, the type of points used, and *Vector*, the corresponding vector type. It also defines all the required functors used for constructions and operations, as for example *Construct_translated_point* or *Construct_sum_of_vectors*.

The class *CGAL::Linear_cell_complex_traits<d,K>* is a model of *LinearCellComplexTraits*. It defines the different types which are obtained from *K* that, depending on *d*, is a model of the concept *Kernel* if *d==2* or *d==3*, and a model of the concept *Kernel_d* otherwise.

28.2.4 Linear Cell Complex Items

The *LinearCellComplexItems* concept refines the *CombinatorialMapItems* concept by adding the requirement that 0-attributes are enabled, and associated with a type of attribute being a model of the *CellAttributeWithPoint* concept.

The class *CGAL::Linear_cell_complex_min_items<d>* is a model of *LinearCellComplexItems*. It uses *CGAL::Dart<d>*, and instances of *CGAL::Cell_attribute_with_point* (which contain no information) associated to each vertex. All other attributes are void.

28.3 Operations

Several operations defined in the combinatorial maps package can be used on a linear cell complex. This is the case for all the iteration operations that do not modify the model (see example in Section 28.4.1). This is also

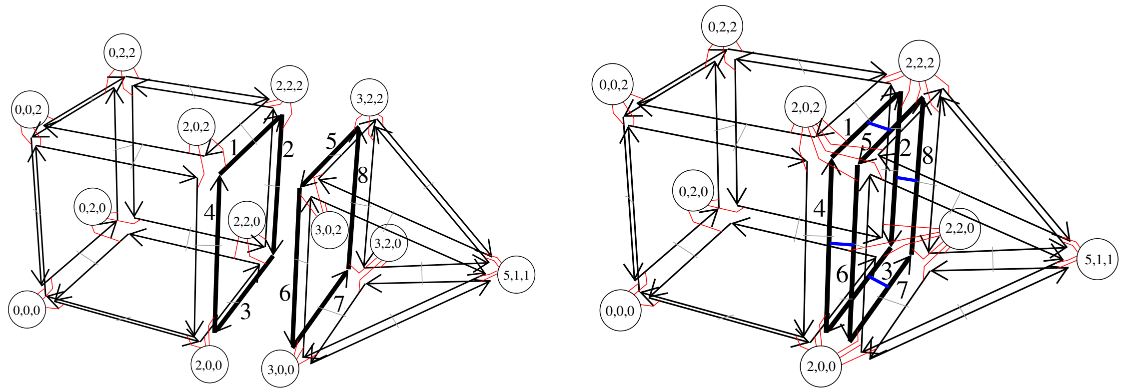

Figure 28.5: Example of 3-sew operation for linear cell complex. **Left**: A 3D linear cell complex containing two 3-cells that are not connected. Vertex attributes are drawn with circles containing point coordinates. Associations between darts and attributes are drawn with small lines between darts and disks. **Right**: The 3D linear cell complex obtained as result of *sew<3>(1,5)* (or *sew<3>(2,8)*, or *sew<3>(3,7)*, or *sew<3>(4,6)*). The eight 0-attributes around the facet between the two 3-cells before the sew operation, are merged into four 0-attributes after. The geometry of the pyramid is deformed since its base is fitted on the 2-cell of the cube.

the case for all the operations that do not create new 0-cells: *sew*, *unsew*, *remove_cell*, *insert_cell_1_in_cell_2*, *insert_cell_2_in_cell_3*. Indeed, all these operations update non void attributes, and thus update vertex attributes of a linear cell complex. Note that some existing 0-attributes can be duplicated by the *unsew* method, but these 0-attributes are not new but copies of existing old 0-attributes.

However, operations that create a new 0-cell can not be directly used since the new 0-cell would not be associated with a vertex attribute. Indeed, it is not possible for these operations to automatically decide which point to create. These operations are: *insert_cell_0_in_cell_1*, *insert_cell_0_in_cell_2 insert_dangling_cell_1_in_cell_2*, plus all the creation operations. For these operations, new versions are proposed taking some points as additional parameters. Lastly, some new operations are defined, which use the geometry (see sections 28.3.2 and 28.3.3).

All the operations given in this section guarantee that given a valid linear cell complex and a possible operation, the result is a valid linear cell complex. As for a combinatorial map, it is also possible to use low level operations but additional operations may be needed to restore the validity conditions.

28.3.1 Sewing and Unsewing

As explained in the combinatorial map user manual, Section 27.5.1, it is possible to glue two *i*-cells along an (*i*-1)-cell by using the *sew<i>* method. Since this method updates non void attributes, and since points are specific attributes, they are automatically updated during the *sew<i>* method. Thus the sewing of two *i*-cells could deform the geometry of the concerned objects.

For example, in Figure 28.5, we want to 3-sew the two initial 3-cells. *sew<3>(1,5)* links by β_3 the pairs of darts (1,5), (2,8), (3,7) and (4,6). The eight vertex attributes around the facet between the two 3-cells before the sew are merged by pair during the sew operation (and the *On_merge* functor is called four times). Thus, after the sew, there are only four 0-attributes around the facet. By default, the attributes associated with the first dart of the sew operation are kept (but this can be modified by defining your own functor in the attribute class as explained in the package combinatorial map, Section 27.5.1). Intuitively, the geometry of the second 2-cell is deformed to fit to the first 2-cell.

This is similar for the unsew operation, which removes β_i links of all the darts in $\langle\beta_1,\ldots,\beta_{i-2},\beta_{i+2},\ldots,\beta_d\rangle(d0)$, and updates non void attributes which are no more associated to a same cell due to the unlinks. If we take the linear cell complex given in Figure 28.5 (Right), and we call *unsew<3>(2)*, we obtain the linear cell complex in Figure 28.5 (Left) except for the coordinates of the new four vertices, which by default are copies of original vertices (this behavior can be modified thanks to the functor *On_split* in the attribute class). The *unsew<3>* operation has removed the four β_3 links, and has duplicated the 0-attributes since vertices are split in two after the unsew operation.

28.3.2 Construction Operations

There are several member functions allowing to insert specific configurations of darts into a linear cell complex. These functions return a *Dart_handle* to the new object. Note that the dimension of the linear cell complex must be large enough: darts must contain all the β used by the operation. All these methods add new darts in the current linear cell complex, existing darts are not modified. These functions are *make_segment*, *make_triangle*, *make_tetrahedron* and *make_hexahedron*.

There are two functions allowing to build a linear cell complex from two other CGAL data types:

- *import_from_triangulation_3(lcc,atr)*: adds in *lcc* all the tetrahedra present in *atr*, a *CGAL::Triangulation_3*;
- *import_from_polyhedron_3(lcc,ap)*: adds in *lcc* all the cells present in *ap*, a *CGAL::Polyhedron_3*.

Lastly, the function *import_from_plane_graph(lcc,ais)* adds in *lcc* all the cells reconstructed from the planar graph read in *ais*, a *std::istream* (see the reference manual for the file format).

28.3.3 Modification Operations

Some methods are defined in *Linear_cell_complex* class to modify a linear cell complex and update the vertex attributes. In the following, we denote by *dh0*, *dh1*, *dh2* the dart handles for the darts *d0*, *d1*, *d2*, respectively. That is *d0 == *dh0*.

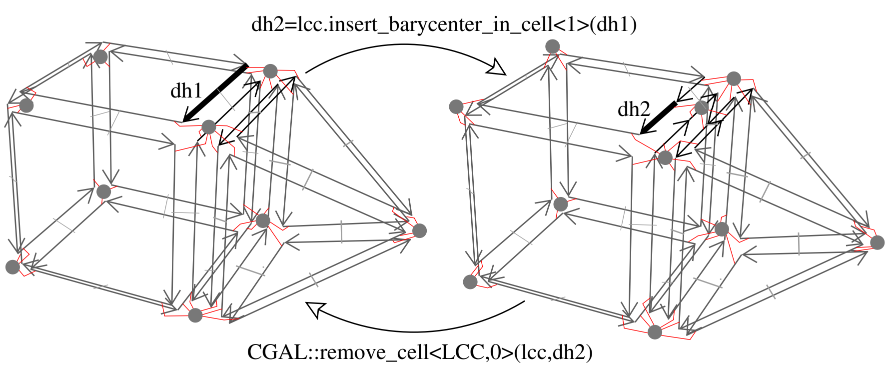

Figure 28.6: Example of *insert_barycenter_in_cell<1>* and *remove_cell<0>* operations. **Left**: Initial linear cell complex. **Right**: After the insertion of a point in the barycenter of the 1-cell containing dart *d1*. Now if we remove the 0-cell containing dart *d2*, we obtain a linear cell complex isomorphic to the initial one.

lcc.insert_barycenter_in_cell<unsigned int i>(dh0) adds the barycenter of the *i*-cell containing dart *d0*. This operation is possible if *d0∈lcc.darts()* (see examples on Figure 28.6 and Figure 28.7).

lcc.insert_point_in_cell<unsigned int i>(dh0,p) is an operation similar to the previous operation, the only difference being that the coordinates of the new point are here given by *p* instead of being computed as the barycenter of the *i*-cell. Currently, these two operations are only defined for *i=1* to insert a point in an edge, or *i=2* to insert a point in a facet.

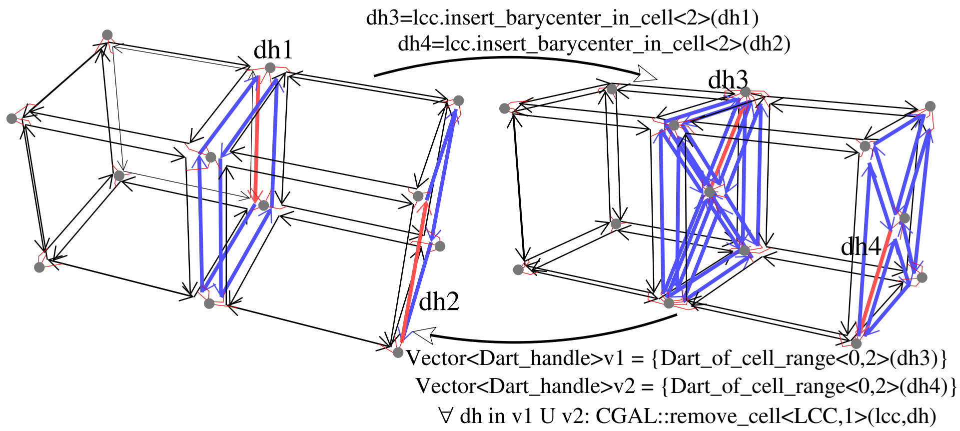

Figure 28.7: Examples of *insert_barycenter_in_cell<2>* operation.

lcc.insert_dangling_cell_1_in_cell_2(dh0,p) adds a 1-cell in the 2-cell containing dart *d0*, the 1-cell being attached by only one of its vertex to the 0-cell containing dart *d0*. The second vertex of the new edge is associated with a new 0-attribute containing a copy of *p* as point. This operation is possible if *d0∈lcc.darts()* (see example on Figure 28.8).

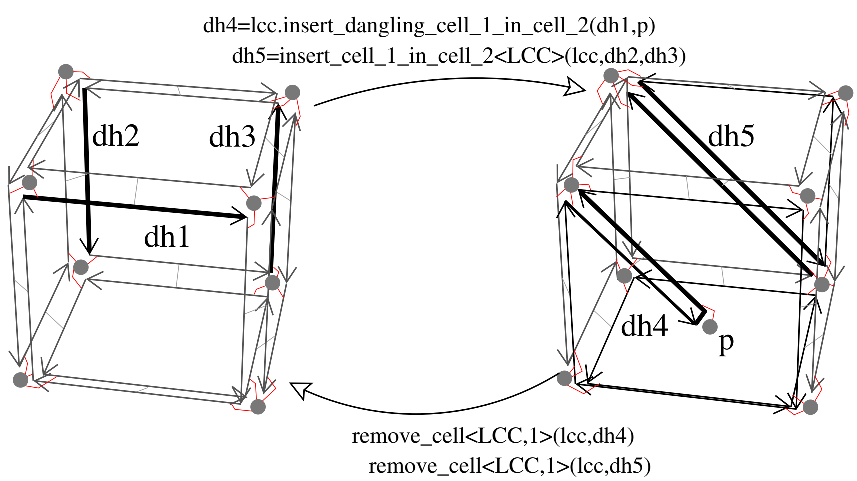

Figure 28.8: Example of *insert_dangling_cell_1_in_cell_2*, *insert_cell_1_in_cell_2* and *remove_cell<1>* operations. **Left**: Initial linear cell complex. **Right**: After the insertion of a dangling 1-cell in the 2-cell containing dart *d1*, and of a 1-cell in the 2-cell containing dart *d2*. Now if we remove the 1-cells containing dart *d4* and *d5*, we obtain a linear cell complex isomorphic to the initial one.

Some examples of use of these operations are given in Section 28.4.2.

28.4 Examples

28.4.1 A 3D Linear Cell Complex

This example uses a 3-dimensional linear cell complex. It creates two tetrahedra and displays all the points of the linear cell complex thanks to a *Vertex_attribute_const_range*. Then, the two tetrahedra are 3-sewn and we translate all the points of the second tetrahedron along vector *v(3,1,1)*. Since the two tetrahedra are 3-sewn, this translation moves also the 2-cell of the first tetrahedron shared with the second one. This is illustrated by displaying all the points of each 3-cell. For that we use a *std::for_each* and the *Display_vol_vertices* functor.

```
#include <CGAL/Linear_cell_complex.h>
#include <CGAL/Linear_cell_complex_operations.h>
#include <iostream>
#include <algorithm>

typedef CGAL::Linear_cell_complex<3> LCC_3;
typedef LCC_3::Dart_handle           Dart_handle;
typedef LCC_3::Point                 Point;
typedef LCC_3::FT                    FT;

// Functor used to display all the vertices of a given volume.
template<class LCC>
struct Display_vol_vertices : public std::unary_function<LCC, void>
{
  Display_vol_vertices(const LCC& alcc) :
    lcc(alcc),
    nb_volume(0)
  {}

  void operator() (typename LCC::Dart& d)
  {
    std::cout<<"Volume "<<++nb_volume<<" : ";
    for (typename LCC::template One_dart_per_incident_cell_range<0,3>::
           const_iterator it=lcc.template one_dart_per_incident_cell<0,3>
           (lcc.dart_handle(d)).begin(),
           itend=lcc.template one_dart_per_incident_cell<0,3>
           (lcc.dart_handle(d)).end();
         it!=itend; ++it)
    {
      std::cout << LCC_3::point(it) << "; ";
    }
    std::cout<<std::endl;
  }
private:
  const LCC& lcc;
  unsigned int nb_volume;
};

int main()
{
  LCC_3 lcc;

  // Create two tetrahedra.
```

```
  Dart_handle d1 = lcc.make_tetrahedron(Point(-1, 0, 0), Point(0, 2, 0),
                                        Point(1, 0, 0), Point(1, 1, 2));
  Dart_handle d2 = lcc.make_tetrahedron(Point(0, 2, -1),
                                        Point(-1, 0, -1),
                                        Point(1, 0, -1),
                                        Point(1, 1, -3));

  // Display all the vertices of the lcc by iterating on the
  // Vertex_attribute container.
  CGAL::set_ascii_mode(std::cout);
  std::cout<<"Vertices: ";
  for (LCC_3::Vertex_attribute_const_range::iterator
         v=lcc.vertex_attributes().begin(),
         vend=lcc.vertex_attributes().end();
       v!=vend; ++v)
    std::cout << v->point() << "; ";
  std::cout<<std::endl;

  // Display the vertices of each volume by iterating on darts.
  std::for_each(lcc.one_dart_per_cell<3>().begin(),
                lcc.one_dart_per_cell<3>().end(),
                Display_vol_vertices<LCC_3>(lcc));

  // 3-Sew the 2 tetrahedra along one facet
  lcc.sew<3>(d1, d2);

  // Display the vertices of each volume by iterating on darts.
  std::for_each(lcc.one_dart_per_cell<3>().begin(),
                lcc.one_dart_per_cell<3>().end(),
                Display_vol_vertices<LCC_3>(lcc));

  // Translate the second tetrahedra by a given vector
  LCC_3::Vector v(3,1,1);
  for (LCC_3::One_dart_per_incident_cell_range<0,3>::iterator
         it=lcc.one_dart_per_incident_cell<0,3>(d2).begin(),
         itend=lcc.one_dart_per_incident_cell<0,3>(d2).end();
       it!=itend; ++it)
  {
    LCC_3::point(it)=LCC_3::Traits::Construct_translated_point_3()
      (LCC_3::point(it),v);
  }

  // Display the vertices of each volume by iterating on darts.
  std::for_each(lcc.one_dart_per_cell<3>().begin(),
                lcc.one_dart_per_cell<3>().end(),
                Display_vol_vertices<LCC_3>(lcc));

  // We display the lcc characteristics.
  std::cout<<"LCC characteristics: ";
  lcc.display_characteristics(std::cout) << ", valid=" << lcc.is_valid()
                                         << std::endl;

  return EXIT_SUCCESS;
}
```

File: examples/Linear_cell_complex/linear_cell_complex_3.cpp

The output is:

```
Vertices: 1 1 2; 1 0 0; 0 2 0; -1 0 0; 1 1 -3; 1 0 -1; -1 0 -1; 0 2 -1;
Volume 1 : -1 0 0; 0 2 0; 1 0 0; 1 1 2;
Volume 2 : 0 2 -1; -1 0 -1; 1 0 -1; 1 1 -3;
Volume 1 : -1 0 0; 0 2 0; 1 0 0; 1 1 2;
Volume 2 : 0 2 0; -1 0 0; 1 0 0; 1 1 -3;
Volume 1 : 2 1 1; 3 3 1; 4 1 1; 1 1 2;
Volume 2 : 3 3 1; 2 1 1; 4 1 1; 4 2 -2;
LCC characteristics: #Darts=24, #0-cells=5, #1-cells=9, #2-cells=7, #3-cells=2, #ccs=1, valid=1
```

The first line gives the points of the linear cell complex before the *sew<3>*. There are eight points, four for each tetrahedron. After the sew, six vertices are merged two by two, thus there are five vertices. We can see the points of each 3-cell (lines Volume 1 and Volume 2) before the sew, after the sew and after the translation of the second volume. We can see that this translation has also modified the three common points between the two 3-cells. The last line shows the number of cells of the linear cell complex, the number of connected components, and finally a Boolean to show the validity of the linear cell complex.

28.4.2 A 4D Linear Cell Complex

This example uses a 4-dimensional linear cell complex embedded in a 5-dimensional ambient space. It creates two tetrahedra having 5D points and sews the two tetrahedra by β_4. Then we use some high level operations, display the number of cells of the linear cell complex, and check its validity. Last we use the reverse operations to get back to the initial configuration.

```
#include <CGAL/Linear_cell_complex.h>

```

28.4.3 A 3D Linear Cell Complex with Colored Vertices

This example illustrates the way to use a 3D linear cell complex by adding another information to vertices. For that, we need to define our own items class. The difference with the *CGAL::Linear_cell_complex_min_items* class is about the definition of the vertex attribute where we use a *CGAL::Cell_attribute_with_point* with a non void info. In this example, the "vextex color" is just given by an *int* (the second template parameter of the *CGAL::Cell_attribute_with_point*). Lastly, we define the *Average_functor* class in order to set the color of a vertex resulting of the merging of two vertices to the average of the two initial values. This functor is associated with the vertex attribute by passing it as template parameter. Using this items class instead of the default one is done during the instantiation of template parameters of the *CGAL::Linear_cell_complex* class.

Now we can use *LCC_3* in which each vertex is associated with an attribute containing both a point and an information. In the following example, we create two cubes, and set the color of the vertices of the first cube to 1 and of the second cube to 19 (by iterating through two *One_dart_per_incident_cell_range<0, 3>* ranges). Then we *3-sew* the two cubes along one facet. This operation merges some vertices (as in the example of Figure 28.5). We insert a vertex in the common 2-cell between the two cubes, and set the information of the new 0-attribute to 5. In the last loop, we display the point and the information of each vertex of the linear cell complex.

```
#include <CGAL/Linear_cell_complex.h>
#include <CGAL/Linear_cell_complex_operations.h>
#include <iostream>
#include <algorithm>

struct Average_functor
{
  template<class CellAttribute>
  void operator()(CellAttribute& ca1,const CellAttribute& ca2)
  { ca1.info()=(ca1.info()+ ca2.info())/2; }
};

struct Myitem
{
  template<class Refs>
  struct Dart_wrapper
  {
    typedef CGAL::Dart<3, Refs > Dart;

    typedef CGAL::Cell_attribute_with_point< Refs, int, CGAL::Tag_true,
                                             Average_functor >
    Vertex_attribute;

    typedef CGAL::cpp0x::tuple<Vertex_attribute> Attributes;
  };
};

typedef CGAL::Linear_cell_complex_traits
<3, CGAL::Exact_predicates_inexact_constructions_kernel> Traits;
typedef CGAL::Linear_cell_complex<3,3,Traits,Myitem>     LCC_3;
```

```
typedef LCC_3::Dart_handle                                    Dart_handle;
typedef LCC_3::Point                                          Point;
typedef LCC_3::FT                                             FT;

Dart_handle make_iso_cuboid(LCC_3& lcc, const Point& basepoint, FT lg)
{
  return lcc.make_hexahedron(basepoint,
                             Traits::Construct_translated_point()
                             (basepoint,Traits::Vector(lg,0,0)),
                             Traits::Construct_translated_point()
                             (basepoint,Traits::Vector(lg,lg,0)),
                             Traits::Construct_translated_point()
                             (basepoint,Traits::Vector(0,lg,0)),
                             Traits::Construct_translated_point()
                             (basepoint,Traits::Vector(0,lg,lg)),
                             Traits::Construct_translated_point()
                             (basepoint,Traits::Vector(0,0,lg)),
                             Traits::Construct_translated_point()
                             (basepoint,Traits::Vector(lg,0,lg)),
                             Traits::Construct_translated_point()
                             (basepoint,Traits::Vector(lg,lg,lg)));
}

int main()
{
  LCC_3 lcc;

  // Create two iso_cuboids.
  Dart_handle d1 = make_iso_cuboid(lcc, Point(-2, 0, 0), 1);
  Dart_handle d2 = make_iso_cuboid(lcc, Point(0, 0, 0), 1);

  // Set the "color" of all vertices of the first cube to 1.
  for (LCC_3::One_dart_per_incident_cell_range<0, 3>::iterator
         it=lcc.one_dart_per_incident_cell<0,3>(d1).begin(),
         itend=lcc.one_dart_per_incident_cell<0,3>(d1).end(); it!=itend;
   ++it)
  { LCC_3::vertex_attribute(it)->info()=1; }

  // Set the "color" of all vertices of the second cube to 19.
  for (LCC_3::One_dart_per_incident_cell_range<0, 3>::iterator it=
         lcc.one_dart_per_incident_cell<0,3>(d2).begin(),
         itend=lcc.one_dart_per_incident_cell<0,3>(d2).end(); it!=itend;
   ++it)
  { LCC_3::vertex_attribute(it)->info()=19; }

  // 3-Sew the two cubes along one facet.
  lcc.sew<3>(d1->beta(1)->beta(1)->beta(2), d2->beta(2));

  // Barycentric triangulation of the facet between the two cubes.
  Dart_handle d3=lcc.insert_barycenter_in_cell<2>(d2->beta(2));

  // Set the color of the new vertex to 5.
  LCC_3::vertex_attribute(d3)->info()=5;
```

```
  // Display all the vertices of the map.
  for (LCC_3::Vertex_attribute_range::iterator
         it=lcc.vertex_attributes().begin(),
         itend=lcc.vertex_attributes().end();
       it!=itend; ++it)
  {
    std::cout<<"point: "<<it->point()<<", "<<"color: "<<it->info()
             <<std::endl;
  }

  return EXIT_SUCCESS;
}
```

File: examples/Linear_cell_complex/linear_cell_complex_3_with_colored_vertices.cpp

The output is:

```
point: -1 1 1, color: 10
point: -1 0 1, color: 10
point: -2 0 1, color: 1
point: -2 1 1, color: 1
point: -2 1 0, color: 1
point: -1 1 0, color: 10
point: -1 0 0, color: 10
point: -2 0 0, color: 1
point: 1 1 1, color: 19
point: 1 0 1, color: 19
point: -1 0.5 0.5, color: 5
point: 1 1 0, color: 19
point: 1 0 0, color: 19
```

Before applying the sew operation, the eight vertices of the first cube are colored by 1, and the eight vertices of the second cube by 19. After the sew operation, there are eight vertices which are merged two by two, and due to the average functor, the color of the four resulting vertices is now 10. Then we insert a vertex in the center of the common 2-cell between the two cubes. The coordinates of this vertex are initialized with the barycenter of the 2-cell (-1,0.5,0.5), and its color is not initialized by the method, thus we set its color manually by using the result of *insert_barycenter_in_cell*<2> which is a dart incident to the new vertex.

28.5 Design and Implementation History

This package was developed by Guillaume Damiand, with the help of Andreas Fabri, Sébastien Loriot and Laurent Rineau. Monique Teillaud and Bernd Gärtner contributed to the manual.

Constructions for Linear cell complex

Operations for Linear cell complex

28.7 Alphabetical List of Reference Pages

LinearCellComplexTraits

Required types and functors for the LinearCellComplexTraits concept. This geometric traits concept is used in the *Linear_cell_complex* class.

Constants

static unsigned int	*ambient_dimension;*	The ambient dimension, must be >1.

Types

LinearCellComplexTraits:: FT	a number type that is a model of FieldNumberType.
LinearCellComplexTraits:: Point	point type.
LinearCellComplexTraits:: Vector	vector type.

Constructions

LinearCellComplexTraits:: Construct_translated_point

Functor that provides *Point operator() (const Point& p, const Vector& v)*, which constructs the translation of point *p* by vector *v*, and *Point operator() (const CGAL::Origin&, const Vector& v)*, which constructs the translation of a point at the origin by vector *v* (used in *Linear_cell_complex::barycenter*).

LinearCellComplexTraits:: Construct_vector

Functor that provides *Vector operator() (const Point& p1, const Point& p2)* which constructs a vector as the difference of points *p2-p1*, and *Vector operator() (const CGAL::Origin&, const Point& p)* which constructs a vector as the difference of point *p* and a point at the origin (used in *Linear_cell_complex::barycenter* and *CGAL::import_from_plane_graph*).

LinearCellComplexTraits:: Construct_sum_of_vectors

Functor that provides *Vector operator() (const Vector& v1, const Vector& v2)* which constructs a vector as the sum of vectors *v1+v2* (used in *Linear_cell_complex::barycenter*, *CGAL::compute_normal_of_cell_0* and *CGAL::compute_normal_of_cell_2*).

LinearCellComplexTraits:: Construct_scaled_vector

Functor that provides *Vector operator() (const Vector& v, FT scale)* which constructs a vector equal to vector *v* scaled by *scale* factor (used in *Linear_cell_complex::barycenter* , *CGAL::compute_normal_of_cell_0* and *CGAL::compute_normal_of_cell_2*).

LinearCellComplexTraits:: Construct_midpoint

Functor that provides *Point operator() (const Point& p1, const Point& p2)* which constructs the midpoint of points *p1* and *p2* (used in *Linear_cell_complex::barycenter*).

If *ambient_dimension==2*

LinearCellComplexTraits:: Direction_2	a model of *Direction_2*.
LinearCellComplexTraits:: Construct_direction_2	
	a model of *ConstructDirection_2* (used in *CGAL::import_from_plane_graph*).

If *ambient_dimension==3*

LinearCellComplexTraits:: Construct_normal_3	
	a model of *ConstructNormal_3* (used in *CGAL::compute_normal_of_cell_2*).
LinearCellComplexTraits:: Collinear_3	a model of *Collinear_3* (used in *CGAL::compute_normal_of_cell_2*).

See Also

CGAL::Linear_cell_complex<d,d2,LCCTraits,Items,Alloc> . . . . page 1975

LinearCellComplexItems

Definition

The concept LinearCellComplexItems refines the concept of *CombinatorialMapItems* by adding the requirement that 0-attributes are enabled, and associated with attributes that are models of the *CellAttributeWithPoint* concept.

Refines

CombinatorialMapItems . . . . page 1934

Requirements

The first type in *Attributes* must be a model of the *CellAttributeWithPoint* concept.

Has Models

CGAL::Linear_cell_complex_min_items<d> . . . . page 1982

CGAL::Linear_cell_complex<d,d2,LCCTraits,Items,Alloc> . . . . page 1975
CellAttributeWithPoint . . . . page 1974
CGAL::Dart<d,CMap> . . . . page 1938

Concept

CellAttributeWithPoint

Definition

The concept CellAttributeWithPoint is a refinement of the *CellAttribute* concept, to represent a cell attribute containing a point.

Refines

CellAttribute . . . page 1932

Types

CellAttributeWithPoint:: Point	Type of the used point.

Creation

CellAttributeWithPoint cawp;	Default constructor.
CellAttributeWithPoint cawp(Point apoint);	Constructor initializing the point of *cawp* by the copy contructor *Point(apoint)*.
CellAttributeWithPoint cawp(Point apoint, Info info);	Constructor initializing the point of *cawp* by the copy contructor *Point(apoint)* and initializing the information of *cawp* by the copy contructor *Info(info)*. Defined only if *Info* is different from *void*.

Access Member Functions

Point&	*cawp.point()*	Returns the point of *cawp*.
Point	*cawp.point() const*	Returns the point of *cawp*, when *cawp* is const.

CGAL::Linear_cell_complex<d,d2,LCCTraits,Items,Alloc>

Class

#include <CGAL/Linear_cell_complex.h>

Definition

The class *Linear_cell_complex<d,d2,LCCTraits,Items,Alloc>* represents a linear cell complex in dimension *d*, in an ambient space of dimension *d2*. This is a model of the concept of *CombinatorialMap* adding a requirement to ensure that each vertex of the map is associated with a model of *CellAttributeWithPoint*.

Is Model for the Concepts

CombinatorialMap . . . . page 1919

Inherits From

CGAL::Combinatorial_map<d,Items,Alloc> . . . . page 1936

Parameters

d an integer for the dimension of the combinatorial map,
d2 an integer for the dimension of the ambient space,
LCCTraits must be a model of the *LinearCellComplexTraits* concept, satisfying *LCCTraits::ambiant_dimension==d2*,
Items must be a model of the *LinearCellComplexItems* concept,
Alloc has to match the standard allocator requirements.

There are four default template arguments: *d2* is equal to *d*, *LCCTraits* is equal to *CGAL::Linear_cell_complex_traits<d2>*, *Items* is equal to *CGAL::Linear_cell_complex_min_items<d>* and *Alloc* is *CGAL_ALLOCATOR(int)*.

advanced

Note that there is an additional, and undocumented, template parameter *CMap* for *Linear_cell_complex<d,d2,LCCTraits,Items,Alloc,CMap>* allowing to inherit from any model of the *CombinatorialMap* concept.

advanced

Creation

Linear_cell_complex<d,d2,LCCTraits,Items,Alloc> lcc;

Constants

static unsigned int *ambient_dimension = d2;*

must be >1.

Types

typedef Linear_cell_complex<d,d2,LCCTraits,Items,Alloc>	*Self;*
typedef Items::Dart_wrapper<Self>::Dart	*Dart;*

The type of dart, must satisfy *Dart::dimension==d*.

typedef LCCTraits	*Traits;*
typedef Items	*Items;*
typedef Alloc	*Alloc;*

typedef Traits::FT	*FT;*
typedef Traits::Point	*Point;*
typedef Traits::Vector	*Vector;*

Linear_cell_complex<d,d2,LCCTraits,Items,Alloc>:: Vertex_attribute

Type of 0-attributes, a model of *CellAttributeWithPoint* concept (a shortcut for *Attribute_type_d<0>::type*).

Linear_cell_complex<d,d2,LCCTraits,Items,Alloc>:: Vertex_attribute_handle

Handle through 0-attributes (a shortcut for *Attribute_handle_type_d<0>::type*).

Linear_cell_complex<d,d2,LCCTraits,Items,Alloc>:: Vertex_attribute_const_handle

Const handle through 0-attributes (a shortcut for *Attribute_const_handle_type_d<0>::type*).

Linear_cell_complex<d,d2,LCCTraits,Items,Alloc>:: Vertex_attribute_range

Range of all the 0-attributes, a model of the *Range* concept (a shortcut for *Attribute_range_d<0>::type*). Iterator inner type is bidirectional iterator and value type is *Vertex_attribute*.

Linear_cell_complex<d,d2,LCCTraits,Items,Alloc>:: Vertex_attribute_const_range

Const range of all the 0-attributes, a model of the *ConstRange* concept a shortcut for *Attribute_const_range_d<0>::type*). Iterator inner type is bidirectional iterator and value type is *Vertex_attribute*.

Range Access Member Functions

Vertex_attribute_range& *lcc.vertex_attributes()*

Returns a range of all the 0-attributes in *lcc* (a shortcut for *attributes<0>()*).

Vertex_attribute_const_range& *lcc.vertex_attributes() const*

Returns a const range of all the 0-attributes in *lcc* (a shortcut for *attributes<0>() const*).

Access Member Functions

bool *lcc.is_valid() const* Returns true iff *lcc* is valid.

A linear cell complex *lcc* is valid if it is a valid combinatorial map, and if for each dart handle *dh* such that **dh*∈*lcc.darts()*: *dh->attribute<0>()!=NULL.*

size_type *lcc.number_of_vertex_attributes() const*

Returns the number of 0-attributes in *lcc* (a shortcut for *number_of_attributes<0>()*).

Static Member Functions

static Vertex_attribute_handle *vertex_attribute(Dart_handle dh)*

Returns the 0-attribute associated with *dh*.

static Vertex_attribute_const_handle *vertex_attribute(Dart_const_handle dh)*

Returns the 0-attribute associated with *dh*, when *dh* is const.

static Point& *point(Dart_handle dh)*

Returns the point in the 0-attribute associated with *dh*.

static Point *point(Dart_const_handle dh)*

Returns the point in the 0-attribute associated with *dh*, when *dh* is const.

Modifiers

Dart_handle *lcc.create_dart(Vertex_attribute_handle vh)*

Creates a new dart in *lcc*, sets its associated 0-attribute to *vh* and returns the corresponding handle.
Precondition: **vh*∈*lcc.vertex_attributes()*.

Dart_handle *lcc.create_dart(Point apoint)*

Creates a new dart in *lcc*, creates a new 0-attribute initialized with *apoint*, sets the associated 0-attribute of the new dart to this new 0-attribute, and returns the corresponding handle.

template<typename T1>
Vertex_attribute_handle *lcc.create_vertex_attribute(T1 t1)*

Creates a new 0-attribute in *lcc*, and returns the corresponding handle (a shortcut for *create_attribute<0> (t1)*). Calls the constructor of *Vertex_attribute* having *T1* as parameter. Overloads of this member function are defined that take from zero to nine arguments. With zero argument, *create_vertex_attribute()* creates a new 0-attribute by using the default constructor.

void *lcc.erase_vertex_attribute(Vertex_attribute_handle vh)*

Removes the 0-attribute pointed to by *vh* from *lcc* (a shortcut for *erase_attribute<0>(vh)*).
Precondition: **vh*$\in$*lcc.vertex_attributes()*.

void *lcc.set_vertex_attribute(Dart_handle dh, Vertex_attribute_handle vh)*

Associates the 0-attribute of all the darts of the 0-cell containing *dh* to *vh* (a shortcut for *set_attribute<0> (dh,vh)*).
Precondition: **dh*$\in$*lcc.darts()* and **vh*$\in$*lcc.vertex_attributes()*.

Operations

template<unsigned int i>
Point *lcc.barycenter(Dart_const_handle dh) const*

Returns the barycenter of the *i*-cell containing *dh*.
Precondition: $1 \leq i \leq$ *dimension* and **dh*$\in$*lcc.darts()*.

template <unsigned int i>
Dart_handle *lcc.insert_point_in_cell(Dart_handle dh, Point p)*

Inserts a point, copy of *p*, in the *i*-cell containing *dh*. Returns a handle on one dart of this cell.
Precondition: $1 \leq$ *dimension* ≤ 2 and **dh*$\in$*lcc.darts()*.
If *i*-attributes are non void, *Attribute_type<i> ::type::On_split*(*a*,*a'*) is called, with *a* the original *i*-attribute associated with *dh* and *a'* each new *i*-attribute created during the operation.

template <unsigned int i>

Dart_handle *lcc.insert_barycenter_in_cell(Dart_handle dh)*

Inserts a point in the barycenter of the *i*-cell containing *dh*. Returns a handle on one dart of this cell.
Precondition: $1 \leq$ *dimension* ≤ 2 and **dh*$\in$*lcc.darts()*.
If *i*-attributes are non void, *Attribute_type<i> ::type::On_split*(*a*,*a'*) is called, with *a* the original *i*-attribute associated with *dh* and *a'* each new *i*-attribute created during the operation.

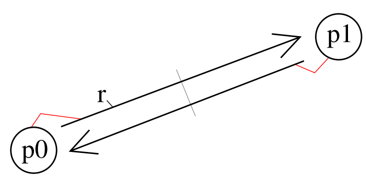
Dart_handle *lcc.insert_dangling_cell_1_in_cell_2(Dart_handle dh, Point p)*

Inserts a 1-cell in the 2-cell containing *dh*, the 1-cell being attached only by one of its vertex to the 0-cell containing *dh*. The second vertex is associated with a new 0-attribute containing a copy of *p* as point. Returns a handle on one dart belonging to the new 0-cell.
Precondition: *dimension* ≥ 2 and **dh*$\in$*lcc.darts()*.

Constructions

Dart_handle *lcc.make_segment(Point p0, Point p1)*

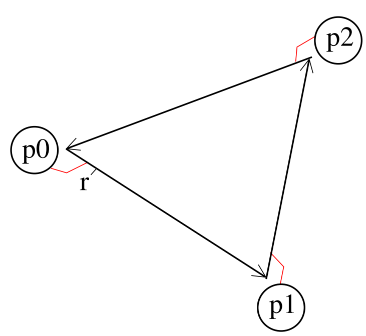
Creates an isolated segment in *lcc* (two darts linked by β_2) having *p0*, *p1* as points. Returns a handle on the dart associated with *p0*.
Precondition: *dimension* ≥ 2.



Example of *r=lcc.make_segment(p0,p1)*.

Dart_handle *lcc.make_triangle(Point p0, Point p1, Point p2)*

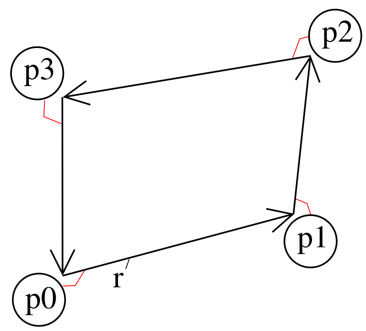
Creates an isolated triangle in *lcc* having *p0*, *p1*, *p2* as points. Returns a handle on the dart associated with *p0*.
Precondition: *dimension* ≥ 1.



Example of *r=lcc.make_triangle(p0,p1,p2)*.

Dart_handle *lcc.make_quadrangle(Point p0, Point p1, Point p2, Point p3)*

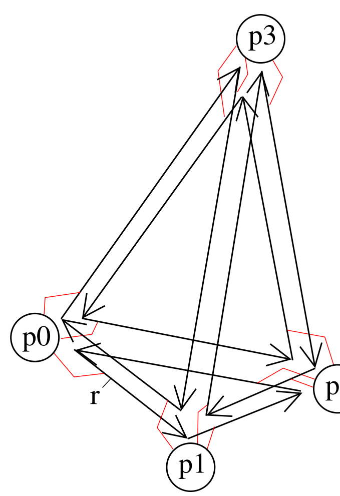
Creates an isolated quadrangle in *lcc* having *p0*, *p1*, *p2*, *p3* as points. Returns a handle on the dart associated with *p0*.
Precondition: *dimension*≥1.



Example of *r=lcc.make_quadrangle(p0,p1,p2,p3)*.

Dart_handle *lcc.make_tetrahedron(Point p0, Point p1, Point p2, Point p3)*

Creates an isolated tetrahedron in *lcc* having *p0*, *p1*,*p2*,*p3* as points. Returns a handle on the dart associated with *p0* and belonging to the 2-cell having *p0*, *p1*, *p2* as points.
Precondition: *dimension*≥2.

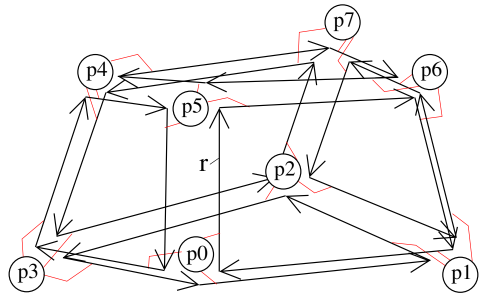


Example of *r=lcc.make_tetrahedron(p0,p1,p2,p3)*.

Dart_handle *make_hexahedron(Point p0,*
Point p1,
Point p2,
Point p3,
Point p4,
Point p5,
Point p6,

Point p7)

Creates an isolated hexahedron in *lcc* having *p0*, *p1*, *p2*, *p3*, *p4*, *p5*, *p6*, *p7* as points. Returns a handle on the dart associated with *p0* and belonging to the 2-cell having *p0*, *p5*, *p6*, *p1* as points.
Precondition: *dimension*≥2.



Example of *r=lcc.make_hexahedron(p0,p1,p2,p3,p4,p5,p6,p7)*.

Class

CGAL::Linear_cell_complex_min_items<d>

#include <CGAL/Linear_cell_complex_min_items.h>

Definition

The class *Linear_cell_complex_min_items<d>* defines the type of darts, which is a *Dart_wrapper::Dart<d,LCC>* , and the traits class used. In this class, 0-attributes are enabled and associated with *Cell_attribute_with_point*.

Is Model for the Concepts

LinearCellComplexItems . . . . page 1973

Parameters

d the dimension of the combinatorial map.

Example

The following example shows one implementation of the *Linear_cell_complex_min_items<d>* class.

```
template <unsigned int d>
struct Linear_cell_complex_min_items
{
  template <class LCC>
  struct Dart_wrapper
  {
    typedef CGAL::Dart<d, LCC> Dart;

    typedef CGAL::Cell_attribute_with_point<LCC> Vertex_attrib;
    typedef CGAL::cpp0x::tuple<Vertex_attrib> Attributes;
  };
};
```

CGAL::Linear_cell_complex_traits<d,K>

#include <CGAL/Linear_cell_complex_traits.h>

Class

Definition

This geometric traits concept is used in the *Linear_cell_complex* class. It can take as parameter any model of the concept *Kernel* (for example any CGAL kernel), and defines inner types and functors corresponding to the given dimension.

Is Model for the Concepts

LinearCellComplexTraits . . . . page 1971

Inherits From

K.

Parameters

d the dimension of the kernel,
K a model of the concept *Kernel* if *d==2* or *d==3*; a model of the concept *Kernel_d* otherwise.

There is a default template arguments for *K* which is *CGAL::Exact_predicates_inexact_constructions_kernel* if *d* is 2 or 3, and is *CGAL::Cartesian_d<double>* otherwise.

Note that the default argument used for *K* when *d*>3 does not use exact predicates because operations that use predicates are only defined in 2D and 3D.

Constants

static unsigned int *ambient_dimension = d;*

Class

CGAL::Cell_attribute_with_point<LCC,Info_,Tag,OnMerge,OnSplit>

#include <CGAL/Cell_attribute_with_point.h>

Definition

The class *Cell_attribute_with_point<LCC,Info_,Tag,OnMerge,OnSplit>* represents an attribute containing a point and containing an information when *Info_* is different from void. This class can typically be used to associate a point to each 0-cell of a combinatorial map.

Is Model for the Concepts

CellAttributeWithPoint . . . . page 1974

Inherits From

CGAL::Cell_attribute<CMap,Info_,Tag,OnMerge,OnSplit> . . . . page 1939

Parameters

LCC must be an instantiation of *Linear_cell_complex* class,
*Info_* is the type of the information contained in the attribute, *void* for no information,
Tag is *Tag_true* to enable the storage of a *Dart_handle* of the associated cell, *Tag_false* otherwise,
OnMerge is a functor called when two attributes are merged,
OnSplit is a functor called when one attribute is split in two.

By default, *OnMerge* and *OnSplit* are equal to *Null_functor*; *Tag* is equal to *Tag_true*; and *Info_* is equal to *void*.

Types

typedef LCC::Point	*Point;*
typedef LCC::Dart_handle	*Dart_handle;*
typedef LCC::Dart_const_handle	*Dart_const_handle;*

CGAL::import_from_plane_graph<LCC>

#include <CGAL/Linear_cell_complex_constructors.h>

template<class LCC>
typename LCC::Dart_handle

import_from_plane_graph(LCC& lcc, std::istream& ais)

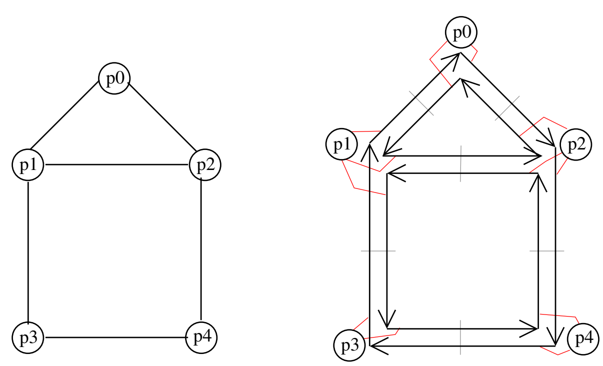
Imports an embedded plane graph read from *ais* into *lcc*. Objects are added in *lcc*, existing darts are not modified. Returns a dart created during the import.
Precondition: *LCC::dimension*≥2 and *LCC::ambient_dimension*==2.

File format

The file format must be the following. First the number of vertices and the number of edges of the planar graph. Then, for each vertex of the planar graph, the coordinates of the i^{th} vertex (two numbers for x and y coordinates). The first vertex index is 0. Then for each edge of the planar graph, the two indices of the two vertices (two numbers between 0 and the number of vertices minus 1).

Here a small example:

```
5 6
1.0 3.0    0.0 2.0    2.0 2.0    0.0 0.0    2.0 0.0
0 1   0 2   1 2   1 3   2 4   3 4
```



Example of *import_graph* reading the above file as istream.
Left: A planar graph embedded in the plane with *P0*=(1.0,3.0), *P1*=(0.0,2.0), *P2*=(2.0,2.0), *P3*=(0.0,0.0), *P4*=(2.0,0.0). **Right**: the 2D linear cell complex reconstructed.

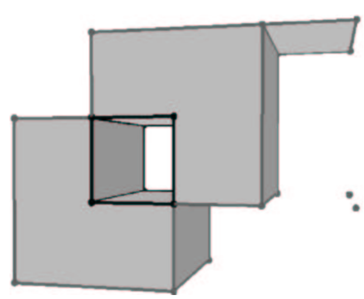
Chapter 29

3D Boolean Operations on Nef Polyhedra

Peter Hachenberger and Lutz Kettner

Contents

29.1 Introduction



In solid modeling, two major representation schemes are used: *constructive solid geometry* (CSG) and *boundary representations* (B-rep). Both have inherent strengths and weaknesses, see [Hof89c] for a discussion.

In CSG a solid is represented as a set-theoretic boolean combination of primitive solid objects, such as blocks, prisms, cylinders, or toruses. The boolean operations are not evaluated, instead, objects are represented implicitly with a tree structure; leaves represent primitive objects and interior nodes represent boolean operations or rigid motions, e.g., translation and rotation. Algorithms on such a CSG-tree first evaluate properties on the primitive objects and propagate the results using the tree structure.

A B-rep describes the incidence structure and the geometric properties of all lower-dimensional features of the boundary of a solid. Surfaces are oriented to decide between the interior and exterior of a solid.

The class of representable objects in a CSG is usually limited by the choice of the primitive solids. A B-rep is usually limited by the choice for the geometry of the supporting curves for edges and the supporting surfaces for surface patches, and, in addition, the connectivity structure that is allowed. In particular, a B-rep is not always closed under boolean set operations. As an example, the class of orientable 2-manifold objects is a popular and well understood class of surfaces commonly used for B-reps. They can be represented and manipulated efficiently, the data structures are compact in storage size, and many algorithms are simple. On the other side, this object class is not closed under boolean set operations, as many examples can illustrate, such as the Figure shown above that can be generated using boolean set operations on cubes. The vertices bounding the tunnel, or the edge connecting the "roof" with the cube are non-manifold situations.

In our implementation of Nef polyhedra in 3D, we offer a B-rep data structure that is closed under boolean operations and with all their generality. Starting from halfspaces (and also directly from oriented 2-manifolds), we can work with set union, set intersection, set difference, set complement, interior, exterior, boundary, closure, and regularization operations (see Section 29.4 for an explaination of regularized set operations). In essence, we can evaluate a CSG-tree with halfspaces as primitives and convert it into a B-rep representation.

In fact, we work with two data structures; one that represents the local neighborhoods of vertices, which is in itself already a complete description, and a data structure that connects these neighborhoods up to a global data structure with edges, facets, and volumes. We offer a rich interface to investigate these data structures, their different elements and their connectivity. We provide affine (rigid) transformations and a point location query operation. We have a custom file format for storing and reading Nef polyhedra from files. We offer a simple OpenGL-based visualizer for debugging and illustrations.

29.2 Definition

The theory of Nef polyhedra has been developed for arbitrary dimensions. The class *CGAL::Nef_polyhedron_3* implements a boundary representation for the 3-dimensional case.

Definition: A *Nef-polyhedron* in dimension d is a point set $P \subseteq \mathbb{R}^d$ generated from a finite number of open halfspaces by set complement and set intersection operations.

Set union, difference and symmetric difference can be reduced to intersection and complement. Set complement changes between open and closed halfspaces, thus the topological operations *boundary*, *interior*, *exterior*, *closure* and *regularization* are also in the modeling space of Nef polyhedra.

A face of a Nef polyhedron is defined as an equivalence class of *local pyramids* that are a characterization of the local space around a point.

Definition: A point set $K \subseteq \mathbb{R}^d$ is called a *cone with apex* 0, if $K = \mathbb{R}^+ K$ (i.e., $\forall p \in K, \forall \lambda > 0 : \lambda p \in K$) and it is called a *cone with apex* x, $x \in \mathbb{R}^d$, if $K = x + \mathbb{R}^+(K - x)$. A cone K is called a *pyramid* if K is a polyhedron.

Now let $P \in \mathbb{R}^d$ be a polyhedron and $x \in \mathbb{R}^d$. There is a neighborhood $U_0(x)$ of x such that the pyramid $Q := x + \mathbb{R}^+((P \cap U(x)) - x)$ is the same for all neighborhoods $U(x) \subseteq U_0(x)$. Q is called the *local pyramid* of P in x and denoted $\mathrm{Pyr}_P(x)$.

Definition: Let $P \in \mathbb{R}^d$ be a polyhedron and $x, y \in \mathbb{R}^d$ be two points. We define an equivalence relation $x \sim y$ iff $\mathrm{Pyr}_P(x) = \mathrm{Pyr}_P(y)$. The equivalence classes of $\sim$ are the *faces* of P. The dimension of a face s is the dimension of its affine hull, $\dim s := \dim \mathrm{aff}\, s$.

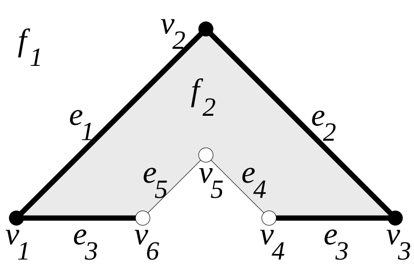
In other words, a *face* s of P is a maximal non-empty subset of $\mathbb{R}^d$ such that all of its points have the same local pyramid Q denoted $\mathrm{Pyr}_P(s)$. This definition of a face partitions $\mathbb{R}^d$ into faces of different dimension. A face s is either a subset of P, or disjoint from P. We use this later in our data structure and store a selection mark in each face indicating its set membership.

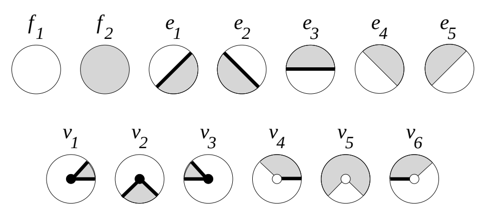
Faces do not have to be connected. There are only two full-dimensional faces possible, one whose local pyramid is the space $\mathbb{R}^d$ itself and the other with the empty set as a local pyramid. All lower-dimensional faces form the *boundary* of the polyhedron. As usual, we call zero-dimensional faces *vertices* and one-dimensional faces *edges*. In the case of polyhedra in space we call two-dimensional faces *facets* and the full-dimensional faces *volumes*. Faces are *relative open* sets, e.g., an edge does not contain its end-vertices.

We illustrate the definitions with an example in the plane. Given the closed halfspaces

$$h_1 : y \geq 0, \qquad h_2 : x - y \geq 0, \qquad h_3 : x + y \leq 3, \qquad h_4 : x - y \geq 1, \qquad h_5 : x + y \leq 2,$$

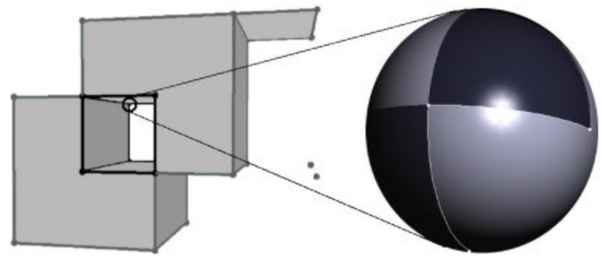
we define our polyhedron $P := (h_1 \cap h_2 \cap h_3) - (h_4 \cap h_5)$.



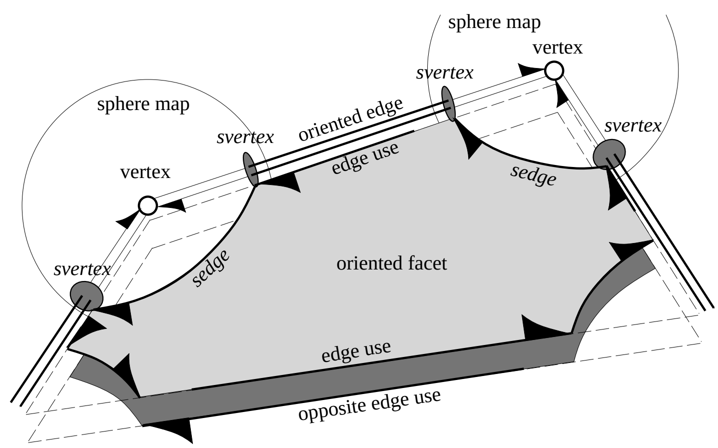


The left figure illustrates the polyhedron with its partially closed and partially open boundary, i.e., vertex v_4, v_5, v_6, and edges e_4 and e_5 are not part of P. The local pyramids for the faces are $\mathrm{Pyr}_P(f_1) = \emptyset$ and $\mathrm{Pyr}_P(f_2) = \mathbb{R}^2$. Examples for the local pyramids of edges are the closed halfspace h_2 for the edge e_1, $\mathrm{Pyr}_P(e_1) = h_2$, and the open halfspace that is the complement of h_4 for the edge e_5, $\mathrm{Pyr}_P(e_5) = \{(x,y) | x - y < 1\}$. The edge e_3 consists actually of two disconnected parts, both with the same local pyramid $\mathrm{Pyr}_P(e_3) = h_1$. In our data structure, we will represent the two connected components of the edge e_3 separately. The figure on the right lists all local pyramids for this example.

The local pyramids of each vertex are represented by conceptually intersecting the local neighborhood with a small ε-sphere. This intersection forms a planar map on the sphere (see next two figures), which together with the set-selection mark for each item (i.e. vertices, edges, loops and faces) forms a two-dimensional Nef polyhedron embedded in the sphere. We add the set-selection mark for the vertex and call the resulting structure the *sphere map* of the vertex. We use the prefix s to distinguish the elements of the sphere map from the three-dimensional elements. See Chapter 21 for further details.



Having sphere maps for all vertices of our polyhedron is a sufficient but not easily accessible representation of the polyhedron. We enrich the data structure with more explicit representations of all the faces and incidences between them.



We depart slightly from the definition of faces in a Nef polyhedron; we represent the connected components of a face individually and do not implement additional bookkeeping to recover the original faces (e.g., all edges on a common supporting line with the same local pyramid) as this is not needed in our algorithms. We discuss features in the increasing order of dimension.

edges: We store two oppositely oriented edges for each edge and have a pointer from one oriented edge to its opposite edge. Such an oriented edge can be identified with an *svertex* in a sphere map; it remains to link one *svertex* with the corresponding opposite *svertex* in the other sphere map.

edge uses: An edge can have many incident facets (non-manifold situation). We introduce two oppositely oriented edge-uses for each incident facet; one for each orientation of the facet. An edge-use points to its corresponding oriented edge and to its oriented facet. We can identify an edge-use with an oriented *sedge* in the sphere map, or, in the special case also with an *sloop*. Without mentioning it explicitly in the remainder, all references to *sedge* can also refer to *sloop*.

facets: We store oriented facets as boundary cycles of oriented edge-uses. We have a distinguished outer boundary cycle and several (or maybe none) inner boundary cycles representing holes in the facet. Boundary cycles are linked in one direction. We can access the other traversal direction when we switch to the oppositely oriented facet, i.e., by using the opposite edge-use.

shells: The volume boundary decomposes into different connected components, the *shells*. A shell consists of a connected set of facets, edges, and vertices incident to this volume. Facets around an edge form a radial order that is captured in the radial order of *sedges* around an *svertex* in the sphere map. Using this information, we can trace a shell from one entry element with a graph search. We offer this graph traversal (to the user) in a visitor design pattern.

volumes: A volume is defined by a set of shells, one outer shell containing the volume and several (or maybe none) inner shells separating voids which are excluded from the volume.

For each face we store a label, e.g., a set-selection mark, which indicates whether the face is part of the solid or if it is excluded. We call the resulting data structure *Selective Nef Complex*, *SNC* for short [GHH+03]. However, in CGAL we identify the names and call the *SNC* data structure *CGAL::Nef_polyhedron_3*.

29.3 Infimaximal Box

We call a Nef polyhedron *bounded* if its boundary is bounded, i.e., finite, and *unbounded* otherwise. Note that unbounded point sets can have a bounded boundary, for example, the complement of a cube has an unbounded outer volume, but its boundary remains bounded.

Using a boundary representation, it is convenient (conceptually and in our implementation) to consider bounded Nef polyhedra only. Bounded Nef polyhedra are also closed under boolean set operations. However, one needs to start with bounded primitives; the conceptually nice halfspaces cannot be used. Instead, we offer a construction from oriented 2-manifolds represented in a *CGAL::Polyhedron_3*, see Section 29.5.4 below.

In order to handle unbounded Nef polyhedra conceptually in the same way as we handle bounded Nef polyhedra, we intersect them with a bounding cubical volume of size $[-R,R]^3$, where R is a symbolical unspecified value, which is finite but larger than all coordinate values that may occur in the bounded part of the polyhedron. As a result, each Nef polyhedron becomes bounded. We call the boundary of the bounding volume the *infimaximal box* [SM00].

We clip lines and rays at the infimaximal box. The intersection points with the infimaximal box are called *non-standard points*, which are points whose coordinates are $-R$ or R in at least one dimension, and linear functions $f(R)$ for the other dimensions. Such extended points (and developed from there also extended segments etc) are provided in CGAL with extended kernels—*CGAL::Extended_cartesian* and *CGAL::Extended_homogeneous*. They are regular CGAL kernels with a polynomial type as coordinate number type.

As long as an extended kernel is used, the full functionality provided by the *CGAL::Nef_polyhedron_3* class is available. If a kernel that does not use polynomials to represent coordinates is used, it is not possible to create or load unbounded Nef polyhedra, but all other operations work as expected. We provided both possibilities, since the restriction to bounded Nef polyhedra improves considerably space requirements (plain number type instead of polynomial), and runtime performance.

29.4 Regularized Set Operations

Since manifolds are not closed under boolean operations, Requicha proposes to use *regularized set operations* [KM76, Req80]. A set is *regular*, if it equals the closure of its interior. A regularized set operation is defined as the standard set operation followed by a regularization of the result. Regularized sets are closed under regularized set operations.

Regularized set operations are important since they simplify the class of solids to exclude lower dimensional features and the boundary belongs to the point set. These properties are considered to reflect the nature of physical solids more closely.

Regularized polyhedral sets are a subclass of Nef polyhedra. We provide the *regularization* operation as a shortcut for the consecutive execution of the *interior* and the *closure* operations.

29.5 Example Programs

The following example gives a first impression of how to instantiate and use *Nef_polyhedron_3*. We use the *CGAL::Cartesian* kernel. All Cartesian and homogeneous kernels of CGAL are suitable if the number type parameter follows the usual requirements of being a model of the *CGAL::FieldNumberType* concept for the Cartesian kernels, or the *CGAL::RingNumberType* concept for the homogeneous kernels, respectively. Note however, that in the current state, the Nef polyhedron works only with CGAL kernels. The implementation makes use of CGAL specific functions in kernel objects, and does not yet offer a designed interface to a clean kernel concept that could be offered by an external kernel as well.

The example creates two Nef polyhedra—*N0* is the empty set, while *N1* represents the full space, i.e., the set of all points in the 3-dimensional space. The assertion assures that the empty set is the complement of the full space.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz>  Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;

int main() {
  Nef_polyhedron N0(Nef_polyhedron::EMPTY);
  Nef_polyhedron N1(Nef_polyhedron::COMPLETE);

  CGAL_assertion (N0 == N1.complement());
  return 0;
}
```

File: examples/Nef_3/nef_3_simple.cpp

29.5.1 Construction and Comparison

This example shows the various constructors. We can create the empty set, which is also the default constructor, and the full space, i.e. all points of $\mathbb{R}^3$ belong to the polyhedron. We can create a halfspace defined by a plane bounding it. It is only available if an extended kernel is used. The halfspace constructor has a second parameter that specifies whether the defining plane belongs to the point set (*Nef_polyhedron::INCLUDED*) or not (*Nef_polyhedron::EXCLUDED*). The default value is *Nef_polyhedron::INCLUDED*. Additionally, we can create a *Nef_polyhedron_3* from a *Polyhedron_3*, see the Section 29.5.4 below.

We can compute the point sets of two Nef polyhedra for equality and proper subset relationships. We offer the usual comparison operators ==, !=, <=, >=, < and >.

Nef polyhedra have the important feature that a representation that is called the *reduced Würzburg structure* is unique, i.e., two point sets of Nef polyhedra are equal if and only if the representations are equal. The proof for the reduced Würzburg structure carries over to our representation and the comparison operators are therefore trivial to implement.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
```

```
typedef CGAL::Extended_homogeneous<CGAL::Gmpz>  Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel>  Nef_polyhedron;
typedef Nef_polyhedron::Plane_3  Plane_3;

int main() {
  Nef_polyhedron N0;
  Nef_polyhedron N1(Nef_polyhedron::EMPTY);
  Nef_polyhedron N2(Nef_polyhedron::COMPLETE);
  Nef_polyhedron N3(Plane_3( 1, 2, 5,-1));
  Nef_polyhedron N4(Plane_3( 1, 2, 5,-1), Nef_polyhedron::INCLUDED);
  Nef_polyhedron N5(Plane_3( 1, 2, 5,-1), Nef_polyhedron::EXCLUDED);

  CGAL_assertion(N0 == N1);
  CGAL_assertion(N3 == N4);
  CGAL_assertion(N0 != N2);
  CGAL_assertion(N3 != N5);

  CGAL_assertion(N4 >= N5);
  CGAL_assertion(N5 <= N4);
  CGAL_assertion(N4 > N5);
  CGAL_assertion(N5 < N4);

  N5 = N5.closure();
  CGAL_assertion(N4 >= N5);
  CGAL_assertion(N4 <= N5);

  return 0;
}
```

File: examples/Nef_3/nef_3_construction.cpp

29.5.2 Point Set Operations

As explained in the introduction, Nef polyhedra are closed under all boolean set operations. The class *Nef_polyhedron_3* provides functions and operators for the most common ones: complement (*operator!*), union (*operator+*), difference (*operator-*), intersection (*operator**) and symmetric difference (*operator^*). Additionally, the operators *=, -=, *= and ^= are defined.

Nef_polyhedron_3 also provides the topological operations *interior()*, *closure()* and *boundary()*. With *interior()* one deselects all boundary items, with *boundary()* one deselects all volumes, and with *closure()* one selects all boundary items.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>

typedef CGAL::Extended_homogeneous<CGAL::Gmpz>  Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel>  Nef_polyhedron;
typedef Kernel::Plane_3  Plane_3;

int main() {
```

```
  Nef_polyhedron N1(Plane_3( 1, 0, 0,-1));
  Nef_polyhedron N2(Plane_3(-1, 0, 0,-1));
  Nef_polyhedron N3(Plane_3( 0, 1, 0,-1));
  Nef_polyhedron N4(Plane_3( 0,-1, 0,-1));
  Nef_polyhedron N5(Plane_3( 0, 0, 1,-1));
  Nef_polyhedron N6(Plane_3( 0, 0,-1,-1));

  Nef_polyhedron I1(!N1 + !N2);  // open slice in yz-plane
  Nef_polyhedron I2(N3 - !N4);   // closed slice in xz-plane
  Nef_polyhedron I3(N5 ^ N6);    // open slice in yz-plane
  Nef_polyhedron Cube1(I2 * !I1);
  Cube1 *= !I3;
  Nef_polyhedron Cube2 = N1 * N2 * N3 * N4 * N5 * N6;

  CGAL_assertion(Cube1 == Cube2);  // both are closed cube
  CGAL_assertion(Cube1 == Cube1.closure());
  CGAL_assertion(Cube1 == Cube1.regularization());
  CGAL_assertion((N1 - N1.boundary()) == N1.interior());
  CGAL_assertion(I1.closure() ==
   I1.complement().interior().complement());
  CGAL_assertion(I1.regularization() == I1.interior().closure());
  return 0;
}
```

File: examples/Nef_3/point_set_operations.cpp

29.5.3 Transformation

Using the *std::transform* function, a Nef polyhedron can be translated, rotated and scaled. The usage is shown in the following example:

```
#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

//instead of

29.5.4 The Interface between `Polyhedron_3` and `Nef_polyhedron_3`

Nef_polyhedron_3 provides an interface for the conversion between polyhedral surfaces represented with the *CGAL::Polyhedron_3* class and *Nef_polyhedron_3*. *Polyhedron_3* represents orientable 2-manifold objects with boundaries. However, we exclude surfaces with boundaries from the conversion to *Nef_polyhedron_3* since they have no properly defined volume.

Both conversion directions can only be performed if the boundary of the point set is an oriented closed 2-manifold. *Nef_polyhedron_3* provides the function *is_simple()* and *Polyhedron_3* provides the function *is_closed()* to test for this property. The usage is illustrated by the example program below.

The conversion gives us the possibility to use several file formats. *Polyhedron_3* can read the (`.off`) file format and can write the (`.off`), OpenInventor (`.iv`), VRML 1.0 and 2.0 (`.wrl`) and Wavefront Advanced Visualizer object format (`.obj`), see Section 25.4.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <iostream>

typedef CGAL::Homogeneous<CGAL::Gmpz>  Kernel;
typedef CGAL::Polyhedron_3<Kernel>  Polyhedron;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Kernel::Vector_3  Vector_3;
typedef Kernel::Aff_transformation_3  Aff_transformation_3;

int main() {
  Polyhedron P;
  std::cin >> P;
```

```
  if(P.is_closed()) {
    Nef_polyhedron N1(P);
    Nef_polyhedron N2(N1);
    Aff_transformation_3 aff(CGAL::TRANSLATION, Vector_3(2,2,0,1));
    N2.transform(aff);
    N1 += N2;

    if(N1.is_simple()) {
      N1.convert_to_polyhedron(P);
      std::cout << P;
    }
    else
      std::cerr << "N1 is not a 2-manifold." << std::endl;
  }
}
```

File: examples/Nef_3/interface_polyhedron.cpp

29.5.5 Using an Extended Kernel

The provided extended kernels are used the same way as any other CGAL kernel. The essential difference is, that coordinates are not represented by the number type that was used to parameterize the kernel type, but by a *Nef_polynomial* parametrized by that number type.

The example iterates all vertices of a given Nef polyhedron and decides whether it is an standard vertex or a vertex on the infimaximal box. Furthermore, it tests whether any of the vertices is at (R,R,R). Recall that R was the symbolical value, large but finite, for the size of the infimaximal box.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Gmpz  NT;
//instead of
//typedef CGAL::Extended_homogeneous<NT>  Kernel;
// workaround for VC++
struct Kernel : public CGAL::Extended_homogeneous<NT> {};

typedef CGAL::Nef_polyhedron_3<Kernel>  Nef_polyhedron;
typedef Nef_polyhedron::RT  RT;
typedef Nef_polyhedron::Point_3  Point_3;
typedef Nef_polyhedron::Plane_3  Plane_3;
typedef Nef_polyhedron::Vertex_const_iterator  Vertex_const_iterator;

int main() {

  Nef_polyhedron N;
  std::cin >> N;

  Vertex_const_iterator v;
  for(v = N.vertices_begin(); v != N.vertices_end(); ++v) {
```

```
    Point_3 p(v->point());
    if(p.hx().degree() > 0 || p.hy().degree() > 0 || p.hz().degree() > 0)
      std::cout << "extended vertex at " << p << std::endl;
    else
      std::cout << "standard vertex at " << p << std::endl;

    if(p == Point_3(RT(0,1), RT(0,1), RT(0,1)))
       std::cout << "  found vertex (right,back,top) of the infimaximal
   box"
                  << std::endl;
  }

  return 0;
}
```

File: examples/Nef_3/extended_kernel.cpp

29.6 File I/O

Nef_polyhedron_3 provides an input and an output operator for a proprietary file format. It includes the complete incidence structure, the geometric data, and the marks of each item. The output depends on the output operators of the geometric primitives provided by the traits class, and on the output operators of the used number type. Therefore, it is necessary to use the same kernel and the same number type for input and output operations.

We recommend the use of the CGAL kernels *Homogeneous*, *Exact_predicates_exact_constructions_kernel*, or *Extended_homogeneous*. The Homogeneous kernel provides reliable fast performance. In combination with *leda_integer* it is the fastest kernel for *Nef_polyhedron_3*. The *Exact_predicates_exact_constructions_kernel* uses filtering. In non-degenerate scenarios it's faster than the *Homogeneous* kernel. The most important advantage of the filtered kernel is that it is a Cartesian kernel, which allows the proper handling of OFF files using floating-point coordinates.

For effective filtering we had to change some concepts. The new concepts must be activated by using the *SNC_indexed_items*, because they don't apply for the extended kernels, yet. The new concepts also speed up *Nef_polyhedron_3* also in combination with all other standard kernels. The following example illustrates their usage.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef CGAL::Polyhedron_3<Kernel>  Polyhedron;
typedef CGAL::Nef_polyhedron_3<Kernel>  Nef_polyhedron;

int main() {

  Polyhedron P;
  std::cin >> P;
  Nef_polyhedron N(P);
```

```
  std::cout << "Exact_predicates_exact_constructions_kernel +
   SNC_indexed_items"
            << std::endl
            << "  allows efficient handling of input "
                 "using floating point coordinates"
            << std::endl;

  if(N.is_simple()) {
    N.convert_to_polyhedron(P);
    std::cout << P;
  }
  else {
    std::cout << N;
  }
}
```

File: examples/Nef_3/handling_double_coordinates.cpp

We provide compatibility between the input and output of various kernels. For most of the CGAL kernels it is possible to write a file constructed with one kernel and reread it with another. Also, it is possible to write a bounded Nef polyhedron using the *Extended_homogeneous* kernel and to read it afterwards using a standard kernel.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <fstream>

typedef CGAL::Gmpz  NT;
typedef CGAL::Homogeneous<NT>  SK;
typedef CGAL::Extended_homogeneous<NT>  EK;
typedef CGAL::Nef_polyhedron_3<SK>  Nef_polyhedron_S;
typedef CGAL::Nef_polyhedron_3<EK>  Nef_polyhedron_E;

int main() {
  Nef_polyhedron_E E;
  Nef_polyhedron_S S;

  std::cin >> E;

  if(E.is_bounded()) {
    std::ofstream out("temp.nef3");
    out << E;
    std::ifstream in("temp.nef3");
    in >> S;
  }
}
```

File: examples/Nef_3/nefIO.cpp

29.7 Further Example Programs

29.7.1 Exploring a Sphere Map

A sphere map is explored by using the function *get_sphere_map*, which returns the sphere map of the specified vertex as a *Nef_polyhedron_S2*. *Nef_polyhedron_S2* provides the functionality necessary for the exploration. Note, that one has to use the type *Nef_polyhedron_S2* as specified in *Nef_polyhedron_3* as is shown in the following example.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;

int main() {

  // We've put the typedefs here as VC7 gives us an ICE if they are
   global typedefs
  typedef Nef_polyhedron_3::Vertex_const_iterator Vertex_const_iterator;
  typedef Nef_polyhedron_3::Nef_polyhedron_S2 Nef_polyhedron_S2;
  typedef Nef_polyhedron_S2::SVertex_const_handle SVertex_const_handle;
  typedef Nef_polyhedron_S2::SHalfedge_const_handle
   SHalfedge_const_handle;
  typedef Nef_polyhedron_S2::SHalfloop_const_handle
   SHalfloop_const_handle;
  typedef Nef_polyhedron_S2::SFace_const_iterator SFace_const_iterator;
  typedef Nef_polyhedron_S2::SFace_cycle_const_iterator
    SFace_cycle_const_iterator;

  Nef_polyhedron_3 N;
  std::cin >> N;

  Vertex_const_iterator v = N.vertices_begin();
  Nef_polyhedron_S2 S(N.get_sphere_map(v));

  int i=0;
  SFace_const_iterator sf;
  for(sf = S.sfaces_begin(); sf != S.sfaces_end(); sf++) {
    SFace_cycle_const_iterator it;
    std::cout << "the sface cycles of sface " << i++ << " start with
   an\n";
    for(it = sf->sface_cycles_begin(); it != sf->sface_cycles_end();
   it++) {
      if (it.is_svertex())
        std::cout << "  svertex at position "
                  << SVertex_const_handle(it)->point() << std::endl;
      else if (it.is_shalfedge())
        std::cout << "  shalfedge from "
                  << SHalfedge_const_handle(it)->source()->point() << "
```

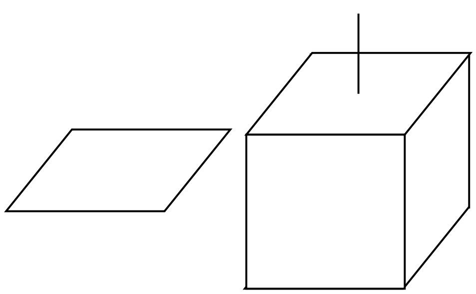
```
  to "
                  << SHalfedge_const_handle(it)->target()->point() <<
  std::endl;
     else if (it.is_shalfloop())
       std::cout << "  shalfloop lying in the plane "
                  << SHalfloop_const_handle(it)->circle() << std::endl;
     // other cases can not occur.
    }
  }

  return 0;
}
```

File: examples/Nef_3/exploration_SM.cpp

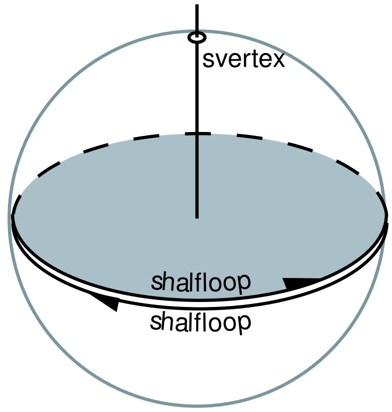
29.7.2 Exploring Shells

A *shell* of a Nef polyhedron is the connected part of the surface incident to a certain volume. Each halffacet, sface and shalfedge belongs to a single shell. The figure below illustrates the notion of a shell. It shows a Nef polyhedron with two volumes and three shells.



The first volume is the outer volume and the second volume is the interior of the cube. The first shell is the whole surface of the left object. The second shell is the outer surface of the right object, and the third shell is the inner surface of the right object.

In detail, the first shell consists of two halffacets, eight halfedges and four vertices. The second shell consists of the eight vertices of the cube plus the two endpoints of the antenna, all halffacets oriented outwards, and all halfedges. The third shell consists of the same eight vertices of the cube, plus the endpoint of the antenna that is in contact with the cube, all halffacets oriented inwards, and all halfedges (the same as for the second shell).



We discuss how sfaces, shalfedges, and sloops belong to the shells with a closeup view of the situation at the antenna foot. As you can see, there are three items on the sphere map - a shalfloop for each halffacet which intersects the sphere, and an svertex where the antenna intersects the sphere. The upper shalfloop lies on the halffacet which is oriented outwards and is therefore also oriented outwards. This shalfloop and the svertex belong to the second shell. The other shalfloop lies on the inwards oriented halffacet and is oriented inwards, too. This shalfloop belongs to the third shell.

Nef_polyhedron_3 offers a visitor interface to explore a shell following the well-known visitor pattern [GHJV95]. The interface is illustrated by the following example.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Vertex_const_handle Vertex_const_handle;
typedef Nef_polyhedron::Halfedge_const_handle Halfedge_const_handle;
typedef Nef_polyhedron::Halffacet_const_handle Halffacet_const_handle;
typedef Nef_polyhedron::SHalfedge_const_handle SHalfedge_const_handle;
typedef Nef_polyhedron::SHalfloop_const_handle SHalfloop_const_handle;
typedef Nef_polyhedron::SFace_const_handle SFace_const_handle;
typedef Nef_polyhedron::Volume_const_iterator Volume_const_iterator;
typedef Nef_polyhedron::Shell_entry_const_iterator
   Shell_entry_const_iterator;
typedef Kernel::Point_3 Point_3;

class Shell_explorer {
  bool first;
  const Nef_polyhedron& N;
  Vertex_const_handle v_min;

public:
  Shell_explorer(const Nef_polyhedron& N_)
    : first(true), N(N_) {}

  void visit(Vertex_const_handle v) {
    if(first ||
   CGAL::lexicographically_xyz_smaller(v->point(),v_min->point())) {
      v_min = v;
```

```
      first=false;
    }
  }

  void visit(Halfedge_const_handle ) {}
  void visit(Halffacet_const_handle ) {}
  void visit(SHalfedge_const_handle ) {}
  void visit(SHalfloop_const_handle ) {}
  void visit(SFace_const_handle ) {}

  Vertex_const_handle& minimal_vertex() { return v_min; }
  void reset_minimal_vertex() { first = true; }
};

int main() {
  Nef_polyhedron N;
  std::cin >> N;

  int ic = 0;
  Volume_const_iterator c;
  Shell_explorer SE(N);
  CGAL_forall_volumes(c,N) {
    std::cout << "Volume " << ic++ << std::endl;
    int is = 0;
    Shell_entry_const_iterator it;
    CGAL_forall_shells_of(it,c) {
      SE.reset_minimal_vertex();
      N.visit_shell_objects(SFace_const_handle(it),SE);
      Point_3 p(SE.minimal_vertex()->point());
      std::cout << "  minimal vertex of shell " << is++
                << " is at " << p << std::endl;
    }
  }
}
```

File: examples/Nef_3/shell_exploration.cpp

The function *visit_shell_objects(SFace_const_handle sf, Visitor& V)* explores a shell starting at the *sf*. The second argument expects any class providing the (possibly empty) functions *visit(Vertex_const_handle)*, *visit(Halfedge_const_handle)* (remember that Halfedge is the same type as SVertex), *visit(Halffacet_const_handle)*, *visit(SHalfedge_const_handle)*, *visit(SHalfloop_const_handle)* and *visit(SFace_const_handle)*. The *visit_shell_objects* function will call *visit* for each item belonging to the shell once. There are no further requirements on that class.

In the example, the class *Shell_explorer* is passed as second argument to *visit_shell_objects*. Its task is to find the lexicographically smallest vertex of a shell. Its internal state consists of three variables. The first one is a reference to the explored Nef polyhedron. This reference is often necessary to retrieve information from the Nef polyhedron. The second variable *v_min* stores the smallest vertex found so far, and the third variable *first* is initialized to *false* to signal that no vertex has been visited so far. After the first vertex has been visited *first* is changed to *true*.

Shell_explorer provides further member functions. After the exploration of a shell the *minimal_vertex* function retrieves the smallest vertex. The *reset_minimal_vertex* function allows one to use the same instance of

Shell_explorer on multiple shells. In this case, the *reset_minimal_vertex* function has to be called between the exploration of two shells.

The example program uses the *Shell_explorer* for each shell of the given Nef polyhedron once and reports the smallest vertex of each shell to the standard output.

29.7.3 Point Location

The *locate(Point_3 p)* function locates the point *p* in the Nef polyhedron and returns the item the point belongs to. The *locate* function returns an instance of *Object_handle*, which is a polymorphic handle type representing any handle type, no matter if it is mutable or const. For further usage of the result, the *Object_handle* has to be casted to the concrete handle type. The *CGAL::assign* function performs such a cast. It returns a boolean that reports the success or the failure of of the cast. Looking at the possible return values of the *locate* function, the *Object_handle* can represent a *Vertex_const_handle*, a *Halfedge_const_handle*, a *Halffacet_handle*, or a *Volume_const_handle*. One of the four casts will succeed.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;
  typedef Kernel::Point_3 Point_3;

int main() {
  //We've put the typedefs here as VC7 gives us an ICE if they are global
     typedefs
  typedef Nef_polyhedron_3::Vertex_const_handle Vertex_const_handle;
  typedef Nef_polyhedron_3::Halfedge_const_handle Halfedge_const_handle;
  typedef Nef_polyhedron_3::Halffacet_const_handle
   Halffacet_const_handle;
  typedef Nef_polyhedron_3::Volume_const_handle Volume_const_handle;
  typedef Nef_polyhedron_3::Object_handle Object_handle;

  Nef_polyhedron_3 N;
  std::cin >> N;

  Vertex_const_handle v;
  Halfedge_const_handle e;
  Halffacet_const_handle f;
  Volume_const_handle c;
  Object_handle o = N.locate(Point_3(0,0,0));
  if(CGAL::assign(v,o))
    std::cout << "Locating vertex" << std::endl;
  else if(CGAL::assign(e,o))
    std::cout << "Locating edge" << std::endl;
  else if(CGAL::assign(f,o))
    std::cout << "Locating facet" << std::endl;
  else if(CGAL::assign(c,o))
    std::cout << "Locating volume" << std::endl;
  //other cases can not occur
```

```
  return 0;
}
```

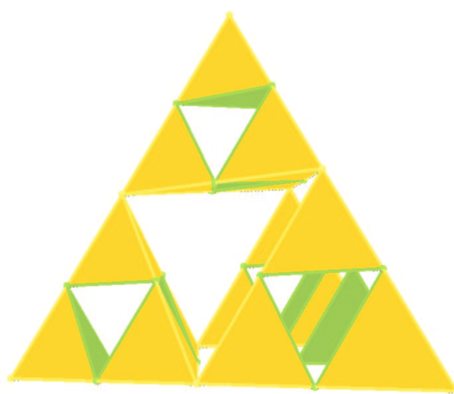
File: examples/Nef_3/nef_3_point_location.cpp

29.8 Visualization

With the *Qt_widget_OpenGL* class an interface to OpenGL visualization via Qt is offered. The class knows how to handle mouse movements and clicks and how to move and scale the 3D object displayed in the widget. *Qt_widget_OpenGL* is a basis for writing Qt widgets displaying 3D objects. A user can derive a new class from *Qt_widget_OpenGL* which implements the drawing method and configures the context menus.

29.8.1 Visualizing a 3D Nef polyhedron

Qt_widget_Nef_3 implements the drawing methods for displaying instances of *Nef_polyhedron_3*. The following example shows how to set up an QApplication with a main widget of type *Qt_widget_Nef_3* and how to start the viewer.



```
#include <CGAL/basic.h>
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/IO/Qt_widget_Nef_3.h>
#include <qapplication.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;

int main(int argc, char* argv[]) {
  Nef_polyhedron_3 N;
  std::cin >> N;
```

```
  QApplication a(argc, argv);
  CGAL::Qt_widget_Nef_3<Nef_polyhedron_3>* w =
    new CGAL::Qt_widget_Nef_3<Nef_polyhedron_3>(N);
  a.setMainWidget(w);
  w->show();
  return a.exec();
}
```

File: demo/Nef_3/visualization_SNC.cpp

29.8.2 Visualizing a Sphere Map

Qt_widget_Nef_S2 is a widget implemented on the basis of *Qt_widget_OpenGL*. It can be used to visualize the sphere map of a vertex in a *Nef_polyhedron_3* using the interface between *Nef_polyhedron_S2* and *Nef_polyhedron_3*.

```
#include <CGAL/basic.h>
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/IO/Qt_widget_Nef_S2.h>
#include <qapplication.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;

int main(int argc, char* argv[]) {

  // We've put the typedefs here as VC7 gives us an ICE if they are
   global typedefs
  typedef Nef_polyhedron_3::Vertex_const_iterator Vertex_const_iterator;
  typedef Nef_polyhedron_3::Nef_polyhedron_S2 Nef_polyhedron_S2;

  Nef_polyhedron_3 N;
  std::cin >> N;
  Vertex_const_iterator v = N.vertices_begin();
  Nef_polyhedron_S2 S(N.get_sphere_map(v));

  QApplication a(argc, argv);
  CGAL::Qt_widget_Nef_S2<Nef_polyhedron_S2>* w =
    new CGAL::Qt_widget_Nef_S2<Nef_polyhedron_S2>(S);
  a.setMainWidget(w);
  w->show();
  return a.exec();
}
```

File: demo/Nef_3/visualization_SM.cpp

3D Boolean Operations on Nef Polyhedra Reference Manual

Peter Hachenberger, Lutz Kettner, and Michael Seel

A Nef polyhedron is any point set generated from a finite number of open halfspaces by set complement and set intersection operations. In our implementation of Nef polyhedra in 3-dimensional space, we offer a B-rep data structures that is closed under boolean operations and with all their generality. Starting from halfspaces (and also directly from oriented 2-manifolds), we can work with set union, set intersection, set difference, set complement, interior, exterior, boundary, closure, and regularization operations. In essence, we can evaluate a CSG-tree with halfspaces as primitives and convert it into a B-rep representation.

In fact, we work with two data structures; one that represents the local neighborhoods of vertices, which is in itself already a complete description, and a data structure that connects these neighborhoods up to a global data structure with edges, facets, and volumes. We offer a rich interface to investigate these data structures, their different elements and their connectivity. We provide affine (rigid) tranformations and a point location query operation. We have a custom file format for storing and reading Nef polyhedra from files. We offer a simple OpenGL visualization for debugging and illustrations.

CGAL::Nef_polyhedron_3<Traits>

Definition

A 3D Nef polyhedron is a subset of the 3-dimensional space that is the result of forming complements and intersections starting from a finite set H of 3-dimensional halfspaces. Nef polyhedra are closed under all binary set operations, i.e., intersection, union, difference, complement, and under the topological operations boundary, closure, and interior.

A 3D Nef polyhedron can be represented by the local pyramids of the minimal elements of its incidence structure. Without going into to much detail, a local pyramid essentially reflects the topologic and geometric situation at a certain location in a point set. For finite polyhedra the minimal elements of the incidence structure are vertices only. This means, that it suffices to model the topological and geometric situation of the vertices. For 3D Nef polyhedra, the local pyramid of a vertex is represented by a planar Nef polyhedra embedded on a sphere.

A *Nef_polyhedron_3* consists of vertices V, a sphere map for each vertex in V, edges E, facets F, volumes C, a mark for every item, and an incidence relation on them. Each edge and each facet is represented by two halfedges or two halffacets, respectively.

#include <CGAL/Nef_polyhedron_3.h>

Parameters

```
template < class Nef_polyhedronTraits_3,
           class Nef_polyhedronItems_3 = CGAL::Default_items<Nef_polyhedronTraits_3>,
           class Nef_polyhedronMarks = bool >
class Nef_polyhedron_3;
```

The first parameter requires one of the following exact kernels: *Homogeneous*, *Simple_homogeneous*, *Extended_homogeneous* parametrized with *Gmpz*, *leda_integer* or any other number type modeling $\mathbb{Z}$, or *Cartesian*, *Simple_cartesian*, *Extended_cartesian* parametrized with *Gmpq*, *leda_rational*, *Quotient<Gmpz>* or any other number type modeling $\mathbb{Q}$.

The second parameter and the third parameter are for future considerations. Neither *Nef_polyhedronItems_3* nor *Nef_polyhedronMarks* is specifed, yet. Do not use any other than the default types for these two template parameters.

Types

Nef_polyhedron_3<Traits>:: Traits	traits class selected for *Nef_polyhedronTraits_3*.
Nef_polyhedron_3<Traits>:: Mark	All object (vertices, edges, etc.) are attributed by a Mark. Mark equals bool.
Nef_polyhedron_3<Traits>:: size_type	size type of *Nef_polyhedron_3*.
Nef_polyhedron_3<Traits>:: Vertex_const_handle	non-mutable handle to a vertex.
Nef_polyhedron_3<Traits>:: Halfedge_const_handle	non-mutable handle to a halfedge.
Nef_polyhedron_3<Traits>:: Halffacet_const_handle	non-mutable handle to a halffacet.

Nef_polyhedron_3<Traits>:: Volume_const_handle non-mutable handle to a volume.
Nef_polyhedron_3<Traits>:: SVertex_const_handle non-mutable handle to a svertex.
Nef_polyhedron_3<Traits>:: SHalfedge_const_handle non-mutable handle to a shalfedge.
Nef_polyhedron_3<Traits>:: SHalfloop_const_handle non-mutable handle to a shalfloop.
Nef_polyhedron_3<Traits>:: SFace_const_handle non-mutable handle to a sface.

Nef_polyhedron_3<Traits>:: Vertex_const_iterator non-mutable iterator over all vertices.
Nef_polyhedron_3<Traits>:: Halfedge_const_iterator non-mutable iterator over all halfeges.
Nef_polyhedron_3<Traits>:: Halffacet_const_iterator non-mutable iterator over all halffacets.
Nef_polyhedron_3<Traits>:: Volume_const_iterator non-mutable iterator over all volumes.
Nef_polyhedron_3<Traits>:: SVertex_const_iterator non-mutable iterator over all svertices.
Nef_polyhedron_3<Traits>:: SHalfedge_const_iterator non-mutable iterator over all shalfedges.
Nef_polyhedron_3<Traits>:: SHalfloop_const_iterator non-mutable iterator over all shalfloops.
Nef_polyhedron_3<Traits>:: SFace_const_iterator non-mutable iterator over all sfaces.

Nef_polyhedron_3<Traits>:: SHalfedge_around_svertex_const_circulator

non-mutable circulator of shalfedges around a svertex (cw).

Nef_polyhedron_3<Traits>:: SHalfedge_around_sface_const_circulator

non-mutable circulator of shalfedges around a sface (ccw).

Nef_polyhedron_3<Traits>:: SHalfedge_around_facet_const_circulator

non-mutable circulator of shalfedges around a halffacet (ccw).

Nef_polyhedron_3<Traits>:: SFace_cycle_const_iterator

non-mutable iterator over the cylces of a sface.

Nef_polyhedron_3<Traits>:: Halffacet_cycle_const_iterator

non-mutable iterator over the cylces of a halffacet.

Nef_polyhedron_3<Traits>:: Shell_entry_const_iterator

non-mutable iterator providing an entry to each shell.

Nef_polyhedron_3<Traits>:: Object_handle a generic handle to an object. The kind of object *(vertex, halfedge, halffacet, volume, svertex, shalfedge, shalfloop, sface)* can be determined and the object can be assigned to a corresponding constant handle by one of the following functions:
bool assign(Vertex_const_handle& h, Object_handle)
bool assign(Halfedge_const_handle& h, Object_handle)
bool assign(Halffacet_const_handle& h, Object_handle)
bool assign(Volume_const_handle& h, Object_handle)
bool assign(SVertex_const_handle& h, Object_handle)
bool assign(SHalfedge_const_handle& h, Object_handle)
bool assign(SHalfloop_const_handle& h, Object_handle)
bool assign(SFace_const_handle& h, Object_handle)
where each function returns *true* iff the assignment to *h* could be accomplished.

Nef_polyhedron_3<Traits>:: Point_3 location of vertices.

Nef_polyhedron_3<Traits>:: Segment_3 segment represented by a halfedge.
Nef_polyhedron_3<Traits>:: Vector_3 direction of a halfedge.
Nef_polyhedron_3<Traits>:: Plane_3 plane of a halffacet lies in.
Nef_polyhedron_3<Traits>:: Aff_transformation_3

affine transformation.

Nef_polyhedron_3<Traits>:: Polylines_tag tag for calling polyline constructor.

enum Boundary { EXCLUDED, INCLUDED};

construction selection.

enum Content { EMPTY, COMPLETE}; construction selection.
enum Intersection_mode { CLOSED_HALFSPACE, OPEN_HALFSPACE, PLANE_ONLY};

intersection selection.

Nef_polyhedron_3<Traits>:: Nef_polyhedron_S2

a sphere map.

Nef_polyhedron_3<Traits>:: Polyhedron a polyhedral surface.

Creation

Nef_polyhedron_3<Traits> N(Content space = EMPTY);

creates a Nef polyhedron and initializes it to the empty set if *plane == EMPTY* and to the whole space if *space == COMPLETE*.

Nef_polyhedron_3<Traits> N(Plane_3 p, Boundary b = INCLUDED);

creates a Nef polyhedron containing the halfspace on the negative side of *p* including *p* if *b==INCLUDED*, excluding *p* if *b==EXCLUDED*.

Nef_polyhedron_3<Traits> N(Polyhedron& P);

creates a Nef polyhedron, which represents the same point set as the polyhedral surface *P* does.

Nef_polyhedron_3<Traits> N(Input_iterator begin, Input_iterator end);

creates a Nef polyhedron consisting of a single polygon spanned by the list of points in the iterator range *[begin,end)*. If the points do not on a common supporting plane, the constructor tries to triangulate the polygon into multiple facets.If the construction does not succeed, the empty set is created.

template <class Forward_iterator>
Nef_polyhedron_3<Traits> N(Forward_iterator it, Forward_iterator end, Polylines_tag);

The iterator range [it, end) defines a set point ranges, each of which defines a polyline.

Access Member Functions

bool	*N.is_simple() const*	returns true, if *N* is a 2-manifold.
bool	*N.is_valid() const*	checks the integrity of *N* .
Size_type	*N.number_of_vertices() const*	returns the number of vertices.
Size_type	*N.number_of_halfedges() const*	return the number of halfedges.
Size_type	*N.number_of_edges() const*	returns the number of halfedge pairs.
Size_type	*N.number_of_halffacets() const*	returns the number of halffacets.
Size_type	*N.number_of_facets() const*	returns the number of halffacet pairs.
Size_type	*N.number_of_volumes() const*	returns the number of volumes.
Vertex_const_iterator	*N.vertices_begin() const*	iterator over all vertices.
Vertex_const_iterator	*N.vertices_end() const*	past-the-end iterator.
Halfedge_const_iterator	*N.halfedges_begin() const*	iterator over all halfedges.
Halfedge_const_iterator	*N.halfedges_end() const*	past-the-end iterator.
Halffacet_const_iterator	*N.halffacets_begin() const*	iterator over all halffacets.
Halffacet_const_iterator	*N.halffacets_end() const*	past-the-end iterator.
Volume_const_iterator	*N.volumes_begin() const*	iterator over all volumes.
Volume_const_iterator	*N.volumes_end() const*	past-the-end iterator.

The following macros are provided: *CGAL_forall_vertices(v,N)*, *CGAL_forall_halfedges(e,N)*, *CGAL_forall_edges(e,N)*, *CGAL_forall_halffacets(f,N)*, *CGAL_forall_facets(f,N)*, *CGAL_forall_volumes(c,N)* where *N* is a *Nef_polyhedron_3*.

Object_handle	*N.locate(Point_3 p) const*	
		returns a generic handle to the object (vertex, edge, facet or volume) which contains the point p in its relative interior.
Nef_polyhedron_S2	*N.get_sphere_map(Vertex_const_iterator v) const*	
		returns the neighborhood of a vertex modeled by a *Nef_polyhedron_S2*.

Point Set Predicates

bool	*N.is_empty() const*	returns true, if *N* is the empty point set.
bool	*N.is_space() const*	returns true, if *N* is the complete 3D space.
bool	$N == N1$	returns true, if *N* and N1 comprise the same point sets.
bool	$N\ != N1$	returns true, if *N* and N1 comprise different point sets.
bool	$N < N1$	returns true, if *N* is a proper subset of N1.
bool	$N > N1$	returns true, if *N* is a proper superset of N1.
bool	$N <= N1$	returns true, if *N* is a subset of N1.
bool	$N >= N1$	returns true, if *N* is a superset of N1.

Unary Set Operations

Nef_polyhedron_3<Traits>	*N.complement() const*	
		returns the complement of *N* .
Nef_polyhedron_3<Traits>	*N.interior() const*	returns the interior of *N* .
Nef_polyhedron_3<Traits>	*N.boundary() const*	
		returns the boundary of *N* .
Nef_polyhedron_3<Traits>	*N.closure() const*	returns the closure of *N* .
Nef_polyhedron_3<Traits>	*N.regularization() const*	
		returns the regularization, i.e. the closure of the interior, of *N* .
Nef_polyhedron_3<Traits>	*!N*	returns the complement of *N* .

Binary Set Operations

Nef_polyhedron_3<Traits>	*N.intersection(N1) const*	
		return the intersection of *N* and N1.
Nef_polyhedron_3<Traits>	*N.join(N1) const*	return the union of *N* and N1. (Note that "union" is a C++ keyword and cannot be used for this operation.)

Nef_polyhedron_3<Traits>	*N.difference(N1) const*	
		return the difference between N and N1.
Nef_polyhedron_3<Traits>	*N.symmetric_difference(N1) const*	
		return the symmetric difference of N and N1.
Nef_polyhedron_3<Traits>	*N.intersection(Plane_3 p, Intersection_mode im) const*	
		returns intersection of N with plane (*im=PLANE_ONLY*), open halfspace (*im=OPEN_HALFSPACE*), or closed halfspace (*im=CLOSED_HALFSPACE*). In the latter two cases, the halfspaces are on the negative side of the plane p. The function is written for the use with standard kernels, where halfspaces are not part of the domain. The function does not work in combination with an extended kernels or with an unbounded polyhedron.

Nef_polyhedron_3<Traits>	$N * N1$	return the intersection of N and N1.
Nef_polyhedron_3<Traits>	$N + N1$	return the union of N and N1.
Nef_polyhedron_3<Traits>	$N - N1$	return the difference between N and N1.
Nef_polyhedron_3<Traits>	$N\,\hat{}\,N1$	return the symmetric difference of N and N1.

void	$N *= N1$	intersects N and N1.
void	$N += N1$	unites N with N1.
void	$N -= N1$	subtracts N1 from N .
void	$N\,\hat{}= N1$	performs a symmetric intersection of N and N1.

Operations

void *N.clear(Content space = EMPTY)*

make N the empty set if *space == EMPTY* and the complete 3D space if *space == COMPLETE*.

void *N.transform(Aff_transformation_3 aff)*

applies an affine transformation to N .

void *N.convert_to_polyhedron(Polyhedron& P) const*

converts N into a Polyhedron.
Precondition: N is simple.

void *N.visit_shell_objects(SFace_const_handle f, Visitor& V) const*

calls the visit function of V for every item which belongs to the same shell as sf.

Class

CGAL::Nef_polyhedron_3<Traits>::Vertex

Definition

A vertex is a point in the 3-dimensional space. Its incidence structure can be accessed creating a sphere map of the vertex. This is done by the member function *get_sphere_map* of the class *Nef_polyhedron_3*.

#include <CGAL/Nef_polyhedron_3.h>

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

Vertex:: Mark	type of mark.
Vertex:: Point_3	point type stored in Vertex.

Creation

There is no need for a user to create a *Vertex* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed vertices internally.

Operations

Mark	*v.mark() const*	the mark of *v* .
Point_3	*v.point() const*	the point of *v* .

CGAL::Nef_polyhedron_3<Traits> . . . . page 2013
CGAL::Nef_polyhedron_S2<Traits> . . . . page 1603

CGAL::Nef_polyhedron_3<Traits>::Halfedge

Class

Definition

A Halfedge has a double meaning. In the global incidence structure of a *Nef_polyhedron_3* it is an oriented edge going from one vertex to another. A halfedge also coincides with an svertex of the sphere map of its source vertex. Because of this, we offer the types *Halfedge* and *SVertex* which are the same. Furthermore, the redundant functions *center_vertex()* and *source()* are provided. The reason is, that we get the same vertex either if we want to have the source vertex of a halfedge, or if we want to have the vertex in the center of the sphere map a svertex lies on. Figures 29.9 and 29.9 illustrate the incidence of a svertex on a sphere map and of a halfedge in the global structure.

As part of the global incidence structure, the member fuctions *source* and *target* return the source and target vertex of an edge. The member function *twin()* returns the opposite halfedge.

Looking at the incidence structure on a sphere map, the member function *out_sedge* returns the first outgoing shalfedge, and *incident_sface* returns the incident sface.

#include <CGAL/Nef_polyhedron_3.h>

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

Halfedge:: Mark	type of mark.
Halfedge:: Sphere_point	sphere point type stored in Halfedge.
Halfedge:: Vertex_const_handle	const handle to vertex.
Halfedge:: Halfedge_const_handle	const handle to halfedge.
Halfedge:: SHalfedge_const_handle	const handle to SHalfedge.
Halfedge:: SFace_const_handle	const handle to SFace.

Creation

There is no need for a user to create a *Halfedge* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed halfedges internally.

Operations

Mark	*e.mark() const*	the mark of *e* .
Sphere_point	*e.point() const*	the sphere point of *e* .
bool	*e.is_isolated() const*	returns —true— if *e* has no adjacent sedges.

Vertex_const_handle	*e.center_vertex() const*	
		the center vertex of the sphere map *e* belongs to.
Vertex_const_handle	*e.source() const*	the source vertex of *e* .
Vertex_const_handle	*e.target() const*	the target vertex *e*.
Halfedge_const_handle	*e.twin() const*	the twin of *e* .
SHalfedge_const_handle		
	e.out_sedge() const	the first out sedge of *e* .
SFace_const_handle	*e.incident_sface() const*	
		the incident sface of *e* .

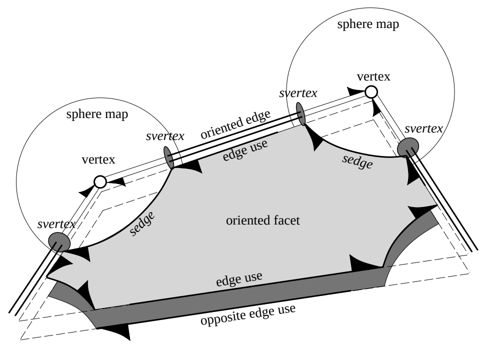
CGAL::Nef_polyhedron_3<Traits>::Halffacet

Class

Definition

A halffacet is an oriented, rectilinear bounded part of a plane. The following figure depicts the incidences to halfedges, vertices and the notion of facet cycles.



The member function *twin* returns the opposite halffacet, *incident_volume* returns the incident volume. A Halffacet cycle either consists of consecutive shalfedges along the border (or a hole) of the halffacet, or of a single shalfloop on the sphere map of a vertex isolated on the halffacet. The iterator range (*halffacet_cycles_begin()*/*halffacet_cycles_end()*) provides an entry element for each halffacet cycle of a halffacet.

#include <CGAL/Nef_polyhedron_3.h>

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

Halffacet:: Mark	type of mark.
Halffacet:: Plane_3	plane type stored in Halffacet.
Halffacet:: Object_list	list of Object handles.
Halffacet:: Halffacet_const_handle	const handle to Halffacet.
Halffacet:: Volume_const_handle	const handle to volume.
Halffacet:: Halffacet_cycle_const_iterator	const iterator over the entries to all halffacet cycles of a halffacet.

Creation

There is no need for a user to create a *Halffacet* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed halffacets internally.

Operations

Mark	*f.mark() const*	the mark of f .
Plane_3	*f.plane() const*	the supporting plane of f .
Halffacet_const_handle	*f.twin() const*	the twin of f .
Volume_const_handle	*f.incident_volume() const*	the incident volume of f .
Halffacet_cycle_const_iterator	*f.facet_cycles_begin() const*	iterator over the entries to all halffacet cycles of f .
Halffacet_cycle_const_iterator	*f.facet_cycles_end() const*	past-the-end iterator.

CGAL::Nef_polyhedron_3<Traits>::Volume

Class

Definition

A volume is a full-dimensional connected point set in $\mathbb{R}^3$. It is bounded by several shells, i.e. a connected part of the boundary incident to a single volume. An entry element to each shell is provided by the iterator range (*shells_begin()*/*shells_end()*). A *Shell_entry_iterator* is assignable to *SFace_handle*.

#include <CGAL/Nef_polyhedron_3.h>

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

Volume:: Mark	type of mark.
Volume:: Object_list	list of Object handles.
Volume:: Volume_const_handle	const handle to Volume.
Volume:: Shell_entry_const_iterator	const iterator over the entries to all shells adjacent to a volume.

Creation

There is no need for a user to create a *Volume* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed volumes internally.

Operations

Mark	*c.mark() const*	the mark of *c* .
Shell_entry_const_iterator	*c.shells_begin() const*	const iterator over the entries to all shells adjacent to *c* .
Shell_entry_const_iterator	*c.shells_end() const*	past-the-end iterator.

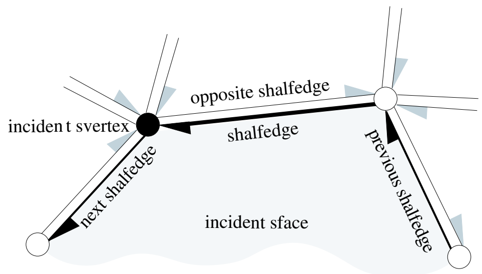
CGAL::Nef_polyhedron_3<Traits>::SHalfedge

Definition

A shalfedge is a great arc on a sphere map. Figure 29.9 depicts the relationship between a shalfedge and its incident shalfedges, svertices, and sfaces on a sphere map. A shalfedge is an oriented sedge between two svertices. It is always paired with a shalfedge pointing in the opposite direction. The *twin()* member function returns this shalfedge of opposite orientation.



The *snext()* member function points to the successor shalfedge around this sface while the *sprev()* member function points to the preceding shalfedge. An successive assignments of the form *se* = *se->snext()* cycles counterclockwise around the sface (or hole).

Similarly, the successive assignments of the form *se* = *se->snext()->twin()* cycle clockwise around the svertex and traverse all halfedges incident to this svertex. The assignment *se* = *se->cyclic_adj_succ()* can be used as a shortcut.

The role of shalfedges in a facet is illustrated in Figure 29.9. The *facet()* member function returns the facet in which the shalfedge is part of one of the facet cycles. The successive assignment of the form *se* = *se->next()* cycles counterclockwise around the facet (or a hole of the facet).

A const circulators is provided for each of the three circular orders. The circulators are bidirectional and assignable to *SHalfedge_const_handle*.

#include <CGAL/Nef_polyhedron_3.h>

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

SHalfedge:: Mark	type of mark.
SHalfedge:: Sphere_circle	sphere circle type stored in SHalfedge.
SHalfedge:: Halffacet_const_handle	const handle to Halffacet.
SHalfedge:: SVertex_const_handle	const handle to SVertex.
SHalfedge:: SHalfedge_const_handle	const handle to SHalfedge.
SHalfedge:: SFace_const_handle	const handle to SFace.

Creation

There is no need for a user to create a *SHalfedge* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed shalfedges internally.

Operations

Mark	*se.mark() const*	the mark of *se* .
Sphere_circle	*se.circle() const*	the sphere circle of *se* .
SHalfedge_const_handle	*se.twin() const*	the twin of *se* .
SVertex_const_handle	*se.source() const*	the source svertex of *se* .
SVertex_const_handle	*se.target() const*	equals *twin()->source()*.
SHalfedge_const_handle	*se.prev() const*	the SHalfedge previous to *se* in a facet cycle.
SHalfedge_const_handle	*se.next() const*	the next SHalfedge of *se* in a facet cycle.
SHalfedge_const_handle	*se.sprev() const*	the SHalfedge previous to *se* in a sface cycle.
SHalfedge_const_handle	*se.snext() const*	the next SHalfedge of *se* in a sface cycle.
SHalfedge_const_handle	*se.cyclic_adj_pred() const*	the edge before *se* in the cyclic ordered adjacency list of source().
SHalfedge_const_handle	*se.cyclic_adj_succ() const*	the edge after *se* in the cyclic ordered adjacency list of source().
Halffacet_const_handle	*se.facet() const*	the facet that corresponds to *se* in the 3D incidence structure.
SFace_const_handle	*se.incident_sface() const*	the incident sface of *se* .
bool	*se.in_outer_sface_cycle() const*	determines whether *se* is in an outer sface cycle.

bool *se.in_inner_sface_cycle() const*

determines whether *se* is in an inner sface cycle.

bool *se.in_outer_facet_cycle() const*

determines whether *se* is in an outer facet cycle.

bool *se.in_inner_facet_cycle() const*

determines whether *se* is in an inner facet cycle.

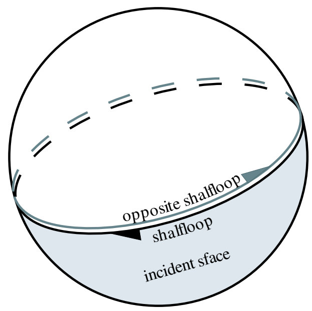
CGAL::Nef_polyhedron_3<Traits>::SHalfloop

Definition

A shalfloop is a great circle on a sphere map. Figure 29.9 depicts the relationship between a shalfloop and its incident shalfloops, and sfaces on a sphere map. A shalfloop is an oriented sloop. It is always paired with a shalfloop whose supporting *Sphere_circle* is pointing in the opposite direction. The *twin()* member function returns this shalfloop of opposite orientation.



A sphere map having a shalfloop models the neighborhood of a vertex which is isolated on a facet. That facet is returned by the member function *facet*.

#include <CGAL/Nef_polyhedron_3.h>

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

SHalfloop:: Mark	type of mark.
SHalfloop:: Sphere_circle	sphere circle type stored in SHalfloop.
SHalfloop:: Halffacet_const_handle	const handle to Halffacet.
SHalfloop:: SHalfloop_const_handle	const handle to SHalfloop.
SHalfloop:: SFace_const_handle	const handle to SFace.

Creation

There is no need for a user to create a *SHalfloop* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed shalfloops internally.

Operations

Mark	*se.mark() const*	the mark of *se* .
Sphere_circle	*se.circle() const*	the sphere circle of *se* .

SHalfloop_const_handle	*se.twin() const*	the twin of *se* .
Halffacet_const_handle	*se.facet() const*	the facet that corresponds to *se* in the 3D incidence structure.
SFace_const_handle	*se.incident_sface() const*	the incident sface of *se* .

CGAL::Nef_polyhedron_3<Traits>::SFace

Class

Definition

Figures 29.9 and 29.9 illustrate the incidences of an sface. An sface is described by its boundaries. An entry item to each boundary cycle can be accessed using the iterator range (*sface_cycles_begin()*/*sface_cycles_end()*). Additionally, *Nef_polyhedron_S2* provides the macro *CGAL_forall_sface_cylces_of*. The iterators are of type *SFace_cycle_const_iterator* and represent either a shalfedge, a shalfloop, or a svertex.

#include <CGAL/Nef_polyhedron_3.h>

Types

The following types are the same as in *Nef_polyhedron_3<Traits>*.

SFace:: Mark	type of mark.
SFace:: Object_list	list of Object handles.
SFace:: Vertex_const_handle	const handle to Vertex.
SFace:: Volume_const_handle	const handle to Volume.
SFace:: SFace_const_handle	const handle to SFace.
SFace:: SFace_cycle_const_iterator	const iterator over the entries to all sface cycles of a sface.

Creation

There is no need for a user to create a *SFace* explicitly. The class *Nef_polyhedron_3<Traits>* manages the needed sfaces internally.

Operations

Mark	*sf.mark() const*	the mark of *sf* .
Vertex_const_handle	*sf.center_vertex() const*	the center vertex of the sphere map *sf* belongs to.
Volume_const_handle	*sf.volume() const*	the volume that corresponds to *sf* in the 3D incidence structure.
SFace_cycle_const_iterator	*sf.sface_cycle_begin() const*	iterator over the entries to all sface cycles of *sf* .

SFace_cycle_const_iterator *sf.sface_cycle_end() const*

past-the-end iterator.

CGAL::Nef_polyhedron_3<Traits>::Halffacet_cycle_iterator

Class

Definition

The type *Halffacet_cycle_iterator* iterates over a list of *Object_handles*. Each item of that list can either be assigned to *SHalfedge_handle* or *SHalfloop_handle*. To find out which of these assignment works out, the member functions *is_shalfedge()* and *is_shalfloop()* are provided.

#include <CGAL/Nef_polyhedron_3.h>

Types

Halffacet_cycle_iterator:: SHalfedge_handle	const handle to SHalfedge.
Halffacet_cycle_iterator:: SHalfloop_handle	const handle to SHalfloop.

Creation

Halffacet_cycle_iterator hfc;	default constructor.

Operations

bool	*hfc.is_shalfedge() const*	returns true if *hfc* represents a *SHalfedge_handle*.
bool	*hfc.is_shalfloop() const*	returns true if *hfc* represents a *SHalfloop_handle*.

CGAL::Nef_polyhedron_3<Traits>::SFace_cycle_iterator

Definition

The type *SFace_cycle_iterator* iterates over a list of *Object_handles*. Each item of that list can either be assigned to *SVertex_handle*, *SHalfedge_handle* or *SHalfloop_handle*. To find out which of these assignment works out, the member functions *is_svertex()*, *is_shalfedge()* and *is_shalfloop()* are provided.

#include <CGAL/Nef_polyhedron_3.h>

Types

SFace_cycle_iterator:: SVertex_handle	const handle to SVertex.
SFace_cycle_iterator:: SHalfedge_handle	const handle to SHalfedge.
SFace_cycle_iterator:: SHalfloop_handle	const handle to SHalfloop.

Creation

SFace_cycle_iterator sfc;	default constructor.

Operations

bool	*sfc.is_svertex() const*	returns true if *sfc* represents a *SVertex_handle*.
bool	*sfc.is_shalfedge() const*	returns true if *sfc* represents a *SHalfedge_handle*.
bool	*sfc.is_shalfloop() const*	returns true if *sfc* represents a *SHalfloop_handle*.
SVertex_handle	*SVertex_handle(sfc)*	casts *sfc* to *SVertex_handle*.
SHalfedge_handle	*SHalfedge_handle(sfc)*	casts *sfc* to *SHalfedge_handle*.
SHalfloop_handle	*SHalfloop_handle(sfc)*	casts *sfc* to *SHalfloop_handle*.

CGAL::OFF_to_nef_3

Definition

This constructor creates a 3D Nef polyhedron from OFF file. OFF file is read from input stream *in*. The purpose of *OFF_to_nef_3* is to create a Nef polyhedron from an OFF file that cannot be handled by the *Nef_polyhedron_3* constructors. It handles double coordinates while using a homogenous kernel, non-coplanar facets, surfaces with boundaries, self-intersecting surfaces, and single facets. Every closed volume gets marked. The function returns the number of facets it could not handle.

template<class Nef_polyhedron_3>
std::size_t *OFF_to_nef_3(std::istream& in, Nef_polyhedron_3& N)*

Class

CGAL::Nef_nary_union_3<Nef_polyhedron_3>

Definition

This class helps to perform the union of a set of 3D Nef polyhedra efficiently. It succesively applies the binary union operation of *Nef_polyhedron_3*, but schedules these union operations in an opportune way. The class is most efficient, if the polyhedra are added in sorted order. Any order that reflects proximity in the three-dimensional space is helpful. To allow saving memory space, the sorting is left to the user. This way the user can generate the polyhedra in a sorted way and add them one by one to *Nef_nary_union_3*.

#include <CGAL/Nef_nary_union_3.h>

Parameters

template < class Nef_polyhedron_3,
class Nef_nary_union_3;

As a template parameter an instantiation of the template class Nef polyhedra is needed.

Creation

Nef_nary_union_3<Nef_polyhedron_3> U;	initialization only.

Member Functions

Nef_polyhedron_3 *U.get_union() const*

returns the union of the polyhedra previously added to the class.

void *U.add_polyhedron(Nef_polyhedron_3 N)*

adds a polyhedron.

CGAL::Nef_polyhedron_3<Traits> . . . . page 2013

CGAL::operator<<

Definition

This operator writes The Nef polyhedron *N* to the output stream *out* using a propriatary file format. It includes the complete incidence structure, the geometric data, and the marks of each item.

Using CGAL stream modifiers the following output formats can be chosen: ASCII(*set_ascii_mode*), binary(*set_binary_mode*) or pretty(*set_pretty_mode*). The mandatory format is the ASCII format. It is recommended to use this format for file input and output.

As the output depends on the output operators of the geometric primitives provided by the traits class, it might not be possible that the input operator and output operators of different traits classes are not compatible. We recommend to use the CGAL kernels *Homogeneous*, *Simple_homogeneous*, or *Extended_homogeneous* parametrized with any exact number type that models $\mathbb{Z}$ (e.g. *Gmpz* or *leda_integer*).

A bounded *Nef_polyhedron_3<Extended_homogeneous>* is automatically written as though *Nef_polyhedron_3<CGAL::Homogeneous>* or *Nef_polyhedron_3<CGAL::Simple_homogeneous>* is used. As a result, the input operator of each of these types can read the output.

#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

template <class Traits>
ostream& *ostream& out << CGAL::Nef_polyhedron_3<Traits> N*

CGAL::Qt_widget_Nef_3<Nef_polyhedron_3>

Definition

The class *Qt_widget_Nef_3* uses the OpenGL interface of Qt to display a *Nef_polyhedron_3*. Its purpose is to provide an easy to use viewer for *Nef_polyhedron_3*. There are no means provided to enhance the functionality of the viewer.

In addition to the functions inherited from the Qt class *OGLWidget* via, *Qt_widget_Nef_3* only has a single public constructor. For the usage of *Qt_widget_Nef_3* see the example below.

#include <CGAL/IO/Qt_widget_Nef_3.h>

Parameters

The template parameter expects an instantiation of *Nef_polyhedron_3<Traits>*.

Creation

Qt_widget_Nef_3<Nef_polyhedron_3> W(Nef_polyhedron_3 N);

Creates a widget *W* for displaying the 3D Nef polyhedron N.

See Also

CGAL::Nef_polyhedron_3<Traits> . . . . page 2013

Example

This example reads a 3D Nef polyhedron from standard input and displays it in a Qt widget.

```
#include <CGAL/basic.h>
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/IO/Qt_widget_Nef_3.h>
#include <qapplication.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;

int main(int argc, char* argv[]) {
  Nef_polyhedron_3 N;
  std::cin >> N;

  QApplication a(argc, argv);
```

```
  CGAL::Qt_widget_Nef_3<Nef_polyhedron_3>* w =
    new CGAL::Qt_widget_Nef_3<Nef_polyhedron_3>(N);
  a.setMainWidget(w);
  w->show();
  return a.exec();
}
```

Chapter 30

Convex Decomposition of Polyhedra

Peter Hachenberger

30.1 Introduction

For many applications on non-convex polyhedra, there are efficient solutions that first decompose the polyhedron into convex pieces. As an example, the Minkowski sum of two polyhedra can be computed by decomposing both polyhedra into convex pieces, compute pair-wise Minkowski sums of the convex pieces, and unite the pair-wise sums.

While it is desirable to have a decomposition into a minimum number of pieces, this problem is known to be NP-hard [Cha84]. Our implementation decomposes a Nef polyhedron N into $O(r^2)$ convex pieces, where r is the number of edges that have two adjacent facets that span an angle of more than 180 degrees with respect to the interior of the polyhedron. Those edges are also called reflex edges. The bound of $O(r^2)$ convex pieces is worst-case optimal [Cha84].

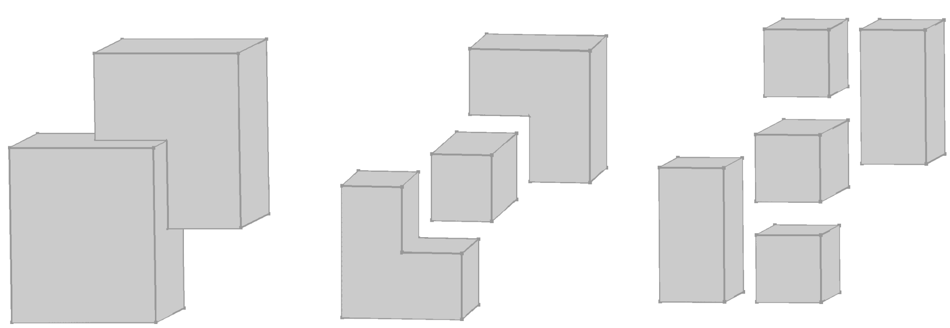

Figure 30.1: Vertical decomposition based on the insertion of vertical facets (viewed from the top). Left: Non-convex polyhedron. Middle: Non-vertical reflex edges have been resolved. Right: Vertical reflex edges have been resolved. The sub-volumes are convex.

Our decomposition runs in two steps. In the first step, each non-vertical reflex edge e is resolved by insertion of vertical facets through e. In the second step, we do the same with the vertical reflex edges. Figure 30.1 illustrates the two steps.

At the moment our implementation is restricted to the decomposition of bounded polyhedra. An extension to unbounded polyhedra is planned.

30.2 Interface and Usage

An instance of *Nef_polyhedron_3* represents a subdivision of the three-dimensional space into vertices, edges, facets, and volumes. Some of these items form the polyhedron (selected), while others represent the outer volume or holes within the polyhedron (unselected). As an example, the unit cube is the point set $[0,1]^3$. The smallest subdivision that represents the unit cube has 8 vertices, 12 edges, 6 facets, and 2 volumes. The volumes enclosed by the vertices, edges, and facets is the interior of the cube and therefore selected. The volume outside the cube does not belong to it and is therefore unselected. The vertices, edges, and facets—also denoted as boundary items—are needed to separate the two volumes, but are also useful for representing topological properties. In case of the (closed) unit cube the boundary items are part of the polyhedron and therefore selected, but in case of the open unit cube $[0,1)^3$ they are unselected. Each item has its own selection mark, which allows the correct representation of Nef polyhedra, which are closed under Boolean and topological operations. Details can be found in the chapter on 3D Boolean operations on Nef polyhedra 29.

Usually, an instance of *Nef_polyhedron_3* does not contain any redundant items. However, the function *convex_decomposition_3* subdivides selected volumes of a given *Nef_polyhedron_3* by selected facets. These additional facets are therefore redundant, i.e., their insertion alters the representation of the polyhedron, but not the polyhedron itself.

When *convex_decomposition_3* resolved all reflex edges, the selected sub-volumes have become convex. Each of them is represented by a separate volume item and can therefore be traversed separately 29.7.2. Another possibility of accessing the convex pieces is to convert them into separate Nef polyhedra, as illustrated by the example code given below.

Note that due to the restriction to bounded polyhedra, the use of extended kernels is unnecessary and expensive. We therefore do not support the use of extended kernels in the convex decomposition (see Chapter 29).

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/Nef_3/SNC_indexed_items.h>
#include <CGAL/convex_decomposition_3.h>
#include <list>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron_3;
typedef CGAL::Nef_polyhedron_3<Kernel, CGAL::SNC_indexed_items>
   Nef_polyhedron_3;
typedef Nef_polyhedron_3::Volume_const_iterator Volume_const_iterator;

int main() {

  Nef_polyhedron_3 N;
  std::cin >> N;

  CGAL::convex_decomposition_3(N);
  std::list<Polyhedron_3> convex_parts;

  // the first volume is the outer volume, which is
```

```
  // ignored in the decomposition
  Volume_const_iterator ci = ++N.volumes_begin();
  for( ; ci != N.volumes_end(); ++ci) {
    if(ci->mark()) {
      Polyhedron_3 P;
      N.convert_inner_shell_to_polyhedron(ci->shells_begin(), P);
      convex_parts.push_back(P);
    }
  }
  std::cout << "decomposition into " << convex_parts.size() << " convex
   parts " << std::endl;

}
```

Functions

void *convex_decomposition_3(Nef_polyhedron_3& N)*

page 2046

30.4 Alphabetical List of Reference Pages

Function

CGAL::convex_decomposition_3

Definition

The function *convex_decomposition_3* inserts additional facets into the given *Nef_polyhedron_3* N, such that each bounded marked volume (the outer volume is unbouned) is subdivided into convex pieces. The modified polyhedron represents a decomposition into $O(r^2)$ convex pieces, where r is the number of edges that have two adjacent facets that span an angle of more than 180 degrees with respect to the interior of the polyhedron.

The worst-case running time of our implementation is $O(n^2 r^4 \sqrt[3]{nr^2} \log(nr))$, where n is the complexity of the polyhedron (the complexity of a *Nef_polyhedron_3* is the sum of its *Vertices*, *Halfedges* and *SHalfedges*) and r is the number of reflex edges.

void *convex_decomposition_3(Nef_polyhedron_3& N)*

Precondition:

The polyhedron N is bounded. Otherwise, the outer volume is ignored.

Postcondition:

If the polyhedron N is non-convex, it is modified to represent the convex decomposition. If N is convex, it is not modified.

Chapter 31

3D Minkowski Sum of Polyhedra

Peter Hachenberger

31.1 Introduction

Figure 31.1: The Minkowski sum of a spoon and a star.

The Minkowski sum of two point sets P and Q in $\mathbb{R}^d$, denoted by $P \oplus Q$, is defined as the set $\{p+q : p \in P, q \in Q\}$. Minkowski sums are used in a wide range of applications such as robot motion planning [Lat91] and computer-aided design [EK99]. Figure 31.2 shows an example how Minkowski sums can be used to plan the motion of a translational robot. We want to know which are legal positions of the robot, and where can the robot go to from a specified starting position. If we model both the robot and the obstacles as a polyhedron and compute the Minkowski sum of the inverted robot (robot reflected at the origin) and the obstacles, then this Minkowski sum represents all illegal positions of the robot, i.e., all positions where it intersects the obstacle. Of course, the complement of that polyhedron describes all legal positions of the robot, i.e., all positions where it does not intersect an obstacle.

The Minkowski sum can be illustrated as follows. Pick an arbitrary reference point r of P (black dot in the lower left corner of the robot in Figure 31.2). Then place the inverted set $-P$ on Q, such that $-r$ is on the boundary of Q. Finally, move $-P$ along the complete boundary of Q. The union of Q and the points swept by $-P$ is the Minkowski sum of P and Q.

Implementing the Minkowski sum, the reference point does not need to be chosen. It is implicitly given as the origin of the coordinate system. Choosing a different reference point is equivalent to translating the coordinate system. Such a translation does not change the shape of the Minkowski sum; it only translates the Minkowski sum by the same vector.

This package provides a function *minkowski_sum_3* that computes the Minkowski sum of two Nef polyhedra.

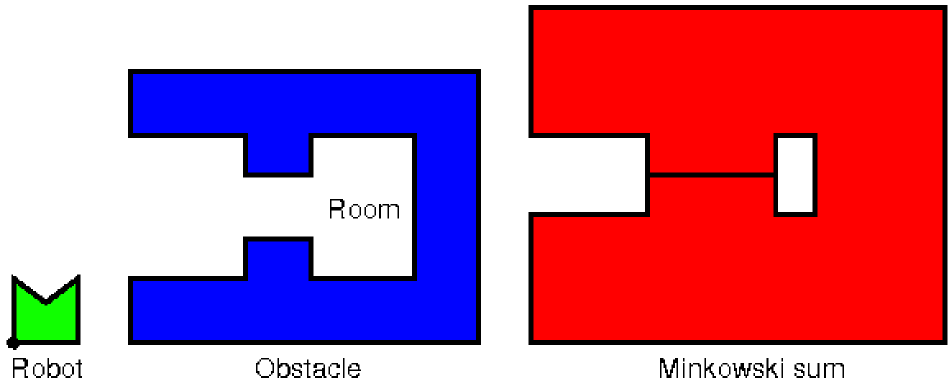

Figure 31.2: Can the robot enter the room? The Minkowski sum of the inverted robot and the obstacle describes the illegal positions of the robot with respect to the obstacle. Since the boundary of the Minkowski sum describes legal positions, there is a path for the robot between the outer area and the room.

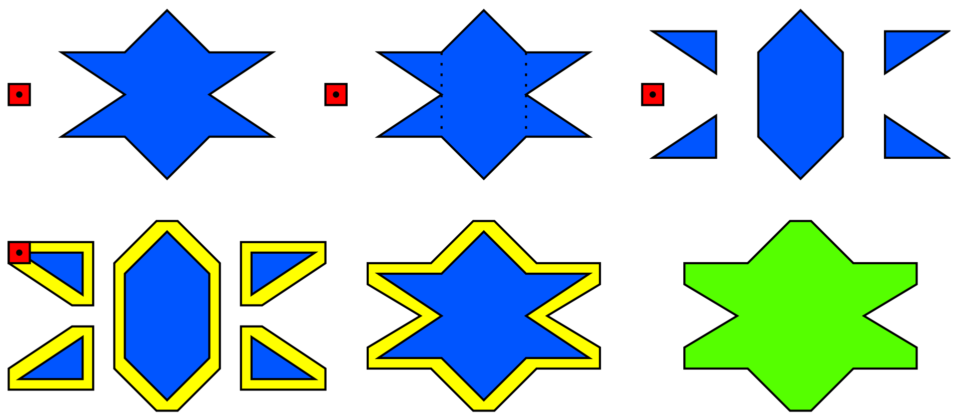

Figure 31.3: The decomposition method decomposes both input polyhedra into convex parts, computes all pairwise Minkowski sums of the convex parts, and merges the pairwise sums.

We do not support arbitrary Nef polyhedra, yet. The restrictions are discussed in detail in Section 31.3.

31.2 Decomposition Method

The decomposition method for computing the Minkowski sum of non-convex polyhedra makes use of the fact that Minkowski sums of convex polyhedra are rather easy to compute. It decomposes both polyhedra into convex pieces, computes all pairwise Minkowski sums of the convex pieces, and merges the pairwise sums [dBvKOS97].

Minkowski sum are inherently complex to compute. Using the decomposition method, each polyhedron might be divided into a quadratic number of pieces, which is worst-case optimal. Then up to n^2m^2 pairwise sums have to be computed and merged, where n and m are the complexities of the two input polyhedra (the complexity of a *Nef_polyhedron_3* is the sum of its *Vertices*, *Halfedges* and *SHalfedges*). In total the operation runs in $O(n^3m^3)$ time.

Since the computation of the Minkowski sum takes quite some time, we give the running times of some

Minkowski sum computations. They were computed with CGAL 3.3 on a machine with a 2.4 GHz AMD Opteron processor and 4 GB RAM. The code was compiled with g++ 3.2 and compiler options -O2. The *Nef_polyhedron_3* class was instantiated with the geometric kernel *Homogeneous<leda_integer>*. The Minkowski sum of the spoon and the star is illustrated in Figure 31.1.

model 1			model 2			running
name	facets	conv. pcs.	name	facets	conv. pcs.	time
mushroom	448	255	cube	6	1	204s
mushroom	448	255	ball1	128	1	553s
spoon	336	186	star	24	5	882s
cup	1000	774	ball2	1000	1	9851s

Table 31.1: Performance of the function *minkowski_sum_3*.

31.3 Features and Restrictions

This package was written to allow the computation of Minkowski sums of full-dimensional polyhedra even in so-called tight-passage scenarios. Tight passage scenarios occur in robot motion planning, when a robot is just as wide as a passage it needs to traverse. In these scenarios at least one polyhedron—the obstacles or the robot—must be modeled as an open set. Then the Minkowski sum will also be an open set and tight passages will occur as lower-dimensional exclusions, i.e., as facets, lines, or vertices that are, in contrast to the volume around them, not part of the resulting point set. Figure 31.2 shows such a tight passage scenario.

Our implementation uses *Nef_polyhedron_3* to model the input polyhedra and the result polyhedron. An instance of *Nef_polyhedron_3* represents a subdivision of the three-dimensional space into vertices, edges, facets, and volumes. Some of these items form the polyhedron (selected), while others represent the outer volume or holes within the polyhedron (unselected). As an example, the unit cube is the point set $[0,1]^3$. The smallest subdivision that represents the unit cube has 8 vertices, 12 edges, 6 facets, and 2 volumes. The volumes enclosed by the vertices, edges, and facets is the interior of the cube and therefore selected. The volume outside the cube does not belong to it and is therefore unselected. The vertices, edges, and facets—also denoted as boundary items—are needed to separate the two volumes, but are also useful for representing topological properties. In case of the (closed) unit cube the boundary items are part of the polyhedron and therefore selected, but in case of the open unit cube $[0,1)^3$ they are unselected. Each item has its own selection mark, which allows the correct representation of Nef polyhedra, which are closed under Boolean and topological operations. Details can be found in the chapter on 3D Boolean operations on Nef polyhedra 29.

The use of *Nef_polyhedron_3* allows many scenarios beyond the Minkowski sum of two solids. First, they can model the input and the result of a tight passage scenario, i.e., they can model open and closed solids as is needed for the input models, and they can model tight passages, which are lower-dimensional exclusions represented as unselected facets, edges, and vertices. We strive for extending the package to work for arbitrary 3D Nef polyhedra. In addition to the Minkowski sums of two solids, we added several features. At the moment we allow an input polyhedron to consist of:

1. singular vertices
2. singular edges
3. singular convex facets without holes
4. surfaces with convex facets that have no holes.
5. three-dimensional features, whose coplanar facets have common selection marks (this includes open and closed solids)

Taking a different viewpoint, the implementation is restricted as follows:

1. The input polyhedra must be bounded (selected outer volume is ignored).

2. All sets of coplanar facets of a full-dimensional feature must have the same selection mark (in case of different selection marks, unselected is assumed).

3. All facets of lower-dimensional features need to be convex and must not have holes (non-convex facets and holes are ignored).

The second restriction might seem a bit odd. It stems from the fact that the Minkowski sum on convex polyhedra can only handle polyhedra, whose sides consist of a single facet. The decomposition process usually yields complex adjacency relations between a convex part, its adjacent convex parts, and the outer volume. The side of a convex piece is then decomposed into several facets, each of which represents one of these adjacency relations. For the convex Minkowski sum, we ignore the decompositions of the sides, but need to find a common selection mark. If there are two facets that are adjacent to the outer volume, but have different selections marks, we cannot set a common selection mark without spoiling the correctness of the Minkowski sum.

31.4 Usage

The function *minkowski_sum_3* should be used with the *Exact_predicates_exact_constructions_kernel*, which often is the most efficient choice and allows floating-point input. Consult Section for more details.

The following example code illustrates the usage of the function *minkowski_sum_3*. Note that either input polyhedra will be modified by the function if it is non-convex. So, if they are needed further on, they need to be copied, first. The copying is not done by the function itself to keep the memory usage as small as possible.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/minkowski_sum_3.h>
#include <fstream>
#include <iostream>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;

int main() {

  Nef_polyhedron N0, N1;
  std::ifstream in("cube.nef3");
  in >> N0;
  std::cin >> N1;
  Nef_polyhedron result = CGAL::minkowski_sum_3(N0, N1);
}
```

File: examples/Minkowski_sum_3/cube_offset.cpp

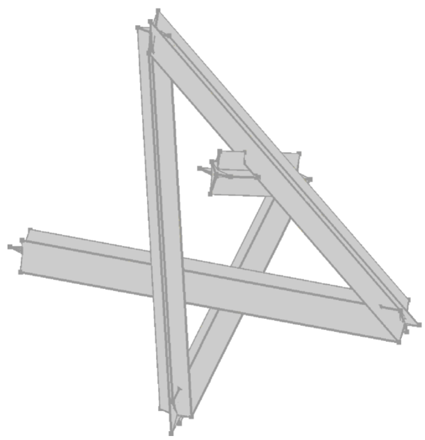

Figure 31.4: The region swept by a star that moves along a polygonal path.

31.5 Glide

With the function *minkowski_sum_3* it is also possible to realize other interesting geometric operations like the glide operation, which computes the point set swept by a polyhedron that moves along a polygonal path. The following example shows how to construct a polygonal path and then compute the glide operation by calling the function *minkowski_sum_3*.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/minkowski_sum_3.h>
#include <iostream>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel>     Nef_polyhedron;
typedef Kernel::Point_3 Point_3;
typedef Point_3* point_iterator;
typedef std::pair<point_iterator,point_iterator>
  point_range;
typedef std::list<point_range> polyline;

int main(int argc, char* argv[])
{
  Nef_polyhedron N0;
  std::cin >> N0;
  Point_3 pl[6] =
```

```
    {Point_3(-100,0,0),
     Point_3(40,-70,0),
     Point_3(40,50,40),
     Point_3(-90,-60,60),
     Point_3(0, 0, -100),
     Point_3(30,0,150)
  };

  polyline poly;
  poly.push_back(point_range(pl,pl+6));
  Nef_polyhedron N1(poly.begin(), poly.end(),
   Nef_polyhedron::Polylines_tag());
  Nef_polyhedron result = CGAL::minkowski_sum_3(N0, N1);
}
```

File: examples/Minkowski_sum_3/glide.cpp

3D Minkowski sum of Polyhedra Reference Manual

Peter Hachenberger

The function *minkowski_sum_3* computes the Minkowski sum of two given 3D Nef polyhedra.

Functions

31.7 Alphabetical List of Reference Pages

Function

CGAL::minkowski_sum_3

Definition

The function *minkowski_sum_3* computes the Minkowski sum of two given 3D Nef polyhedra $N0$ and $N1$. Note that the function runs in $O(n^3 m^3)$ time in the worst case, where n and m are the complexities of the two input polyhedra (the complexity of a *Nef_polyhedron_3* is the sum of its *Vertices*, *Halfedges* and *SHalfedges*).

Nef_polyhedron_3   *minkowski_sum_3(Nef_polyhedron_3 N0, Nef_polyhedron_3 N1)*

Precondition:

An input polyhedron may consist of:

1. singular vertices
2. singular edges
3. singular convex facets without holes
4. surfaces with convex facets that have no holes.
5. three-dimensional features, whose coplanar facets have common selection marks (this includes open and closed solids)

Taking a different viewpoint, the implementation is restricted as follows:

1. The input polyhedra must be bounded (selected outer volume is ignored).
2. All sets of coplanar facets of a full-dimensional feature must have the same selection mark (in case of different selection marks, unselected is assumed).
3. All facets of lower-dimensional features need to be convex and must not have holes (non-convex facets and holes are ignored).

Postcondition:

If either of the input polyhedra is non-convex, it is modified during the computation, i.e., it is decomposed into convex pieces.

Part VIII

Arrangements

Chapter 32

2D Arrangements

Ron Wein, Eric Berberich, Efi Fogel, Dan Halperin, Michael Hemmer, Oren Salzman, and Baruch Zukerman

Contents

32.1 Introduction

Given a set $\mathcal{C}$ of planar curves, the *arrangement* $\mathcal{A}(\mathcal{C})$ is the subdivision of the plane into zero-dimensional, one-dimensional and two-dimensional cells, called *vertices*, *edges* and *faces*, respectively induced by the curves in $\mathcal{C}$. Arrangements are ubiquitous in the computational-geometry literature and have many applications; see, e.g., [AS00, Hal04].

The curves in $\mathcal{C}$ can intersect each other (a single curve may also be self-intersecting or may be comprised of several disconnected branches) and are not necessarily x-monotone.[1] We construct a collection $\mathcal{C}''$ of x-monotone subcurves that are pairwise disjoint in their interiors in two steps as follows. First, we decompose each curve in $\mathcal{C}$ into maximal x-monotone subcurves (and possibly isolated points), obtaining the collection $\mathcal{C}'$. Note that an x-monotone curve cannot be self-intersecting. Then, we decompose each curve in $\mathcal{C}'$ into maximal connected subcurves not intersecting any other curve (or point) in $\mathcal{C}'$. The collection $\mathcal{C}''$ may also contain isolated points, if the curves of $\mathcal{C}$ contain such points. The arrangement induced by the collection $\mathcal{C}''$ can be conveniently embedded as a planar graph, whose vertices are associated with curve endpoints or with isolated points, and whose edges are associated with subcurves. It is easy to see that $\mathcal{A}(\mathcal{C}) = \mathcal{A}(\mathcal{C}'')$. This graph can be represented using a *doubly-connected edge list* data-structure (DCEL for short), which consists of containers of vertices, edges and faces and maintains the incidence relations among these objects.

The main idea behind the DCEL data-structure is to represent each edge using a pair of directed *halfedges*, one going from the xy-lexicographically smaller (left) endpoint of the curve toward its the xy-lexicographically larger (right) endpoint, and the other, known as its *twin* halfedge, going in the opposite direction. As each halfedge is directed, we say it has a *source* vertex and a *target* vertex. Halfedges are used to separate faces, and to connect vertices (with the exception of *isolated vertices*, which are unconnected).

If a vertex v is the target of a halfedge e, we say that v and e are *incident* to each other. The halfedges incident to a vertex v form a circular list oriented in a clockwise order around this vertex. (An isolated vertex has no incident halfedges.)

[1] A continuous planar curve C is *x-monotone* if every vertical line intersects it at most once. For example, a non-vertical line segment is always x-monotone and so is the graph of any continuous function $y = f(x)$. For convenience, we treat vertical line segments as *weakly x-monotone*, as there exists a single vertical line that overlaps them. A circle of radius r centered at (x_0, y_0) is not x-monotone, as the vertical line $x = x_0$ intersects it at $(x_0, y_0 - r)$ and at $(x_0, y_0 + r)$.

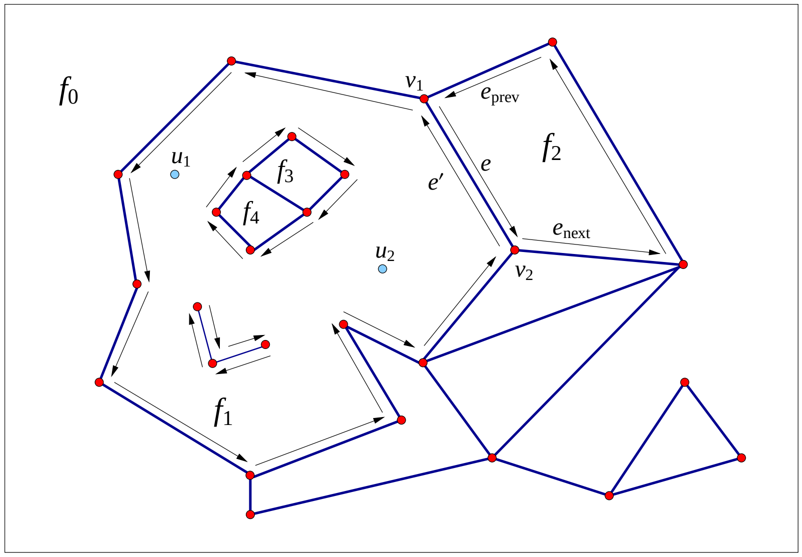

Figure 32.1: An arrangement of interior-disjoint line segments with some of the DCEL records that represent it. The unbounded face f_0 has a single connected component that forms a hole inside it, and this hole is comprised if several faces. The half-edge e is directed from its source vertex v_1 to its target vertex v_2. This edge, together with its twin e', correspond to a line segment that connects the points associated with v_1 and v_2 and separates the face f_1 from f_2. The predecessor e_{prev} and successor e_{next} of e are part of the chain that form the outer boundary of the face f_2. The face f_1 has a more complicated structure as it contains two holes in its interior: One hole consists of two adjacent faces f_3 and f_4, while the other hole is comprised of two edges. f_1 also contains two isolated vertices u_1 and u_2 in its interior.

Each halfedge e stores a pointer to its *incident face*, which is the face lying to its left. Moreover, every halfedge is followed by another halfedge sharing the same incident face, such that the target vertex of the halfedge is the same as the source vertex of the next halfedge. The halfedges are therefore connected in circular lists, and form chains, such that all edges of a chain are incident to the same face and wind along its boundary. We call such a chain a *connected component of the boundary* (or *CCB* for short).

The unique CCB of halfedges winding in a counterclockwise orientation along a face boundary is referred to as the *outer CCB* of the face. For the time being let us consider only arrangements of bounded curves, such that exactly one unbounded face exists in every arrangement. The unbounded face does not have an outer boundary. Any other connected component of the boundary of the face is called a *hole* (or *inner CCB*), and can be represented as a circular chain of halfedges winding in a clockwise orientation around it. Note that a hole does not necessarily correspond to a single face, as it may have no area, or alternatively it may consist of several connected faces. Every face can have several holes contained in its interior (or no holes at all). In addition, every face may contain isolated vertices in its interior. See Figure 32.1 for an illustration of the various DCEL features. For more details on the DCEL data structure see [dBvKOS00, Chapter 2].

The x-monotone curves of an arrangement are embedded in an rectangular two-dimensional area called the parameter space.[2] The parameter space is defined as $X \times Y$, where X and Y are open, half-open, or closed intervals with endpoints in the compactified real line $\mathbb{R} \cup \{-\infty, +\infty\}$. Let b_l, b_r, b_b, and b_t denote the endpoints of X and Y, respectively. We typically refer to these values as the left, right, bottom, and top sides of the boundary of the parameter space. If the parameter space is, for example, the entire compactified plane, which is currently the only option supported by the package, $b_l = b_b = -\infty$ and $b_r = b_t = +\infty$.

The rest of this chapter is organized as follows: In Section 32.2 we review in detail the interface of the

[2]The term parameter space stems from a major extension the arrangement package is going through to support arrangements embedded on certain two-dimensional parametric surfaces in three-dimensions (or higher).

Arrangement_2 class-template, which is the central component in the arrangement package. In Section 32.3 we show how queries on an arrangement can be issued. In Section 32.4 we review some important free (global) functions that operate on arrangements, the most important ones being the free insertion-functions. Section 32.6 contains detailed descriptions of the various geometric traits classes included in the arrangement package. Using these traits classes it is possible to construct arrangements of different families of curves. In Section 32.7 we review the notification mechanism that allows external classes to keep track of the changes that an arrangement instance goes through. Section 32.8 explains how to extend the DCEL records, to store extra data with them, and to efficiently update this data. In Section 32.9 we introduce the fundamental operation of overlaying two arrangements. Section 32.10 describes the *Arrangement_with_history_2* class-template that extends the arrangement by storing additional history records with its curves. Finally, in Section 32.11 we review the arrangement input/output functions.

32.2 The Main Arrangement Class

The class *Arrangement_2<Traits,Dcel>* is the main class in the arrangement package. It is used to represent planar arrangements and provides the interface needed to construct them, traverse them, and maintain them. An arrangement is defined by a geometric *traits* class that determines the family of planar curves that form the arrangement, and a DCEL class, which represents the *topological structure* of the planar subdivision. It supplies a minimal set of geometric operations (predicates and constructions) required to construct and maintain the arrangement and to operate on it.

The design of the arrangement package is guided by the need to separate between the representation of the arrangements and the various geometric algorithms that operate on them, and by the need to separate between the topological and geometric aspects of the planar subdivision. The separation is exhibited by the two template parameters of the *Arrangement_2* template:

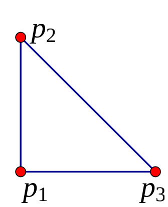
- The *Traits* template-parameter should be instantiated with a model of the *ArrangementBasicTraits_2* concept. The traits class defines the types of x-monotone curves and two-dimensional points, *X_monotone_curve_2* and *Point_2* respectively, and supports basic geometric predicates on them.

  In the first sections of this chapter we always use *Arr_segment_traits_2* as our traits class, to construct arrangements of line segments. However, the arrangement package contains several other traits classes that can handle also polylines (continuous piecewise-linear curves), conic arcs, and arcs of rational functions. We exemplify the usage of these traits classes in Section 32.6.

- The *Dcel* template-parameter should be instantiated with a class that is a model of the *ArrangementDcel* concept. The value of this parameter is *Arr_default_dcel<Traits>* by default. However, in many applications it is necessary to extend the DCEL features; see Section 32.8 for further explanations and examples.

32.2.1 A Simple Program

The simple program listed below constructs a planar map of three line segments forming a triangle. The constructed arrangement is instantiated with the *Arr_segment_traits_2* traits class to handle segments only. The resulting arrangement consists of two faces, a bounded triangular face and the unbounded face. The program is not very useful as it is, since it ends immediately after the arrangement is constructed. We give more enhanced examples in the rest of this chapter.



```
#include <CGAL/Cartesian.h>
#include <CGAL/MP_Float.h>
```

```
#include <CGAL/Quotient.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

typedef CGAL::Quotient<CGAL::MP_Float>     Number_type;
typedef CGAL::Cartesian<Number_type>       Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel> Traits_2;
typedef Traits_2::Point_2                  Point_2;
typedef Traits_2::X_monotone_curve_2       Segment_2;
typedef CGAL::Arrangement_2<Traits_2>      Arrangement_2;

int main()
{
  Arrangement_2   arr;
  Segment_2       cv[3];
  Point_2         p1 (0, 0), p2 (0, 4), p3 (4, 0);

  cv[0] = Segment_2 (p1, p2);
  cv[1] = Segment_2 (p2, p3);
  cv[2] = Segment_2 (p3, p1);
  CGAL::insert (arr, &cv[0], &cv[3]);

  return (0);
}
```

32.2.2 Traversing the Arrangement

The simplest and most fundamental arrangement operations are the various traversal methods, which allow users to systematically go over the relevant features of the arrangement at hand.

As mentioned above, the arrangement is represented as a DCEL, which stores three containers of vertices, halfedges and faces. Thus, the *Arrangement_2* class supplies iterators for these containers. For example, the methods *vertices_begin()* and *vertices_end()* return *Arrangement_2::Vertex_iterator* objects that define the valid range of arrangement vertices. The value type of this iterator is *Arrangement_2::Vertex*. Moreover, the vertex-iterator type is equivalent to *Arrangement_2::Vertex_handle*, which serves as a pointer to a vertex. As we show next, all functions related to arrangement features accept handle types as input parameters and return handle types as their output.

In addition to the iterators for arrangement vertices, halfedges and faces, the arrangement class also provides *edges_begin()* and *edges_end()* that return *Arrangement_2::Edge_iterator* objects for traversing the arrangement edges. Note that the value type of this iterator is *Arrangement_2::Halfedge*, representing one of the twin halfedges that represent the edge.

All iterator, circulator[3] and handle types also have non-mutable (*const*) counterparts. These non-mutable iterators are useful to traverse an arrangement without changing it. For example, the arrangement has a non-constant member function called *vertices_begin()* that returns a *Vertex_iterator* object and another const member function that returns a *Vertex_const_iterator* object. In fact, all methods listed in this section that return an iterator, a circulator or a handle have non-mutable counterparts. It should be noted that, for example, *Vertex_handle* can be readily converted into a *Vertex_const_handle*, but not vice-verse.

Conversion of a non-mutable handle to a corresponding mutable handle are nevertheless possible, and can be performed using the static function *Arrangement_2::non_const_handle()* (see, e.g., Section 32.3.1). There are

[3] A *circulator* is used to traverse a circular list, such as the list of halfedges incident to a vertex — see below.

three variant of this function, one for each type of handle.

Traversal Methods for an Arrangement Vertex

A vertex is always associated with a geometric entity, namely with a *Point_2* object, which can be obtained by the *point()* method of the *Vertex* class nested within *Arrangement_2*.

The *is_isolated()* method determines whether a vertex is isolated or not. Recall that the halfedges incident to a non-isolated vertex, namely the halfedges that share a common target vertex, form a circular list around this vertex. The *incident_halfedges()* method returns a circulator of type *Arrangement_2::Halfedge_around_vertex_circulator* that enables the traversal of this circular list in a clockwise direction. The value type of this circulator is *Halfedge*.

The following function prints all the neighbors of a given arrangement vertex (assuming that the *Point_2* type can be inserted into the standard output using the << operator). The arrangement type is the same as in the simple example above.

```
void print_neighboring_vertices (Arrangement_2::Vertex_const_handle v)
{
  if (v->is_isolated()) {
    std::cout << "The vertex (" << v->point() << ") is isolated" << std::endl;
    return;
  }

  Arrangement_2::Halfedge_around_vertex_const_circulator first, curr;
  first = curr = v->incident_halfedges();

  std::cout << "The neighbors of the vertex (" << v->point() << ") are:";
  do {
    // Note that the current halfedge is directed from u to v:
    Arrangement_2::Vertex_const_handle u = curr->source();
    std::cout << " (" << u->point() << ")";
  } while (++curr != first);
  std::cout << std::endl;
}
```

In case of an isolated vertex, it is possible to obtain the face that contains this vertex using the *face()* method.

Traversal Methods for an Arrangement Halfedge

Each arrangement edge, realized as a pair of twin halfedges, is associated with an *X_monotone_curve_2* object, which can be obtained by the *curve()* method of the *Halfedge* class nested in the *Arrangement_2* class.

The *source()* and *target()* methods return handles to the halfedge source and target vertices respectively. We can obtain a handle to the twin halfedge using the *twin()* method. From the definition of halfedges, it follows that if *he* is a halfedge handle, then:

- *he->curve()* is equivalent to *he->twin()->curve()*,
- *he->source()* is equivalent to *he->twin()->target()*, and

- *he->target()* is equivalent to *he->twin()->source()*.

Every halfedge has an incident face that lies to its left, which can be obtained by the *face()* method. Recall that a halfedge is always one link in a connected chain of halfedges that share the same incident face, known as a *CCB*. The *prev()* and *next()* methods return handles to the previous and next halfedges in the CCB respectively.

As the CCB is a circular list of halfedges, it is only natural to traverse it using a circulator. The *ccb()* method returns a *Arrangement_2::Ccb_halfedge_circulator* object for the halfedges along the CCB.

The function *print_ccb()* listed below prints all *x*-monotone curves along a given CCB (assuming that the *Point_2* and the *X_monotone_curve_2* types can be inserted into the standard output using the << operator).

```
void print_ccb (Arrangement_2::Ccb_halfedge_const_circulator circ)
{
  Ccb_halfedge_const_circulator curr = circ;
  std::cout << "(" << curr->source()->point() << ")";
  do {
    Arrangement_2::Halfedge_const_handle he = curr->handle();
    std::cout << "   [" << he->curve() << "]   "
              << "(" << he->target()->point() << ")";
  } while (++curr != circ);
  std::cout << std::endl;
}
```

Traversal Methods for an Arrangement Face

An arrangement of bounded curves always has a single unbounded face. The function *unbounded_face()* returns a handle to this face. (Note that an empty arrangement contains nothing *but* the unbounded face.)

Given a *Face* object, we can use the *is_unbounded()* method to determine whether it is unbounded. Bounded faces have an outer CCB, and the *outer_ccb()* method returns a circulator for the halfedges along this CCB. Note that the halfedges along this CCB wind in a counterclockwise orientation around the outer boundary of the face.

A face can also contain disconnected components in its interior, namely holes and isolated vertices:

- The *holes_begin()* and *holes_end()* methods return *Arrangement_2::Hole_iterator* iterators that define the range of holes inside the face. The value type of this iterator is *Ccb_halfedge_circulator*, defining the CCB that winds in a clockwise orientation around a hole.
- The *isolated_vertices_begin()* and *isolated_vertices_end()* methods return *Arrangement_2::Isolated_vertex_iterator* iterators that define the range of isolated vertices inside the face. The value type of this iterator is *Vertex*.

The function *print_face()* listed below prints the outer and inner boundaries of a given face, using the function *print_ccb()*, which was introduced in the previous subsection.

```
void print_face (Arrangement_2::Face_const_handle f)
{
  // Print the outer boundary.
  if (f->is_unbounded())
    std::cout << "Unbounded face. " << std::endl;
```

```
  else {
    std::cout << "Outer boundary: ";
    print_ccb (f->outer_ccb());
  }

  // Print the boundary of each of the holes.
  Arrangement_2::Hole_const_iterator hi;
  int                                 index = 1;
  for (hi = f->holes_begin(); hi != f->holes_end(); ++hi, ++index) {
    std::cout << "    Hole #" << index << ": ";
    print_ccb (*hi);
  }

  // Print the isolated vertices.
  Arrangement_2::Isolated_vertex_const_iterator iv;
  for (iv = f->isolated_vertices_begin(), index = 1;
       iv != f->isolated_vertices_end(); ++iv, ++index)
  {
    std::cout << "    Isolated vertex #" << index << ": "
              << "(" << iv->point() << ")" << std::endl;
  }
}
```

Additional Example

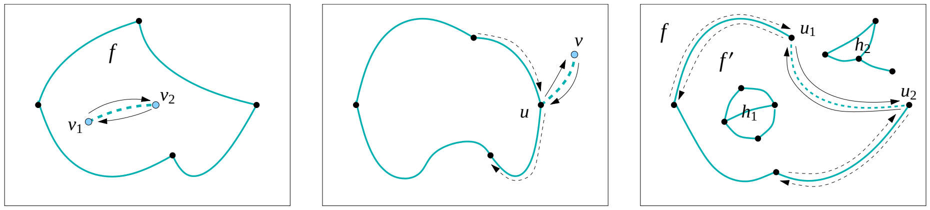
The function listed below prints the current setting of a given arrangement. This concludes the preview of the various traversal methods.[4]

```
void print_arrangement (const Arrangement_2& arr)
{
  // Print the arrangement vertices.
  Vertex_const_iterator vit;
  std::cout << arr.number_of_vertices() << " vertices:" << std::endl;
  for (vit = arr.vertices_begin(); vit != arr.vertices_end(); ++vit) {
    std::cout << "(" << vit->point() << ")";
    if (vit->is_isolated())
      std::cout << " - Isolated." << std::endl;
    else
      std::cout << " - degree " << vit->degree() << std::endl;
  }

  // Print the arrangement edges.
  Edge_const_iterator eit;
  std::cout << arr.number_of_edges() << " edges:" << std::endl;
  for (eit = arr.edges_begin(); eit != arr.edges_end(); ++eit)
    std::cout << "[" << eit->curve() << "]" << std::endl;

  // Print the arrangement faces.
  Face_const_iterator fit;
```

[4]The file *arr_print.h*, which can be found under the examples folder, includes this function and the rest of the functions listed in this section. Over there they are written in a more generic fashion, where the arrangement type serves as a template parameter for these functions, so different instantiations of the *Arrangement_2<Traits,Dcel>* template can be provided to the same function templates.



(a) (b) (c)

Figure 32.2: The various specialized insertion procedures. The inserted x-monotone curve is drawn with a light dashed line, surrounded by two solid arrows that represent the pair of twin half-edges added to the DCEL. Existing vertices are shown as black dots while new vertices are shown as light dots. Existing half-edges that are affected by the insertion operations are drawn as dashed arrows. (a) Inserting a curve as a new hole inside the face f. (b) Inserting a curve from an existing vertex u that corresponds to one of its endpoints. (c) Inserting an x-monotone curve whose endpoints are the already existing vertices u_1 and u_2. In our case, the new pair of half-edges close a new face f', where the hole h_1, which used to belong to f, now becomes an enclave in this new face.

```
  std::cout << arr.number_of_faces() << " faces:" << std::endl;
  for (fit = arr.faces_begin(); fit != arr.faces_end(); ++fit)
    print_face (fit);
}
```

32.2.3 Modifying the Arrangement

In this section we review the various member functions of the *Arrangement_2* class that allow users to modify the topological structure of the arrangement by introducing new edges or vertices, modifying them, or removing them.

The arrangement member-functions that insert new curves into the arrangement, thus enabling the construction of a planar subdivision, are rather specialized, as they require a-priori knowledge on the location of the inserted curve. Indeed, for most purposes it is more convenient to construct an arrangement using the free (global) insertion-functions.

Inserting Non-Intersecting x-Monotone Curves

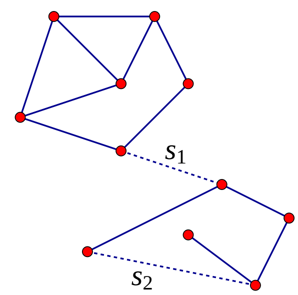
The most important functions that allow users to modify the arrangement, and perhaps the most frequently used ones, are the specialized insertion functions of x-monotone curves whose interior is disjoint from any other curve in the existing arrangement and do not contain any vertex of the arrangement. In addition, these function require that the location of the curve in the arrangement is known.

The motivation behind these rather harsh restrictions on the nature of the inserted curves is the decoupling of the topological arrangement representation from the various algorithms that operate on it. While the insertion of an x-monotone curve whose interior is disjoint from all existing arrangement features is quite straightforward (as we show next), inserting curves that intersect with the curves already inserted into the arrangement is much more complicated and requires the application of non-trivial geometric algorithms. These insertion operations are therefore implemented as free functions that operate on the arrangement and the inserted curve(s); see Section 32.4 for more details and examples.[5]

[5]You may skip to Section 32.4, and return to this subsection at a later point in time.

When an x-monotone curve is inserted into an existing arrangement, such that the interior of this curve is disjoint from any arrangement feature, only the following three scenarios are possible, depending on the status of the endpoints of the inserted subcurve:

1. In case both curve endpoints do not correspond to any existing arrangement vertex we have to create two new vertices corresponding to the curve endpoints and connect them using a pair of twin halfedges. This halfedge pair initiates a new hole inside the face that contains the curve in its interior.
2. If exactly one endpoint corresponds to an existing arrangement vertex (we distinguish between a vertex that corresponds to the left endpoint of the inserted curve and a vertex corresponding to its right endpoint), we have to create a new vertex that corresponds to the other endpoint of the curve and to connect the two vertices by a pair of twin halfedges that form an “antenna” emanating from the boundary of an existing connected component (note that if the existing vertex used to be isolated, this operation is actually equivalent to forming a new hole inside the face that contains this vertex).
3. If both endpoints correspond to existing arrangement vertices, we connect these vertices using a pair of twin halfedges. (If one or both vertices are isolated this case reduces to one of the two previous cases respectively.) The two following subcases may occur:
   - Two disconnected components are merged into a single connected component (as is the case with the segment s_1 in the figure to the left).
   - A new face is created, a face that splits from an existing arrangement face. In this case we also have to examine the holes and isolated vertices in the existing face and move the relevant ones inside the new face (as is the case with the segment s_2 in the figure to the left).



The *Arrangement_2* class offers insertion functions named *insert_in_face_interior()*, *insert_from_left_vertex()*, *insert_from_right_vertex()* and *insert_at_vertices()* that perform the special insertion procedures listed above. The first function accepts an x-monotone curve c and an arrangement face f that contains this curve in its interior. The other functions accept an x-monotone curve c and handles to the existing vertices that correspond to the curve endpoint(s). Each of the four functions returns a handle to one of the twin halfedges that have been created, where:

- *insert_in_face_interior(c, f)* returns a halfedge directed from the vertex corresponding to the left endpoint of c toward the vertex corresponding to its right endpoint.
- *insert_from_left_vertex(c, v)* and *insert_from_right_vertex(c, v)* returns a halfedge whose source is the vertex v that and whose target is the new vertex that has just been created.
- *insert_at_vertices(c, v1, v2)* returns a halfedge directed from v_1 to v_2.

The following program demonstrates the usage of the four insertion functions. It creates an arrangement of five line segments, as depicted in Figure 32.3.[6] As the arrangement is very simple, we use the simple Cartesian kernel of CGAL with integer coordinates for the segment endpoints. We also use the *Arr_segment_traits_2* class that enables the efficient maintenance of arrangements of line segments; see more details on this traits class in Section 32.6. This example, as many others in this chapter, uses some print-utility functions from the file *print_arr.h*; these functions are also listed in Section 32.2.2.

```
#include <CGAL/Simple_cartesian.h>
```

[6]Notice that in all figures in the rest of this chapter the coordinate axes are drawn only for illustrative purposes and are *not* part of the arrangement.

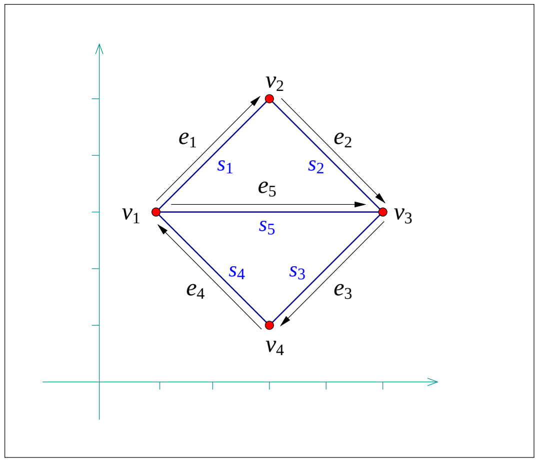


Figure 32.3: The arrangement of the line segments $s_1, \ldots, s_5$ constructed in *edge_insertion.cpp*. The arrows mark the direction of the halfedges returned from the various insertion functions.

```
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

#include "arr_print.h"

typedef int                                             Number_type;
typedef CGAL::Simple_cartesian<Number_type>             Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>              Traits_2;
typedef Traits_2::Point_2                               Point_2;
typedef Traits_2::X_monotone_curve_2                    Segment_2;
typedef CGAL::Arrangement_2<Traits_2>                   Arrangement_2;
typedef Arrangement_2::Vertex_handle                    Vertex_handle;
typedef Arrangement_2::Halfedge_handle                  Halfedge_handle;

int main()
{
  Arrangement_2   arr;

  Segment_2       s1(Point_2(1, 3), Point_2(3, 5));
  Segment_2       s2(Point_2(3, 5), Point_2(5, 3));
  Segment_2       s3(Point_2(5, 3), Point_2(3, 1));
  Segment_2       s4(Point_2(3, 1), Point_2(1, 3));
  Segment_2       s5(Point_2(1, 3), Point_2(5, 3));

  Halfedge_handle e1 = arr.insert_in_face_interior(s1,
   arr.unbounded_face());
  Vertex_handle   v1 = e1->source();
  Vertex_handle   v2 = e1->target();
  Halfedge_handle e2 = arr.insert_from_left_vertex(s2, v2);
  Vertex_handle   v3 = e2->target();
  Halfedge_handle e3 = arr.insert_from_right_vertex(s3, v3);
  Vertex_handle   v4 = e3->target();
  arr.insert_at_vertices(s4, v4, v1);
  arr.insert_at_vertices(s5, v1, v3);
```

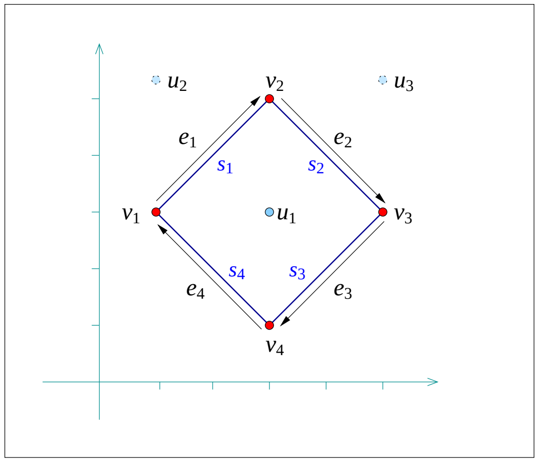

Figure 32.4: An arrangement of line segments containing three isolated vertices, as constructed in *isolated_vertices.cpp*. The vertices u_2 and u_3 are eventually removed from the arrangement.

```
  print_arrangement(arr);
  return 0;
}
```

File: examples/Arrangement_on_surface_2/edge_insertion.cpp

Observe that the first line segment is inserted in the interior of the unbounded face. The other line segments are inserted using the vertices created by the insertion of previous segments. The resulting arrangement consists of three faces, where the two bounded faces form together a hole in the unbounded face.

Manipulating Isolated Vertices

Isolated points are in general simpler geometric entities than curves and indeed the member functions that manipulate them are easier to understand.

The function *insert_in_face_interior(p, f)* inserts an isolated point p, located in the interior of a given face f, into the arrangement and returns a handle to the arrangement vertex it has created and associated with p. Naturally, this function has a precondition that p is really an isolated point, namely it does not coincide with any existing arrangement vertex and does not lie on any edge. As mentioned in Section 32.2.2, it is possible to obtain the face containing an isolated vertex handle v by calling *v->face()*.

The function *remove_isolated_vertex(v)* receives a handle to an isolated vertex and removes it from the arrangement.

The following program demonstrates the usage of the arrangement member-functions for manipulating isolated vertices. It first inserts three isolated vertices located inside the unbounded face, then it inserts four line segments that form a rectangular hole inside the unbounded face (see Figure 32.4 for an illustration). Finally, it traverses the vertices and removes those isolated vertices that are still contained in the unbounded face (u_2 and u_3 in this case):

```
#include "arr_inexact_construction_segments.h"
#include "arr_print.h"

int main()
{
  // Insert isolated points.
  Arrangement arr;
  Face_handle uf = arr.unbounded_face();
  arr.insert_in_face_interior(Point(3, 3), uf);
  arr.insert_in_face_interior(Point(1, 5), uf);
  arr.insert_in_face_interior(Point(5, 5), uf);

  // Insert four segments that form a square-shaped face.
  Point p1(1, 3), p2(3, 5), p3(5, 3), p4(3, 1);
  Segment s1(p1, p2), s2(p2, p3), s3(p3, p4), s4(p4, p1);

  Halfedge_handle e1 = arr.insert_in_face_interior(s1, uf);
  Vertex_handle   v1 = e1->source();
  Vertex_handle   v2 = e1->target();
  Halfedge_handle e2 = arr.insert_from_left_vertex(s2, v2);
  Vertex_handle   v3 = e2->target();
  Halfedge_handle e3 = arr.insert_from_right_vertex(s3, v3);
  Vertex_handle   v4 = e3->target();
  arr.insert_at_vertices(s4, v4, v1);

  // Remove the isolated vertices located in the unbounded face.
  Arrangement::Vertex_iterator curr, next = arr.vertices_begin();
  for (curr = next++; curr != arr.vertices_end(); curr = next++) {
    // Keep an iterator to the next vertex, as curr might be deleted.
    if (curr->is_isolated() && curr->face() == uf)
      arr.remove_isolated_vertex(curr);
  }

  print_arrangement(arr);
  return 0;
}
```

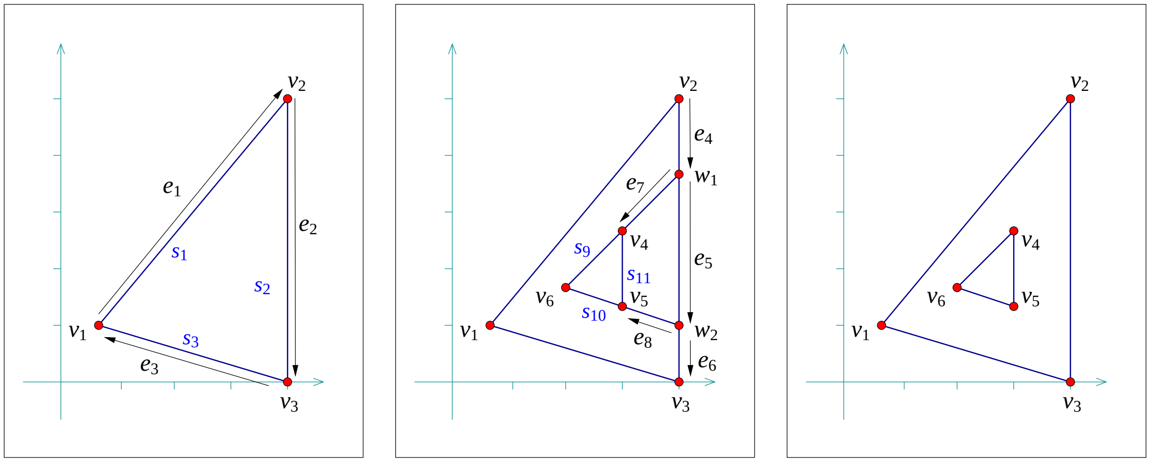
Manipulating Halfedges

In the previous subsection we showed how to introduce new isolated vertices in the arrangement. But how does one create a vertex that lies on an existing arrangement edge (more precisely, on an x-monotone curve that is associated with an arrangement edge)?

It should be noted that such an operation involves the splitting of a curve at a given point in its interior, while the traits class used by *Arrangement_2* does not necessarily have the ability to perform such a split operation. However, if users have the ability to split an x-monotone curve into two at a given point p (this is usually the case when employing a more sophisticated traits class; see Section 32.6 for more details) they can use the *split_edge(e, c1, c2)* function, were c_1 and c_2 are the two subcurves resulting from splitting the x-monotone curve



(a) (b) (c)

Figure 32.5: An arrangement of line segments as constructed in *edge_manipulation.cpp*. Note that the edges e_7 and e_8 and the vertices w_1 and w_2, introduced in step (b) are eventually removed in step (c).

associated with the halfedge e at some point (call it p) in its interior. The function splits the halfedge pair into two pairs, both incident to a new vertex v associated with p, and returns a handle to a halfedge whose source equals e's source vertex and whose target is the new vertex v.

The reverse operation is also possible. Suppose that we have a vertex v of degree 2, whose two incident halfedges, e_1 and e_2, are associated with the curves c_1 and c_2. Suppose further that it is possible to merge these two curves into a single continuous x-monotone curve c. Calling *merge_edge(e1, e2, c)* will merge the two edges into a single edge associated with the curve c, essentially removing the vertex v from the arrangement.

Finally, the function *remove_edge(e)* removes the edge e from the arrangement. Note that this operation is the reverse of an insertion operation, so it may cause a connected component to split into two, or two faces to merge into one, or a hole to disappear. By default, if the removal of e causes one of its end-vertices to become isolated, we remove this vertex as well. However, users can control this behavior and choose to keep the isolated vertices by supplying additional Boolean flags to *remove_edge()* indicating whether the source and the target vertices are to be removed should they become isolated.

In the following example program we show how the edge-manipulation functions can be used. The program works in three steps, as demonstrated in Figure 32.5. Note that here we still stick to integer coordinates, but as we work on a larger scale we use an unbounded integer number-type (in this case, the *Gmpz* type taken from the GMP library) instead of the built-in *int* type.[7] In case the GMP library is not installed (as indicated by the *CGAL_USE_GMP* flag defined in *CGAL/basic.h*), we use *MP_Float*, a number-type included in CGAL's support library that is capable of storing floating-point numbers with unbounded mantissa. We also use the standard Cartesian kernel of CGAL as our kernel. This is recommended when the kernel is instantiated with a more complex number type, as we demonstrate in other examples in this chapter.

```
#include <CGAL/basic.h>

#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
```

[7] As a rule of thumb, one can use a bounded integer type for representing line segments whose coordinates are bounded by $\lfloor \sqrt[3]{M} \rfloor$, where M is the maximal representable integer value. This guarantees that no overflows occur in the computations carried out by the traits class, hence all traits-class predicates always return correct results.

```
#include "arr_print.h"

typedef CGAL::Exact_predicates_exact_constructions_kernel   Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                  Traits_2;
typedef Traits_2::Point_2                                   Point_2;
typedef Traits_2::X_monotone_curve_2                        Segment_2;
typedef CGAL::Arrangement_2<Traits_2>
   Arrangement_2;
typedef Arrangement_2::Vertex_handle
   Vertex_handle;
typedef Arrangement_2::Halfedge_handle
   Halfedge_handle;

int main()
{
  // Step(a) - construct a triangular face.
  Arrangement_2   arr;

  Segment_2       s1(Point_2(667, 1000), Point_2(4000, 5000));
  Segment_2       s2(Point_2(4000, 0), Point_2(4000, 5000));
  Segment_2       s3(Point_2(667, 1000), Point_2(4000, 0));

  Halfedge_handle e1 = arr.insert_in_face_interior(s1,
   arr.unbounded_face());
  Vertex_handle   v1 = e1->source();
  Vertex_handle   v2 = e1->target();
  Halfedge_handle e2 = arr.insert_from_right_vertex(s2, v2);
  Vertex_handle   v3 = e2->target();
  arr.insert_at_vertices(s3, v3, v1);

  // Step (b) - create additional two faces inside the triangle.
  Point_2         p1(4000, 3666), p2(4000, 1000);
  Segment_2       s4(Point_2(4000, 5000), p1);
  Segment_2       s5(p1, p2);
  Segment_2       s6(Point_2(4000, 0), p2);

  Halfedge_handle e4 = arr.split_edge(e2, s4, Segment_2(Point_2(4000, 0),
    p1));
  Vertex_handle   w1 = e4->target();
  Halfedge_handle e5 = arr.split_edge(e4->next(), s5, s6);
  Vertex_handle   w2 = e5->target();
  Halfedge_handle e6 = e5->next();

  Segment_2       s7(p1, Point_2(3000, 2666));
  Segment_2       s8(p2, Point_2(3000, 1333));
  Segment_2       s9(Point_2(3000, 2666), Point_2(2000, 1666));
  Segment_2       s10(Point_2(3000, 1333), Point_2(2000, 1666));
  Segment_2       s11(Point_2(3000, 1333), Point_2(3000, 2666));

  Halfedge_handle e7 = arr.insert_from_right_vertex(s7, w1);
  Vertex_handle   v4 = e7->target();
  Halfedge_handle e8 = arr.insert_from_right_vertex(s8, w2);
  Vertex_handle   v5 = e8->target();
```

```
  Vertex_handle   v6 =
    arr.insert_in_face_interior(Point_2(2000, 1666), e8->face());

  arr.insert_at_vertices(s9, v4, v6);
  arr.insert_at_vertices(s10, v5, v6);
  arr.insert_at_vertices(s11, v4, v5);

  // Step(c) - remove and merge faces to form a single hole in the
    traingle.
  arr.remove_edge(e7);
  arr.remove_edge(e8);

  e5 = arr.merge_edge(e5, e6, Segment_2(e5->source()->point(),
                                          e6->target()->point()));
  e2 = arr.merge_edge(e4, e5, s2);

  print_arrangement(arr);
  return 0;
}
```

File: examples/Arrangement_on_surface_2/edge_manipulation.cpp

Note how we use the halfedge handles returned from *split_edge()* and *merge_edge()*. Also note the insertion of the isolated vertex v_6 located inside the triangular face (the incident face of e_7). This vertex seizes from being isolated, as it is gets connected to other vertices.

In this context, we should mention the two member functions *modify_vertex(v, p)*, which sets p to be the point associated with the vertex v, and *modify_edge(e, c)*, which sets c to be the x-monotone curve associated with the halfedge e. These functions have preconditions that p is geometrically equivalent to *v->point()* and c is equivalent to *e->curve()* (i.e., the two curves have the same graph), respectively, to avoid the invalidation of the geometric structure of the arrangement. At a first glance it may seen as these two functions are of little use. However, we should keep in mind that there may be extraneous data (probably non-geometric) associated with the point objects or with the curve objects, as defined by the traits class. With these two functions we can modify this data; see more details in Section 32.6.

In addition, we can use these functions to replace a geometric object (a point or a curve) with an equivalent object that has a more compact representation. For example, we can replace the point $(\frac{20}{40}, \frac{99}{33})$ associated with some vertex v, by $(\frac{1}{2}, 3)$.

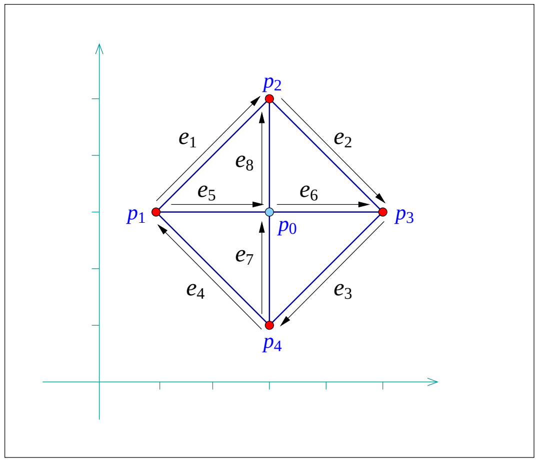


Figure 32.6: An arrangement of line segments, as constructed in *special_edge_insertion.cpp*. Note that p_0 is initially inserted as an isolated point and later on connected to the other four vertices.

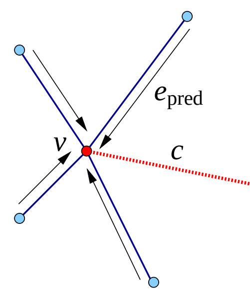
advanced

Advanced Insertion Functions



Assume that the specialized insertion function *insert_from_left_vertex(c,v)* is invoked for a curve c, whose left endpoint is already associated with a non-isolated vertex v. Namely, v has already several incident halfedges. It is necessary in this case to locate the exact place for the new halfedge mapped to the inserted new curve c in the circular list of halfedges incident to v. More precisely, it is sufficient to locate one of the halfedges *pred* directed toward v such that c is located between *pred* and *pred->next()* in clockwise order around v, in order to complete the insertion (see Figure 32.2 for an illustration). This may take $O(d)$ time where d is the degree of the vertex. However, if the halfedge *pred* is known in advance, the insertion can be carried out in constant time.

The *Arrangement_2* class provides the advanced versions of the specialized insertion functions for a curve c — namely we have *insert_from_left_vertex(c,pred)* and *insert_from_right_vertex(c,pred)* that accept a halfedge *pred* as specified above, instead of a vertex v. These functions are more efficient, as they take constant time and do not perform any geometric operations. Thus, they should be used when the halfedge *pred* is known. In case that the vertex v is isolated or that the predecessor halfedge for the new inserted curve is not known, the simpler versions of these insertion functions should be used.

Similarly, there exist two overrides of the *insert_at_vertices()* function: One that accept the two predecessor halfedges around the two vertices v_1 and v_2 that correspond to the curve endpoints, and one that accepts a handle for one vertex and a predecessor halfedge around the other vertex.

The following program shows how to construct the arrangement depicted in Figure 32.6 using the specialized insertion functions that accept predecessor halfedges:

```
#include "arr_inexact_construction_segments.h"
#include "arr_print.h"

int main()
{
```

```
  Point           p0(3, 3), p1(1, 3), p2(3, 5), p3(5, 3), p4(3, 1);
  Segment         s1(p1, p2), s2(p2, p3), s3(p3, p4), s4(p4, p1);
  Segment         s5(p1, p0), s6(p0, p3), s7(p4, p0), s8(p0, p2);

  Arrangement     arr;
  Vertex_handle   v0 = arr.insert_in_face_interior(p0,
   arr.unbounded_face());
  Halfedge_handle e1 = arr.insert_in_face_interior(s1,
   arr.unbounded_face());
  Halfedge_handle e2 = arr.insert_from_left_vertex(s2, e1);
  Halfedge_handle e3 = arr.insert_from_right_vertex(s3, e2);
  Halfedge_handle e4 = arr.insert_at_vertices(s4, e3, e1->twin());
  Halfedge_handle e5 = arr.insert_at_vertices(s5, e1->twin(), v0);
  Halfedge_handle e6 = arr.insert_at_vertices(s6, e5, e3->twin());
  arr.insert_at_vertices(s7, e4->twin(), e6->twin());
  arr.insert_at_vertices(s8, e5, e2->twin());

  print_arrangement(arr);
  return 0;
}
```

File: examples/Arrangement_on_surface_2/special_edge_insertion.cpp

It is possible to perform even more refined operations on an *Arrangement_2* instance given specific topological information. As most of these operations are very fragile and perform no precondition testing on their input in order to gain efficiency, they are not included in the public interface of the arrangement class. Instead, the *Arr_accessor<Arrangement>* class allows access to these internal arrangement operations — see more details in the Reference Manual.

advanced

32.3 Issuing Queries on an Arrangement

One of the most important query types defined on arrangements is the *point-location* query: Given a point, find the arrangement cell that contains it. Typically, the result of a point-location query is one of the arrangement faces, but in degenerate situations the query point can be located on an edge or coincide with a vertex.

Point-location queries are not only common in many applications, they also play an important role in the free insertion-functions (see Section 32.4). Therefore, it is crucial to have the ability to answer such queries effectively for any arrangement instance.

32.3.1 Point-Location Queries

The arrangement package includes several classes (more precisely, class templates parameterized by an arrangement class) that model the *ArrangementPointLocation_2* concept. Namely, they all have a member function called *locate(q)* that accepts a query point q and result with a CGAL *Object* that wraps a handle to the arrangement cell containing the query point. This object can be assigned to either a *Face_const_handle*, *Halfedge_const_handle* or a *Vertex_const_handle*, depending on whether the query point is located inside a face, on an edge or on a vertex.

Note that the handles returned by the *locate()* functions are *const* (non-mutable) handles. If necessary, such handles may be casted to mutable handles using the static functions *Arrangement_on_surface_2::non_const_handle()* provided by the arrangement class.

An instance of any point-location class must be attached to an *Arrangement_on_surface_2* instance so we can use it to issue point-location queries. This attachment can be performed when the point-location instance is constructed, or at a later time, using the *init(arr)* method, where *arr* is the attached *Arrangement_on_surface_2* instance. In this chapter we always use the first option.

The following function template, which can be found in the example file *point_location_utils.h*, accepts a point-location object (whose type can be any of the models to the *ArrangementPointLocation_2* concept) and a query point, and prints out the result of the point-location query for the given point. Observe how we use the function *CGAL::assign()* is order to cast the resulting *CGAL::Object* into a handle to an arrangement feature. The point-location object *pl* is assumed to be already associated with an arrangement:

```
template <class PointLocation>
void point_location_query
        (const PointLocation& pl,
         const typename PointLocation::Arrangement_on_surface_2::Point_2& q)
{
  // Perform the point-location query.
  CGAL::Object obj = pl.locate (q);

  // Print the result.
  typedef typename PointLocation::Arrangement_on_surface_2  Arrangement_on_surface_2;

  typename Arrangement_on_surface_2::Vertex_const_handle    v;
  typename Arrangement_on_surface_2::Halfedge_const_handle  e;
  typename Arrangement_on_surface_2::Face_const_handle      f;

  std::cout << "The point " << q << " is located ";
  if (CGAL::assign (f, obj)) {
    // q is located inside a face:
    if (f->is_unbounded())
      std::cout << "inside the unbounded face." << std::endl;
    else
      std::cout << "inside a bounded face." << std::endl;
  }
  else if (CGAL::assign (e, obj)) {
    // q is located on an edge:
    std::cout << "on an edge: " << e->curve() << std::endl;
  }
  else if (CGAL::assign (v, obj)) {
    // q is located on a vertex:
    if (v->is_isolated())
      std::cout << "on an isolated vertex: " << v->point() << std::endl;
    else
      std::cout << "on a vertex: " << v->point() << std::endl;
  }
  else {
    CGAL_assertion_msg (false, "Invalid object.");
  }
}
```

Choosing a Point-Location Strategy

Each of the various point-location classes employs a different algorithm or *strategy*[8] for answering queries:

- *Arr_naive_point_location<Arrangement>* locates the query point naively, by exhaustively scanning all arrangement cells.
- *Arr_walk_along_a_line_point_location<Arrangement>* simulates a traversal, in reverse order, along an imaginary vertical ray emanating from the query point: It starts from the unbounded face of the arrangement and moves downward toward the query point until locating the arrangement cell containing it.
- *Arr_landmarks_point_location<Arrangement,Generator>* uses a set of "landmark" points whose location in the arrangement is known. Given a query point, it uses a KD-tree to find the nearest landmark and then traverses the straight line segment connecting this landmark to the query point.

  There are various ways to select the landmark set in the arrangement, determined by the *Generator* template parameter. By default, the generator class *Arr_landmarks_vertices_generator* is used and the arrangement vertices are the selected landmarks, but other landmark generators, such as sampling random points or choosing points on a grid, are also available; see the Reference Manual for more details.
- *Arr_trapezoid_ric_point_location<Arrangement>* implements a point location algorithm presented by Seidel [Sei91], which uses the randomized incremental construction described by Mulmuley [Mul90] (see also [dBvKOS00, Chapter 6]). The arrangement faces are decomposed into simpler cells of constant complexity known as *pseudo-trapezoids* and a search-structure (a directed acyclic graph) is constructed on top of these cells, allowing to locate the pseudo-trapezoid (hence the arrangement cell) containing a query point in logarithmic time.

The main advantage of the first two strategies is that they do not require any extra data, so the respective classes just store a pointer to an arrangement object and operate directly on it. Attaching such point-location objects to an existing arrangement has virtually no running-time cost at all, but the query time is linear in the size of the arrangement (the performance of the "walk" strategy is much better in practice, but its worst-case performance is linear). Using these strategies is therefore recommended only when a relatively small number of point-location queries are issued by the application, or when the arrangement is constantly changing (i.e., changes in the arrangement structure are more frequent than point-location queries).

On the other hand, the landmarks and the trapezoid RIC strategies require auxiliary data structures on top of the arrangement, which they need to construct once they are attached to an arrangement object and need to keep up-to-date as this arrangement changes. The data structure needed by the landmarks strategy can be constructed in $O(N \log N)$ time (where N is the overall number of edges in the arrangement), whereas the construction of the data structure needed by the trapezoid RIC strategy takes expected $O(N \log N)$, but may require several rebuilds. As shown in [HKH12], one can expect only a small number of rebuilds. In practice, the construction needed by the landmark algorithm is significantly faster. In addition, although both resulting data structures are asymptotically linear in size, the KD-tree that the landmark algorithm stores needs significantly less memory.

We note that the trapezoid RIC algorithm guarantees a logarithmic query time for any scenario making it advantageous comparing to other strategies. The query time of the landmarks strategy, on the other hand, is only logarithmic on average — and we may have scenarios where the query time can be linear. In practice, in many scenarios the query times of both strategies are competitive. For a detailed experimental comparison, see [HH08].

Another advantageous feature of the trapezoid RIC strategy when compared with other methods is the unbounded curves support. Currently, this is the most efficient strategy suitable for general unbounded subdivisions.

[8] We use the term *strategy* following the design pattern taxonomy [GHJV95].

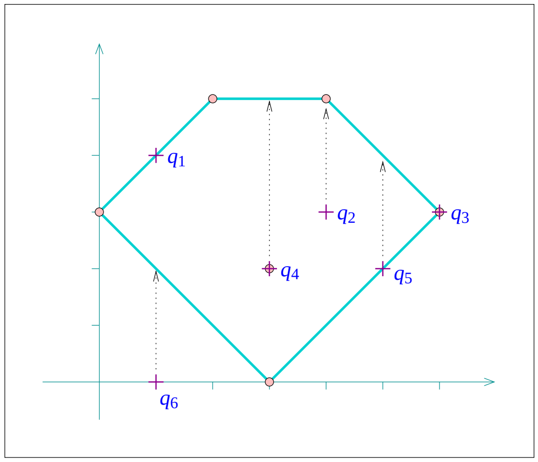


Figure 32.7: The arrangement of line segments, as constructed in *point_location.cpp*, *vertical_ray_shooting.cpp*, and *batched_point_location.cpp*. The arrangement vertices are drawn as small discs, while the query points $q_1, \ldots, q_6$ are marked with crosses.

The main drawback in the current implementation of the landmark strategy, compared to the trapezoidal RIC strategy, is that while the updating the auxiliary data structures related to the trapezoidal decomposition is done very efficiently, the KD-tree maintained by the landmark algorithm needs to be frequently rebuilt as the arrangement changes. In addition, using the landmark point-location class adds some extra requirement from the traits class (that is, the traits class should be a model of a refined concept *ArrangementLandmarkTraits_2*; see Section 32.6 for the details). However, most built-in traits classes that come with the CGAL public release support these extra operations.

It is therefore recommended to use the *Arr_landmarks_point_location* class when the application frequently issues point-location queries on a bounded arrangement that only seldom changes. If the arrangement consists of unbounded curves or is more dynamic and is frequently going through changes, the *Arr_trapezoid_ric_point_location* class should be the selected point-location strategy.

An Example

The following program constructs a simple arrangement of five line segments that form a pentagonal face, with a single isolated vertex in its interior, as depicted in Figure 32.7 (the arrangement construction is performed by the function *construct_segment_arr()* whose listing is omitted here and can be found in *point_location_utils.h*). It then employs the naive and the landmark strategies to issue several point-location queries on this arrangement:

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_naive_point_location.h>
#include <CGAL/Arr_landmarks_point_location.h>

#include "point_location_utils.h"

typedef int
   Number_type;
typedef CGAL::Simple_cartesian<Number_type>                   Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                    Traits_2;
```

```
typedef Traits_2::Point_2                                       Point_2;
typedef CGAL::Arrangement_2<Traits_2>
    Arrangement_2;
typedef CGAL::Arr_naive_point_location<Arrangement_2>           Naive_pl;
typedef CGAL::Arr_landmarks_point_location<Arrangement_2>
    Landmarks_pl;

int main ()
{
  // Construct the arrangement.
  Arrangement_2    arr;
  Naive_pl         naive_pl (arr);
  Landmarks_pl     landmarks_pl;

  construct_segments_arr (arr);

  // Perform some point-location queries using the naive strategy.
  Point_2          q1 (1, 4);
  Point_2          q2 (4, 3);
  Point_2          q3 (6, 3);

  point_location_query (naive_pl, q1);
  point_location_query (naive_pl, q2);
  point_location_query (naive_pl, q3);

  // Attach the landmarks object to the arrangement and perform queries.
  Point_2          q4 (3, 2);
  Point_2          q5 (5, 2);
  Point_2          q6 (1, 0);

  landmarks_pl.attach (arr);

  point_location_query (landmarks_pl, q4);
  point_location_query (landmarks_pl, q5);
  point_location_query (landmarks_pl, q6);

  return 0;
}
```

File: examples/Arrangement_on_surface_2/point_location.cpp

Note that the program uses the auxiliary *point_location_query()* function template to nicely print the result of each query. This function can be found in the header file *point_location_utils.h*.

32.3.2 Vertical Ray Shooting

Another important query issued on arrangements is the vertical ray-shooting query: Given a query point, which arrangement feature do we encounter if we shoot a vertical ray emanating upward (or downward) from this point? In the general case the ray hits an edge, but it is possible that it hits a vertex, or that the arrangement does not have any feature lying directly above (or below) the query point.

All point-location classes listed in the previous section are also models of the *ArrangementVerticalRayShoot_2* concept. That is, they all have member functions called *ray_shoot_up(q)* and *ray_shoot_down(q)* that accept a query point *q* and output a CGAL *Object*. This can be assigned to either a *Halfedge_const_handle* or to a *Vertex_const_handle*. Alternatively, the returned value is a *Face_const_handle* for the unbounded face of the arrangement, in case there is no edge or vertex lying directly above (or below) *q*.

The following function template, *vertical_ray_shooting_query()*, which also located in the header file *point_location_utils.h*, accepts a vertical ray-shooting object, whose type can be any of the models to the *ArrangementVerticalRayShoot_2* concept and prints out the result of the upward vertical ray-shooting operations from a given query point. The ray-shooting object *vrs* is assumed to be already associated with an arrangement:

```
template <class VerticalRayShoot>
void vertical_ray_shooting_query
    (const VerticalRayShoot& vrs,
     const typename VerticalRayShoot::Arrangement_on_surface_2::Point_2& q)
{
  // Perform the point-location query.
  CGAL::Object    obj = vrs.ray_shoot_up (q);

  // Print the result.
  typedef typename VerticalRayShoot::Arrangement_on_surface_2  Arrangement_on_surface_2;

  typename Arrangement_on_surface_2::Vertex_const_handle    v;
  typename Arrangement_on_surface_2::Halfedge_const_handle  e;
  typename Arrangement_on_surface_2::Face_const_handle      f;

  std::cout << "Shooting up from " << q << " : ";
  if (CGAL::assign (e, obj)) {
    // We hit an edge:
    std::cout << "hit an edge: " << e->curve() << std::endl;
  }
  else if (CGAL::assign (v, obj)) {
    // We hit a vertex:
    if (v->is_isolated())
      std::cout << "hit an isolated vertex: " << v->point() << std::endl;
    else
      std::cout << "hit a vertex: " << v->point() << std::endl;
  }
  else if (CGAL::assign (f, obj)) {
    // We did not hit anything:
    CGAL_assertion (f->is_unbounded());

    std::cout << "hit nothing." << std::endl;
  }
  else {
    CGAL_assertion_msg (false, "Invalid object.");
  }
}
```

The following program uses the auxiliary function listed above to perform vertical ray-shooting queries on an arrangement. The arrangement and the query points are exactly the same as in *point_location.cpp* (see Figure 32.7):

```
#include <CGAL/Cartesian.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_walk_along_line_point_location.h>
#include <CGAL/Arr_trapezoid_ric_point_location.h>

#include "point_location_utils.h"

typedef CGAL::MP_Float
   Number_type;
typedef CGAL::Cartesian<Number_type>                             Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                       Traits_2;
typedef Traits_2::Point_2                                        Point_2;
typedef CGAL::Arrangement_2<Traits_2>
   Arrangement_2;
typedef CGAL::Arr_walk_along_line_point_location<Arrangement_2> Walk_pl;
typedef CGAL::Arr_trapezoid_ric_point_location<Arrangement_2>   Trap_pl;

int main ()
{
  // Construct the arrangement.
  Arrangement_2     arr;

The number type we use in this example is CGAL's built-in *MP_Float* type which is a floating-point number with an unbounded mantissa and a 32-bit exponent. It supports construction from an integer or from a machine *float* or *double* and performs additions, subtractions and multiplications in an exact number.

32.3.3 Batched Point-Location

Suppose that at a given moment our application has to issue a relatively large number m of point-location queries on a specific arrangement instance. It is possible of course to define a point-location object and to issue separate queries on the arrangement. However, as explained in Section 32.3.1, choosing a simple point-location strategy (either the naive or the walk strategy) means inefficient queries, while the more sophisticated strategies need to construct auxiliary structures that incur considerable overhead in running time.

On the other hand, the arrangement package includes a free *locate()* function that accepts an arrangement a range of query points as its input and sweeps through the arrangement to locate all query points in one pass. The function outputs the query results as pairs, where each pair is comprised of a query point and a CGAL *Object* that represents the cell containing the point (see Section 32.3.1). The output pairs are sorted in increasing xy-lexicographical order of the query point.

The batched point-location operation can be performed in $O((m+N)\log(m+N))$ time, where N is the number of edges in the arrangement. This means that when the number m of point-location queries is of the same order of magnitude as N, this operation is more efficient than issuing separate queries. This suggestion is also backed up by experimental results. Moreover, the batched point-location operation is also advantageous as it does not have to construct and maintain additional data structures.

The following program issues a batched point-location query, which is essentially equivalent to the six separate queries performed in *point_location.cpp* (see Section 32.3.1):

```
#include <CGAL/Cartesian.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_batched_point_location.h>
#include <list>

#include "point_location_utils.h"

typedef CGAL::MP_Float                                     Number_type;
typedef CGAL::Cartesian<Number_type>                       Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                 Traits_2;
typedef Traits_2::Point_2                                  Point_2;
typedef CGAL::Arrangement_2<Traits_2>                      Arrangement_2;
typedef std::pair<Point_2, CGAL::Object>                   Query_result;

int main ()
{
  // Construct the arrangement.
  Arrangement_2    arr;

  construct_segments_arr (arr);

  // Perform a batched point-location query.
  std::list<Point_2>       query_points;
```

```
  std::list<Query_result>  results;

  query_points.push_back (Point_2 (1, 4));
  query_points.push_back (Point_2 (4, 3));
  query_points.push_back (Point_2 (6, 3));
  query_points.push_back (Point_2 (3, 2));
  query_points.push_back (Point_2 (5, 2));
  query_points.push_back (Point_2 (1, 0));

  locate (arr, query_points.begin(), query_points.end(),
          std::back_inserter (results));

  // Print the results.
  std::list<Query_result>::const_iterator  res_iter;
  Arrangement_2::Vertex_const_handle       v;
  Arrangement_2::Halfedge_const_handle     e;
  Arrangement_2::Face_const_handle         f;

  for (res_iter = results.begin(); res_iter != results.end();
   ++res_iter) {
    std::cout << "The point (" << res_iter->first << ") is located ";
    if (CGAL::assign (f, res_iter->second)) {
      // The current qeury point is located inside a face:
      if (f->is_unbounded())
        std::cout << "inside the unbounded face." << std::endl;
      else
        std::cout << "inside a bounded face." << std::endl;
    }
    else if (CGAL::assign (e, res_iter->second)) {
      // The current qeury point is located on an edge:
      std::cout << "on an edge: " << e->curve() << std::endl;
    }
    else if (CGAL::assign (v, res_iter->second)) {
      // The current qeury point is located on a vertex:
      if (v->is_isolated())
        std::cout << "on an isolated vertex: " << v->point() <<
   std::endl;
      else
        std::cout << "on a vertex: " << v->point() << std::endl;
    }
  }

  return 0;
}
```

32.4 Free Functions in the Arrangement Package

In Section 32.2 we reviewed in details the *Arrangement_2* class, which represents two-dimensional subdivisions induced by planar curves, and mentioned that its interface is minimal in the sense that the member functions hardly perform any geometric algorithms and are mainly used for maintaining the topological structure of the subdivision. In this section we explain how to utilize the free (global) functions that operate on arrangements. The implementation of these operations typically require non-trivial geometric algorithms or load some extra requirements on the traits class.

32.4.1 Incremental Insertion Functions

Inserting Non-Intersecting Curves

In Section 32.2 we explained how to construct arrangements of x-monotone curves that are pairwise disjoint in their interior, when the location of the segment endpoints in the arrangement is known. Here we relax this constraint, and allow the location of the inserted x-monotone curve endpoints to be arbitrary, as it may be unknown at the time of insertion. We retain, for the moment, the requirement that the interior of the inserted curve is disjoint from all existing arrangement edges and vertices.

The free function *insert_non_intersecting_curve(arr, c, pl)* inserts the x-monotone curve c into the arrangement *arr*, with the precondition that the interior of c is disjoint from all *arr*'s existing edges and vertices. The third argument *pl* is a point-location object attached to the arrangement, which is used for performing the insertion. It locates both curve endpoints in the arrangement, where each endpoint is expected to either coincide with an existing vertex or lie inside a face. It is possible to invoke one of the specialized insertion functions (see Section 32.2), based on the query results, and insert c at its proper position.[9] The insertion operation thus hardly requires any geometric operations on top on the ones needed to answer the point-location queries. Moreover, it is sufficient that the arrangement class is instantiated with a traits class that models the *ArrangementBasicTraits_2* concept (or the *ArrangementLandmarkTraits_2* concept, if the landmark point-location strategy is used), which does not have to support the computation of intersection points between curves.

The variant *insert_non_intersecting_curve(arr, c)* is also available. Instead of accepting a user-defined point-location object, it defines a local instance of the walk point-location class and uses it to insert the curve.

Inserting x-Monotone Curves

The *insert_non_intersecting_curve()* function is very efficient, but its preconditions on the input curves are still rather restricting. Let us assume that the arrangement is instantiated with a traits class that models the refined *ArrangementXMonotoneTraits_2* concept and supports intersection computations (see Section 32.6 for the exact details). Given an x-monotone curve, it is sufficient to locate its left endpoint in the arrangement and to trace its *zone*, namely the set of arrangement features crossing the curve, until the right endpoint is reached. Each time the new curve c crosses an existing vertex or an edge, the curve is split into subcurves (in the latter case, we have to split the curve associated with the existing halfedge as well) and associate new edges with the resulting subcurves. Recall that an edge is represented by a pair of twin halfedges, so we split it into two halfedge pairs.

The free function *insert(arr, c, pl)* performs this insertion operation. It accepts an x-monotone curve c, which may intersect some of the curves already in the arrangement *arr*, and inserts it into the arrangement by computing its zone. Users may supply a point-location object *pl*, or use the default walk point-location strategy (namely, the variant *insert(arr, c)* is also available). The running-time of this insertion function is proportional to the complexity of the zone of the curve c.

advanced

In some cases users may have a prior knowledge of the location of the left endpoint of the x-monotone curve c they wish to insert, so they can perform the insertion without issuing any point-location queries. This can

[9]The *insert_non_intersecting_curve()* function, as all other functions reviewed in this section, is a function template, parameterized by an arrangement class and a point-location class (a model of the *ArrangementPointLocation_2* concept).

be done by calling *insert(arr, c, obj)*, where *obj* is an object represents the location of *c*'s left endpoint in the arrangement — namely it wraps a *Vertex_const_handle*, a *Halfedge_const_handle* or a *Face_const_handle* (see also Section 32.3.1).

advanced

Inserting General Curves

So far all our examples were of arrangements of line segments, where the *Arrangement_2* template was instantiated with the *Arr_segment_traits_2* class. In this case, the fact that *insert()* accepts an x-monotone curve does not seem to be a restriction, as all line segments are x-monotone (note that we consider vertical line segments to be *weakly* x-monotone).

Suppose that we construct an arrangement of circles. A circle is obviously not x-monotone, so we cannot insert it in the same way we inserted x-monotone curves. [10] However, it is possible to subdivide each circle into two x-monotone circular arcs (its upper half and its lower half) and to insert each x-monotone arc separately.

The free function *insert()* also supports general curve and not necessarily x-monotone curves. In this case it requires that the traits class used by the arrangement *arr* to be a model of the concept *ArrangementTraits_2*, which refines the *ArrangementXMonotoneTraits_2* concept. It has to define an additional *Curve_2* type (which may differ from the *X_monotone_curve_2* type), and support the subdivision of curves of this new type into x-monotone curves (see the exact details in Section 32.6). The *insert(arr, c, pl)* function performs the insertion of the curve c, which does not need to be x-monotone, into the arrangement by subdividing it (if needed) into x-monotone subcurves and inserting each one separately. Users may supply a point-location object *pl*, or use the default walk point-location strategy by calling *insert(arr, c)*.

Inserting Points

The arrangement class enables us to insert a point as an isolated vertex in a given face. The free function *insert_point(arr, p, pl)* inserts a vertex into *arr* that corresponds to the point p at an arbitrary location. It uses the point-location object *pl* to locate the point in the arrangement (by default, the walk point-location strategy is used), and acts according to the result as follows:

- If p is located inside a face, it is inserted as an isolated vertex inside this face.
- If p lies on an edge, the edge is split to create a vertex associated with p.
- Otherwise, p coincides with an existing vertex and we are done.

In all cases, the function returns a handle to the vertex associated with p.

The arrangement *arr* should be instantiated with a traits class that models the *ArrangementXMonotoneTraits_2* concept, as the insertion operation may involve splitting curves.

An Example

The program below constructs an arrangement of intersecting line-segments. We know that s_1 and s_2 do not intersect, so we use *insert_non_intersecting_curve()* to insert them into the empty arrangement. The rest of the

[10] Note that a key operation performed by *insert()* is to locate the left endpoint of the curve in the arrangement. A circle, however, does not have any endpoints!

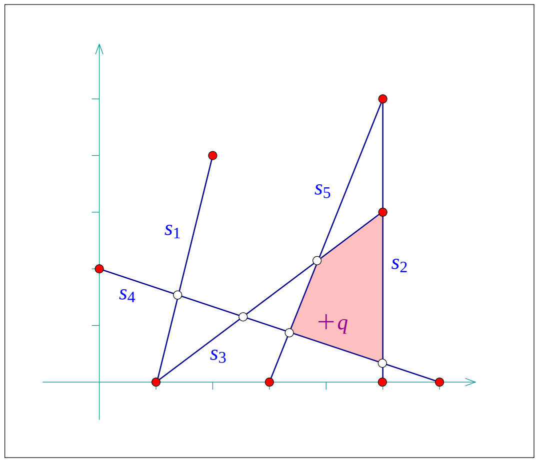

Figure 32.8: An arrangement of five intersecting line segments, as constructed in *incremental_insertion.cpp* and *aggregated_insertion.cpp*. The segment endpoints are marked by black disks and the arrangement vertices that correspond to intersection points are marked by circles. The query point q is marked with a cross and the face that contains it is shaded.

segments are inserted using *insert()*. The resulting arrangement consists of 13 vertices, 16 edges, and 5 faces, as can be seen in Figure 32.8.

In the earlier examples, all arrangement vertices corresponded to segment endpoints. In this example we have additional vertices that correspond to intersection points between two segments. The coordinates of these intersection points are rational numbers, if the input coordinates are rational (or integer). Therefore, the *Quotient*< *int*> number type is used to represent the coordinates:

```
#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_walk_along_line_point_location.h>

#include "arr_print.h"

typedef CGAL::Quotient<int>
    Number_type;
typedef CGAL::Cartesian<Number_type>                            Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                      Traits_2;
typedef Traits_2::Point_2                                       Point_2;
typedef Traits_2::X_monotone_curve_2
    Segment_2;
typedef CGAL::Arrangement_2<Traits_2>
    Arrangement_2;
typedef CGAL::Arr_walk_along_line_point_location<Arrangement_2> Walk_pl;

int main ()
{
  // Construct the arrangement of five intersecting segments.
  Arrangement_2  arr;
  Walk_pl        pl(arr);
```

```
  Segment_2      s1 (Point_2(1, 0), Point_2(2, 4));
  Segment_2      s2 (Point_2(5, 0), Point_2(5, 5));
  Segment_2      s3 (Point_2(1, 0), Point_2(5, 3));
  Segment_2      s4 (Point_2(0, 2), Point_2(6, 0));
  Segment_2      s5 (Point_2(3, 0), Point_2(5, 5));

  insert_non_intersecting_curve (arr, s1, pl);
  insert_non_intersecting_curve (arr, s2, pl);
  insert (arr, s3, pl);
  insert (arr, s4, pl);
  insert (arr, s5, pl);

  // Print the size of the arrangement.
  std::cout << "The arrangement size:" << std::endl
            << "   V = " << arr.number_of_vertices()
            << ",  E = " << arr.number_of_edges()
            << ",  F = " << arr.number_of_faces() << std::endl;

  // Perform a point-location query on the resulting arrangement and
    print
  // the boundary of the face that contains it.
  Point_2        q (4, 1);
  CGAL::Object   obj = pl.locate (q);

  Arrangement_2::Face_const_handle  f;
  CGAL_assertion_code (bool           success =) CGAL::assign (f, obj);

  CGAL_assertion (success);
  std::cout << "The query point (" << q << ") is located in: ";
  print_face<Arrangement_2> (f);

  return 0;
}
```

File: examples/Arrangement_on_surface_2/incremental_insertion.cpp

Other Zone Related Functions

In this section we have described so far free functions that insert curves and points to a given arrangement. Now we will describe functions that don't insert curves or points to an arrangement nor do they change the arrangement, but they are closely related to the incremental insertion functions as they also use the zone algorithm.

The free function *do_intersect()* checks if a given curve or x-monotone curve intersects an existing arrangement's edges or vertices. If the give curve is not an x-monotone curve then the function subdivides the given curve into x-monotone subcurves and isolated vertices . Each subcurve is in turn checked for intersection. The function uses the zone algorithm to check if the curve intersects the arrangement. First, the curve's left endpoint is located. Then, its zone is computed starting from its left endpoint location. The zone computation terminates when an intersection with an arrangement's edge/vertex is found or when the right endpoint is reached. A given point-location object is used for locating the left endpoint of the given curve in the existing arrangement. By default, the function uses the "walk along line" point-location strategy — namely an instance of the class *Arr_walk_along_line_point_location*. If the given curve is x-monotone then the traits class must model the

ArrangementXMonotoneTraits_2 concept. If the curve is not x-monotone curve then the traits class must model the *ArrangementTraits_2* concept.

The *zone()* function computes the zone of a given x-monotone curve in a given arrangement. Meaning, it outputs all the arrangement's elements (vertices, edges and faces) that the x-monotone curve intersects in the order that they are discovered when traversing the x-monotone curve from left to right. The function uses a given point-location object to locate the left endpoint of the given x-monotone curve. By default, the function uses the "walk along line" point-location strategy. The function requires that the traits class will model the *ArrangementXMonotoneTraits_2* concept.

32.4.2 Aggregated Insertion Functions

Let us assume that we have to insert a set of m input curves into an arrangement. It is possible to do this incrementally, inserting the curves one by one, as shown in the previous section. However, the arrangement package provides three free functions that aggregately insert a range of curves into an arrangement:

- *insert_non_intersecting_curves(arr, begin, end)* inserts a range of x-monotone curves given by the input iterators *[begin, end)* into an arrangement *arr*. The x-monotone curves should be pairwise disjoint in their interior and also interior-disjoint from all existing edges and vertices of *arr*.
- *insert(arr, begin, end)* inserts a range of general (not necessarily x-monotone) curves of type *Curve_2* or *X_monotone_curve_2* that may intersect one another, given by the input iterators *[begin, end)*, into the arrangement *arr*.

We distinguish between two cases: (i) The given arrangement *arr* is empty (has only an unbounded face), so we have to construct it from scratch. (ii) We have to insert m input curves to a non-empty arrangement *arr*.

In the first case, we sweep over the input curves, compute their intersection points and construct the DCEL that represents their planar arrangement. This process is performed in $O\left((m+k)\log m\right)$ time, where k is the total number of intersection points. The running time is asymptotically better than the time needed for incremental insertion, if the arrangement is relatively sparse (when k is bounded by $\frac{m^2}{\log m}$), but in practice it is recommended to use this aggregated construction process even for dense arrangements, since the sweep-line algorithm needs less geometric operations compared to the incremental insertion algorithms and hence typically runs much faster in practice.

Another important advantage the aggregated insertion functions have is that they do not issue point-location queries. Thus, no point-location object needs to be attached to the arrangement. As explained in Section 32.3.1, there is a trade-off between construction time and query time in each of the point-location strategies, which affects the running times of the incremental insertion process. Naturally, this trade-off is irrelevant in case of aggregated insertion as above.

The example below shows how to construct the arrangement of line segments depicted in Figure 32.8 and built incrementally in *incremental_insertion.cpp*, as shown in the previous section. We use the aggregated insertion function *insert()* as we deal with line segments. Note that no point-location object needs to be defined and attached to the arrangement:

```
#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <list>
```

```
typedef CGAL::Quotient<int>                              Number_type;
typedef CGAL::Cartesian<Number_type>                     Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>               Traits_2;
typedef Traits_2::Point_2                                Point_2;
typedef Traits_2::X_monotone_curve_2                     Segment_2;
typedef CGAL::Arrangement_2<Traits_2>                    Arrangement_2;

int main ()
{
  // Construct the arrangement of five intersecting segments.
  Arrangement_2            arr;
  std::list<Segment_2>     segments;

  segments.push_back (Segment_2 (Point_2(1, 0), Point_2(2, 4)));
  segments.push_back (Segment_2 (Point_2(5, 0), Point_2(5, 5)));
  segments.push_back (Segment_2 (Point_2(1, 0), Point_2(5, 3)));
  segments.push_back (Segment_2 (Point_2(0, 2), Point_2(6, 0)));
  segments.push_back (Segment_2 (Point_2(3, 0), Point_2(5, 5)));

  insert (arr, segments.begin(), segments.end());

  // Print the size of the arrangement.
  std::cout << "The arrangement size:" << std::endl
            << "   V = " << arr.number_of_vertices()
            << ",  E = " << arr.number_of_edges()
            << ",  F = " << arr.number_of_faces() << std::endl;

  return 0;
}
```

File: examples/Arrangement_on_surface_2/aggregated_insertion.cpp

In case we have to insert a set of m curves into an existing arrangement, where we denote the number of edges in the arrangement by N. As a rule of thumb, if $m = o(\sqrt{N})$, we insert the curves one by one. For larger input sets, we use the aggregated insertion procedures.

In the example below we aggregately construct an arrangement of a set $\mathcal{S}_1$ containing five line segments. Then we insert a single segment using the incremental insertion function. Finally, we add a set $\mathcal{S}_2$ with five more line segments in an aggregated fashion. Notice that the line segments of $\mathcal{S}_1$ are pairwise interior-disjoint, so we use *insert_non_intersecting_curves()*. $\mathcal{S}_2$ also contain pairwise interior-disjoint segments, but as they intersect the existing arrangement, we have to use *insert()* to insert them. Also note that the single segment s we insert incrementally overlaps an existing arrangement edge:

```
#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_naive_point_location.h>

#include "arr_print.h"
```

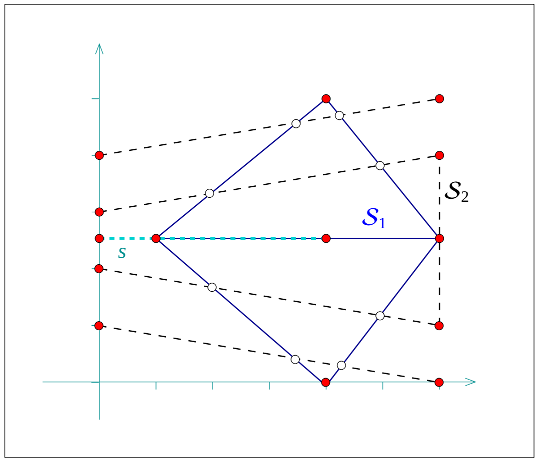

Figure 32.9: An arrangement of intersecting line segments, as constructed in *global_insertion.cpp*. The segments of $\mathcal{S}_1$ are drawn in solid lines and the segments of $\mathcal{S}_2$ are drawn in dark dashed lines. Note that the segment s (light dashed line) overlaps one of the segments in $\mathcal{S}_1$.

```
typedef CGAL::Quotient<CGAL::MP_Float>                   Number_type;
typedef CGAL::Cartesian<Number_type>                     Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>               Traits_2;
typedef Traits_2::Point_2                                Point_2;
typedef Traits_2::X_monotone_curve_2                     Segment_2;
typedef CGAL::Arrangement_2<Traits_2>                    Arrangement_2;
typedef CGAL::Arr_naive_point_location<Arrangement_2> Naive_pl;

int main ()
{
  // Construct the arrangement of five intersecting segments.
  Arrangement_2      arr;
  Segment_2          S1 [5];

  S1[0] = Segment_2 (Point_2 (1, 2.5), Point_2 (4, 5));
  S1[1] = Segment_2 (Point_2 (1, 2.5), Point_2 (6, 2.5));
  S1[2] = Segment_2 (Point_2 (1, 2.5), Point_2 (4, 0));
  S1[3] = Segment_2 (Point_2 (4, 5), Point_2 (6, 2.5));
  S1[4] = Segment_2 (Point_2 (4, 0), Point_2 (6, 2.5));

  insert_non_intersecting_curves (arr, S1, S1 + 5);

  // Perform an incremental insertion of a single overlapping segment.
  Naive_pl           pl (arr);

  insert (arr, Segment_2 (Point_2 (0, 2.5), Point_2 (4, 2.5)), pl);

  // Aggregately insert an additional set of five segments.
  Segment_2          S2 [5];

  S2[0] = Segment_2 (Point_2 (0, 4), Point_2 (6, 5));
  S2[1] = Segment_2 (Point_2 (0, 3), Point_2 (6, 4));
  S2[2] = Segment_2 (Point_2 (0, 2), Point_2 (6, 1));
```

```
  S2[3] = Segment_2 (Point_2 (0, 1), Point_2 (6, 0));
  S2[4] = Segment_2 (Point_2 (6, 1), Point_2 (6, 4));

  insert (arr, S2, S2 + 5);

  // Print the size of the arrangement.
  std::cout << "The arrangement size:" << std::endl
            << "   V = " << arr.number_of_vertices()
            << ",  E = " << arr.number_of_edges()
            << ",  F = " << arr.number_of_faces() << std::endl;
  return 0;
}
```

File: examples/Arrangement_on_surface_2/global_insertion.cpp

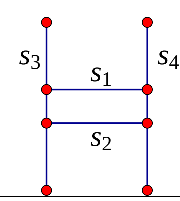
The number type used in the example above, *Quotient<MP_Float>*, is comprised of a numerator and a denominator of type *MP_Float*, namely floating-point numbers with unbounded mantissa. This number type is therefore capable of exactly computing the intersection points as long as the segment endpoints are given as floating-point numbers.

32.4.3 Removing Vertices and Edges

The free functions *remove_vertex()* and *remove_edge()* handle the removal of vertices and edges from an arrangement. The difference between these functions and the member functions of the *Arrangement_2* template having the same name is that they allow the merger of two curves associated with adjacent edges to form a single edge. Thus, they require that the traits class that instantiates the arrangement instance is a model of the refined *ArrangementXMonotoneTraits_2* concept (see Section 32.6).

The function *remove_vertex(arr, v)* removes the vertex v from the given arrangement *arr*, where v is either an isolated vertex or is a *redundant* vertex — namely, it has exactly two incident edges that are associated with two curves that can be merged to form a single x-monotone curve. If neither of the two cases apply, the function returns an indication that it has failed to remove the vertex.

The function *remove_edge(arr, e)* removes the edge e from the arrangement by simply calling *arr.remove_edge(e)* (see Section 32.2.3). In addition, if either of the end vertices of e becomes isolated or redundant after the removal of the edge, it is removed as well.



The following example demonstrates the usage of the free removal functions. In creates an arrangement of four line segment forming an H-shape with a double horizontal line. Then it removes the two horizontal edges and clears all redundant vertices, such that the final arrangement consists of just two edges associated with the vertical line segments:

```
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_naive_point_location.h>

#include "arr_print.h"
```

```
typedef int                                              Number_type;
typedef CGAL::Cartesian<Number_type>                     Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>               Traits_2;
typedef Traits_2::Point_2                                Point_2;
typedef Traits_2::X_monotone_curve_2                     Segment_2;
typedef CGAL::Arrangement_2<Traits_2>                    Arrangement_2;
typedef Arrangement_2::Vertex_handle                     Vertex_handle;
typedef Arrangement_2::Halfedge_handle                   Halfedge_handle;
typedef CGAL::Arr_naive_point_location<Arrangement_2> Naive_pl;

int main ()
{
  // Create an arrangement of four line segments forming an H-shape:
  Arrangement_2   arr;
  Naive_pl        pl (arr);

  Segment_2       s1 (Point_2 (1, 3), Point_2 (4, 3));
  Halfedge_handle e1 = arr.insert_in_face_interior (s1,
   arr.unbounded_face());
  Segment_2       s2 (Point_2 (1, 4), Point_2 (4, 4));
  Halfedge_handle e2 = arr.insert_in_face_interior (s2,
   arr.unbounded_face());
  Segment_2       s3 (Point_2 (1, 1), Point_2 (1, 6));
  Segment_2       s4 (Point_2 (4, 1), Point_2 (4, 6));

  insert (arr, s3, pl);
  insert (arr, s4, pl);

  std::cout << "The initial arrangement:" << std::endl;
  print_arrangement (arr);

  // Remove the horizontal edge from the arrangement, and its end
   vertices:
  Vertex_handle   v1 = e1->source(), v2 = e1->target();
  arr.remove_edge (e1);
  remove_vertex (arr, v1);
  remove_vertex (arr, v2);

  // Remove the second horizontal edge e2 from the arrangement:
  remove_edge (arr, e2);

  std::cout << "The final arrangement:" << std::endl;
  print_arrangement (arr);
  return 0;
}
```

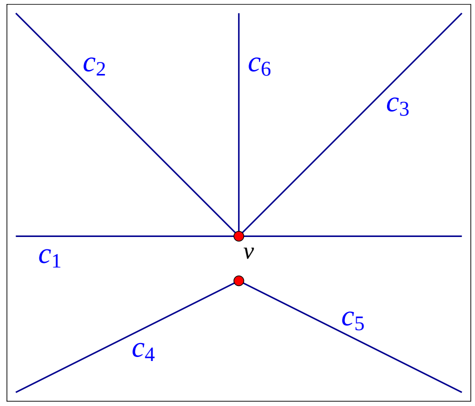

Figure 32.10: An arrangement of unbounded linear objects, as constructed in *unbounded_non_intersecting.cpp*.

32.5 Arrangements of Unbounded Curves

Previous sections dealt only with arrangements of line segments, namely of bounded curves. Such arrangements always have one unbounded face that contains all other arrangement features. This section explains how to construct arrangements of unbounded curves, such as lines and rays.

32.5.1 Basic Manipulation and Traversal Methods

Consider the arrangement induced by the two lines $y = x$ and $y = -x$. These two lines intersect at the origin, such that the arrangement contains a single vertex $v = (0,0)$, with four infinite rays emanating from it. Each ray corresponds to an arrangement edge, and these edges subdivide the plane into four unbounded faces. Consider a halfedge pair that represents one of the edges. The source vertex of one of these halfedges is v and its target is at infinity, while the other has its source at infinity and v is its target.

If e is an object of the nested type *Arrangement_2::Halfedge*, then the predicates *e.source_at_infinity()* and *e.target_at_infinity()* indicate whether the halfedge represents a curve with an infinite end. In general there is no need to access the source (or the target) of a halfedge if it lies at infinity, since this vertex is not associated with any valid point. Similarly, calling *arr.number_of_vertices()* for an arrangement object *arr* counts only the vertices associated with finite points, and ignores vertices at infinity (and the range *[vertices_begin(), vertices_end())* contains only finite vertices). The method *arr.number_of_vertices_at_infinity()* counts the number of vertices at infinity.

As mentioned above, arrangements of unbounded curves usually have more than one unbounded face. The function *arr.number_of_unbounded_faces()* returns the number of unbounded arrangement faces (Thus, *arr.number_of_faces() - arr.number_of_unbounded_faces()* is the number of bounded faces). The functions *arr.unbounded_faces_begin()* and *arr.unbounded_faces_end()* return iterators of type *Arrangement_2::Unbounded_face_iterator* that specify the range of unbounded faces. Naturally, the value-type of this iterator is *Arrangement_2::Face*.

The specialized insertion functions listed in Section 32.2.3 can also be used for inserting x-monotone unbounded curves, provided that they are interior-disjoint from any subcurve that already exists in the arrangement. For example, if you wish to insert a ray r emanating from $(0,0)$ in the direction of $(1,0)$, to the arrangement of $y = -x$ and $y = x$, you can use the function *arr.insert_from_left_vertex()*, as the left endpoint of r is already associated with an arrangement vertex. Other edge-manipulation functions can also be applied on edges associated with unbounded curves.

The following example demonstrates the use of the insertion function for pairwise interior-disjoint unbounded curves. In this example we use the traits class *Arr_linear_traits_2<Kernel>* to instantiate the *Arrangement_2* template. This traits class is capable of representing line segments as well as unbounded linear curves (namely lines and rays). Observe that objects of the type *X_monotone_curve_2* defined by this traits class are constructible from *Line_2*, *Ray_2*, and *Segment_2* objects, as defined in the instantiated kernel.

The first three curves are inserted using the special insertion functions for x-monotone curves whose location in the arrangement is known. Notice that inserting an unbounded curve in the interior of an unbounded face, or from an existing vertex that represents the bounded end of the curve, may cause an unbounded face to split (this is never the case when inserting a bounded curve — compare with Section 32.2.3). Then, three additional rays are inserted incrementally, using the insertion function for x-monotone curves whose interior is disjoint from all arrangement features. Finally, the program prints the size of the arrangement (compare to the illustration in Figure 32.10) and the outer boundaries of its six unbounded faces:

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Arr_linear_traits_2.h>
#include <CGAL/Arrangement_2.h>

typedef int                                           Number_type;
typedef CGAL::Simple_cartesian<Number_type>           Kernel;
typedef CGAL::Arr_linear_traits_2<Kernel>             Traits_2;
typedef Traits_2::Point_2                             Point_2;
typedef Traits_2::Segment_2                           Segment_2;
typedef Traits_2::Ray_2                               Ray_2;
typedef Traits_2::Line_2                              Line_2;
typedef Traits_2::X_monotone_curve_2                  X_monotone_curve_2;
typedef CGAL::Arrangement_2<Traits_2>                 Arrangement_2;
typedef Arrangement_2::Vertex_handle                  Vertex_handle;
typedef Arrangement_2::Halfedge_handle                Halfedge_handle;

int main ()
{
  Arrangement_2      arr;

  // Insert a line in the (currently single) unbounded face of the
   arrangement,
  // then split it into two at (0,0). Assign v to be the split point.
  X_monotone_curve_2 c1 = Line_2 (Point_2 (-1, 0), Point_2 (1, 0));
  Halfedge_handle    e1 = arr.insert_in_face_interior (c1,

   arr.unbounded_face());

  X_monotone_curve_2 c1_left = Ray_2 (Point_2 (0, 0), Point_2 (-1, 0));
  X_monotone_curve_2 c1_right = Ray_2 (Point_2 (0, 0), Point_2 (1, 0));

  e1 = arr.split_edge (e1, c1_left, c1_right);
  Vertex_handle      v = e1->target();

  CGAL_assertion (! v->is_at_open_boundary());

  // Add two more rays using the specialized insertion functions.
  X_monotone_curve_2 c2 = Ray_2 (Point_2 (0, 0), Point_2 (-1, 1));
  X_monotone_curve_2 c3 = Ray_2 (Point_2 (0, 0), Point_2 (1, 1));

  arr.insert_from_right_vertex (c2, v);
```

```
  arr.insert_from_left_vertex (c3, v);

  // Insert three more interior-disjoint rays.
  X_monotone_curve_2 c4 = Ray_2 (Point_2 (0, -1), Point_2 (-2, -2));
  X_monotone_curve_2 c5 = Ray_2 (Point_2 (0, -1), Point_2 (2, -2));
  X_monotone_curve_2 c6 = Ray_2 (Point_2 (0, 0), Point_2 (0, 1));

  insert_non_intersecting_curve (arr, c4);
  insert_non_intersecting_curve (arr, c5);
  insert_non_intersecting_curve (arr, c6);

  // Print out the size of the resulting arrangement.
  std::cout << "The arrangement size:" << std::endl
            << "   V = " << arr.number_of_vertices()
            << " (plus " << arr.number_of_vertices_at_infinity()
            << " at infinity)"
            << ",  E = " << arr.number_of_edges()
            << ",  F = " << arr.number_of_faces()
            << " (" << arr.number_of_unbounded_faces() << " unbounded)"
            << std::endl << std::endl;

  // Print the outer CCBs of the unbounded faces.
  Arrangement_2::Face_const_iterator            fit;

32.5.2 Free Functions

In principle, all queries and operations that relate to arrangements of bounded curves can also be applied to arrangements of unbounded curves. For example, it is possible to issue point-location and vertical ray-shooting queries (see also Section 32.3) on arrangements of lines, where the only restriction is that the query point has finite coordinates.[11]

In the following example we show how an arrangement of unbounded lines is utilized to solve the following problem: Given a set of points, does the set contain at least three collinear points? In this example a set of input points is read from a file. The file *points.dat* is used by default. It contains definitions of 100 points randomly selected on the grid $[-10000, 10000] \times [-10000, 10000]$. We construct an arrangement of the dual lines, where the line p^* dual to the point $p = (p_x, p_y)$ is given by the equation $y = p_x * x - p_y$, and check whether three (or more) of the dual lines intersect at a common point, by searching for a (dual) vertex, whose degree is greater than 4. If such a vertex exists, then there are at least three dual lines that intersect at a common point, which implies that there are at least three collinear points.

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_linear_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <cstdlib>

typedef CGAL::Cartesian<Number_type>                    Kernel;
typedef CGAL::Arr_linear_traits_2<Kernel>               Traits_2;
typedef Traits_2::Point_2                               Point_2;
typedef Traits_2::Line_2                                Line_2;
typedef Traits_2::X_monotone_curve_2                    X_monotone_curve_2;
typedef CGAL::Arrangement_2<Traits_2>                   Arrangement_2;

int main (int argc, char *argv[])
{
  // Get the name of the input file from the command line, or use the
   default
  // points.dat file if no command-line parameters are given.
  const char * filename = (argc > 1) ? argv[1] : "points.dat";

  // Open the input file.
  std::ifstream     in_file (filename);

  if (! in_file.is_open()) {
    std::cerr << "Failed to open " << filename << "!" << std::endl;
    return 1;
  }

  // Read the points from the file, and consturct their dual lines.
  // The input file format should be (all coordinate values are
   integers):
  // <n>                                  // number of point.
```

[11]Currently, all point-location strategies except the trapezoidal RIC point-location strategy are capable of handling arrangements of unbounded curves.

```
// <x_1> <y_1>                              // point #1.
// <x_2> <y_2>                              // point #2.
//   :       :         :        :
// <x_n> <y_n>                              // point #n.
std::vector<Point_2>            points;

   (points[k1],

   points[k2]);
  X_monotone_curve_2 dual_p_mid = Line_2 (Number_type(p_mid.x()),
                                          Number_type(-1),
                                          Number_type(-p_mid.y()));

  insert (arr, dual_p_mid);

  // Make sure that we now have three collinear points.
  found_collinear = false;
  for (vit = arr.vertices_begin(); vit != arr.vertices_end(); ++vit) {
    if (vit->degree() > 4) {
      found_collinear = true;
      break;
    }
  }
  CGAL_assertion (found_collinear);
  return (0);
}
```

File: examples/Arrangement_on_surface_2/dual_lines.cpp

Note that there are no three collinear points among the points defined in the input file *points.dat*. In the second part of the example the existence of collinearity is forced and verified as follows. A line dual to the midpoint of two randomly selected points is introduced, and inserted into the arrangement. This operation is followed by a test that verifies that a vertex of degree greater than 4 exists. This implied that collinearity indeed exists as explained above.

advanced

32.5.3 Representation of Unbounded Arrangements

Given a set $\mathcal{C}$ of unbounded curves, a simple approach for representing the arrangement induced by $\mathcal{C}$ would be to clip the unbounded curves using an axis-parallel rectangle that contains all finite curve endpoints and intersection points between curves in $\mathcal{C}$. This process would result in a set $\mathcal{C}$ of bounded curves (line segments if $\mathcal{C}$ contains lines and rays), and it would be straightforward to compute the arrangement induced by this set. However, we would like to operate directly on the unbounded curves without having to preprocess them. Therefore, we use an implicit bounding rectangle embedded in the DCEL structure. Figure 32.11 shows the arrangement of four lines that subdivide the plane into eight unbounded faces and two bounded ones. Notice that in this case the unbounded faces have outer boundaries, and the halfedges along these outer CCBs are drawn as arrows. The bounding rectangle is drawn with a dashed line. The vertices $v_1, v_2, \ldots, v_8$, which represent the unbounded ends of the four lines, and lie on the bounding rectangle, actually exist at infinity, and the halfedges

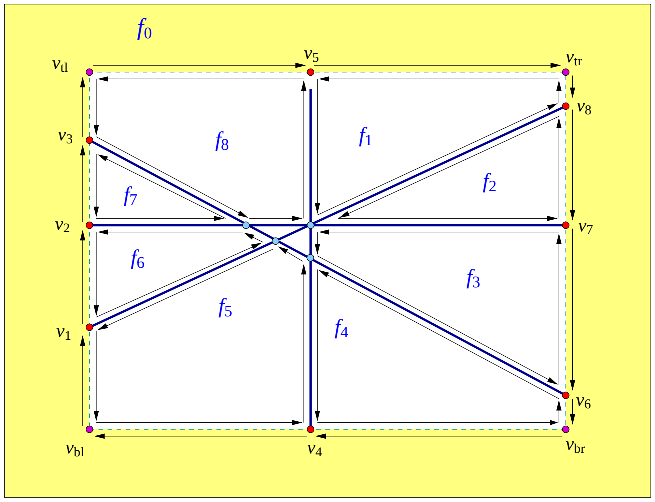

Figure 32.11: A DCEL representing an arrangement of four lines. Halfedges are drawn as thin arrows. The vertices $v_1, \ldots, v_8$ lie at infinity, and are not associated with valid points. The halfedges that connect them are fictitious, and are not associated with concrete curves. The face denoted f_0 (lightly shaded) is the fictitious "unbounded face" which lies outside the bounding rectangle (dashed) that bounds the actual arrangement. The four fictitious vertices v_{bl}, v_{tl}, v_{br} and v_{tr} represent the four corners of the bounding rectangle.

connecting them are *fictitious*, and represent portions of the bounding rectangle. Note that the outer CCBs of the unbounded faces contain fictitious halfedges. The twins of these halfedges form together one connected component that corresponds to the entire bounding rectangle, which forms a single hole in a face f_0. We say that f_0 is *fictitious*, as it does not correspond to a real two-dimensional cell of the arrangement.

Observe that there are four extra vertices at infinity that do not lie on any curve; they are denoted as v_{bl}, v_{tl}, v_{br}, and v_{tr}, and represent the bottom-left, top-left, bottom-right, and top-right corners of the bounding rectangle, respectively. Similarly, there are fictitious halfedges that lie on the top, the bottom, the left, or the right edge of the bounding rectangle. When the arrangement is empty, there are exactly four pairs of fictitious halfedges, that divide the plane into two faces, namely a fictitious face lying outside of the bounding rectangle and a single unbounded face bounded by the bounding rectangle.

Summarizing the above, there are four types of arrangement vertices, which differ from one another by their location with respect to the bounding bounding rectangle:

1. A vertex, associated with a point in $\mathbb{R}^2$ whose coordinates are bounded. Such a vertex always lies inside the bounding rectangle.
2. A vertex that represents an unbounded end of an x-monotone curve that is defined at $x = -\infty$ or at $x = \infty$. In case of a horizontal line or a curve with a horizontal asymptote, the y-coordinate of the curve end may be finite (see for example the vertices v_2 and v_7 in Figure 32.11), but in general the curve end also goes to $y = \pm\infty$ (see for instance the vertices v_1, v_3, v_6 and v_8 in Figure 32.11). For our convenience, we will always take a "tall" enough bounding rectangle and treat such vertices as lying on either the left or right rectangle edges (that is, if a curve is defined at $x = -\infty$, its left end will be represented by a vertex on the left edge of the bounding rectangle, and if it is defined at $x = \infty$, its right end will be represented by a vertex of the right edge).
3. A vertex that represent the unbounded end of a vertical line or of a curve with a vertical asymptote (finite x-coordinate and an unbounded y-coordinate). Such a vertex always lies on one of the horizontal edges of the bounding rectangle (either the bottom one if $y = -\infty$, or the top one if $y = \infty$). The vertices v_4 and v_5 in Figure 32.11 are of this type.

4. The fictitious vertices that represent the four corners of the bounding bounding rectangle.

A vertex (at infinity) of Type 2 or Type 3 above always has three incident edges: one concrete edge that is associated with an unbounded portion of an x-monotone curve, and two fictitious edges connecting the vertex to its neighboring vertices at infinity. Fictitious vertices (of type 4 above) have exactly two incident edges. See Section 32.6 on how the traits-class interface helps imposing the fact that we never have more than one curve incident to any true vertex at infinity.

The nested types defined in the *Arrangement_2* class support the following methods, in addition to the ones listed in Section 32.2.2:

- The *Vertex* class provides three-valued predicates *parameter_space_in_x()* and *parameter_space_in_y()*, which return the location of the geometric embedding of the vertex in the parameter space. In particular, the former returns *ARR_LEFT_BOUNDARY*, *ARR_INTERIOR*, or *ARR_RIGHT_BOUNDARY*, and the latter returns *ARR_BOTTOM_BOUNDARY*, *ARR_INTERIOR*, or *ARR_TOP_BOUNDARY*. As the package currently supports only the case where the parameter space is the compactified plane, the former returns *ARR_INTERIOR* if the x-coordinate associated with the vertex is finite, *ARR_LEFT_BOUNDARY* if it is $-\infty$, and *ARR_RIGHT_BOUNDARY* if it is ∞. The latter returns *ARR_INTERIOR* if the y-coordinate associated with the vertex is finite, *ARR_BOTTOM_BOUNDARY* if it is $-\infty$, and *ARR_TOP_BOUNDARY* if it is ∞. The Boolean predicate *is_at_open_boundary()* is also provided. You can access the point associated with a vertex only if it is not a vertex at an open boundary (recall that a vertex at an open boundary is not associated with a *Point_2* object).
- The nested *Halfedge* class provides the Boolean predicate *is_fictitious()*. The x-monotone curve associated with a halfedge can be accessed by the *curve()* method only if the halfedge is not fictitious.
- The nested *Face* class provides the Boolean predicate *f.is_fictitious()*. The method *outer_ccb()* has the precondition that the face is not fictitious. Note that non-fictitious unbounded faces always have valid CCBs (although this CCB may comprise only fictitious halfedge in case the arrangement contains only bounded curves).

The method *arr.number_of_edges()* does not count the number of fictitious edges, (which is always *arr.number_of_vertices_at_infinity()* + *4*), and the iterators returned by *arr.edges_begin()* and *arr.edges_end()* specify a range of non-fictitious edges. Similarly, *arr.number_of_faces()* does not count the fictitious face. However, the *Ccb_halfedge_circulator* of the outer boundary of an unbounded face or the *Halfegde_around_vertex_circulator* of a vertex at infinity do traverse fictitious halfedges. For example, it is possible to traverse the outer boundaries of the unbounded arrangement edges using the following procedure:

```
Arrangement_2::Unbounded_face_const_iterator  fit;
Arrangement_2::Ccb_halfedge_const_circulator  first, curr;
Arrangement_2::Halfedge_const_handle          he;
int                                           k = 1;

for (fit = arr.unbounded_faces_begin();
     fit != arr.unbounded_faces_end(); ++fit, k++)
{

32.6 Traits Classes

As mentioned in the introduction of this chapter, the traits class encapsulates the definitions of the geometric entities and implements the geometric predicates and constructions needed by the *Arrangement_2* class and by its peripheral algorithms. We also mention throughout the chapter that there are different levels of requirements from the traits class, namely the traits class can model different concept refinement-levels.

32.6.1 The Hierarchy of Traits-Class Concepts

The Basic Concept

A model of the basic concept, *ArrangementBasicTraits_2*, needs to define the types *Point_2* and *X_monotone_curve_2*, where objects of the first type are the geometric mapping of arrangement vertices, and objects of the latter type are the geometric mapping of edges. Such a model has to support in addition the following set of operations:

Compare_x_2: Compares the x-coordinates of two points.

Compare_xy_2: Compares two points lexicographically, by their x-coordinates and then (in case of equality) by their y-coordinates.

Construct_min_vertex_2,*Construct_max_vertex_2*: Returns the left endpoint (similarly, the right endpoint) of an x-monotone curve.

Compare_y_at_x_2: Given an x-monotone curve c and a point p that lies in its x-range, this predicate determines whether p lies below, above or on c.

Compare_y_at_x_right_2: Given two x-monotone curves c_1 and c_2 that share a common left endpoint p, this predicate determines whether c_1 lies above or under c_2 immediately to the right of p, or whether the two curves coincide there.

Equal_2: Checks two points and two curves for equality (two curves are equal if their graph is the same).

Is_vertical_2: Determines whether an x-monotone curve is vertical.

Each model of the concept *ArrangementBasicTraits_2* needs to define a tag named *Has_left_category*. It determines whether the traits class supports the following predicate:

Compare_y_at_x_left_2: Given two x-monotone curves c_1 and c_2 that share a common right endpoint p, this predicate determines whether c_1 lies above or under c_2 immediately to the left of p, or whether the two curves coincide there.

This predicate is optional, as it can be answered using the other traits-class primitives, and we wish to alleviate the need to implement an extra method that is not absolutely necessary. However, as implementing the predicate directly may prove to be more efficient, the traits-class implementer may choose to provide it.

The basic set of predicates is sufficient for constructing arrangements of x-monotone curves that do not reach or approach the boundary of the parameter space. The nature of the input curves, i.e., whether some of them are expected to reach or approach the left, right, bottom, or top side of the boundary of the parameter space, must be conveyed by the traits class. This is done through the definition of four additional nested types, namely *Left_side_category*, *Right_side_category*, *Bottom_side_category*, and *Top_side_category*. Each of those types must be convertible to the type *Arr_oblivious_side_tag* for the class to be a model of the concept *ArrangementBasicTraits_2*.

The Landmarks Concept

The landmark point-location strategy (see Section 32.3.1) needs its associated arrangement to be instantiated with a model of the refined *ArrangementLandmarkTraits_2* traits concept. A model of this concept must define a fixed precision number type (typically *double*) and support the additional operations:

Approximate_2: Given a point p, approximate the x and y-coordinates of p using the fixed precision number type. We use this operation for approximate computations—there are certain operations in the search for the location of the point that need not be exact and we can perform them faster than other operations.

Construct_x_monotone_curve_2: Given two points p_1 and p_2, this predicate constructs an x-monotone curve connecting p_1 and p_2.

Supporting Intersecting x-Monotone Curves

A traits class that models the *ArrangementXMonotoneTraits_2* concept, which refines the *ArrangementBasicTraits_2* concept, has to support the following functions:

Intersection_2: Computes all intersection points and overlapping sections of two given x-monotone curves. If possible, computes also the multiplicity of each intersection point.[12] Knowing the multiplicity of an intersection point is not required, but it can speed up the arrangement construction.

Split_2: Splits an x-monotone curve c into two subcurves at a point p lying in the interior of c.

Are_mergeable_2: Given two x-monotone curve c_1 and c_2 that share a common endpoint, this predicate determines whether c_1 and c_2 are *mergeable*, that is, whether they can be merged to form a single continuous x-monotone curve of the type supported by the traits class.

Merge_2: Merges two mergeable x-monotone curves.

Using a model of the *ArrangementXMonotoneTraits_2*, it is possible to construct arrangements of sets of x-monotone curves (and points) that may intersect one another.

[12] If the two curves intersect at a point p but have different tangents, p is of multiplicity 1. If the tangents are also equal but the their curvatures are not the same, p is of multiplicity 2, etc.

Supporting Arbitrary Curves

The concept *ArrangementTraits_2* refines the *ArrangementXMonotoneTraits_2* concept by adding the notion of a general, not necessarily x-monotone (and not necessarily continuous) curve. A model of this concept must define the *Curve_2* type and support the subdivision of a curve into a set of continuous x-monotone curves and isolated points using the predicate *Make_x_monotone_2*. For example, the curve $C: \ (x^2+y^2)(x^2+y^2-1)=0$ is the unit circle (the loci of all points for which $x^2+y^2=1$) with the origin $(0,0)$ as a singular point in its interior. C should therefore be divided into two circular arcs (the upper part and the lower part of the unit circle) and a single isolated point.

Note that the refined model *ArrangementTraits_2* is required only when using the free *insert()* functions (see Section 32.4), which accept a *Curve_2* object in the incremental version, or a range of *Curve_2* objects in the aggregated version. In all other cases it is sufficient to use a model of the *ArrangementXMonotoneTraits_2* concept.

Supporting Unbounded Curves

An arrangement that supports unbounded x-monotone curves maintains an implicit bounding rectangle in the DCEL structure; see Section 32.5.3. The unbounded ends of vertical rays, vertical lines, and curves with vertical asymptotes are represented by vertices that lie on the bottom or top sides of this bounding rectangle. These vertices are not associated with points, but are associated with (finite) x-coordinates. The unbounded ends of all other curves are represented by vertices that lie on the left or right sides of this bounding rectangle. These vertices are not associated with points either. Edges connect these vertices and the four vertices that represents the corners of this bounding rectangle to form the rectangle.

Several predicates are required to handle x-monotone curves that approach infinity and thus approach the boundary of the parameter space. These predicates are sufficient to handle not only curves embedded in an unbounded parameter space, but also curves embedded in a bounded parameter space with open boundaries. Let b_l and b_r denote the x-coordinates of the left and right boundaries of the parameter space, respectively. Let b_b and b_t denote the y-coordinates of the bottom and top boundaries of the parameter space, respectively. Recall that currently the general code of the arrangement only supports the case where the parameter space is the entire compactified plane, thus $b_l = b_b = -\infty$ and $b_r = b_t = +\infty$. Nonetheless, when the parameter space is bounded, it is the exact geometric embedding of the implicit bounding rectangle. In the following we assume that an x monotone curve C can be considered as a parametric curve $C(t) = (X(t), Y(t))$ defined over a closed, open, or half open interval with endpoints 0 and 1.

Models of the concept *ArrangementOpenBoundaryTraits_2* handle curves that approach the boundary of the parameter space. This concept refines the concept *ArrangementBasicTraits_2*. The arrangement template instantiated with a traits class that models this concept can handle curves that are unbounded in any direction. If some curves inserted into an arrangement object are expected to be unbounded, namely, there exists $d \in \{0,1\}$ such that $\lim_{t\rightarrow d} X(t) = \pm\infty$ or $\lim_{t\rightarrow d} y(t) = \pm\infty$ holds for at least one input curve $C(t) = (X(t), Y(t))$, the arrangement template must be instantiated with a model of the *ArrangementOpenBoundaryTraits* concept.[13]

All the four types *Left_side_category*, *Right_side_category*, *Bottom_side_category*, and *Top_side_category* nested in a model of the concept *ArrangementOpenBoundaryTraits* must be convertible to *Arr_open_side_tag*.[14] For example, the *Arr_rational_function_traits_2* traits-model supports unbounded curves; see Section 32.6.6. Thus, all four nested types are defined as *Arr_open_side_tag*. Adversely, all four types nested in the *Arr_segment_traits_2* traits-model (see Section 32.6.2) are defined as *Arr_oblivious_side_tag*, as segments are always

[13] We intend to enhance the arrangement template to handle curves confined to a bounded yet open parameter space. A curve that reaches the boundary of the parameter space in this case is bounded and open.

[14] The tags *Arr_oblivious_side_tag* and *Arr_open_side_tag* are only two out of a larger number of options for the side categories included in major extension the code is going through.

bounded.[15]

A model of the concept *ArrangementOpenBoundaryTraits_2* must provide the additional predicates listed below. x-coordinates and y-coordinates are differently handled. This asymmetry is brought on by the various algorithms applied to arrangements, the input and output arguments of which are x-monotone curves. Indeed, all curves maintained by any arrangement are continuous weakly x-monotone curves. A non x-monotone curve is divided into x-monotone sub curves (and perhaps points) before it is inserted into an arrangement. This asymmetry is also reflected in the additional predicates listed below.

Parameter_space_in_x_2: Given a parametric x-monotone curve $C(t) = (X(t),Y(t))$ and an enumerator that specifies either the minimum end or the maximum end of the curve, and thus maps to a parameter value $d \in \{0,1\}$, this predicate determines the location of the curve end along the x-dimension. Formally, the predicate determines whether $\lim_{t\to d} X(t)$ evaluates to b_l, b_r, or a value in between.

Compare_y_near_boundary_2: Given two x-monotone curves C_1 and C_2 and an enumerator i that specifies either the minimum ends or the maximum ends of the two curves, this predicate compares the y-coordinates of the curves near their respective ends. That is, the predicate compares the y-coordinates of the vertical projection of a point p onto C_1 and onto C_2. If the enumerator i specifies the minimum ends, the curves must approach the left boundary-side. In this case p is located far to the left, such that the result is invariant under a translation of p farther to the left. If i specifies the maximum ends, the curves must approach the right boundary-side. In that case p is located far to the right in a similar manner.

Parameter_space_in_y_2: Given a parametric x-monotone curve $C(t) = (X(t),Y(t))$ and an enumerator that specifies either the minimum end or the maximum end of the curve, and thus maps to a parameter value $d \in \{0,1\}$, this predicate determines the location of the curve end along the y-dimension. Formally, the predicate determines whether $\lim_{t\to d} Y(t)$ evaluates to b_b, b_t, or a value in between.

Compare_x_at_limit_2: Two versions of this predicate are provided: (i) Given a point p, a parametric x-monotone curve $C(t) = (X(t),Y(t))$, and an enumerator that specifies either the minimum end or the maximum end of the curve, and thus maps to a parameter value $d \in \{0,1\}$, this predicate compares the x-coordinate of p and $\lim_{t\to d} X(t)$. If the parameter space is unbounded, a precondition assures that C has a vertical asymptote at its d-end; that is $\lim_{t\to d} X(t)$ is finite. (ii) Given two parametric x-monotone curves $C_1(t) = (X_1(t),Y_1(t))$ and $C_2(t) = (X_2(t),Y_2(t))$ and two enumerators that specify either the minimum end or the maximum end of each curve, and thus map to parameter values $d_1 \in \{0,1\}$ and $d_2 \in \{0,1\}$ for C_1 and for C_2, respectively, this predicate compares $\lim_{t\to d_1} X_1(t)$ and $\lim_{t\to d_2} X_2(t)$. If the parameter space is unbounded, a precondition assures that C_1 and C_2 have vertical asymptote at their respective ends; that is $\lim_{t\to d_1} X_1(t)$ and $\lim_{t\to d_2} X_2(t)$ are finite.

Compare_x_near_limit_2: Given two x-monotone curves C_1 and C_2 and an enumerator i that specifies either the minimum ends or the maximum ends of the two curves, this predicate compares the x-coordinates of the curves near their respective ends. That is, the predicate compares the x-coordinates of the horizontal projection of a point p onto C_1 and onto C_2. If the parameter space is unbounded, a precondition assures that C_1 and C_2 have vertical asymptote at their respective ends. Furthermore, both curves approach the same boundary-side, either the bottom or the top, at their respective ends. If both curves approach the bottom boundary-side, p is located far to the bottom, such that the result is invariant under a translation of p farther to the bottom. If both curves approach the top boundary-side, p is located far to the top in a similar manner. Another precondition assures that the x-coordinates of the limits of the curves at their respective ends are equal. That is, the predicate *Compare_x_at_limit_2* applied to C_1, C_2, and i evaluates to *EQUAL*.

In the rest of this section we review the traits classes included in the public distribution of CGAL, that handle line segments, polylines, conic arcs, rational functions, and arcs of Bézier and algebraic curves. The last subsection overviews decorators for geometric traits classes distributed with CGAL, which extend other geometric traits-class by attaching auxiliary data with the geometric objects.

[15] We intend to introduce more concepts that require only a subset of the categories to be convertible to *Arr_open_side_tag*.

32.6.2 Traits Classes for Line Segments and Linear Objects

The *Arr_segment_traits_2<Kernel>* class used so far in most example programs in this chapter is a model of the concepts *ArrangementTraits_2*, *ArrangementLandmarkTraits_2*, and *ArrangementDirectionalXMonotoneTraits_2*; the later enables Boolean set operations. It is parameterized by a geometric kernel and uses the *Kernel::Point_2* type as it point type. However, neither the *Curve_2* nor the *X_monotone_curve_2* types are identical to the *Kernel::Segment_2* type. A kernel segment is typically represented by its two endpoints, and these may have a large bit-size representation, if the segment is intersected and split several times (in comparison with the representation of its original endpoints). The large representation may significantly slow down the various traits-class operations involving such a segment. In contrast, the *Arr_segment_traits_2* represents a segment using its supporting line and the two endpoints, such that most computations are performed on the supporting line, which never changes as the segment is split. It also caches some additional information with the segment to speed up various predicates. An *X_monotone_curve_2* object can still be constructed from two endpoints or from a kernel segment. Moreover, an *X_monotone_curve_2* instance can also be casted or assigned to a *Kernel::Segment_2* object. The two types are thus fully convertible to one another.

The *Arr_segment_traits_2<Kernel>* class is very efficient for maintaining arrangements of a large number of intersecting line segments, especially if it is instantiated with the appropriate geometric kernel. Using *Cartesian< Gmpq>* as the kernel type is generally a good choice; the coordinates of the segment endpoints are represented as exact rational numbers, and this ensures the robustness and correctness of any computation. However, if the GMP library is not installed, it is possible to use the *Quotient<MP_Float>* number-type, provided by the support library of CGAL, which is somewhat less efficient.[16]

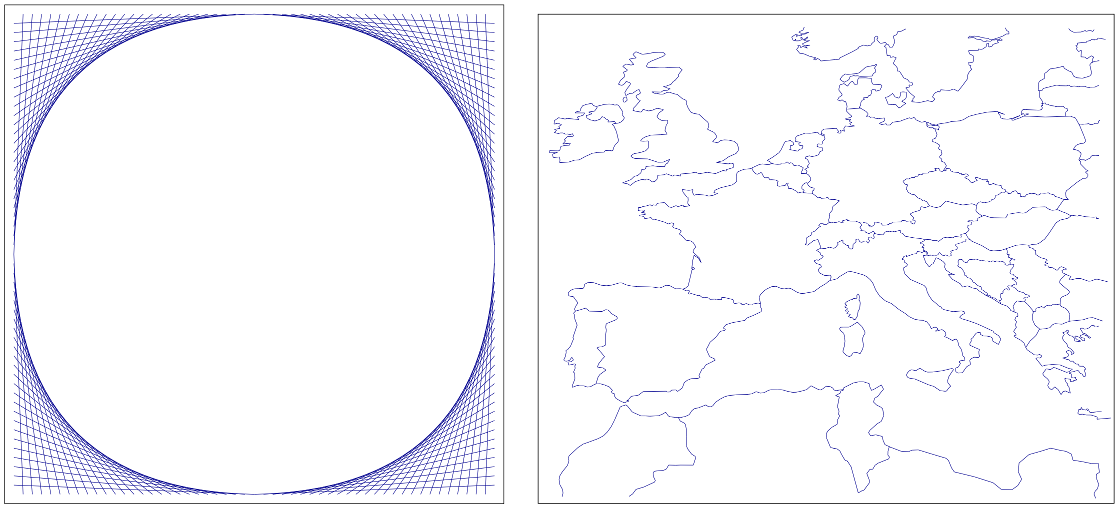
Exact computations are of course less efficient, compared to machine-precision floating-point arithmetic, so constructing an arrangement using the *Cartesian<Gmpq>* kernel (or, similarly, *Cartesian<Quotient<MP_Float> >*) is several times slower in comparison to a *Simple_cartesian<double>* kernel. However, in the latter case the correctness of the computation results is not guaranteed. In many cases it is possible to use *filtered* computations and benefit from both approaches, namely achieve fast running times with guaranteed results. In case we handle a set of line segments that have no degeneracies, namely no two segments share a common endpoint, and no three segments intersect at a common point — or alternatively, degeneracies exist but their number is relatively small — then filtered computation incur only a minor overhead compared to the floating-point arithmetic, while ensuring the correctness of the computation results.

In the following example we use the predefined *Exact_predicates_exact_constructions_kernel* for instantiating our segment-traits class. This kernel use interval arithmetic to filter the exact computations. The program reads a set of line segments with integer coordinates from a file and computes their arrangement. By default it opens the *fan_grids.dat* input-file, located in the examples folder, which contains 104 line segments that form four "fan-like" grids and induce a dense arrangement, as illustrated in Figure 32.12(a):

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Timer.h>
#include <list>
#include <fstream>

typedef CGAL::Exact_predicates_exact_constructions_kernel  Kernel;
typedef Kernel::FT                                         Number_type;
typedef CGAL::Arr_segment_traits_2<Kernel>                 Traits_2;
typedef Traits_2::Point_2                                  Point_2;
```

[16] Many of the example programs in the rest of the chapter include a header file named *arr_rational_nt.h*, which defines a type named *Number_type* as either *Gmpq* or *Quotient<MP_Float>*, depending on whether GMP is installed or not.



(a) (b)

Figure 32.12: (a) An arrangement of 104 line segments from the input file *fan_grids.dat*. (b) An arrangement of more than 3000 interior disjoint line segments, defined in the input file *Europe.dat*.

```
typedef Traits_2::X_monotone_curve_2                          Segment_2;
typedef CGAL::Arrangement_2<Traits_2>                         Arrangement_2;

int main (int argc, char *argv[])
{
  // Get the name of the input file from the command line, or use the
   default
  // fan_grids.dat file if no command-line parameters are given.
  const char * filename = (argc > 1) ? argv[1] : "fan_grids.dat";

  // Open the input file.
  std::ifstream     in_file (filename);

  if (! in_file.is_open()) {
    std::cerr << "Failed to open " << filename << " ..." << std::endl;
    return (1);
  }

  // Read the segments from the file.
  // The input file format should be (all coordinate values are
   integers):
  // <n>                              // number of segments.
  // <sx_1> <sy_1>  <tx_1> <ty_1>     // source and target of segment
   #1.
  // <sx_2> <sy_2>  <tx_2> <ty_2>     // source and target of segment
   #2.
  //   :      :        :      :
  // <sx_n> <sy_n>  <tx_n> <ty_n>     // source and target of segment
   #n.

  std::list<Segment_2>  segments;
```

```
  unsigned int n;
  in_file >> n;
  unsigned int i;
  for (i = 0; i < n; ++i) {
    int sx, sy, tx, ty;
    in_file >> sx >> sy >> tx >> ty;
    segments.push_back (Segment_2 (Point_2 (Number_type(sx),
   Number_type(sy)),
                                   Point_2 (Number_type(tx),
   Number_type(ty))));
  }
  in_file.close();

  // Construct the arrangement by aggregately inserting all segments.
  Arrangement_2                  arr;
  CGAL::Timer                    timer;

  std::cout << "Performing aggregated insertion of "
            << n << " segments." << std::endl;

  timer.start();
  insert (arr, segments.begin(), segments.end());
  timer.stop();

  // Print the arrangement dimensions.
  std::cout << "V = " << arr.number_of_vertices()
            << ",  E = " << arr.number_of_edges()
            << ",  F = " << arr.number_of_faces() << std::endl;

  std::cout << "Construction took " << timer.time()
            << " seconds." << std::endl;

  return 0;
}
```

File: examples/Arrangement_on_surface_2/predefined_kernel.cpp

The arrangement package also offers a simpler alternative segment-traits class. The traits class *Arr_non_caching_segment_basic_traits_2<Kernel>* models the *ArrangementBasicTraits_2* concept. It uses *Kernel::Point_2* as its point type and *Kernel::Segment_2* as its x-monotone curve type. As this traits class does not support intersecting and splitting segments, the kernel representation is sufficient. It is still less efficient than *Arr_segment_traits_2* for constructing arrangements of pairwise disjoint line segments in many cases, as it performs no caching at all, but using this traits class may be preferable as it reduces the memory consumption a bit, since no extra data is stored with the line segments.

The class *Arr_non_caching_segment_traits_2<Kernel>* inherits from *Arr_non_caching_segment_basic_traits_2< Kernel>* and extends it to be a model of the concepts *ArrangementTraits_2*, *ArrangementLandmarkTraits_2*,and *ArrangementDirectionalXMonotoneTraits_2*. It may thus be used to construct arrangement of intersecting line segments, but as explained above, for efficiency reasons it is recommended to use it only when the arrangement is very sparse and contains hardly any intersection points.

In the following example we read an input file containing a set of line segments that are pairwise disjoint in their interior. As the segments do not intersect, no new points are constructed and we can instantiate the *Arr_non_caching_segment_traits_basic_2<Kernel>* class-template with the predefined *Exact_predicates_inexact_constructions_kernel*. Note that we use the *insert_non_intersecting_curves()* function to construct the arrangement. By default, the example opens the *Europe.dat* input-file, located in the examples folder, which contains more than 3000 line segments with floating-point coordinates that form the map of Europe, as depicted in Figure 32.12(b):

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Arr_non_caching_segment_basic_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Timer.h>
#include <list>
#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel   Kernel;
typedef Kernel::FT
   Number_type;
typedef CGAL::Arr_non_caching_segment_basic_traits_2<Kernel>  Traits_2;
typedef Traits_2::Point_2                                     Point_2;
typedef Traits_2::X_monotone_curve_2                          Segment_2;
typedef CGAL::Arrangement_2<Traits_2>
   Arrangement_2;

int main (int argc, char *argv[])
{
  // Get the name of the input file from the command line, or use the
   default
  // Europe.dat file if no command-line parameters are given.
  const char * filename = (argc > 1) ? argv[1] : "Europe.dat";

  // Open the input file.
  std::ifstream     in_file (filename);

  if (! in_file.is_open()) {
    std::cerr << "Failed to open " << filename << " ..." << std::endl;
    return (1);
  }

  // Read the segments from the file.
  // The input file format should be (all coordinate values are double
  // precision floating-point numbers):
  // <n>                                // number of segments.
  // <sx_1> <sy_1>  <tx_1> <ty_1>       // source and target of segment
   #1.
  // <sx_2> <sy_2>  <tx_2> <ty_2>       // source and target of segment
   #2.
  //   :       :       :       :
  // <sx_n> <sy_n>  <tx_n> <ty_n>       // source and target of segment
   #n.
  std::list<Segment_2>  segments;

  unsigned int n;
  in_file >> n;
  unsigned int i;
  for (i = 0; i < n; ++i) {
```

```
    double sx, sy, tx, ty;
    in_file >> sx >> sy >> tx >> ty;
    segments.push_back (Segment_2 (Point_2 (Number_type(sx),
   Number_type(sy)),
                                   Point_2 (Number_type(tx),
   Number_type(ty))));
  }
  in_file.close();

  // Construct the arrangement by aggregately inserting all segments.
  Arrangement_2                  arr;
  CGAL::Timer                    timer;

  std::cout << "Performing aggregated insertion of "
            << n << " segments." << std::endl;

  timer.start();
  insert_non_intersecting_curves (arr, segments.begin(), segments.end());
  timer.stop();

  // Print the arrangement dimensions.
  std::cout << "V = " << arr.number_of_vertices()
            << ",  E = " << arr.number_of_edges()
            << ",  F = " << arr.number_of_faces() << std::endl;

  std::cout << "Construction took " << timer.time()
            << " seconds." << std::endl;

  return 0;
}
```

File: examples/Arrangement_on_surface_2/predefined_kernel_non_intersecting.cpp

The *Arr_linear_traits_2*<*Kernel*> class used for demonstrating the construction of arrangements of unbounded curves is capable of handling bounded and unbounded linear objects, namely lines, rays and line segments. It is parameterized by a geometric kernel and such that its nested *Point_2* type is the same as the kernel point. The *Curve_2* (and *X_monotone_curve_2*) type it defines is constructible from a *Kernel::Line_2*, a *Kernel::Ray_2* or from a *Kernel::Segment_2* object. Just like the default segment-traits class, the linear-traits class also use caching techniques to speed up its predicates and constructions.

32.6.3 The Polyline-Traits Class

The *Arr_polyline_traits_2*<*SegmentTraits*> class can be used to maintain arrangements of polylines (a.k.a. poly-segments), which are continuous piecewise linear curves. A polyline can be created from a range of points, where the i-th and $(i+1)$-st points in the range represent the endpoints of the i-th segment of the polyline. The polyline traits class is parameterized with a segment-traits class that supports the basic operations on segments.

Polylines are the simplest form of a curves that are not necessarily x-monotone. They can be used to approximate more complicated curves in a convenient manner, as the algebra needed to handle them is elementary — rational arithmetic is sufficient to construct an arrangement of polylines is an exact and robust manner. Note, however,

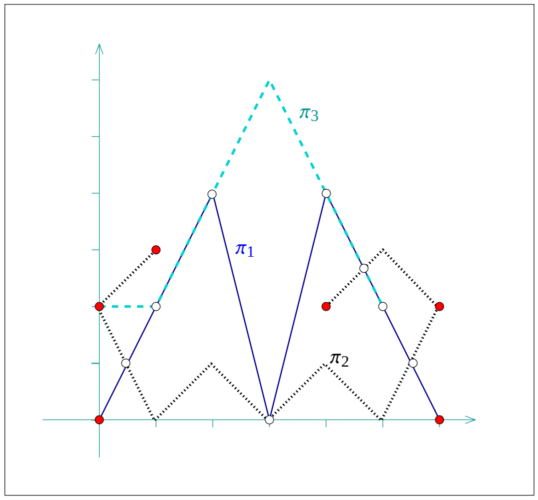


Figure 32.13: An arrangement of three polylines, as constructed in *polylines.cpp*. Disks mark vertices associated with polyline endpoints, while circles mark vertices that correspond to intersection points. Note that π_2 is split into three x-monotone polylines, and that π_1 and π_3 have two overlapping sections.

that a single polyline can be split into many x-monotone polylines, and that the number of intersection points (or overlapping sections) between two polylines can also be large.

The polyline-traits class is a model of the *ArrangementTraits_2* concept and of the *ArrangementLandmarkTraits_2* concept. It inherits its point type from the segment-traits class, and defines the polyline type, which serves as its *Curve_2*. Polyline curve objects can be constructed from a range of points. They also enable the traversal over the range of defining points, whose first and past-the-end iterators can be obtained through the methods *begin()* and *end()*. The nested *X_monotone_curve_2* type inherits from *Curve_2*. The points in an x-monotone curve are always stored in lexicographically increasing order of their coordinates.

The following example program constructs an arrangement of three polylines, as depicted in Figure 32.13. Note that most points defining the polylines are not associated with arrangement vertices. The arrangement vertices are either the extreme points of each x-monotone polyline or the intersection points between two polylines:

32.6.4 A Traits Class for Circular Arcs and Line Segments

Circles and circular arcs are the simplest form of non-linear curves. We handle circles whose centers have rational coordinates and whose squared radii is also rational. If we denote the circle center by (x_0, y_0) and its radius by r, then the equation of the circle — that is, $(x-x_0)^2 + (y-y_0)^2 = r^2$ — has rational coefficients. The intersection points of two such circles are therefore solutions of a quadratic equation with rational coefficients, or algebraic numbers of degree 2. The same applies for intersection points between such a rational circle and a

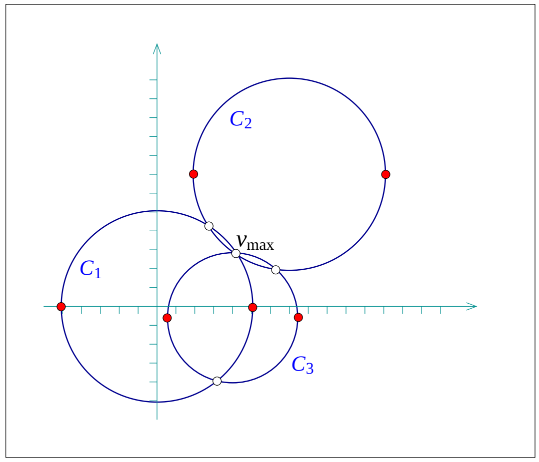

Figure 32.14: An arrangement of three circles constructed in *circles.cpp*. Each circle is split into two x-monotone circular arcs, whose endpoints are drawn as disks. Circles mark vertices that correspond to intersection points. The vertex $v_{\max}$ is a common intersection point of all three circles.

line, or a line segment, with rational coefficients (a line whose equation is $ax + by + c = 0$, where a, b and c are rational). Such numbers can be expressed as $\alpha + \beta\sqrt{\gamma}$, where α, β and γ are all rational numbers.

Arrangement of circular arcs and of line segment are very useful, as they occur in many applications. For example, when dilating a polygon by some radius we obtain a shape whose boundary is comprised of line segments, which correspond to dilated polygon edges, and circular arcs, which result from dilated polygon vertices. Using the arrangement of the boundary curves it is possible, for example, to compute the union of a set of dilated polygons.

The *Arr_circle_segment_traits_2<Kernel>* class-template is designed for efficient handling of arrangements of circular arcs and line segments. It is a model of the concepts *ArrangementTraits_2* and *ArrangementDirectionalXMonotoneTraits_2*; the later enables Boolean set operations. Note that it is not a model of *ArrangementLandmarkTraits_2* concept, so it is impossible to use the landmark point-location strategy. The traits class template is parameterized by a geometric kernel, and can handle arrangements of segments of *Kernel::Circle_2* objects (full circles are also supported) or of *Kernel::Line_2* objects—namely circular arcs and line segments. It is important to observe that the nested *Point_2* type defined by the traits class, whose coordinates are typically algebraic numbers of degree 2, is *not* the same as the *Kernel::Point_2* type, which is capable of representing a point with rational coordinates. The coordinates of a point are represented using the nested *CoordNT* number-type.

In the following example an arrangement of three full circles is constructed, as shown in Figure 32.14. Then, the vertex of maximal degree is searched for. The geometric mapping of this vertex is the point $(4,3)$, as all three circles intersect at this point and the associated vertex has six incident edges:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_circle_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

typedef CGAL::Cartesian<Number_type>                    Kernel;
typedef Kernel::Circle_2                                Circle_2;
typedef CGAL::Arr_circle_segment_traits_2<Kernel>       Traits_2;
typedef Traits_2::CoordNT                               CoordNT;
```

```
typedef Traits_2::Point_2                                   Point_2;
typedef Traits_2::Curve_2                                   Curve_2;
typedef CGAL::Arrangement_2<Traits_2>                       Arrangement_2;

int main ()
{
  // Create a circle centered at the origin with radius 5.
  Kernel::Point_2  c1 = Kernel::Point_2 (0, 0);
  Number_type      sqr_r1 = Number_type (25);       // = 5^2
  Circle_2         circ1 = Circle_2 (c1, sqr_r1, CGAL::CLOCKWISE);
  Curve_2          cv1 = Curve_2 (circ1);

  // Create a circle centered at (7,7) with radius 5.
  Kernel::Point_2  c2 = Kernel::Point_2 (7, 7);
  Number_type      sqr_r2 = Number_type (25);       // = 5^2
  Circle_2         circ2 = Circle_2 (c2, sqr_r2, CGAL::CLOCKWISE);
  Curve_2          cv2 = Curve_2 (circ2);

  // Create a circle centered at (4,-0.5) with radius 3.5 (= 7/2).
  Kernel::Point_2  c3 = Kernel::Point_2 (4, Number_type (-1,2));
  Number_type      sqr_r3 = Number_type (49, 4);    // = 3.5^2
  Circle_2         circ3 = Circle_2 (c3, sqr_r3, CGAL::CLOCKWISE);
  Curve_2          cv3 = Curve_2 (circ3);

  // Construct the arrangement of the three circles.
  Arrangement_2    arr;

  insert (arr, cv1);
  insert (arr, cv2);
  insert (arr, cv3);

  // Locate the vertex with maximal degree.
  Arrangement_2::Vertex_const_iterator  vit;
  Arrangement_2::Vertex_const_handle    v_max;
  unsigned int                          max_degree = 0;

  for (vit = arr.vertices_begin(); vit != arr.vertices_end(); ++vit) {
    if (vit->degree() > max_degree) {
      v_max = vit;
      max_degree = vit->degree();
    }
  }

  std::cout << "The vertex with maximal degree in the arrangement is: "
            << "v_max = (" << v_max->point() << ") "
            << "with degree " << max_degree << "." << std::endl;
  return 0;
}
```

File: examples/Arrangement_on_surface_2/circles.cpp

The *Curve_2* type nested in *Arr_circle_segment_traits_2* can be used to represent circles, circular arcs, or line segments. Curve objects can therefore be constructed from a *Kernel::Circle_2* object or from a

Kernel::Segment_2 object. A circular arc is typically defined by a supporting circle and two endpoints, where the endpoints are instances of the *Point_2* type, with rational or irrational coordinates. The orientation of the arc is determined by the orientation of the supporting circle. Similarly, we also support the construction of lines segments given their supporting line (of type *Kernel::Line_2*) and two endpoints, which may have irrational coordinates (unlike the *Kernel::Segment_2* type).

Note that the *Kernel::Circle_2* type represents a circle whose *squared radius* is rational, where the radius itself may be irrational. However, if the radius is known to be rational, it is advisable to use it, for efficiency reasons. It is therefore also possible to construct a circle, or a circular arc specifying the circle center (a *Kernel::Point_2*), its rational radius, and its orientation. Finally, we also support the construction of a circular arcs that is defined by two endpoints and an arbitrary midpoint that lies on the arc in between its endpoint. In this case, all three points are required to have rational coordinates (to be kernel points).

The following example demonstrates the usage of the various construction methods for circular arcs and line segments. Note the usage of the constructor of *CoordNT (alpha, beta, gamma)*, which creates a degree-2 algebraic number whose value is $\alpha+\beta\sqrt{\gamma}$.

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_circle_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

typedef CGAL::Cartesian<Number_type>                     Kernel;
typedef Kernel::Circle_2                                 Circle_2;
typedef Kernel::Segment_2                                Segment_2;
typedef CGAL::Arr_circle_segment_traits_2<Kernel>        Traits_2;
typedef Traits_2::CoordNT                                CoordNT;
typedef Traits_2::Point_2                                Point_2;
typedef Traits_2::Curve_2                                Curve_2;
typedef CGAL::Arrangement_2<Traits_2>                    Arrangement_2;

int main ()
{
  std::list<Curve_2>  curves;

  // Create a circle centered at the origin with squared radius 2.
  Kernel::Point_2  c1 = Kernel::Point_2 (0, 0);
  Circle_2         circ1 = Circle_2 (c1, Number_type (2));

  curves.push_back (Curve_2 (circ1));

  // Create a circle centered at (2,3) with radius 3/2 - note that
  // as the radius is rational we use a different curve constructor.
  Kernel::Point_2  c2 = Kernel::Point_2 (2, 3);

  curves.push_back (Curve_2 (c2, Number_type(3, 2)));

  // Create a segment of the line (y = x) with rational endpoints.
  Kernel::Point_2  s3 = Kernel::Point_2 (-2, -2);
  Kernel::Point_2  t3 = Kernel::Point_2 (2, 2);
  Segment_2        seg3 = Segment_2 (s3, t3);

  curves.push_back (Curve_2 (seg3));
```

```
  // Create a line segment with the same supporting line (y = x), but
  // having one endpoint with irrational coefficients.
  CoordNT           sqrt_15 = CoordNT (0, 1, 15); // = sqrt(15)
  Point_2           s4 = Point_2 (3, 3);
  Point_2           t4 = Point_2 (sqrt_15, sqrt_15);

  curves.push_back (Curve_2 (seg3.supporting_line(), s4, t4));

  // Create a circular arc that correspond to the upper half of the
  // circle centered at (1,1) with squared radius 3. We create the
  // circle with clockwise orientation, so the arc is directed from
  // (1 - sqrt(3), 1) to (1 + sqrt(3), 1).
  Kernel::Point_2  c5 = Kernel::Point_2 (1, 1);
  Circle_2          circ5 = Circle_2 (c5, 3, CGAL::CLOCKWISE);
  CoordNT           one_minus_sqrt_3 = CoordNT (1, -1, 3);
  CoordNT           one_plus_sqrt_3 = CoordNT (1, 1, 3);
  Point_2           s5 = Point_2 (one_minus_sqrt_3, CoordNT (1));
  Point_2           t5 = Point_2 (one_plus_sqrt_3, CoordNT (1));

  curves.push_back (Curve_2 (circ5, s5, t5));

  // Create a circular arc of the unit circle, directed clockwise from
  // (-1/2, sqrt(3)/2) to (1/2, sqrt(3)/2). Note that we orient the
  // supporting circle accordingly.
  Kernel::Point_2  c6 = Kernel::Point_2 (0, 0);
  CoordNT           sqrt_3_div_2 = CoordNT (Number_type(0),
   Number_type(1,2), Number_type(3));
  Point_2           s6 = Point_2 (Number_type (-1, 2), sqrt_3_div_2);
  Point_2           t6 = Point_2 (Number_type (1, 2), sqrt_3_div_2);

  curves.push_back (Curve_2 (c6, 1, CGAL::CLOCKWISE, s6, t6));

  // Create a circular arc defined by two endpoints and a midpoint,
  // all having rational coordinates. This arc is the upper-right
  // quarter of a circle centered at the origin with radius 5.
  Kernel::Point_2  s7 = Kernel::Point_2 (0, 5);
  Kernel::Point_2  mid7 = Kernel::Point_2 (3, 4);
  Kernel::Point_2  t7 = Kernel::Point_2 (5, 0);

  curves.push_back (Curve_2 (s7, mid7, t7));

  // Construct the arrangement of the curves.
  Arrangement_2     arr;

  insert (arr, curves.begin(), curves.end());

  // Print the size of the arrangement.
  std::cout << "The arrangement size:" << std::endl
            << "   V = " << arr.number_of_vertices()
            << ",  E = " << arr.number_of_edges()
            << ",  F = " << arr.number_of_faces() << std::endl;

  return 0;
}
```

File: `examples/Arrangement_on_surface_2/circular_arcs.cpp`

It is also possible to construct x-monotone curve objects, which represent x-monotone circular arcs or line segments, using similar constructors. Construction from a full circle is obviously not supported. See the Reference Manual for more details.

The traits class-template *Arr_circular_line_arc_traits_2<CircularKernel>* offered by the arrangement package also handles circular arcs and line segments. It is an alternative to the *Arr_circle_segment_traits_2<Kernel>* class-template. These two class templates, while serve similar purposes, are based on different concepts, and posses different characteristics. You are encouraged to experiment with both, compare their performance, and use the most suitable for your case.

32.6.5 A Traits Class for Conic Arcs

A *conic curve* is an algebraic curve of degree 2. Namely, it is the locus of all points (x,y) satisfying the equation $C:\ rx^2+sy^2+txy+ux+vy+w=0$, where the six coefficients $\langle r,s,t,u,v,w\rangle$ completely characterize the curve. The sign of the expression $\Delta_C = 4rs-t^2$ determines the type of curve:

- If $\Delta_C > 0$ the curve is an ellipse. A circle is a special case of an ellipse, where $r=s$ and $t=0$.
- If $\Delta_C = 0$ the curve is a parabola — an unbounded conic curve with a single connected branch. When $r=s=t=0$ we have a line, which can be considered as a degenerate parabola.
- If $\Delta_C < 0$ the curve is a hyperbola. That is, it is comprised of two disconnected unbounded branches.

As the arrangement package is suitable for bounded curves, we consider bounded segments of conic curves, referred to as *conic arcs*. A conic arc a may be either (i) a full ellipse, or (ii) defined by the tuple $\langle C,p_s,p_t,o\rangle$, where C is a conic curve and p_s and p_t are two points on C (namely $C(p_s)=C(p_t)=0$) that define the *source* and *target* of the arc, respectively. The arc is formed by traversing C from the source to the target going in the orientation specified by o, which is typically clockwise or counterclockwise orientation (but may also be collinear in case of degenerate conic curves).

We always assume that the conic coefficients $\langle r,s,t,u,v,w\rangle$ are rational. When dealing with linear curves (line segments and polylines), similar assumptions guarantee that all intersection points also have rational coordinates, such that the arrangement of such curves can be constructed and maintained using only rational arithmetic. Unfortunately, this does not hold for conic curves, as the coordinates of intersection points of two conic curves with rational coefficients are in general algebraic numbers of degree 4.[17] In addition, conic arcs may not necessarily be x-monotone, and must be split at points where the tangent to the arc is vertical. In the general case, such points typically have coordinates that are algebraic numbers of degree 2. It is therefore clear that we have to use different number types to represent the conic coefficients and the point coordinates. Note that as arrangement vertices induced by intersection points and points with vertical tangents are likely to have algebraic coordinates, we also allow the original endpoints of the input arcs p_s and p_t to have algebraic coordinates.

The *Arr_conic_traits_2<RatKernel, AlgKernel, NtTraits>* class template is designed for efficient handling of arrangements of bounded conic arcs. The template has three parameters, defined as follows:

- The *RatKernel* class is a geometric kernel, whose field type is an exact rational type. It is used to define basic geometric entities (e.g., a line segment or a circle) with rational coefficients. Typically we use one of the standard CGAL kernels, instantiated with the number type *NtTraits::Rational* (see below).

[17] Namely, they are roots of polynomials with integer coefficients of degree 4. However, in some special cases, for example when handling only circles and circular arcs, the coordinates of the intersection points are only of degree 2, namely they are solutions of quadratic equations.

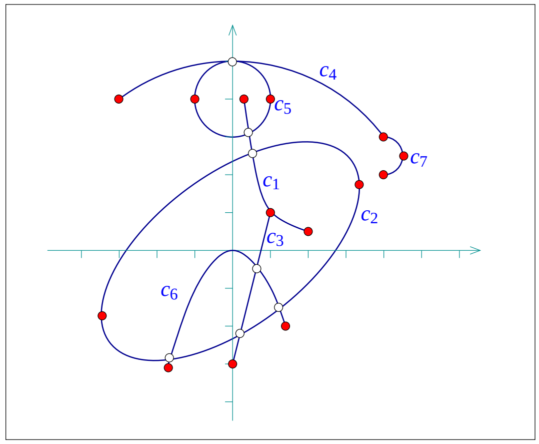

Figure 32.15: An arrangement of mixed conic arcs, as constructed in *conics.cpp*.

- The *AlgKernel* class is a geometric kernel whose field type is an exact algebraic type. It is used to define points with algebraic coordinates. Typically we use one of the standard CGAL kernels, instantiated with the number type *NtTraits::Algebraic* (see below).
- The *NtTraits* class (the number-type traits class) encapsulates all the numeric operations needed for performing the geometric computation carried out by the geometric traits class. It defines the *Integer*, *Rational* and *Algebraic* number-types, and supports several operations on these types, such as conversion between number types, solving quadratic equations and extracting the real roots of a polynomial with integer coefficients. It is highly recommended to use the *CORE_algebraic_number_traits* class, which is included in the arrangement package. It relies on the exact number types implemented in the CORE library and performs exact computations on the number types it defines.

The *Arr_conic_traits_2* models the *ArrangementTraits_2* and *ArrangementLandmarkTraits_2* concepts. (It supports the landmark point-location strategy). Its *Point_2* type is derived from *AlgKernel::Point_2*, while the *Curve_2* type represents a bounded, not necessarily x-monotone, conic arc. The *X_monotone_curve_2* type is derived from *Curve_2*, but its constructors are to be used only by the traits class. You should therefore construct only *Curve_2* objects and insert them into the arrangement using the *insert()* or *insert()* functions.

Conic arcs can be constructed from full ellipses or by specifying a supporting curve, two endpoints and an orientation. However, several constructors of *Curve_2* are available to allow for some special cases, such as circular arcs or line segments. The *Curve_2* (and the derived *X_monotone_curve_2*) classes also support basic access functions such as *source()*, *target()* and *orientation()*.

Examples for Arrangements of Conics

The following example demonstrates the usage of the various constructors for conic arcs. The resulting arrangement is depicted in Figure 32.15. Especially noteworthy are the constructor of a circular arc that accepts three points and the constructor that allows specifying approximate endpoints, where the exact endpoints are given explicitly as intersections of the supporting conic with two other conic curves. Also note that as the preconditions required by some of these constructors are rather complicated (see the Reference Manual for the details), a precondition violation does not cause the program to terminate — instead, an *invalid* arc is created. We can verify the validity of an arc by using the *is_valid()* method. Needless to say, inserting invalid arcs into an arrangement is not allowed.

```
#include <CGAL/basic.h>
```

```
#ifndef CGAL_USE_CORE
#include <iostream>
int main ()
{
  std::cout << "Sorry, this example needs CORE ..." << std::endl;
  return 0;
}
#else

#include <CGAL/Cartesian.h>

          << "   V = " << arr.number_of_vertices()
          << ",  E = " << arr.number_of_edges()
          << ",  F = " << arr.number_of_faces() << std::endl;
```

```
  return 0;
}

#endif
```

File: examples/Arrangement_on_surface_2/conics.cpp

The last example in this section demonstrates how the conic-traits class can handle intersection points with multiplicity. The supporting curves of the two arcs, a circle centered at $(0, \frac{1}{2})$ with radius $\frac{1}{2}$, and the hyperbola $y = \frac{x^2}{1-x}$,[18] intersect at the origin such that the intersection point has multiplicity 3 (note that they both have the same horizontal tangent at $(0,0)$ and the same curvature 1). In addition, they have another intersection point at $(\frac{1}{2}, \frac{1}{2})$ of multiplicity 1:

```
#include <CGAL/basic.h>

32.6.6 A Traits Class for Arcs of Rational Functions

The traits class *Arr_rational_function_traits_2<AlgebraicKernel_d_1>* handles bounded and unbounded arcs of rational functions, referred to as *rational arcs* (in particular, such an arc may correspond to the entire graph of a rational function), and enables the construction and maintenance of arrangements of such arcs. Rational functions, and polynomial functions in particular, are not only interesting in their own right, they are also very useful for approximating or interpolating more complicated curves; see, e.g., [PTVF02, Chapter 3].

Arr_rational_function_traits_2<AlgebraicKernel_d_1> is a model of the concepts *ArrangementTraits_2*, *ArrangementOpenBoundaryTraits_2*, and *ArrangementDirectionalXMonotoneTraits_2*; the later enables Boolean set operations. Note that it is not a model of *ArrangementLandmarkTraits_2* concept, so it is impossible to use the landmark point-location strategy with this traits class.

A rational function $y = \frac{P(x)}{Q(x)}$ is defined by two polynomials P and Q of arbitrary degrees. If $Q(x) = 1$ then the function is a simple polynomial function. Usually the domain is $\mathbb{R}$ but the function may also be restricted to a bounded interval $[x_{\min}, x_{\max}]$ or defined over a ray $(-\infty, x_{\max}]$ or $[x_{\min}, \infty)$. Rational functions are represented by the nested type *Curve_2*. A rational arc is always x-monotone in the mathematical sense. However, it is not necessarily continuous, as it may have singularities. An arc that has singularities must be split into continuous portions before being inserted into the arrangement. Arbitrary rational functions are represented by the nested type *Curve_2* and continuous portions of rational functions are represented by the nested type *X_monotone_curve_2*. Constructors for both types are provided by the traits. A *Curve_2* may be split up into several *X_monotone_curve_2* using *Make_x_monotone_2*.

Using the *Arr_rational_function_traits_2<AlgebraicKernel_d_1>* class template it is possible to construct and maintain arrangement of rational arcs. The template parameter of the traits must be a model of the concept *AlgebraicKernel_d_1*. A rational function is represented as the quotient of two polynomials P and Q of type *AlgebraicKernel_d_1::Polynomial_1* and an x-interval over which the polynomials are defined. The type of the polynomial coefficients, namely *AlgebraicKernel_d_1::Coefficient*, cannot be algebraic. Moreover, it is recommended that this type is not made rational either, since using rational, as opposed to integral, coefficients does not extend the range of the rational arcs and is typically less efficient. The type of the interval bounds, namely *AlgebraicKernel_d_1::Bound*, however, can be algebraic. A point is represented by a rational function and its x-coordinate, which is of type *AlgebraicKernel_d_1::Algebraic_real_1*. Note that an explicit representation of the y-coordinate is only computed upon request, as it can be a rather costly operation.

The constructed rational functions are cached by the traits class. The cache is local to each traits class object. It is therefore necessary to construct curves using only the constructor objects provided by member functions of the traits class. Moreover, a curve must only be used by the traits class object that was used to construct it. The cache is automatically cleaned up from time to time. The amortized clean up costs are constant. In addition, there is also a separate member function that cleans up the cache on demand.

The curve constructors have an additional advantage. They conveniently enable the provision of two polynomials that define a rational arc using rational coefficients. For example, let P and Q denote two polynomials with integral coefficients that define a rational arc at interest, and let P' and Q' denote two polynomials with rational coefficients that define the same rational arc; that is, the quotients P/Q and P'/Q' are identical. You can construct the rational arc providing the coefficients of P' and Q' to the constructor. In this case the constructor normalizes the coefficients and stores the desired polynomials P and Q.

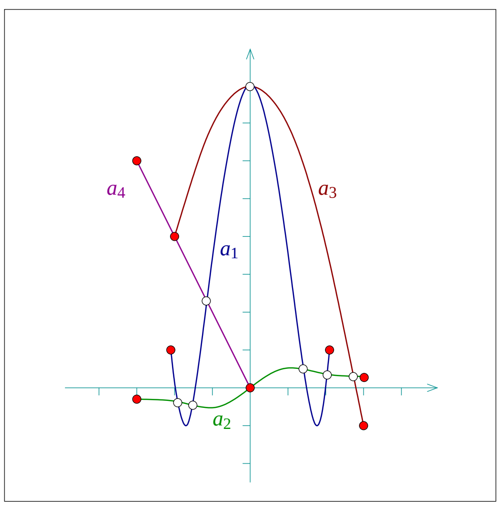

Figure 32.16: An arrangement of four arcs of rational functions, as constructed in *rational_functions.cpp*.

The following example demonstrates the construction of an arrangement of rational arcs depicted in Figure 32.16. Note the usage of the two constructors, for polynomial arcs and for rational arcs:

```
#include <CGAL/basic.h>

#ifndef CGAL_USE_CORE
```

```
#include <iostream>
int main ()
{
  std::cout << "Sorry, this example needs CORE ..." << std::endl;
  return 0;
}

#else

#include <CGAL/CORE_BigInt.h>                        // NT
#include <CGAL/Algebraic_kernel_d_1.h>               // Algebraic Kernel
#include <CGAL/Arr_rational_function_traits_2.h>     // Traits
#include <CGAL/Arrangement_2.h>                      // Arrangement

typedef CORE::BigInt                                 Number_type;
typedef CGAL::Algebraic_kernel_d_1<Number_type>      AK1;
typedef CGAL::Arr_rational_function_traits_2<AK1>    Traits_2;

typedef Traits_2::Polynomial_1                       Polynomial_1;
typedef Traits_2::Algebraic_real_1                   Alg_real_1;

typedef CGAL::Arrangement_2<Traits_2>                Arrangement_2;

int main ()
{
  CGAL::set_pretty_mode(std::cout);               // for nice printouts.

  // create a polynomial representing x .-)
  Polynomial_1 x = CGAL::shift(Polynomial_1(1),1);

  // Traits class object
  Traits_2 traits;
  Traits_2::Construct_x_monotone_curve_2 construct_arc
    = traits.construct_x_monotone_curve_2_object();

  // container storing all arcs
  std::vector<Traits_2::X_monotone_curve_2>  arcs;

  // Create an arc supported by the polynomial y = x^4 - 6x^2 + 8,
  // defined over the interval [-2.1, 2.1]:
  Polynomial_1 P1 = x*x*x*x - 6*x*x + 8;
  Alg_real_1 l(Traits_2::Algebraic_kernel_d_1::Bound(-2.1));
  Alg_real_1 r(Traits_2::Algebraic_kernel_d_1::Bound(2.1));
  arcs.push_back(construct_arc(P1, l, r));

  // Create an arc supported by the function y = x / (1 + x^2),
  // defined over the interval [-3, 3]:
  Polynomial_1 P2 = x;
  Polynomial_1 Q2 = 1+x*x;

  arcs.push_back(construct_arc(P2, Q2, Alg_real_1(-3), Alg_real_1(3)));

  // Create an arc supported by the parbola y = 8 - x^2,
  // defined over the interval [-2, 3]:
```

```
  Polynomial_1 P3 = 8 - x*x;
  arcs.push_back(construct_arc(P3, Alg_real_1(-2), Alg_real_1(3)));

  // Create an arc supported by the line y = -2x,
  // defined over the interval [-3, 0]:
  Polynomial_1 P4 = -2*x;
  arcs.push_back(construct_arc(P4, Alg_real_1(-3), Alg_real_1(0)));

  // Construct the arrangement of the four arcs.

  // Print the arcs.
  for (unsigned int i(0); i < arcs.size(); ++i)
    std::cout << arcs[i]<<std::endl;

  Arrangement_2 arr(&traits);
  insert(arr, arcs.begin(), arcs.end());

  // Print the arrangement size.
  std::cout << "The arrangement size:" << std::endl
            << "   V = " << arr.number_of_vertices()
            << ",  E = " << arr.number_of_edges()
            << ",  F = " << arr.number_of_faces() << std::endl;

  return 0;
}

#endif
```

File: examples/Arrangement_on_surface_2/rational_functions.cpp

The following example demonstrates the construction of an arrangement of six rational arcs—four unbounded arcs and two bounded ones—as depicted in Figure 32.17. Note the usage of the constructors of an entire rational function and of an infinite "ray" of such a function. Also observe that the hyperbolas $y = \pm\frac{1}{x}$ and $y = \pm\frac{1}{2x}$ never intersect, although they have common vertical and horizontal asymptotes, so very "thin" unbounded faces are created between them:

```
#include <CGAL/basic.h>

#ifndef CGAL_USE_CORE
#include <iostream>
int main ()
{
  std::cout << "Sorry, this example needs CORE ..." << std::endl;
  return 0;
}

#else

#include <CGAL/CORE_BigInt.h>                      // NT
#include <CGAL/Algebraic_kernel_d_1.h>             // Algebraic Kernel
#include <CGAL/Arr_rational_function_traits_2.h> // Traits
```

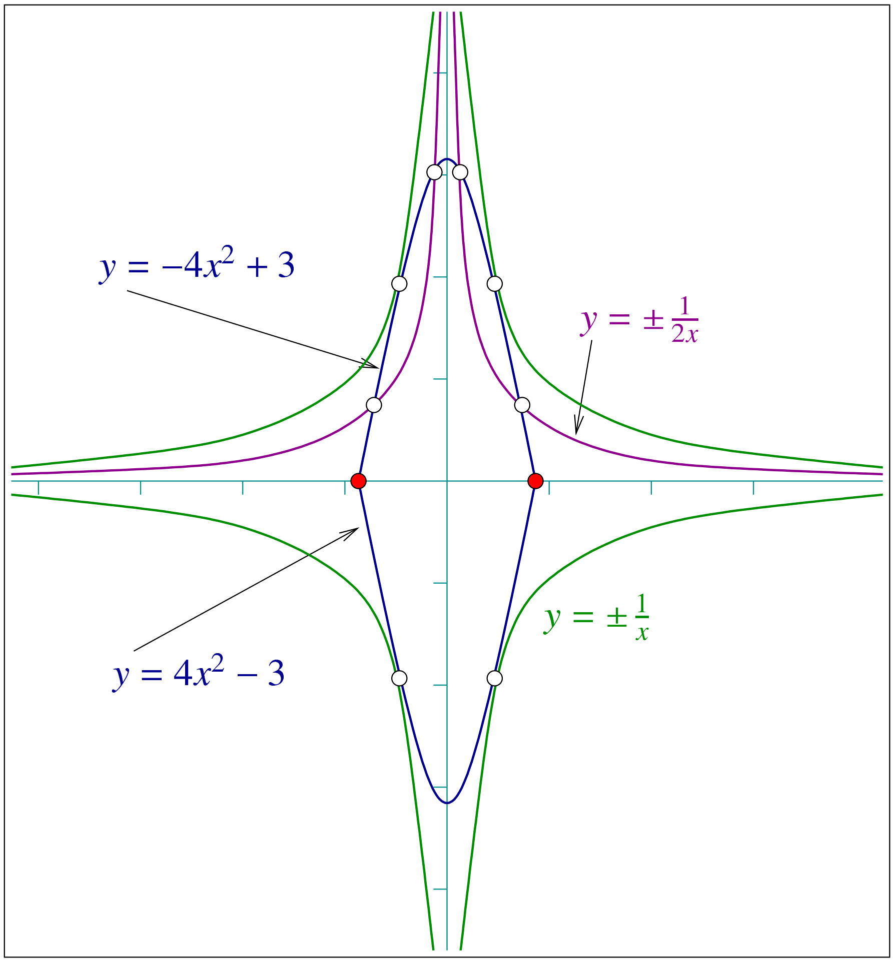

Figure 32.17: An arrangement of six arcs of rational functions, as constructed in *unbounded_rational_functions.cpp*.

```
#include <CGAL/Arrangement_2.h>                          // Arrangement

typedef CORE::BigInt                                       Number_type;
typedef CGAL::Algebraic_kernel_d_1<Number_type>            AK1;
typedef CGAL::Arr_rational_function_traits_2<AK1>          Traits_2;

typedef Traits_2::Polynomial_1                             Polynomial_1;
typedef Traits_2::Algebraic_real_1                         Alg_real_1;

typedef CGAL::Arrangement_2<Traits_2>                      Arrangement_2;

int main ()
{
  CGAL::set_pretty_mode(std::cout);                       // for nice printouts.

  // Traits class object
  AK1 ak1;
  Traits_2 traits(&ak1);
```

```
// constructor for rational functions

32.6.7 A Traits Class for Planar Bézier Curves

A planar *Bézier curve B* is a parametric curve defined by a sequence of *control points* $p_0, \ldots, p_n$ as follows:

$$B(t) = (X(t), Y(t)) = \sum_{k=0}^{n} p_k \cdot \frac{n!}{k!(n-k)!} \cdot t^k (1-t)^{n-k} \,.$$

where $t \in [0,1]$. The degree of the curve is therefore n — namely, $X(t)$ and $Y(t)$ are polynomials of degree n. Bézier curves have numerous applications in computer graphics and solid modelling. They are used, for example, in free-form sketches and for defining the true-type fonts.

Using the *Arr_Bezier_curve_traits_2<RatKernel, AlgKernel, NtTraits>* class template it is possible to construct and maintain arrangements of Bézier curves that are given by rational control points (a sequence of objects of the *RatKernel::Point_2* type). We can handle curves of arbitrary degree (in general, a sequence of $n+1$ control points define a Bézier curve of degree n). The template parameters are the same ones used by the *Arr_conic_traits_2* class template, and here it is also recommended to use the *CORE_algebraic_number_traits* class, with Cartesian kernels instantiated with the *Rational* and *Algebraic* number-types defined by this class.

As mentioned above, we assume that the coordinates of all control points that define a Bézier curve are rational numbers, so both $X(t)$ and $Y(t)$ are polynomials with rational coefficients. The intersection points between curves are however algebraic numbers, and their exact computation is time-consuming. The traits class therefore contains a layer of geometric filtering that performs all computation in an approximate manner whenever possible. Thus, it resorts to exact computations only when the approximate computation fails to produce an unambiguous result. Note that most arrangement vertices are therefore associated with approximated points. You cannot access the coordinates of such points and obtain them as algebraic numbers, and only access to the approximate coordinates in possible. See the Reference Manual for the exact interface of the *Point_2*, *Curve_2* and *X_monotone_curve_2* defined by the traits class.

The *Arr_Bezier_curve_traits_2* is a model of the *ArrangementTraits_2* concept (but not of the *ArrangementLandmarkTraits_2* concept, so it is impossible to use the landmark point-location strategy for arrangements of rational arcs).

The following example reads a set of Bézier curves from an input file, where each file is specified by an integer stating its number of control points, followed by the sequence of control points, given in integer or rational coordinates. By default, the program uses the *Bezier.dat* file, which contains ten curves of degree 5 each; their resulting arrangement is depicted in Figure 32.18.

```
#include <CGAL/basic.h>

#ifndef CGAL_USE_CORE
#include <iostream>
int main ()
{
  std::cout << "Sorry, this example needs CORE ..." << std::endl;
```

32.6.8 A Traits Class for Planar Algebraic Curves of Arbitrary Degree

An algebraic curve C in the plane is defined as the (real) zero locus of a polynomial $f(x,y)$ in two variables. The curve is uniquely defined by f (although several polynomials might define the same curve). We call f a *defining polynomial* of C.

We consider arrangements induced by algebraic curves or by (weakly) x-monotone segments for algebraic curves (Such a segment is not necessarily the maximal possible (weakly) x-monotone segment; see below.) When talking about algebraic curves, we use the term "segment" for a continuous, possibly non-linear subset of an algebraic curve – see the definition below. There are no restrictions on the algebraic curve, that means, we support unbounded curves, vertical curves or segments, and isolated points.

The *Arr_algebraic_segment_traits_2<Coefficient>* class template is a model of the *ArrangementTraits_2* concept (but not of the *ArrangementLandmarkTraits_2* concept, so it is impossible to use the landmark point-location

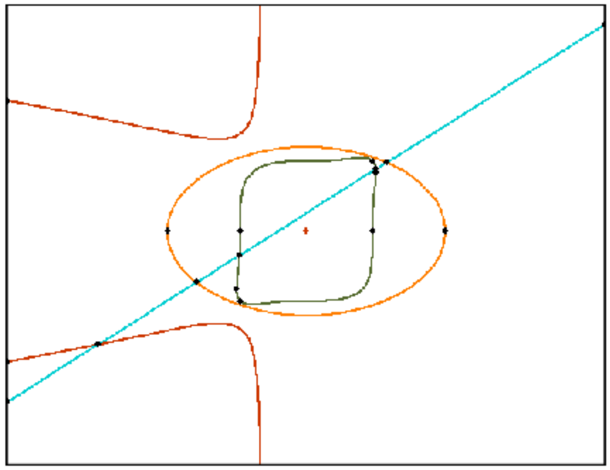

Figure 32.19: An arrangement of algebraic curves of degrees 1, 2, 3, and 6, as constructed in *algebraic_curves.cpp*.

strategy for arrangements of algebraic curves). The template argument *Coefficient* determines the type of the scalar coefficients of the polynomial. Currently supported types are *leda_integer*, *CORE::BigInt*, and any instance of *CGAL::Sqrt_extension<A,B>* instantiated with one of the integral types above.

The traits class defines a type *Curve_2* for algebraic curves. Such a type can be constructed by the *Construct_curve_2* functor, which accepts an instance of *Polynomial_2* as an argument. This polynomial type is also available by the traits class and constitutes a valid model of the concept *Polynomial_d* with two variables (see ??).

The following examples computes the arrangement induced by the four curves in Figure 32.19

```
#include <CGAL/basic.h>
#include <iostream>

#if (!CGAL_USE_CORE) && (!CGAL_USE_LEDA) && (!(CGAL_USE_GMP &&
    CGAL_USE_MPFI))
int main ()
{
  std::cout << "Sorry, this example needs CORE, LEDA, or GMP+MPFI ..."
            << std::endl;
  return 0;

File: examples/Arrangement_on_surface_2/algebraic_curves.cpp

We first give a precise definition of segments of algebraic curves. A point p on a curve $C_f \subset \mathbb{R}^2$ (with f its defining equation) is called *semi-regular*, if locally around p, C_f can be written as a function graph of some continuous function in x or in y (we also say that p is parameterizable in x or y, respectively). The only two cases of non-semi-regular points are isolated points, and self-intersections. A *segment* of a curve is a closed and continuous point set such that each interior point is semi-regular. It follows that a weakly x-monotone segment is either a completely vertical segment, or a segment whose interior points are all parameterizable in x.

The traits class allows to construct weakly x-monotone segments of a curve using the *Construct_x_monotone_segment_2* functor. The *X_monotone_curve_2* type of the traits class represents weakly x-monotone segments of a curve; however, segments may need to be further subdivided into several (sub-)segments, for technical reasons. Therefore, *Construct_x_monotone_segment_2* constructs a sequence of *X_monotone_curve_2* objects, whose union represents the weakly x-monotone segment that was queried. We call a segment *terminal* if it can be represented by the type *X_monotone_curve_2*.

advanced

The subdivision of segments is due to the internal representation of x-monotone segments, which is based on a vertical decomposition. We assume the defining polynomial f of the curve C to be *square-free*, that means, it contains no divisor g^2 of total degree greater than zero. We define a *(complex) critical point* $p \in \mathbb{C}^2$ by

$$f(p) = 0 = \frac{\partial f}{\partial y}(p).$$

An x-coordinate $\alpha \in \mathbb{R}$ is *critical* if either some critical point has x-coordinate α, or if the leading coefficient of f, considered as a polynomial in y, vanishes. In particular, vertical lines of and isolated point of C can only take place at critical x-coordinates. Between two consecutive critical x-coordinates, the curve decomposes into a finite number of x-monotone segments (the same is true on the left of the leftmost, and on the right of the rightmost critical x-coordinate). The type *X_monotone_curve_2* is only able to represent such segments (and sub-segments of them). See Figure 32.20 for an example of a decomposition into terminal segments. Formally, a terminal segment is a weakly x-monotone segment that is either vertical, or its x-range contains no critical point in its interior.

advanced

Coordinates of points are represented by the type *Algebraic_real_1*, which is defined in the traits class. This type is taken from a model of the *AlgebraicKernel_1* concept, which is also available by the type *Algebraic_kernel_1*. One can use this model to create algebraic numbers as roots of univariate polynomials, and process them, for instance, compare them, or approximate them to any precision. See the documentation of *AlgebraicKernel_1* for more information. One can construct an object of type *Point_2* by a triple (x_0,cv,i), which means that the i-th point (counted from below) in the fiber of cv at the x-coordinate x_0 is constructed. This is also how points are presented internally. In the example displayed in Figure 32.20, if x_1 denotes the x-coordinate of p, and *cv*

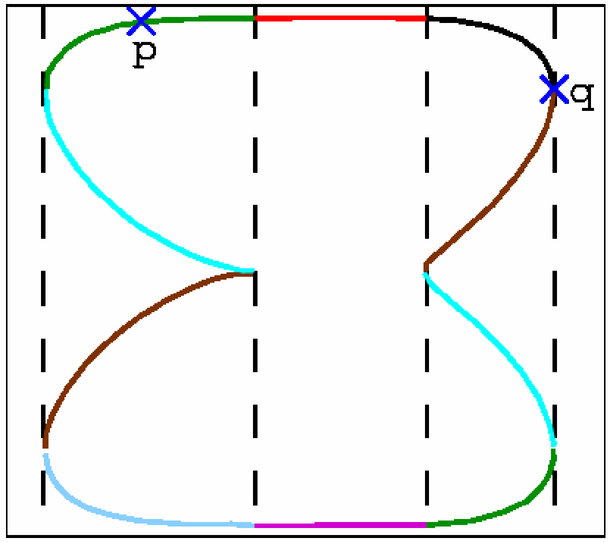

Figure 32.20: The critical x-coordinates of an algebraic curve (dashed lines), and its decomposition into terminal segments (in different colors). The segment from p to q consists of the union of three terminal segments.

represents the algebraic curve, then p could be represented by $(x_1, cv, 3)$. If x_2 is the x-coordinate of q, then $(x_2, cv, 1)$ is a valid representation of q. Although the y-coordinate of an object of type *Point_2* can be queried, we recommend to be careful with that option, since computing an explicit representation of the y-coordinate as an *Algebraic_real_1* object can become rather expensive.

The following code exemplifies various methods to construct algebraic segments. The computed arrangement is displayed in Figure 32.21.

```
#include <CGAL/basic.h>
#include <iostream>

#if (!CGAL_USE_CORE) && (!CGAL_USE_LEDA) && (!(CGAL_USE_GMP &&

32.6.9 Traits-Class Decorators

Geometric traits-class decorators allow you to attach auxiliary data to curves and to points. The data is automatically manipulated by the decorators and distributed to the constructed geometric entities. Note that additional information can alternatively be maintained by extending the vertex, halfedge, or face types provided by the DCEL class used by the arrangement; see the details in Section 32.8.

The arrangement package includes a generic traits-class decorator template named *Arr_curve_data_traits_2<BaseTraits, XMonotoneCurveData, Merge, CurveData, Convert>*. This decorator is used to attach a data field to curves and to x-monotone curves. It is parameterized by a base-traits class, which is one of the geometric traits classes described in the previous subsections, or a user-defined traits class. The curve-data decorator derives itself from the base-traits class, and in particular inherits its *Point_2* type. In addition:

- *Curve_2* is derived from the basic *BaseTraits::Curve_2* class, extending it by an extra field of type *CurveData*.
- *X_monotone_curve_2* is derived from the basic *BaseTraits::X_monotone_curve_2* class, extending it by an extra field of type *XMonotoneCurveData*.

Note that the *Curve_2* and *X_monotone_curve_2* are not the same, even if the *BaseTraits::Curve_2* and *BaseTraits::X_monotone_curve_2* are (as in the case of the segment-traits class for example). The extended curve types support the additional methods *data()* and *set_data()* for accessing and modifying the data field.

You can create an extended curve (or an extended x-monotone curve) from a basic curve and a curve-data object. When curves are inserted into an arrangement, they may be split, and the decorator handles their data fields automatically:

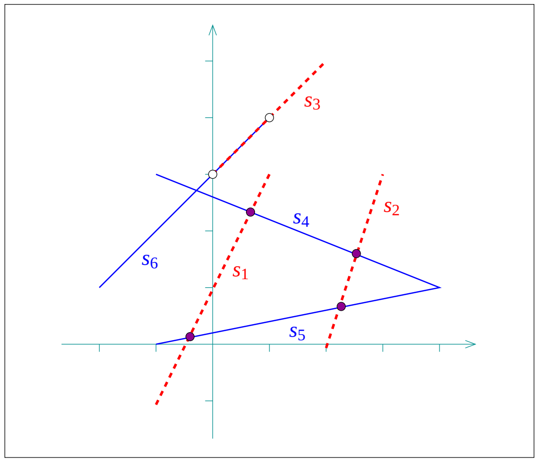

Figure 32.22: An arrangement of six red and blue segments, as constructed in *consolidated_curve_data.cpp*. Disks correspond to red–blue intersection points, while circles mark the endpoints of red–blue overlaps.

- When a curve is subdivided into x-monotone subcurves, its data field of type *CurveData* is converted to an *XMonotoneCurveData* object d using the *Convert* functor. The object d is automatically associated with each of the resulting x-monotone subcurves.

  Note that by default, the *CurveData* type is identical to the *XMonotoneCurveData* type (and the conversion functor *Convert* is trivially defined). Thus, the data field associated with the original curve is just duplicated and stored with the x-monotone subcurves.

- When an x-monotone curve is split into two, the decorator class automatically copies its data field to both resulting subcurves.

- When intersecting two x-monotone curves c_1 and c_2, the result may include overlapping sections, represented as x-monotone curves. In this case the data fields of c_1 and c_2 are merged into a single *XMonotoneCurveData* object, using the *Merge* functor, which is supplied as a parameter to the traits class-template. The resulting object is assigned to the data field of the overlapping subcurves.

- Merging two x-monotone curves is allowed only when (i) the two curves are geometrically mergeable — that is, the base-traits class allows to merge them — and (ii) the two curves store the same data field.

The *Arr_consolidated_curve_data_traits_2<BaseTraits, Data>* decorator specializes the generic curve-data decorator. It extends the basic *BaseTraits::Curve_2* by a single *Data* field, and the basic *BaseTraits::X_monotone_curve_2* with a *set* of (distinct) data objects. The *Data* type is required to support the equality operator, used to ensure that each set contains only distinct data objects with no duplicates. When a curve with a data field d is subdivided into x-monotone subcurves, each subcurve is associated with a set $S = \{d\}$. In case of an overlap between two x-monotone curves c_1 and c_2 with associated data sets S_1 and S_2, respectively, the overlapping subcurve is associated with the consolidated set $S_1 \cup S_2$.

Examples

In the following example, we use *Arr_segment_traits_2* as our base-traits class, attaching an additional *color* field to the segments using the consolidated curve-data traits class. A color may be either *blue* or *red*. Having constructed the arrangement of colored segments, as depicted in Figure 32.22, we detect the vertices that have incident edges mapped to both blue and red segments. Thus, they correspond to red–blue intersection points. We also locate the edge that corresponds to overlaps between red and blue line segments:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_consolidated_curve_data_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_landmarks_point_location.h>

enum Segment_color {
  RED,
  BLUE
};

typedef CGAL::Cartesian<Number_type>                       Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>
    Segment_traits_2;
typedef Segment_traits_2::Curve_2                          Segment_2;
typedef CGAL::Arr_consolidated_curve_data_traits_2
                   <Segment_traits_2, Segment_color>       Traits_2;
typedef Traits_2::Point_2                                  Point_2;
typedef Traits_2::Curve_2
    Colored_segment_2;
typedef CGAL::Arrangement_2<Traits_2>                      Arrangement_2;
typedef CGAL::Arr_landmarks_point_location<Arrangement_2> Landmarks_pl;

int main ()
{
  // Construct an arrangement containing three RED line segments.
  Arrangement_2     arr;
  Landmarks_pl      pl (arr);

  Segment_2         s1 (Point_2(-1, -1), Point_2(1, 3));
  Segment_2         s2 (Point_2(2, 0), Point_2(3, 3));
  Segment_2         s3 (Point_2(0, 3), Point_2(2, 5));

  insert (arr, Colored_segment_2 (s1, RED), pl);
  insert (arr, Colored_segment_2 (s2, RED), pl);
  insert (arr, Colored_segment_2 (s3, RED), pl);

  // Insert three BLUE line segments.
  Segment_2         s4 (Point_2(-1, 3), Point_2(4, 1));
  Segment_2         s5 (Point_2(-1, 0), Point_2(4, 1));
  Segment_2         s6 (Point_2(-2, 1), Point_2(1, 4));

  insert (arr, Colored_segment_2 (s4, BLUE), pl);
  insert (arr, Colored_segment_2 (s5, BLUE), pl);
  insert (arr, Colored_segment_2 (s6, BLUE), pl);

  // Go over all vertices and print just the ones corresponding to
   intersection
  // points between RED segments and BLUE segments. Note that we skip
   endpoints
  // of overlapping sections.
  Arrangement_2::Vertex_const_iterator   vit;
```

```
Segment_color                          color;

for (vit = arr.vertices_begin(); vit != arr.vertices_end(); ++vit) {
  // Go over the incident halfedges of the current vertex and examine
 their
  // colors.
  bool        has_red = false;
  bool        has_blue = false;

  Arrangement_2::Halfedge_around_vertex_const_circulator  eit, first;

  eit = first = vit->incident_halfedges();
  do {
    // Get the color of the current half-edge.
    if (eit->curve().data().size() == 1) {
      color = eit->curve().data().front();

      if (color == RED)
        has_red = true;
      else if (color == BLUE)
        has_blue = true;
    }

    ++eit;
  } while (eit != first);

  // Print the vertex only if incident RED and BLUE edges were found.
  if (has_red && has_blue)
  {
    std::cout << "Red-blue intersection at (" << vit->point() << ")"
              << std::endl;
  }
}

// Locate the edges that correspond to a red-blue overlap.
Arrangement_2::Edge_iterator   eit;

for (eit = arr.edges_begin(); eit != arr.edges_end(); ++eit)
{
  // Go over the incident edges of the current vertex and examine their
  // colors.
  bool        has_red = false;
  bool        has_blue = false;

  Traits_2::Data_container::const_iterator       dit;

  for (dit = eit->curve().data().begin(); dit !=
 eit->curve().data().end();
       ++dit)
  {
    if (*dit == RED)
      has_red = true;
    else if (*dit == BLUE)
      has_blue = true;
```

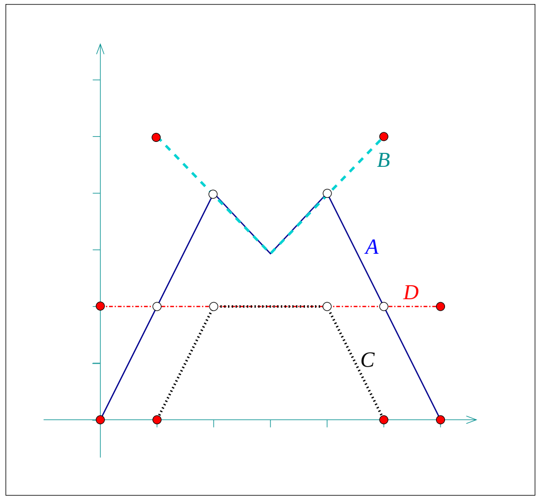

Figure 32.23: An arrangement of four polylines, named A–D, as constructed in *generic_curve_data.cpp*.

```
    }

    // Print the edge only if it corresponds to a red-blue overlap.
    if (has_red && has_blue)
      std::cout << "Red-blue overlap at [" << eit->curve() << "]"  <<
   std::endl;
  }
  return 0;
}
```

File: examples/Arrangement_on_surface_2/consolidated_curve_data.cpp

In the following example, we use *Arr_polyline_traits_2* as our base-traits class, attaching an additional *name* field to each polyline using the generic curve-data traits class. In case of overlaps, we simply concatenate the names of the overlapping polylines. Also notice how we replace the curve associated with the edges that correspond to overlapping polylines with geometrically equivalent curves, but with a different data fields:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_polyline_traits_2.h>
#include <CGAL/Arr_curve_data_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <string>

// Define a functor for concatenating name fields.
typedef std::string   Name;

struct Merge_names
{
  Name operator() (const Name& s1, const Name& s2) const
  {
```

```
    return (s1 + " " + s2);
  }
};

typedef CGAL::Cartesian<Number_type>                      Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                Segment_traits_2;
typedef CGAL::Arr_polyline_traits_2<Segment_traits_2>
   Polyline_traits_2;
typedef Polyline_traits_2::Curve_2                        Polyline_2;
typedef CGAL::Arr_curve_data_traits_2<Polyline_traits_2, Name,
   Merge_names>
                                                          Traits_2;
typedef Traits_2::Point_2                                 Point_2;
typedef Traits_2::Curve_2                                 Curve_2;
typedef Traits_2::X_monotone_curve_2
   X_monotone_curve_2;
typedef CGAL::Arrangement_2<Traits_2>                     Arrangement_2;

int main ()
{
  // Construct an arrangement of four polylines named A--D.

  Arrangement_2::Edge_iterator    eit;

  for (eit = arr.edges_begin(); eit != arr.edges_end(); ++eit) {
    if (eit->curve().data().length() > 1) {
      std::cout << "[" << eit->curve() << "]  "
                << "named: " << eit->curve().data() << std::endl;

      // Rename the curve associated with the edge.
      arr.modify_edge (eit, X_monotone_curve_2 (eit->curve(),
   "overlap"));
    }
  }
  return 0;
}
```

File: examples/Arrangement_on_surface_2/generic_curve_data.cpp

The third example we give in this section is based on *dual_lines.cpp* given in Section 32.5.2. It constructs the arrangement of the dual lines for a set of point given in an input file (by default we use *coll_points.dat*, which contains 50 points randomly selected on the grid $[-100,100] \times [-100,100]$; the file contains two distinct triplets of collinear points). Here we use the generic curve-data decorator to attach the index of the primal point to each of the lines. Doing so, we can go over the incident edges of each vertex whose degree is greater than 4 and report the subsets collinear points (if we have a vertex of degree d, we actually need to go over $\frac{d}{2}$ edges, as each incident line contributes exactly 2 edges). Note that in this case the dual line cannot overlap, so we use a dummy merge functor to instantiate the curve-data traits:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_linear_traits_2.h>
#include <CGAL/Arr_curve_data_traits_2.h>
#include <CGAL/Arrangement_2.h>

typedef CGAL::Cartesian<Number_type>                         Kernel;
typedef CGAL::Arr_linear_traits_2<Kernel>                    Linear_traits_2;
typedef Linear_traits_2::Point_2                             Point_2;
typedef Linear_traits_2::Line_2                              Line_2;
typedef CGAL::Arr_curve_data_traits_2<Linear_traits_2,
                                      unsigned int>      Traits_2;
typedef Traits_2::X_monotone_curve_2
   X_monotone_curve_2;
typedef CGAL::Arrangement_2<Traits_2>                        Arrangement_2;

int main (int argc, char *argv[])
{
  // Get the name of the input file from the command line, or use the
   default
  // points.dat file if no command-line parameters are given.
  const char * filename = (argc > 1) ? argv[1] : "coll_points.dat";

  // Open the input file.
  std::ifstream     in_file (filename);

  if (! in_file.is_open()) {
    std::cerr << "Failed to open " << filename << " ..." << std::endl;
    return (1);
  }

  // Read the points from the file, and consturct their dual lines.
  std::vector<Point_2>            points;
  std::list<X_monotone_curve_2>   dual_lines;

  unsigned int n;
  in_file >> n;
  points.resize (n);
  unsigned int k;
  for (k = 0; k < n; ++k) {
    int px, py;
    in_file >> px >> py;
```

```
    points[k] = Point_2 (px, py);

    // The line dual to the point (p_x, p_y) is y = p_x*x - p_y,
    // or: p_x*x - y - p_y = 0:
    Line_2 dual_line = Line_2(Number_type(px),
                              Number_type(-1),
                              Number_type(-py));

    // Generate the x-monotone curve based on the line and the point
   index.
    dual_lines.push_back (X_monotone_curve_2 (dual_line, k));
  }
  in_file.close();

  // Construct the dual arrangement by aggragately inserting the lines.
  Arrangement_2      arr;

  insert (arr, dual_lines.begin(), dual_lines.end());

  // Look for vertices whose degree is greater than 4.
  Arrangement_2::Vertex_const_iterator                    vit;
  Arrangement_2::Halfedge_around_vertex_const_circulator  circ;
  unsigned int                                            d;

  for (vit = arr.vertices_begin(); vit != arr.vertices_end(); ++vit) {
    if (vit->degree() > 4) {
      // There should be vit->degree()/2 lines intersecting at the
   current
      // vertex. We print their primal points and their indices.
      circ = vit->incident_halfedges();
      for (d = 0; d < vit->degree() / 2; d++) {
        k = circ->curve().data();      // The index of the primal point.
        std::cout << "Point no. " << k+1 << ": (" << points[k] << "), ";
        ++circ;
      }
      std::cout << "are collinear." << std::endl;
    }
  }
  return 0;
}
```

32.7 The Notification Mechanism

For some applications it is essential to know exactly what happens inside a specific arrangement-instance. For example, when a new curve is inserted into an arrangement, it might be desired to keep track of the faces that are split due to this insertion operation. Other important examples are the point-location strategies that require auxiliary data-structures (see Section 32.3.1), which must be notified on various local changes in the arrangement, in order to keep their data structures up-to-date. The arrangement package offers a mechanism that uses *observers* (see [GHJV95]) that can be attached to an arrangement instance and receive notifications about the changes this arrangement goes through.

The *Arr_observer<Arrangement>* class-template is parameterized with an arrangement class. It stores a pointer to an arrangement object, and is capable of receiving notifications *just before* a structural change occurs in the arrangement and *immediately after* such a change takes place. *Arr_observer* serves as a base class for other observer classes and defines a set of virtual notification functions, with default empty implementations.

The set of functions can be divided into three categories, as follows:

1. Notifiers of changes that affect the entire topological structure of the arrangement. This category consists of two pairs that notify the observer of the following changes:
   - The arrangement is cleared.
   - The arrangement is assigned with the contents of another arrangement.
2. Pairs of notifiers of a local change that occurs in the topological structure. Most notifier functions belong to this category. The relevant local changes include:
   - A new vertex is constructed and associated with a point.
   - An edge[19] is constructed and associated with an x-monotone curve.
   - An edge is split into two edges.
   - An existing face is split into two faces, as a consequence of the insertion of a new edge.
   - A hole is created in the interior of a face.
   - Two holes are merged to form a single hole, as a consequence of the insertion of a new edge.
   - A hole is moved from one face to another, as a consequence of a face split.
   - Two edges are merged into one edge.
   - Two faces are merged into one face, as a consequence of the removal of an edge that used to separate them.
   - One hole is split into two, as a consequence of the deletion of an edge that used to connect the two components.
   - A vertex is removed.
   - An edge is removed.
   - A hole is deleted from the interior of a face.
3. Notifiers about a change applied by a free (global) function. This category consists of a single pair of notifiers, namely *before_global_change()* and *after_global_change()*. Neither of these functions is invoked by methods of the *Arrangement_2* class. Instead, they are called by the free functions themselves. It is implied that no point-location queries (or any other queries for that matter) are issued between the calls to the notification functions above.

See the Reference Manual for a detailed specification of the *Arr_observer* class along with the exact prototypes of all notification functions.

Each arrangement object stores a (possibly empty) list of pointers to *Arr_observer* objects, and whenever one of the structural changes listed in the first two categories above is about to take place, the arrangement object performs a *forward* traversal on this list and invokes the appropriate function of each observer. After the change takes place the observer list is traversed in a *backward* manner (from tail to head), and the appropriate notification function is invoked for each observer. This allows the nesting of observer objects.

[19]The term “edge” refers here to a pair of twin half-edges.

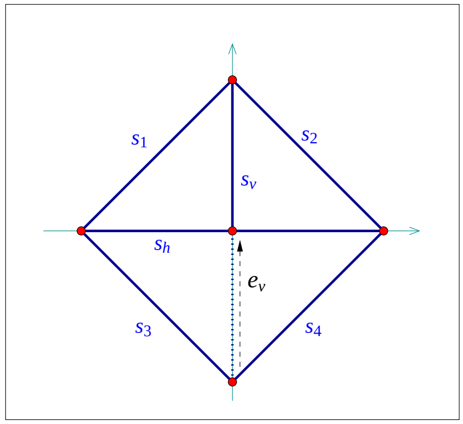

Figure 32.24: An arrangement of five line segments, as constructed in *observer.cpp*. The halfedge e_v (dashed) is eventually removed, so that the final arrangement consists of four faces (one unbounded and three bounded ones).

Concrete arrangement-observer classes should inherit from *Arr_observer*. When an observer is constructed, it is attached to a valid arrangement supplied to the observed constructor, or alternatively the observer can be attached to the arrangement at a later time. When this happens, the observer instance inserts itself into the observer list of the associated arrangement and starts receiving notifications whenever this arrangement changes thereafter. Naturally, the observer object unregisters itself by removing itself from this list just before it is destroyed.

The trapezoidal RIC and the landmark point-location strategies both use observers to keep their auxiliary data structures up-to-date. Besides them, users can define their own observer classes, by inheriting from the base observer class and overriding the relevant notification functions, as required by their applications.

The following example shows how to define and use an observer class. The observer in the example keeps track of the arrangement faces, and prints a message whenever a face is split into two due to the insertion of an edge, and whenever two faces merge into one due to the removal of an edge. The layout of the arrangement is depicted in Figure 32.24:

```
#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_observer.h>

typedef CGAL::Quotient<CGAL::MP_Float>                    Number_type;
typedef CGAL::Cartesian<Number_type>                      Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                Traits_2;
typedef Traits_2::Point_2                                 Point_2;
typedef Traits_2::X_monotone_curve_2                      Segment_2;
typedef CGAL::Arrangement_2<Traits_2>                     Arrangement_2;

// An arrangement observer, used to receive notifications of face splits
   and
// face mergers.
class My_observer : public CGAL::Arr_observer<Arrangement_2>
{
```

```
public:

  My_observer (Arrangement_2& arr) :
    CGAL::Arr_observer<Arrangement_2> (arr)
  {}

  return 0;
}
```

File: examples/Arrangement_on_surface_2/observer.cpp

Observers are especially useful when the DCEL records are extended and store additional data, as they help updating this data on-line. See Section 32.8 for more details and examples.

32.8 Extending the DCEL

For many applications of the arrangement package it is necessary to store additional information (perhaps of non-geometric nature) with the arrangement cells. As vertices are associated with *Point_2* objects and edges (halfedge pairs) are associated with *X_monotone_curve_2* objects, both defined by the traits class, it is possible to extend the traits-class type by using a traits-class decorator, as explained in Section 32.6.9, which may be a sufficient solution for some applications. However, the DCEL faces are not associated with any geometric object, so it is impossible to extend them using a traits-class decorator. Extending the DCEL face records comes handy is such cases. As a matter of fact, it is possible to conveniently extend all DCEL records (namely vertices, halfedges and faces), which can also be advantageous for some applications.

All examples presented so far use the default *Arr_default_dcel<Traits>*. This is done implicitly, as this class serves as a default parameter for the *Arrangement_2* template. The default DCEL class just associates points with vertices and *x*-monotone curves with halfedge, but nothing more. In this section we show how to use alternative DCEL types to extend the desired DCEL records.

32.8.1 Extending the DCEL Faces

The *Arr_face_extended_dcel<Traits, FaceData>* class-template is used to associate auxiliary data field of type *FaceData* to each face record in the DCEL.

When an *Arrangement_2* object is parameterized by this DCEL class, its nested *Face* type is extended with the access function *data()* and with the modifier *set_data()*. Using these extra functions it is straightforward to access and maintain the auxiliary face-data field.

Note that the extra data fields must be maintained by the application programmers. They may choose to construct their arrangement, and only then go over the faces and attach the appropriate data fields to the arrangement faces. However, in some cases the face data can only be computed when the face is created (split from another face, or merged with another face). In such cases one can use an arrangement observer tailored for this task, which receives updates whenever a face is modified and sets its data field accordingly.

The next example constructs an arrangement that contains seven bounded faces induced by six line segments (see Figure 32.25). An observer gets notified each time a new face f is created and it associates f with a

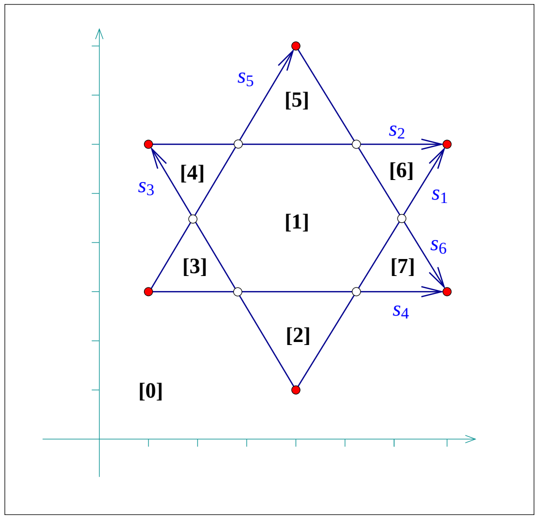

Figure 32.25: An arrangement of six line segments, as constructed in *face_extension.cpp* and *dcel_extension.cpp* (in *dcel_extension.cpp* we treat the segments as directed, so they are drawn as arrows directed from the source to the target). The indices associated with the halfedges in *face_extension.cpp* are shown in brackets.

running index, (where the index of the unbounded face is 0). As a result, the faces are numbered according to their creation order, as one can easily verify by examining the insertion order of the segments:[20]

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arr_observer.h>

typedef CGAL::Cartesian<Number_type>                          Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                    Traits_2;
typedef Traits_2::Point_2                                     Point_2;
typedef Traits_2::X_monotone_curve_2                          Segment_2;
typedef CGAL::Arr_face_extended_dcel<Traits_2, int>           Dcel;
typedef CGAL::Arrangement_2<Traits_2, Dcel>                   Arrangement_2;

// An arrangement observer, used to receive notifications of face splits
   and
// to update the indices of the newly created faces.
class Face_index_observer : public CGAL::Arr_observer<Arrangement_2>
{
private:
  int      n_faces;          // The current number of faces.

public:

  Face_index_observer (Arrangement_2& arr) :
    CGAL::Arr_observer<Arrangement_2> (arr),
```

[20]For simplicity, the particular observer used must be attached to an empty arrangement. It is not difficult however to modify the program to handle the general case of attaching a similar observer to a non-empty arrangement.

```
    n_faces (0)
  {
    CGAL_precondition (arr.is_empty());

    arr.unbounded_face()->set_data (0);
    n_faces++;
  }

  virtual void after_split_face (Face_handle /* old_face */,
                                 Face_handle new_face, bool )
  {
    // Assign index to the new face.
    new_face->set_data (n_faces);
    n_faces++;
  }
};

  Segment_2      s4 (Point_2(1, 3), Point_2(7, 3));
  Segment_2      s5 (Point_2(1, 3), Point_2(4, 8));
  Segment_2      s6 (Point_2(4, 8), Point_2(7, 3));

  insert_non_intersecting_curve (arr, s1);
  insert_non_intersecting_curve (arr, s2);
  insert_non_intersecting_curve (arr, s3);
  insert (arr, s4);
  insert (arr, s5);
  insert (arr, s6);

  // Go over all arrangement faces and print the index of each face and
   it
  // outer boundary. The face index is stored in its data field in our
   case.
  Arrangement_2::Face_const_iterator            fit;
  Arrangement_2::Ccb_halfedge_const_circulator  curr;

  std::cout << arr.number_of_faces() << " faces:" << std::endl;
  for (fit = arr.faces_begin(); fit != arr.faces_end(); ++fit) {
    std::cout << "Face no. " << fit->data() << ": ";
    if (fit->is_unbounded())
      std::cout << "Unbounded." << std::endl;
    else {
      curr = fit->outer_ccb();
      std::cout << curr->source()->point();
      do {
        std::cout << " --> " << curr->target()->point();
```

```
        ++curr;
      } while (curr != fit->outer_ccb());
      std::cout << std::endl;
    }
  }

  return 0;
}
```

File: examples/Arrangement_on_surface_2/face_extension.cpp

32.8.2 Extending All DCEL Records

The *Arr_extended_dcel<Traits, VertexData, HalfedgeData, FaceData>* class-template is used to associate auxiliary data fields of types *VertexData HalfedgeData*, and *FaceData* to each DCEL vertex, halfedge, and face record types, respectively.

When an *Arrangement_2* object is injected with this DCEL class, each one of its nested *Vertex*, *Halfedge* and *Face* classes is extended by the access function *data()* and by the modifier *set_data()*.

The next example shows how to use a DCEL with extended vertex, halfedge, and face records. In this example each vertex is associated with a color, which may be blue, red, or white, depending on whether the vertex is isolated, represents a segment endpoint, or whether it represents an intersection point. Each halfedge is associated with Boolean flag indicating whether its direction is the same as the direction of its associated segment (in this example segments are treated as directed objects). Each face is also extended to store the size of its outer boundary.

The constructed arrangement, depicted in Figure 32.25, is similar to the arrangement constructed in the previous example. Note that all auxiliary data fields are set during the construction phase. Also note that the data fields are properly maintained when the arrangement is copied to another arrangement instance:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_extended_dcel.h>

enum Color {BLUE, RED, WHITE};

typedef CGAL::Cartesian<Number_type>                              Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                        Traits_2;
typedef Traits_2::Point_2                                         Point_2;
typedef Traits_2::X_monotone_curve_2
   Segment_2;
typedef CGAL::Arr_extended_dcel<Traits_2,Color, bool, int>       Dcel;
typedef CGAL::Arrangement_2<Traits_2, Dcel>
   Arrangement_2;

int main ()
{
  // Construct the arrangement containing two intersecting triangles.
```

```
Arrangement_2          arr;

Segment_2      s1 (Point_2(4, 1), Point_2(7, 6));
Segment_2      s2 (Point_2(1, 6), Point_2(7, 6));
Segment_2      s3 (Point_2(4, 1), Point_2(1, 6));
Segment_2      s4 (Point_2(1, 3), Point_2(7, 3));
Segment_2      s5 (Point_2(1, 3), Point_2(4, 8));
Segment_2      s6 (Point_2(4, 8), Point_2(7, 3));

insert_non_intersecting_curve (arr, s1);
insert_non_intersecting_curve (arr, s2);
insert_non_intersecting_curve (arr, s3);
insert (arr, s4);
insert (arr, s5);
insert (arr, s6);

// Go over all arrangement vertices and set their colors according to
 our
// coloring convention.
Arrangement_2::Vertex_iterator            vit;
unsigned int                              degree;

for (vit = arr.vertices_begin(); vit != arr.vertices_end(); ++vit)
{
  degree = vit->degree();
  if (degree == 0)
    vit->set_data (BLUE);       // Isolated vertex.
  else if (degree <= 2)
    vit->set_data (RED);        // Vertex represents an endpoint.
  else
    vit->set_data (WHITE);      // Vertex represents an intersection
 point.
}

// Go over all arrangement edges and set their flags.
Arrangement_2::Edge_iterator              eit;
bool                                      flag;

for (eit = arr.edges_begin(); eit != arr.edges_end(); ++eit) {
  // Check if the halfegde has the same diretion as its associated
  // segment. Note that its twin always has an opposite direction.
  flag = (eit->source()->point() == eit->curve().source());
  eit->set_data (flag);
  eit->twin()->set_data (!flag);
}

// For each arrangement face, print the outer boundary and its size.
Arrangement_2::Face_iterator              fit;
Arrangement_2::Ccb_halfedge_circulator    curr;
int                                       boundary_size;

for (fit = arr.faces_begin(); fit != arr.faces_end(); ++fit) {
  boundary_size = 0;
  if (! fit->is_unbounded()) {
```

```
      curr = fit->outer_ccb();
      do {
        ++boundary_size;
        ++curr;
      } while (curr != fit->outer_ccb());
    }
    fit->set_data (boundary_size);
  }

  // Copy the arrangement and print the vertices.
  Arrangement_2    arr2 = arr;

  std::cout << "The arrangement vertices:" << std::endl;
  for (vit = arr2.vertices_begin(); vit != arr2.vertices_end(); ++vit) {
    std::cout << '(' << vit->point() << ") - ";
    switch (vit->data()) {
     case BLUE  : std::cout << "BLUE."  << std::endl; break;
     case RED   : std::cout << "RED."   << std::endl; break;
     case WHITE : std::cout << "WHITE." << std::endl; break;
    }
  }

  return 0;
}
```

advanced

The various DCEL classes presented in this section are perfectly sufficient for most applications based on the arrangement package. However, users may also use their own implementation of a DCEL class to instantiate the *Arrangement_2* class-template, in case they need special functionality from their DCEL. Such a class must be a model of the concept *ArrangementDcel*, whose exact specification is listed in the Reference Manual.

advanced

32.9 Overlaying Arrangements

Assume that we are given two geographic maps represented as arrangements with some data objects attached to their faces, representing some geographic information — for example, a map of the annual precipitation in some country and a map of the vegetation in the same country. It is interesting to overlay the two maps to locate, for example, the regions where there is a pine forest and the annual precipitation is between 1000 mm and 1500 mm.

Computing the overlay of two planar arrangement is also useful for supporting Boolean set operations on polygons (or generalized polygons, see, e.g., [BEH+02]).

The function *overlay (arr_a, arr_b, ovl_arr, ovl_traits)* accepts two input arrangement instances *arr_a* and *arr_b*, and constructs their overlay instance *ovl_arr*. All three arrangements must use the same geometric primitives. More precisely, let *arr_a* be of type *Arrangement_2<Traits_A,Dcel_A>*, *arr_b* be of type *Arrangement_2<Traits_B,Dcel_B>* and the resulting *ovl_arr* be of type *Arrangement_2<Traits_R,Dcel_R>*. All types nested in geometry traits *Traits_A*, e.g., *Point_2* and *X_monotone_curve_2*, must be convertible to the corresponding types nested in geometry traits *Traits_R*. The same holds for all types nested in geometry traits *Traits_B*. The *ovl_traits* parameter is an instance of an *overlay traits-class*, which enables the creation of *Dcel_R* records in the overlaid arrangement from the DCEL features of *arr_a* and *arr_b* that they correspond to.

In principle, we distinguish between three levels of overlay:

Simple overlay: An overlay of two arrangements that store no additional data with their DCEL records. That is, they are defined using the default DCEL class *Arr_default_dcel*. Typically, the overlaid arrangement in this case stores no extra data with its DCEL records as well (or if it does, the additional data fields cannot be computed by the overlay operation), so by overlaying the two arrangement we just compute the arrangement of all curves that induce *arr_a* and *arr_b*. Note that the same result can be obtained using the standard insertion operations, but users may choose to use overlay computation in order to achieve better running times.

The *Arr_default_overlay_traits* class should be used as an overlay traits-class for such simple overlay operations.

Face overlay: An overlay of two arrangements that store additional data fields with their faces (e.g., the geographic-map example given in the beginning of this section). The resulting overlaid arrangement typically also stores extraneous data fields with its faces, where the data field that is attached to an overlaid face can be computed from the data fields of the two faces (in *arr_a* and *arr_b*) that induce the overlaid face.

The *Arr_face_overlay_traits* class should be used as an overlay traits-class for face-overlay operations. It operates on arrangement, whose DCEL representation is based on the *Arr_face_extended_dcel* class-template (see Section 32.8.1). The face-overlay traits-class is parameterized by a functor that is capable of combining two face-data fields of types *Dcel_A::Face_data* and *Dcel_B::Face_data*, and computing the output *Dcel_R::Face_data* object. The overlay traits-class uses this functor to properly construct the overlaid faces.

Full overlay: An overlay of two arrangements that store additional data fields with all their DCEL records. That is, their DCEL classes are instantiations of the *Arr_extended_dcel* class-template (see Section 32.8.2), where the resulting arrangement also extends it DCEL records with data fields computed on the basis of the overlapping DCEL features of the two input arrangements.

In the following subsections we give some examples for the simple and the face-overlay operations and demonstrate how to use the auxiliary overlay traits-classes. For the full overlay operations users need to implement their specialized overlay traits-class, which models the *OverlayTraits* concept. The details of this concept are given in the Reference Manual.

32.9.1 Example for a Simple Overlay

The next program constructs two simple arrangements, as depicted in Figure 32.26 and computes their overlay:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_overlay_2.h>
#include <CGAL/Arr_default_overlay_traits.h>

typedef CGAL::Cartesian<Number_type>                    Kernel;
```

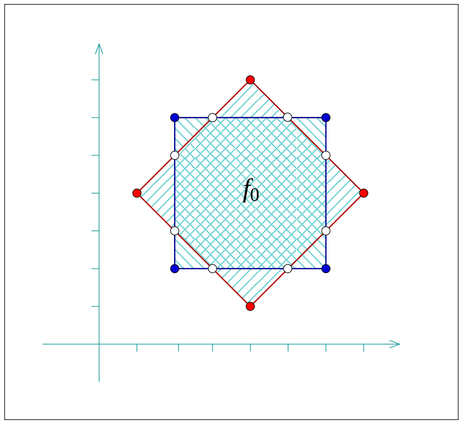

Figure 32.26: Overlaying two simple arrangements of line segments, as done in *overlay.cpp* and *ex_face_extension_overlay.cpp*. In *face_extension_overlay.cpp* the two bounded faces are considered as *marked*, and the octagonal face which is the intersection of the two marked faces is denoted by f_0.

```
typedef CGAL::Arr_segment_traits_2<Kernel>                    Traits_2;
typedef Traits_2::Point_2                                     Point_2;
typedef Traits_2::X_monotone_curve_2                          Segment_2;
typedef CGAL::Arrangement_2<Traits_2>                         Arrangement_2;
typedef CGAL::Arr_default_overlay_traits<Arrangement_2>  Overlay_traits;

int main ()
{
  // Construct the first arrangement, containing a square-shaped face.
  Arrangement_2          arr1;

  Segment_2      s1 (Point_2(2, 2), Point_2(6, 2));
  Segment_2      s2 (Point_2(6, 2), Point_2(6, 6));
  Segment_2      s3 (Point_2(6, 6), Point_2(2, 6));
  Segment_2      s4 (Point_2(2, 6), Point_2(2, 2));

  insert_non_intersecting_curve (arr1, s1);
  insert_non_intersecting_curve (arr1, s2);
  insert_non_intersecting_curve (arr1, s3);
  insert_non_intersecting_curve (arr1, s4);

  // Construct the second arrangement, containing a rhombus-shaped face.
  Arrangement_2          arr2;

  Segment_2      t1 (Point_2(4, 1), Point_2(7, 4));
  Segment_2      t2 (Point_2(7, 4), Point_2(4, 7));
  Segment_2      t3 (Point_2(4, 7), Point_2(1, 4));
  Segment_2      t4 (Point_2(1, 4), Point_2(4, 1));

  insert_non_intersecting_curve (arr2, t1);
  insert_non_intersecting_curve (arr2, t2);
  insert_non_intersecting_curve (arr2, t3);
  insert_non_intersecting_curve (arr2, t4);

  // Compute the overlay of the two arrangements.
```

```
  Arrangement_2          overlay_arr;
  Overlay_traits         overlay_traits;

  overlay (arr1, arr2, overlay_arr, overlay_traits);

  // Print the size of the overlaid arrangement.
  std::cout << "The overlaid arrangement size:" << std::endl
            << "   V = " << overlay_arr.number_of_vertices()
            << ",  E = " << overlay_arr.number_of_edges()
            << ",  F = " << overlay_arr.number_of_faces() << std::endl;

  return 0;
}
```

32.9.2 Examples for a Face Overlay

The following example shows how to compute the intersection of two polygons using the *overlay()* function. It uses a face-extended DCEL class to define our arrangement class. The DCEL extends each face with a Boolean flag. A polygon is represented as a *marked* arrangement face, (whose flag is set). The example uses a face-overlay traits class, instantiated with a functor that simply performs a logical *and* operations on Boolean flags. As a result, a face in the overlaid arrangement is marked only when it corresponds to an overlapping region of two marked cells in the input arrangements. Namely, it is part of the intersection of the two polygons.

The example computes the intersection between a square and a rhombus, (which is actually also a square). The resulting polygon is an octagon, denoted by f_0 in Figure 32.26:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arr_overlay_2.h>
#include <CGAL/Arr_default_overlay_traits.h>

typedef CGAL::Cartesian<Number_type>                          Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                    Traits_2;
typedef Traits_2::Point_2                                     Point_2;
typedef Traits_2::X_monotone_curve_2
   Segment_2;
typedef CGAL::Arr_face_extended_dcel<Traits_2, bool>          Dcel;
typedef CGAL::Arrangement_2<Traits_2, Dcel>
   Arrangement_2;
typedef CGAL::Arr_face_overlay_traits<Arrangement_2,
                                      Arrangement_2,
                                      Arrangement_2,
                                      std::logical_and<bool> >
   Overlay_traits;

int main ()
```

```
{
  // Construct the first arrangement, containing a square-shaped face.
  Arrangement_2          arr1;

  Segment_2      s1 (Point_2(2, 2), Point_2(6, 2));
  Segment_2      s2 (Point_2(6, 2), Point_2(6, 6));
  Segment_2      s3 (Point_2(6, 6), Point_2(2, 6));
  Segment_2      s4 (Point_2(2, 6), Point_2(2, 2));

  insert_non_intersecting_curve (arr1, s1);
  insert_non_intersecting_curve (arr1, s2);
  insert_non_intersecting_curve (arr1, s3);
  insert_non_intersecting_curve (arr1, s4);

  // Mark just the bounded face.
  Arrangement_2::Face_iterator   fit;

  CGAL_assertion (arr1.number_of_faces() == 2);
  for (fit = arr1.faces_begin(); fit != arr1.faces_end(); ++fit)
    fit->set_data (fit != arr1.unbounded_face());

  // Construct the second arrangement, containing a rhombus-shaped face.
  Arrangement_2          arr2;

  Segment_2      t1 (Point_2(4, 1), Point_2(7, 4));
  Segment_2      t2 (Point_2(7, 4), Point_2(4, 7));
  Segment_2      t3 (Point_2(4, 7), Point_2(1, 4));
  Segment_2      t4 (Point_2(1, 4), Point_2(4, 1));

  insert_non_intersecting_curve (arr2, t1);
  insert_non_intersecting_curve (arr2, t2);
  insert_non_intersecting_curve (arr2, t3);
  insert_non_intersecting_curve (arr2, t4);

  // Mark just the bounded face.
  CGAL_assertion (arr2.number_of_faces() == 2);
  for (fit = arr2.faces_begin(); fit != arr2.faces_end(); ++fit)
    fit->set_data (fit != arr2.unbounded_face());

  // Compute the overlay of the two arrangements, marking only the faces
   that
  // are intersections of two marked faces in arr1 and arr2,
   respectively.
  Arrangement_2          overlay_arr;
  Overlay_traits         overlay_traits;

  overlay (arr1, arr2, overlay_arr, overlay_traits);

  // Go over the faces of the overlaid arrangement and print just the
   marked
  // ones.
  Arrangement_2::Ccb_halfedge_circulator    curr;

  std::cout << "The union is: ";
```

```
  for (fit = overlay_arr.faces_begin(); fit != overlay_arr.faces_end();
   ++fit) {
    if (! fit->data())
      continue;

    curr = fit->outer_ccb();
    std::cout << curr->source()->point();
    do {
      std::cout << " --> " << curr->target()->point();
      ++curr;
    } while (curr != fit->outer_ccb());
    std::cout << std::endl;
  }

  return 0;
}
```

File: examples/Arrangement_on_surface_2/face_extension_overlay.cpp

The next example demonstrates the face overlay of two arrangements that have unbounded faces as well. The first arrangement is formed by the two lines $y = x$ and $y = -x$, that subdivide the plane into four unbounded faces, denoted A, B, C and D. The second arrangement comprises four line segments that form a square-shaped face. When we overlay the two arrangements, each of the four faces A, B, C and D is split into an unbounded face (indexed 1) and a bounded face (indexed 2):

```
#include <string>
#include <boost/lexical_cast.hpp>

#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Arr_linear_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arr_overlay_2.h>
#include <CGAL/Arr_default_overlay_traits.h>

// Define a functor for creating a label from a characer and an integer.
struct Overlay_label
{
  std::string operator() (char c, int i) const
  {
    return boost::lexical_cast<std::string>(c) +
      boost::lexical_cast<std::string>(i);
  }
};

typedef CGAL::Exact_predicates_exact_constructions_kernel   Kernel;
typedef CGAL::Arr_linear_traits_2<Kernel>                   Traits_2;

  }

  return 0;
}
```

File: examples/Arrangement_on_surface_2/overlay_unbounded.cpp

32.10 Storing the Curve History

As stated at the beginning of this chapter (Section 32.1), when one constructs an arrangement induced by a set $\mathcal{C}$ of arbitrary planar curves, she or he constructs a collection $\mathcal{C}''$ of x-monotone subcurves of $\mathcal{C}$ that are pairwise disjoint in their interior, and these subcurves are associated with the arrangement edges (more precisely, with the DCEL halfedges). Doing so, the connection between the originating input curves and the arrangement edges is lost. This loss might be acceptable for some applications. However, in many practical cases it is important to determine the input curves that give rise to the final subcurves.

The *Arrangement_with_history_2<Traits,Dcel>* class-template extends the *Arrangement_2* class by keeping an additional container of input curves representing $\mathcal{C}$, and by maintaining a cross-mapping between these curves and the arrangement edges they induce. The traits class that is used for instantiating the template should be a model of the *ArrangementTraits_2* concept (see Section 32.4.1). That is, it should define the *Curve_2* type (and not just the *X_monotone_curve_2* type). The *Dcel* parameter should model the *ArrangementDcel* concept. Users can use the default DCEL class or an extended DCEL class according to their needs.

32.10.1 Traversing an Arrangement with History

The *Arrangement_with_history_2* class extends the *Arrangement_2* class, thus all the iterator and circulator types that are defined by the arrangement class are also available in *Arrangement_with_history_2*. The reader is referred to Section 32.2.2 for a comprehensive review of these functions.

As mentioned above, the *Arrangement_with_history_2* class maintains a container of input curves, which can be accessed using curve handles. The member function *number_of_curves()* returns the number of input curves stored in the container, while *curves_begin()* and *curves_end()* return *Arrangement_with_history_2::Curve_iterator* objects that define the valid range of curves that induce the arrangement. The value type of this iterator is *Curve_2*. Moreover, the curve-iterator type is equivalent to *Arrangement_with_history_2::Curve_handle*, which is used for accessing the stored curves. Conveniently, the corresponding constant-iterator and constant-handle types are also defined.

As mentioned in the previous paragraph, a *Curve_handle* object *ch* serves as a pointer to a curve stored in an arrangement-with-history instance *arr*. Using this handle, it is possible to obtain the number of arrangement edges this curve induces by calling *arr.number_of_induced_edges(ch)*. The functions *arr.induced_edges_begin(ch)* and *arr.induced_edges_end(ch)* return iterators of type *Arrangement_with_history_2::Induced_edges_iterator* that define the valid range of edges induced by *ch*. The value type of these iterators is *Halfedge_handle*. It is thus possible to traverse all arrangement edges induced by an input curve.

It is also important to be able to perform the inverse mapping. Given an arrangement edge, we would like to be able to determine which input curve induces it. In case the edge represents an overlap of several curves, we should be able to trace all input curves that overlap over this edge. The *Arrangement_with_history_2* class is extended by several member functions that enable such an inverse mapping. Given a halfedge handle *e* in an arrangement with history *arr*, then *arr.number_of_originating_curves(e)* returns the number of curves that induce the edge (which should be 1 in non-degenerate cases, and 2 or more in case of overlaps), while *arr.originating_curves_begin(e)* and *arr.originating_curves_end(e)* return *Arrangement_with_history_2::Originating_curve_iterator* objects that define the range of curves that induce *e*. The value type of these iterator is *Curve_2*.

It is possible to overlay two *Arrangement_with_history_2* instances instantiated by the same traits class. In this case, the resulting arrangement will store a consolidated container of input curves, and automatically preserve the cross-mapping between the arrangement edges and the consolidated curve set. Users can employ an overlay-traits class to maintain any type of auxiliary data stored with the DCEL features (see Section 32.9).

32.10.2 Modifying an Arrangement with History

As the *Arrangement_with_history_2* class extends the *Arrangement_2* class, it inherits the fundamental modification operations, such as *assign()* and *clear()*, from it. The vertex-manipulation functions are also inherited and supported (see Sections 32.2.3 and 32.4.1 for the details). However, there are some fundamental differences between the interfaces of the two classes, which we highlight in this subsection.

The most significant difference between the arrangement-with-history class and the basic arrangement class is the way they handle their input curves. *Arrangement_with_history_2* always stores the *Curve_2* objects that induce it, thus it is impossible to insert x-monotone curves into an arrangement with history. The free *insert_non_intersecting_curve()* and *insert()* that receives x-monotone curve (as well as their aggregated versions) are therefore not available for arrangement-with-history instances and only the free *insert()* and *insert()* functions that receive *Curve_2* (the incremental insertion function and the aggregated insertion function) are supported — see also Section 32.4.1. Notice however that while the incremental insertion function *insert(arr,c)* for an *Arrangement_2* object *arr* does not have a return value, the corresponding arrangement-with-history function returns a *Curve_handle* to the inserted curve.

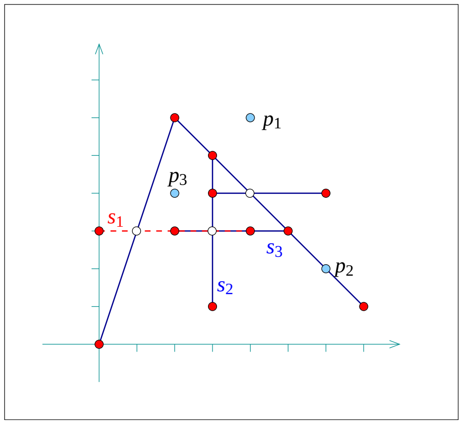

Figure 32.27: An arrangement with history as constructed in *curve_history.cpp*. Note that s_1 and s_3 overlap over two edges. The point-location query points are drawn as lightly shaded dots.

As we are able to keep track of all edges induced by an input curve, we also provide a free function that removes a curve from an arrangement. By calling *remove(arr,ch)*, where *ch* is a valid curve handle, the given curve is deleted from the curve container, and all edges induced solely by this curve (i.e., excluding overlapping edges) are removed from the arrangement. The function returns the number of edges that have been removed.

In some cases, users may need to operate directly on the arrangement edges. We first mention that the specialized insertion functions (see Section 32.2.3) are not supported, as they accept x-monotone curves. Insertion can only be performed via the free insertion-functions. The other edge-manipulation functions (see Section 32.2.3) are however available, but have a different interface that does not use x-monotone curves:

- Invoking *split_edge(e,p)* splits the edge e at a given point p that lies in its interior.
- Invoking *merge_edge(e1,e2)* merges the two given edges. There is a precondition that *e1* and *e2* shared a common end-vertex of degree 2, and that the x-monotone subcurves associated with these edges are mergeable.
- It is possible to remove an edge by simply invoking *remove_edge(e)*.

In all cases, the maintenance of cross-pointers for the appropriate input curves will be done automatically.

It should be noted that it is possible to attach observers to an arrangement-with-history instance in order to get detailed notifications of the changes the arrangements undergoes (see Section 32.7 for the details).

32.10.3 Examples

In the following example we construct a simple arrangement of six line segments, as depicted in Figure 32.27, while maintaining the curve history. The example demonstrates the usage of the special traversal functions. It also shows how to issue point-location queries on the resulting arrangement, using the auxiliary function *point_location_query()* defined in the header file *point_location_utils.h* (see also Section 32.3.1).

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
```

```
#include <CGAL/Arrangement_on_surface_with_history_2.h>
#include <CGAL/Arrangement_with_history_2.h>
#include <CGAL/Arr_simple_point_location.h>

#include "point_location_utils.h"

typedef CGAL::Cartesian<Number_type>                          Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                    Traits_2;
typedef Traits_2::Point_2                                     Point_2;
typedef Traits_2::Curve_2                                     Segment_2;

```

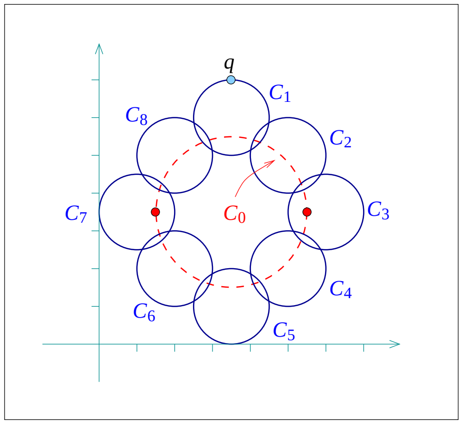

Figure 32.28: An arrangement with history of nine circle as constructed in *edge_manipulation_curve_history.cpp*. Note the vertical tangency points of C_0, marked as dark dots, which subdivide this circle into an upper half and a lower half, each consists of 9 edges. The large circle C_0 is eventually removed from the arrangement, with all 18 edges it induces.

```
    for (ocit = arr.originating_curves_begin (eit);
         ocit != arr.originating_curves_end (eit); ++ocit)
    {
      std::cout << " [" << *ocit << "]" << std::flush;
    }
    std::cout << std::endl;
  }

  // Perform some point-location queries:
  Point_location   pl(arr);

  Point_2          p1(4, 6);
  point_location_query(pl, p1);
  Point_2          p2(6, 2);
  point_location_query(pl, p2);
  Point_2          p3(2, 4);
  point_location_query(pl, p3);

  return 0;
}
```

File: examples/Arrangement_on_surface_2/curve_history.cpp

The following example demonstrates the usage of the free *remove()* function. We construct an arrangement of nine circles, while keeping a handle to each inserted circle. We then remove the large circle C_0, which induces 18 edges, as depicted in Figure 32.28. The example also shows how to use the *split_edge()* and *merge_edge()* functions when operating on an arrangement-with-history instance:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_circle_segment_traits_2.h>
```

```
#include <CGAL/Arrangement_with_history_2.h>

typedef CGAL::Cartesian<Number_type>                    Kernel;
typedef Kernel::Point_2                                 Rat_point_2;
typedef Kernel::Circle_2                                Circle_2;
typedef CGAL::Arr_circle_segment_traits_2<Kernel>       Traits_2;
typedef Traits_2::Point_2                               Point_2;
typedef Traits_2::Curve_2                               Curve_2;
typedef CGAL::Arrangement_with_history_2<Traits_2>      Arr_with_hist_2;
typedef Arr_with_hist_2::Curve_handle                   Curve_handle;
typedef CGAL::Arr_walk_along_line_point_location<Arr_with_hist_2>
                                                        Point_location;

int main ()
{
  // Construct an arrangement containing nine circles: C[0] of radius 2
   and
  // C[1], ..., C[8] of radius 1.
  const Number_type _7_halves = Number_type (7, 2);
  Arr_with_hist_2   arr;
  Curve_2           C[9];
  Curve_handle      handles[9];
  int               k;

32.11 Input/Output Streams

In some cases, one would like to save an arrangement object constructed by some application, so that later on it can be restored. In other cases one would like to create nice drawings that represent arrangements constructed by some application. These drawings can be hard printed or displayed on a computer screen.

32.11.1 Input/Output Stream

Consider an arrangement that represents a very complicated geographical map, and assume that there are various applications that need to answer point-location queries on this map. Naturally, you can store the set of curves that induces the arrangement, but this implies that you would need to construct the arrangement from scratch each time you need to reuse it. A more efficient solution is to write the arrangement to a file in a format that other applications can read.

This package provides an *inserter* (the << operator) and an *extractor* (the >> operator) for the *Arrangement_2<Traits,Dcel>* class that inserts and an arrangement object into an output stream and extracts an arrangement object from an input stream respectively. The arrangement is written using a simple predefined ASCII format that encodes the arrangement topology, as well as all geometric entities associated with vertices and edges.

The ability to use the input/output operators, requires that the *Point_2* type and the *X_monotone_curve_2* type defined by the traits class both support the << and >> operators. The *Arr_conic_traits_2* class (see Section 32.6.5), the *Arr_rational_function_traits_2* class (see Section 32.6.6), and the *Arr_linear_traits_2* class (see Section 32.6.2) currently do not provide these operators for the geometric types they define. Thus, only arrangements of line segments or of polylines can be written or read.

The following example constructs the arrangement depicted in Figure 32.7 and writes it to an output file. It also demonstrates how to re-read the arrangement from a file:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/IO/Arr_iostream.h>
#include <fstream>

#include "point_location_utils.h"

typedef CGAL::Cartesian<Number_type>                   Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>             Traits_2;
typedef CGAL::Arrangement_2<Traits_2>                  Arrangement_2;

int main ()
{
  // Construct the arrangement.
  Arrangement_2    arr;

  construct_segments_arr (arr);

  std::cout << "Writing an arrangement of size:" << std::endl
            << "   V = " << arr.number_of_vertices()
            << ",  E = " << arr.number_of_edges()
            << ",  F = " << arr.number_of_faces() << std::endl;

  // Write the arrangement to a file.
  std::ofstream    out_file ("arr_ex_io.dat");

  out_file << arr;
  out_file.close();

  // Read the arrangement from the file.
  Arrangement_2    arr2;
  std::ifstream    in_file ("arr_ex_io.dat");

  in_file >> arr2;
  in_file.close();

  std::cout << "Read an arrangement of size:" << std::endl
            << "   V = " << arr2.number_of_vertices()
            << ",  E = " << arr2.number_of_edges()
            << ",  F = " << arr2.number_of_faces() << std::endl;

  return (0);
}
```

advanced

32.11.2 Arrangements with Auxiliary Data

The inserter and extractor both ignore any auxiliary data stored with the arrangement features. Thus, they are ideal for arrangements instantiated using the *Arr_default_dcel* class. However, as explained in Section 32.8, one can easily extend the arrangement faces by using the *Arr_face_extended_dcel* template, or extend all DCEL records by using the *Arr_extended_dcel* template. In such cases, it might be crucial that the auxiliary data fields are written to the file and read from there.

The arrangement package includes the free functions *write(arr, os, formatter)*, which writes the arrangement *arr* to an output stream *os*, and *read(arr, os, formatter)*, which reads the arrangement *arr* from an input stream *is*. Both operations are performed using a *formatter* object, which defines the I/O format. The package contains three formatter classes:

- *Arr_text_formatter<Arrangement>* defines a simple textual I/O format for the arrangement topology and geometry, disregarding any auxiliary data that may be associated with the arrangement features. This is the default formatter used by the arrangement inserter and the arrangement extractor, as defined above.
- *Arr_face_extended_text_formatter<Arrangement>* operates on arrangements whose DCEL representation is based on the *Arr_face_extended_dcel<Traits,FaceData>* class (see Section 32.8.1). It supports reading and writing the auxiliary data objects stored with the arrangement faces provided that the *FaceData* class supports an inserter and an extractor.
- *Arr_extended_dcel_text_formatter<Arrangement>* operates on arrangements whose DCEL representation is based on the *Arr_extended_dcel<Traits,VertexData,HalfedgeData,FaceData>* class (see Section 32.8.2). It supports reading and writing the auxiliary data objects stored with the arrangement vertices, edges and faces, provided that the *VertexData*, *HalfedgeData* and *FaceData* classed all have inserters and extractors.

The following example constructs the same arrangement as the example *dcel_extension* does (see Section 32.8.2), depicted in Figure 32.25, and writes it to an output file. It also demonstrates how to re-read the arrangement from a file:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/IO/Arr_text_formatter.h>
#include <CGAL/IO/Arr_iostream.h>
#include <fstream>

enum Color {BLUE, RED, WHITE};

std::ostream& operator<< (std::ostream& os, const Color& color)
{
  switch (color)
  {
```

```
  case BLUE:  os << "BLUE";  break;
  case RED:   os << "RED";   break;
  case WHITE: os << "WHITE"; break;
  default: os << "ERROR!";
  }
  return (os);
}

std::istream& operator>> (std::istream& is, Color& color)
{
  std::string   str;
  is >> str;

  if (str == "BLUE")
    color = BLUE;
  else if (str == "RED")
    color = RED;
  else if (str == "WHITE")
    color = WHITE;

  return (is);
}

typedef CGAL::Cartesian<Number_type>                        Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                  Traits_2;
typedef Traits_2::Point_2                                   Point_2;
typedef Traits_2::X_monotone_curve_2                        Segment_2;
typedef CGAL::Arr_extended_dcel<Traits_2,

  for (vit = arr2.vertices_begin(); vit != arr2.vertices_end(); ++vit)
    std::cout << '(' << vit->point() << ") - " << vit->data() <<
   std::endl;

  return (0);
}
```

File: examples/Arrangement_on_surface_2/dcel_extension_io.cpp

You may develop your own own formatter classes — models of the *ArrangementInputFormatter* and *ArrangementOutputFormatter* concepts, as defined in the Reference Manual. Doing so, you can define other I/O formats, such as an XML-based format or a binary format.

advanced

32.11.3 Arrangements with Curve History

Section 32.10 introduces the *Arrangement_with_history_2<Traits,Dcel>* class, which saves the set of curves inducing an arrangement and maintains the relations between these curves and the edges they induce. Naturally, when reading or writing an arrangement-with-history instance we would like this information to be saved to the output stream or restored from the input stream alongside with the basic arrangement structure.

The arrangement package supplies an inserter and an extractor for the *Arrangement_with_history_2<Traits,Dcel>* class. The arrangement is represented using a simple predefined ASCII format. An object of the *Arrangement_with_history_2<Traits,Dcel>* type can be saved and restored, as long as the *Curve_2* type defined by the traits class — as well as the *Point_2* type and the *X_monotone_curve_2* types — support the << and>> operators.

The following example constructs the same arrangement as example *curve_history* does (see Section 32.10.3), depicted in Figure 32.27, and writes it to an output file. It also demonstrates how to re-read the arrangement-with-history from a file:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_with_history_2.h>
#include <CGAL/IO/Arr_with_history_iostream.h>
#include <fstream>

typedef CGAL::Cartesian<Number_type>                       Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                 Traits_2;
typedef Traits_2::Point_2                                  Point_2;
typedef Traits_2::Curve_2                                  Segment_2;
```

```
typedef CGAL::Arrangement_with_history_2<Traits_2>    Arr_with_hist_2;

int main ()
{
  Arr_with_hist_2   arr;

  // Insert six additional segments aggregately:
  Segment_2         segs[6];
  segs[0] = Segment_2 (Point_2 (2, 6), Point_2 (7, 1));
  segs[1] = Segment_2 (Point_2 (3, 2), Point_2 (3, 5));
  segs[2] = Segment_2 (Point_2 (2, 3), Point_2 (5, 3));
  segs[3] = Segment_2 (Point_2 (2, 6), Point_2 (7, 1));
  segs[4] = Segment_2 (Point_2 (0, 0), Point_2 (2, 6));
  segs[5] = Segment_2 (Point_2 (3, 4), Point_2 (6, 4));
  insert (arr, segs, segs + 6);

  std::cout << "Writing an arrangement of "
            << arr.number_of_curves() << " input segments:" << std::endl
            << "   V = " << arr.number_of_vertices()
            << ",  E = " << arr.number_of_edges()
            << ",  F = " << arr.number_of_faces() << std::endl;

  // Write the arrangement to a file.
  std::ofstream     out_file ("arr_ex_io_hist.dat");

  out_file << arr;
  out_file.close();

  // Read the arrangement from the file.
  Arr_with_hist_2   arr2;
  std::ifstream     in_file ("arr_ex_io_hist.dat");

  in_file >> arr2;
  in_file.close();

  std::cout << "Read an arrangement of "
            << arr2.number_of_curves() << " input segments:" << std::endl
            << "   V = " << arr2.number_of_vertices()
            << ",  E = " << arr2.number_of_edges()
            << ",  F = " << arr2.number_of_faces() << std::endl;

  return (0);
}
```

advanced

The arrangement package also includes the free functions *write(arr, os, formatter)* and *read(arr, os, formatter)* that operate on a given arrangement-with-history instance *arr*. Both functions are parameterized by a *formatter* object, which define the I/O format. The package contains a template called, *Arr_with_hist_text_formatter< ArranagmentFormatter>*, which extends an arrangement formatter class (see Section 32.11.2) and defines a simple textual input/output format.

advanced

32.11.4 Output QT-widget Stream

You can display the drawings of arrangements in a graphical window powered by QT interactively. All you need to do is follow the guidelines for handling *Qt_widget* objects, and apply the *inserter*, which inserts an arrangement into a *Qt_widget* stream to complete the drawing.

The ability to use this output operator, requires that the *Point_2* and *X_monotone_curve_2* types defined by the traits class both support the << operator that inserts the respective geometric object into a *Qt_widget* stream. The *Arr_rational_function_traits_2* class (see Section 32.6.6) and the *Arr_linear_traits_2* class (see Section 32.6.2) currently do not provide this operator for the geometric types they define. Thus, only arrangements of line segments, polylines, or conic ards can be written. The << operator for polylines and conic arcs defined in *CGAL/IO/Qt_widget_Polyline_2.h* and *CGAL/IO/Qt_widget_Conic_arc_2.h* must be explicitly included, to insert polylines and conic arcs respectively into *Qt_widget* streams.

32.12 Adapting to BOOST Graphs

BOOST[21] is a collection of portable C++ libraries that extend the Standard Template Library (STL). The BOOST Graph Library (BGL), which one of the libraries in the collection, offers an extensive set of generic graph algorithms parameterized through templates. As our arrangements are embedded as planar graphs, it is only natural to extend the underlying data structure with the interface that the BGL expects, and gain the ability to perform the operations that the BGL supports, such as shortest-path computation. This section describes how apply the graph algorithms implemented in the BGL to *Arrangement_2* instances.

An instance of *Arrangement_2* is adapted to a BOOST graph through the provision of a set of free functions that operate on the arrangement features and conform with the relevant BGL concepts. Besides the straightforward adaptation, which associates a vertex with each DCEL vertex and an edge with each DCEL halfedge, the package also offer a *dual* adaptor, which associates a graph vertex with each DCEL face, such that two vertices are connected, iff there is a DCEL halfedge that connects the two corresponding faces.

32.12.1 The Primal Arrangement Representation

Arrangement instances are adapted to BOOST graphs by specializing the *boost:graph_traits* template for *Arrangement_2* instances. The graph-traits states the graph concepts that the arrangement class models (see below) and defines the types required by these concepts.

In this specialization the *Arrangement_2* vertices correspond to the graph vertices, where two vertices are adjacent if there is at least one halfedge connecting them. More precisely, *Arrangement_2::Vertex_handle* is the graph-vertex type, while *Arrangement_2::Halfedge_handle* is the graph-edge type. As halfedges are directed, we consider the graph to be directed as well. Moreover, as several interior-disjoint x-monotone curves (say circular arcs) may share two common endpoints, inducing an arrangement with two vertices that are connected with several edges, we allow parallel edges in our BOOST graph.

Given an *Arrangement_2* instance, we can efficiently traverse its vertices and halfedges. Thus, the arrangement graph is a model of the concepts *VertexListGraph* and *EdgeListGraph* introduced by the BGL. At the same

[21] See also BOOST's homepage at: `www.boost.org`.

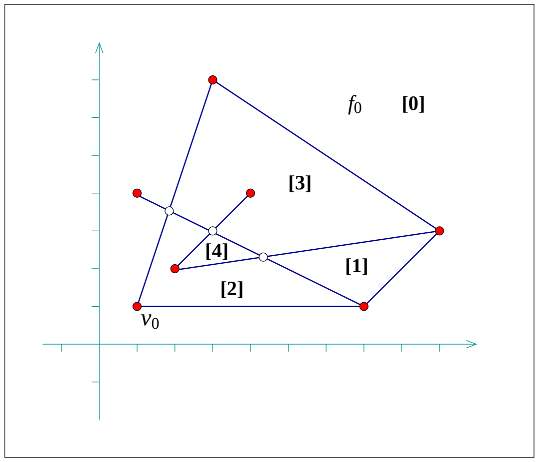

Figure 32.29: An arrangement of 7 line segments, as constructed by *bgl_primal_adapter.cpp* and *bgl_dual_adapter.cpp*. The breadth-first visit times for the arrangement faces, starting from the unbounded face f_0, are shown is brackets.

time, we use an iterator adapter of the circulator over the halfedges incident to a vertex (*Halfedge_around_vertex_circulator* — see Section 32.2.2), so it is possible to go over the ingoing and outgoing edges of a vertex in linear time. Thus, our arrangement graph is a model of the concept *BidirectionalGraph* (this concept refines *IncidenceGraph*, which requires only the traversal of outgoing edges).

It is important to notice that the vertex descriptors we use are *Vertex_handle* objects and *not* vertex indices. However, in order to gain more efficiency in most BGL algorithm, it is better to have them indexed $0, 1, \ldots, (n-1)$, where n is the number of vertices. We therefore introduce the *Arr_vertex_index_map<Arrangement>* class-template, which maintains a mapping of vertex handles to indices, as required by the BGL. An instance of this class must be attached to a valid arrangement vertex when it is created. It uses the notification mechanism (see Section 32.7) to automatically maintain the mapping of vertices to indices, even when new vertices are inserted into the arrangement or existing vertices are removed.

In most algorithm provided by the BGL, the output is given by *property maps*, such that each map entry corresponds to a vertex. For example, when we compute the shortest paths from a given source vertex s to all other vertices we can obtain a map of distances and a map of predecessors — namely for each v vertex we have its distance from s and a descriptor of the vertex that precedes v in the shortest path from s. If the vertex descriptors are simply indices, one can use vectors to efficiently represent the property maps. As this is not the case with the arrangement graph, we offer the *Arr_vertex_property_map<Arrangement,Type>* template allows for an efficient mapping of *Vertex_handle* objects to properties of type *Type*. Note however that unlike the *Arr_vertex_index_map* class, the vertex property-map class is not kept synchronized with the number of vertices in the arrangement, so it should not be reused in calls to BGL functions in case the arrangement is modified in between these calls.

In the following example we construct an arrangement of 7 line segments, as shown in Figure 74.1, then use Dijkstra's shortest-paths algorithm from the BGL to compute the graph distance of all vertices from the leftmost vertex in the arrangement v_0. Note the usage of the *Arr_vertex_index_map* and the *Arr_vertex_property_map* classes. The latter one, instantiated by the type *double* is used to map vertices to their distances from v_0.

32.12.2 The Dual Arrangement Representation

It is possible to give a dual graph representation for an arrangement instance, such that each arrangement face corresponds to a graph vertex and two vertices are adjacent iff the corresponding faces share a common edge on their boundaries. This is done by specializing the *boost:graph_traits* template for *Dual<Arrangement_2>* instances, where *Dual<Arrangement_2>* is a template specialization that gives a dual interpretation to an arrangement instance.

In dual representation, *Arrangement_2::Face_handle* is the graph-vertex type, while *Arrangement_2::Halfedge_handle* is the graph-edge type. We treat the graph edges as directed, such that a halfedge e is directed from f_1, which is its incident face, to f_2, which is the incident face of its twin halfedge. As two arrangement faces may share more than a single edge on their boundary, we allow parallel edges in our BOOST graph. As is the case in the primal graph, the dual arrangement graph is also a model of the concepts *VertexListGraph*, *EdgeListGraph* and *BidirectionalGraph* (thus also of *IncidenceGraph*).

Since we use *Face_handle* objects as the vertex descriptors, we define the *Arr_face_index_map*<*Arrangement*> class-template, which maintains an efficient mapping of face handles to indices. We also provide the template *Arr_face_property_map*<*Arrangement,Type*> for associating arbitrary data with the arrangement faces.

In the following example we construct the same arrangement as in example *bgl_primal_adapter.cpp* (see Figure 74.1), and perform breadth-first search on the graph faces, starting from the unbounded face. We extend the DCEL faces with an unsigned integer, marking the discover time of the face and use a breadth-first-search visitor to obtain these times and update the faces accordingly:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arrangement_2.h>

#include <climits>
#include <boost/graph/dijkstra_shortest_paths.hpp>

#include <CGAL/graph_traits_Dual_Arrangement_2.h>
#include <CGAL/Arr_face_index_map.h>

#include "arr_print.h"

typedef CGAL::Cartesian<Number_type>                        Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                  Traits_2;
typedef Traits_2::Point_2                                   Point_2;
typedef Traits_2::X_monotone_curve_2                        Segment_2;
typedef CGAL::Arr_face_extended_dcel<Traits_2,
                                     unsigned int>          Dcel;
typedef CGAL::Arrangement_2<Traits_2, Dcel>                 Arrangement_2;
typedef CGAL::Dual<Arrangement_2>
   Dual_arrangement_2;

// A BFS visitor class that associates each vertex with its discover
   time.
// In our case graph vertices represent arrangement faces.
template <class IndexMap>
class Discover_time_bfs_visitor : public boost::default_bfs_visitor
{
private:

  const IndexMap  *index_map;      // Mapping vertices to indices.
  unsigned int     time;           // The current time stamp.

32.13 How To Speed Up Your Computation

Before the specific tips, we remind you that compiling programs with debug flags disabled and with optimization flags enabled significantly reduces the running time.

1. When the curves to be inserted into an arrangement are x-monotone and pairwise disjoint in their interior to start with, then it is more efficient (in running time) and less demanding (in traits-class functionality) to use the non-intersection insertion-functions instead of the general ones; e.g., *insert()*.

2. When the curves to be inserted into an arrangement are segments that are pairwise disjoint in their interior, it is more efficient to use the traits class *Arr_non_caching_segment_traits_2* rather then the default one (*Arr_segment_traits_2*).

   If the segments may intersect each other, the default traits class *Arr_segment_traits_2* can be safely used with the somehow limited number type *Quotient<MP_float>*.

   On rare occasions the traits class *Arr_non_caching_segment_traits_2* exhibits slightly better performance than the default one (*Arr_segment_traits_2* even when the segments intersect each other, due to the small overhead of the latter (optimized) traits class. (For example, when the so called LEDA rational kernel is used).

3. Prior knowledge of the combinatorial structure of the arrangement can be used to accelerate operations that insert x-monotone curves, whose interior is disjoint from existing edges and vertices of the arrangement. The specialized insertion functions, i.e., *insert_in_face_interior()*, *insert_from_left_vertex()*, *insert_from_right_vertex()*, and *insert_at_vertices()* can be used according to the available information. These functions hardly involve any geometric operations, if at all. They accept topologically related parameters, and use them to operate directly on the DCEL records, thus saving algebraic operations, which are especially expensive when high-degree curves are involved.

   A polygon, represented by a list of segments along its boundary, can be inserted into an empty arrangement as follows. First, one segment is inserted using *insert_in_face_interior()* into the unbounded face. Then, a segment with a common end point is inserted using either *insert_from_left_vertex()* or *insert_from_right_vertex()*, and so on with the rest of the segments except for the last, which is inserted using *insert_at_vertices()*, as both endpoints of which are the mapping of known vertices.

4. The main trade-off among point-location strategies, is between time and storage. Using the naive or walk strategies, for example, takes more query time but does not require preprocessing or maintenance of auxiliary structures and saves storage space.

5. If point-location queries are not performed frequently, but other modifying functions, such as removing, splitting, or merging edges are, then using a point-location strategy that does not require the maintenance of auxiliary structures, such as the naive or walk strategies, is preferable.

6. There is a trade-off between two modes of the trapezoidal RIC strategy that enables the user to choose whether preprocessing should be performed or not. If preprocessing is not used, the creation of the structure is faster. However, for some input sequences the structure might be unbalanced and therefore queries and updates might take longer, especially, if many removal and split operations are performed.

7. When the curves to be inserted into an arrangement are available in advance (as opposed to supplied on-line), it is advised to use the more efficient aggregate (sweep-based) insertion over the incremental insertion; e.g., *insert()*.

8. The various traits classes should be instantiated with an exact number type to ensure robustness, when the input of the operations to be carried out might be degenerate, although inexact number types could be used at the user's own risk.

9. Maintaining short bit-lengths of coordinate representations may drastically decrease the time consumption of arithmetic operations on the coordinates. This can be achieved by caching certain information or normalization (of rational numbers). However, both solutions should be used cautiously, as the former may lead to an undue space consumption, and indiscriminate normalization may considerably slow down the overall process.

10. Geometric functions (e.g., traits methods) dominate the time consumption of most operations. Thus, calls to such function should be avoided or at least their number should be decreased, perhaps at the expense of increased combinatorial-function calls or increased space consumption. For example, repetition of geometric-function calls could be avoided by storing the results obtained by the first call, and reusing them when needed.

Design and Implementation History

The code of this package is the result of a long development process. Initially (and until version 3.1), the code was spread among several components, namely, *Topological_map*, *Planar_map_2*, *Planar_map_with_intersections_2* and *Arrangement_2*, that were developed by Ester Ezra, Eyal Flato, Efi Fogel, Dan Halperin, Iddo Hanniel, Idit Haran, Shai Hirsch, Eugene Lipovetsky, Oren Nechushtan, Sigal Raab, Ron Wein, Baruch Zukerman, and Tali Zvi.

In version 3.2, as part of the ACS project, the packages have gone through a major re-design, resulting in an improved and unified *2D Arrangements* package. The code of the new package was restructured and developed by Efi Fogel, Idit Haran, Ron Wein, and Baruch Zukerman. This version included for the first time a new geometry-traits class that handles circular and linear curves, and is based on the circular kernel. The circular kernel was developed by Monique Teillaud, Sylvain Pion, and Julien Hazebrouck.

Version 3.3 features arrangements of unbounded curves for the first time. The design and development of this feature required yet another restructuring of the entire package. All this was done by Eric Berberich, Efi Fogel, Dan Halperin, Ophir Setter, and Ron Wein. Michael Hemmer helped tuning up parts of the geometry-traits concept related to unbounded curves.

Version 3.7 introduced a geometry-traits class that handles planar algebraic curves of arbitrary degree. It was developed by Eric Berberich and Michael Kerber.

Version 3.9 introduced a new geometry-traits class that handles rational arcs. It was developed by Oren Salzman and Michael Hemmer. It replaced an old traits, which handled the same family of curves, developed by Ron Wein.

Version 4.1 introduces a revised implementation of the point location class via a randomized incremental construction of the trapezoidal map. The old class was implemented by Oren Nechushtan, while the revamp was done by Michal Kleinbort and Michael Hemmer. The new class adds support for unbounded curves and can now guarantee logarithmic query time in all cases.

2D Arrangements
Reference Manual

Ron Wein, Efi Fogel, Baruch Zukerman, Dan Halperin, Eric Berberich, and Oren Zalzman

Given a set $\mathcal{C}$ of planar curves, the *arrangement* $\mathcal{A}(\mathcal{C})$ is the subdivision of the plane induced by the curves in $\mathcal{C}$ into maximally connected cells. The cells can be 0-dimensional (*vertices*), 1-dimensional (*edges*) or 2-dimensional (*faces*).

The class *Arrangement_2<Traits,Dcel>* encapsulates a data structure that maintains arrangements of arbitrary bounded planar curves. It comes with a variety of algorithms that operate on planar arrangement, such as point-location queries and overlay computations, which are implemented as peripheral classes or as free (global) functions.

CGAL::Arrangement_2<Traits,Dcel>

Definition

An object *arr* of the class *Arrangement_2<Traits,Dcel>* represents the planar subdivision induced by a set of x-monotone curves and isolated points into maximally connected cells. The arrangement is represented as a doubly-connected edge-list (DCEL) such that each DCEL vertex is associated with a point of the plane and each edge is associated with an x-monotone curve whose interior is disjoint from all other edges and vertices. Recall that an arrangement edge is always comprised of a pair of twin DCEL halfedges.

The *Arrangement_2<Traits,Dcel>* template has two parameters:

- The *Traits* template-parameter should be instantiated with a model of the *ArrangementBasicTraits_2* concept. The traits class defines the types of x-monotone curves and two-dimensional points, namely *X_monotone_curve_2* and *Point_2*, respectively, and supports basic geometric predicates on them.
- The *Dcel* template-parameter should be instantiated with a class that is a model of the *ArrangementDcel* concept. The value of this parameter is by default *Arr_default_dcel<Traits>*.

The available traits classes and DCEL classes are described below.

#include <CGAL/Arrangement_2.h>

Types

typedef Arrangement_2<Traits_2,Dcel>	*Self;*	a private type used as an abbreviation of the *Arrangement_2<Traits,Dcel>* type hereafter.
Arrangement_2<Traits,Dcel>:: Traits_2		the traits class in use.
Arrangement_2<Traits,Dcel>:: Dcel		the DCEL representation of the arrangement.
typedef typename Traits_2::Point_2	*Point_2;*	the point type, as defined by the traits class.
typedef typename Traits_2::X_monotone_curve_2	*X_monotone_curve_2;*	the x-monotone curve type, as defined by the traits class.
typedef typename Dcel::Size	*Size;*	the size type (equivalent to *size_t*).

Arrangement_2<Traits,Dcel>:: Vertex	represents a 0-dimensional cell in the subdivision. A vertex is always associated with a point.
Arrangement_2<Traits,Dcel>:: Halfedge	represents (together with its twin — see below) a 1-dimensional cell in the subdivision. A halfedge is always associated with an x-monotone curve.
Arrangement_2<Traits,Dcel>:: Face	represents a 2-dimensional cell in the subdivision.

The following handles, iterators, and circulators all have respective constant counterparts (for example, in addition to *Vertex_iterator* the type *Vertex_const_iterator* is also defined). See [MS96] for a discussion of constant versus mutable iterator types. The mutable types are assignable to their constant counterparts.

Vertex_iterator, *Halfedge_iterator*, and *Face_iterator* are equivalent to the respective handle types (namely, *Vertex_handle*, *Halfedge_handle*, and *Face_handle*). Thus, wherever the handles appear in function parameter lists, the respective iterators can be passed as well.

Arrangement_2<Traits,Dcel>:: Vertex_handle	a handle for an arrangement vertex.
Arrangement_2<Traits,Dcel>:: Halfedge_handle	a handle for a halfedge. The halfedge and its twin form together an arrangement edge.
Arrangement_2<Traits,Dcel>:: Face_handle	a handle for an arrangement face.
Arrangement_2<Traits,Dcel>:: Vertex_iterator	a bidirectional iterator over the vertices of the arrangement. Its value-type is *Vertex*.
Arrangement_2<Traits,Dcel>:: Halfedge_iterator	a bidirectional iterator over the halfedges of the arrangement. Its value-type is *Halfedge*.
Arrangement_2<Traits,Dcel>:: Edge_iterator	a bidirectional iterator over the edges of the arrangement. (That is, it skips every other halfedge.) Its value-type is *Halfedge*.
Arrangement_2<Traits,Dcel>:: Face_iterator	a bidirectional iterator over the faces of arrangement. Its value-type is *Face*.
Arrangement_2<Traits,Dcel>:: Unbounded_face_iterator	a bidirectional iterator over the unbounded faces of arrangement. Its value-type is *Face*.
Arrangement_2<Traits,Dcel>:: Halfedge_around_vertex_circulator	a bidirectional circulator over the halfedges that have a given vertex as their target. Its value-type is *Halfedge*.
Arrangement_2<Traits,Dcel>:: Ccb_halfedge_circulator	a bidirectional circulator over the halfedges of a CCB (connected component of the boundary). Its value-type is *Halfedge*. Each bounded face has a single CCB representing it outer boundary, and may have several inner CCBs representing its holes.
Arrangement_2<Traits,Dcel>:: Hole_iterator	a bidirectional iterator over the holes (i.e., inner CCBs) contained inside a given face. Its value type is *Ccb_halfedge_circulator*.
Arrangement_2<Traits,Dcel>:: Isolated_vertex_iterator	a bidirectional iterator over the isolated vertices contained inside a given face. Its value type is *Vertex*.

Creation

Arrangement_2<Traits,Dcel> arr;	constructs an empty arrangement containing one unbounded face, which corresponds to the entire plane.

Arrangement_2<Traits,Dcel> arr(Self other); copy constructor.

*Arrangement_2<Traits,Dcel> arr(const Traits_2 *traits);*

constructs an empty arrangement that uses the given *traits* instance for performing the geometric predicates.

Assignment Methods

Self&	*arr = other*	assignment operator.
void	*arr.assign(Self other)*	assigns the contents of another arrangement.
void	*arr.clear()*	clears the arrangement.

Access Functions

*Traits_2**	*arr.get_traits()*	returns the traits object used by the arrangement instance. A *const* version is also available.
bool	*arr.is_empty() const*	determines whether the arrangement is empty (contains only the unbounded face, with no vertices or edges).

All *_begin()* and *_end()* methods listed below also have *const* counterparts, returning constant iterators instead of mutable ones:

• *Accessing the Arrangement Vertices:*

Size *arr.number_of_vertices() const*

returns the number of vertices in the arrangement.

Size *arr.number_of_isolated_vertices() const*

returns the total number of isolated vertices in the arrangement.

Vertex_iterator	*arr.vertices_begin()*	returns the begin-iterator of the vertices in the arrangement.
Vertex_iterator	*arr.vertices_end()*	returns the past-the-end iterator of the vertices in the arrangement.

Size *arr.number_of_vertices_at_infinity() const*

returns the number of arrangement vertices that lie at infinity and are not associated with valid points. Such vertices are not considered to be regular arrangement vertices and *arr.number_of_vertices()* does not count them.

• *Accessing the Arrangement Edges:*

Size	*arr.number_of_halfedges() const*	
		returns the number of halfedges in the arrangement.
Halfedge_iterator	*arr.halfedges_begin()*	returns the begin-iterator of the halfedges in the arrangement.
Halfedge_iterator	*arr.halfedges_end()*	returns the past-the-end iterator of the halfedges in the arrangement.
Size	*arr.number_of_edges() const*	
		returns the number of edges in the arrangement (equivalent to *arr.number_of_halfedges() / 2*).
Edge_iterator	*arr.edges_begin()*	returns the begin-iterator of the edges in the arrangement.
Edge_iterator	*arr.edges_end()*	returns the past-the-end iterator of the edges in the arrangement.

• *Accessing the Arrangement Faces:*

Face_handle	*arr.unbounded_face()*	returns a handle for an unbounded face of the arrangement. In case the arrangement comprises only bounded curves, there is a single unbounded face and the function returns a handle to it. Otherwise, a handle to an arbitrary unbounded face is returned.
Size	*arr.number_of_faces() const*	
		returns the number of faces in the arrangement.
Face_iterator	*arr.faces_begin()*	returns the begin-iterator of the faces in the arrangement.
Face_iterator	*arr.faces_end()*	returns the past-the-end iterator of the faces in the arrangement.
Size	*arr.number_of_unbounded_faces() const*	
		returns the number of unbounded faces in the arrangement. Note *arr.number_of_faces()* also counts the unbounded faces of the arrangement.
Unbounded_face_iterator		
	arr.unbounded_faces_begin()	
		returns the begin-iterator of the unbounded faces in the arrangement.

Unbounded_face_iterator

	arr.unbounded_faces_end()	returns the past-the-end iterator of the unbounded faces in the arrangement.
Face_handle	*arr.fictitious_face()*	returns a handle to the fictitious face of the arrangement. If the arrangement is not unbounded, there is no fictitious face. In this case the result is not deterministic. A const version is also available.

advanced

Casting away Constness

It is sometime necessary to convert a constant (non-mutable) handle to a mutable handle. For example, the result of a point-location query is a non-mutable handle for the arrangement cell containing the query point. Assume that the query point lies on a edge, so we obtain a *Halfedge_const_handle*; if we wish to use this handle and remove the edge, we first need to cast away its "constness".

Vertex_handle *arr.non_const_handle(Vertex_const_handle v)*

casts the given constant vertex handle to an equivalent mutable handle.

Halfedge_handle *arr.non_const_handle(Halfedge_const_handle e)*

casts the given constant halfedge handle to an equivalent mutable handle.

Face_handle *arr.non_const_handle(Face_const_handle f)*

casts the given constant face handle to an equivalent mutable handle.

advanced

Modifiers

• *Specialized Insertion Methods:*

Vertex_handle *arr.insert_in_face_interior(Point_2 p, Face_handle f)*

inserts the point p into the arrangement as an isolated vertex in the interior of the face f and returns a handle for the newly created vertex.
Precondition: p lies in the interior of the face f.

Halfedge_handle *arr.insert_in_face_interior(X_monotone_curve_2 c, Face_handle f)*

inserts the curve c that is entirely contained in the interior of a given face f. If c is a bounded curve two new vertices that correspond to c's endpoints are created and connected with a newly created halfedge pair, which forms a new hole (inner component) in the face f. If c is unbounded, at least one of the two vertices that represents its end lies at infinity, and its creation modifies the outer boundary of f. The function returns a handle for one of the new halfedges corresponding to the inserted curve, directed in lexicographic increasing order (from left to right).
Precondition: c lies entirely in the interior of the face f and is disjoint from all existing arrangement vertices and edges (in particular, both its endpoints are not already associated with existing arrangement vertices).
Precondition: In case c is an unbounded curve, f must be an unbounded face.

Halfedge_handle *arr.insert_from_left_vertex(X_monotone_curve_2 c, Vertex_handle v)*

inserts the curve c into the arrangement, such that its left endpoint corresponds to a given arrangement vertex. As a result, a new vertex that correspond to c's right endpoint is created and connected to v with a newly created halfedge pair. If c has an unbounded right end, the new vertex lies at infinity and the unbounded face that contains the interior of the curve is split. The function returns a handle for one of the new halfedges corresponding to the inserted curve, directed towards the newly created vertex — that is, directed in lexicographic increasing order (from left to right).
Precondition: The interior of c is disjoint from all existing arrangement vertices and edges.
Precondition: v is associated with the left endpoint of c.
Precondition: The right endpoint of c is not already associated with an existing arrangement vertex.

Halfedge_handle *arr.insert_from_right_vertex(X_monotone_curve_2 c, Vertex_handle v)*

inserts the curve c into the arrangement, such that its right endpoint corresponds to a given arrangement vertex. As a result, a new vertex that correspond to c's left endpoint is created and connected to v with a newly created halfedge pair. If c has an unbounded left end, the new vertex lies at infinity and the unbounded face that contains the interior of the curve is split. The function returns a handle for one of the new halfedges corresponding to the inserted curve, directed to the newly created vertex — that is, directed in lexicographic decreasing order (from right to left).
Precondition: The interior of c is disjoint from all existing arrangement vertices and edges.
Precondition: v is associated with the right endpoint of c.
Precondition: The left endpoint of c is not already associated with an existing arrangement vertex.

Halfedge_handle *arr.insert_at_vertices(X_monotone_curve_2 c, Vertex_handle v1, Vertex_handle v2)*

inserts the curve *c* into the arrangement, such that both *c*'s endpoints correspond to existing arrangement vertices, given by *v1* and *v2*. The function creates a new halfedge pair that connects the two vertices, and returns a handle for the halfedge directed from *v1* to *v2*.
Precondition: The interior of *c* is disjoint from all existing arrangement vertices and edges.
Precondition: *c* must not be an unbounded curve.
Precondition: *v1* and *v2* are associated with *c*'s endpoints.
Precondition: If *v1* and *v2* are already connected by an edge, this edge represents an *x*-monotone curve that is interior-disjoint from *c*).

advanced

Halfedge_handle *arr.insert_in_face_interior(X_monotone_curve_2 c, Halfedge_handle fict_pred1, Halfedge_handle fict_pred2 = Halfedge_handle())*

inserts an unbounded curve *c* into the arrangement, such that *c* is entirely contained within a single unbounded face of the arrangement. *fict_pred1* specifies the fictitious halfedge that should contain the vertex at infinity that corresponds to the unbounded end of *c*. If both ends of *c* are unbounded, *fict_pred1* indicated the place for its left end and *fict_pred2* indicated a place for its right end. The function returns a handle for one of the new halfedges directed (lexicographically) from left to right.
Precondition: *c* is an unbounded curve disjoint from all existing arrangement vertices and edges.
Precondition: *fict_pred1* (and *fict_pred2*) are fictitious halfedges that contains the unbounded end(s) of *c*. If both halfedges are given they must be both incident to the same unbounded face.

Halfedge_handle *arr.insert_from_left_vertex(X_monotone_curve_2 c, Halfedge_handle pred)*

inserts the curve *c* into the arrangement, such that its left endpoint corresponds to a given arrangement vertex. This vertex is the target vertex of the halfedge *pred*, such that *c* is inserted to the circular list of halfedges around *pred->target()* right between *pred* and its successor. The function returns a handle for one of the new halfedges directed (lexicographically) from left to right.
Precondition: The interior of *c* is disjoint from all existing arrangement vertices and edges.
Precondition: *pred->target()* is associated with the left endpoint of *c*, and *c* should be inserted after *pred* in a clockwise order around this vertex.
Precondition: The right endpoint of *c* is not already associated with an existing arrangement vertex.

Halfedge_handle *arr.insert_from_left_vertex(X_monotone_curve_2 c,*
Halfedge_handle pred,
Halfedge_handle fict_pred)

inserts an unbounded curve c into the arrangement, such that its left endpoint is bounded and corresponds to a given arrangement vertex. This vertex is the target vertex of the halfedge *pred*, such that c is inserted to the circular list of halfedges around *pred->target()* right between *pred* and its successor. Similarly, *fict_pred* specifies the fictitious halfedge that should contain the vertex at infinity that corresponds to the unbounded right end of c. The function returns a handle for one of the new halfedges directed (lexicographically) from left to right.
Precondition: The interior of c is disjoint from all existing arrangement vertices and edges. c must have a bounded left endpoint and an unbounded right end.
Precondition: *pred->target()* is associated with the left endpoint of c, and c should be inserted after *pred* in a clockwise order around this vertex.
Precondition: *fict_pred* is a fictitious halfedge that contains the unbounded right end of c.

Halfedge_handle *arr.insert_from_right_vertex(X_monotone_curve_2 c, Halfedge_handle pred)*

inserts the curve c into the arrangement, such that its right endpoint corresponds to a given arrangement vertex. This vertex is the target vertex of the halfedge *pred*, such that c is inserted to the circular list of halfedges around *pred->target()* right between *pred* and its successor. The function returns a handle for one of the new halfedges directed (lexicographically) from right to left.
Precondition: The interior of c is disjoint from all existing arrangement vertices and edges.
Precondition: *pred->target()* is associated with the right endpoint of c, and c should be inserted after *pred* in a clockwise order around this vertex.
Precondition: The left endpoint of c is not already associated with an existing arrangement vertex.

Halfedge_handle *arr.insert_from_right_vertex(X_monotone_curve_2 c,*
Halfedge_handle pred,

Halfedge_handle fict_pred)

inserts an unbounded curve *c* into the arrangement, such that its right endpoint is bounded and corresponds to a given arrangement vertex. This vertex is the target vertex of the halfedge *pred*, such that *c* is inserted to the circular list of halfedges around *pred->target()* right between *pred* and its successor. Similarly, *fict_pred* specifies the fictitious halfedge that should contain the vertex at infinity that corresponds to the unbounded left end of *c*. The function returns a handle for one of the new halfedges directed (lexicographically) from right to left.
Precondition: The interior of *c* is disjoint from all existing arrangement vertices and edges. *c* must have a bounded right endpoint and an unbounded left end.
Precondition: *pred->target()* is associated with the right endpoint of *c*, and *c* should be inserted after *pred* in a clockwise order around this vertex.
Precondition: *fict_pred* is a fictitious halfedge that contains the unbounded left end of *c*.

Halfedge_handle *arr.insert_at_vertices(X_monotone_curve_2 c,*
Halfedge_handle pred1,
Vertex_handle v2)

inserts the curve *c* into the arrangement, such that both *c*'s endpoints correspond to existing arrangement vertices, given by *pred1->target()* and *v2*. The function creates a new halfedge pair that connects the two vertices (where the corresponding halfedge is inserted right between *pred1* and its successor around *pred1*'s target vertex) and returns a handle for the halfedge directed from *pred1->target()* to *v2*.
Precondition: The interior of *c* is disjoint from all existing arrangement vertices and edges.
Precondition: *pred1->target()* and *v2* are associated with *c*'s endpoints.
Precondition: If *pred1->target* and *v2* are already connected by an edge, this edge represents an *x*-monotone curve that is interior-disjoint from *c*).

Halfedge_handle *arr.insert_at_vertices(X_monotone_curve_2 c,*
Halfedge_handle pred1,

Halfedge_handle pred2)

inserts the curve *c* into the arrangement, such that both *c*'s endpoints correspond to existing arrangement vertices, given by *pred1->target()* and *pred2->target()*. The function creates a new halfedge pair that connects the two vertices (with *pred1* and *pred2* indicate the exact place for these halfedges around the two target vertices) and returns a handle for the halfedge directed from *pred1->target()* to *pred2->target()*.
Precondition: The interior of *c* is disjoint from all existing arrangement vertices and edges.
Precondition: *pred1->target()* and *pred2->target()* are associated with *c*'s endpoints.
Precondition: If *pred1->target* and *pred2->target()* are already connected by an edge, this edge represents an *x*-monotone curve that is interior-disjoint from *c*).

advanced

• *Modifying Vertices and Edges:*

Vertex_handle *arr.modify_vertex(Vertex_handle v, Point_2 p)*

sets *p* to be the point associated with the vertex *v*. The function returns a handle for the modified vertex (same as *v*).
Precondition: *v* is not a vertex at infinity and *p* is geometrically equivalent to the point currently associated with *v*.

Face_handle *arr.remove_isolated_vertex(Vertex_handle v)*

removes the isolated vertex *v* from the arrangement. The function returns the face *f* that used to contain the isolated vertex.
Precondition: *v* is an isolated vertex (has no incident edges).

Halfedge_handle *arr.modify_edge(Halfedge_handle e, X_monotone_curve_2 c)*

sets *c* to be the *x*-monotone curve associated with the edge *e*. The function returns a handle for the modified edge (same as *e*).
Precondition: *c* is geometrically equivalent to the curve currently associated with *e*.

Halfedge_handle *arr.split_edge(Halfedge_handle e, X_monotone_curve_2 c1, X_monotone_curve_2 c2)*

splits the edge *e* into two edges (more precisely, into two halfedge pairs), associated with the given subcurves *c1* and *c2*, and creates a vertex that corresponds to the split point. The function returns a handle for the halfedge, whose source is the same as *e->source()* and whose target vertex is the split point.
Precondition: Either *c1*'s left endpoint and *c2*'s right endpoint correspond to *e*'s end-vertices such that *c1*'s right endpoint and *c2*'s left endpoint are equal and define the split point — or vice-versa (with change of roles between *c1* and *c2*).

Halfedge_handle *arr.merge_edge(Halfedge_handle e1, Halfedge_handle e2, X_monotone_curve_2 c)*

merges the edges represented by *e1* and *e2* into a single edge, associated with the given merged curve *c*. Denote *e1*'s end-vertices as u_1 and v, while *e2*'s end-vertices are denoted u_2 and v. The function removes the common vertex v returns a handle for one of the merged halfedges, directed from u_1 to u_2.
Precondition: *e1* and *e2* share a common end-vertex, such that the two other end-vertices of the two edges are associated with *c*'s endpoints.

Face_handle *arr.remove_edge(Halfedge_handle e, bool remove_source = true, bool remove_target = true)*

removes the edge *e* from the arrangement. Since the *e* may be the only edge incident to its source vertex (or its target vertex), this vertex can be removed as well. The flags *remove_source* and *remove_target* indicate whether the endpoints of *e* should be removed, or whether they should be left as isolated vertices in the arrangement. If the operation causes two faces to merge, the merged face is returned. Otherwise, the face to which the edge was incident is returned.

Miscellaneous

bool *arr.is_valid() const*

returns *true* if *arr* represents a valid instance of *Arrangement_2<Traits,Dcel>*. In particular, the functions checks the topological structure of the arrangement and assures that it is valid. In addition, the function performs several simple geometric tests to ensure the validity of some of the geometric properties of the arrangement. Namely, it checks that all arrangement vertices are associated with distinct points, and that the halfedges around every vertex are ordered clockwise.

CGAL::Arr_accessor<Arrangement>

Class

Definition

Arr_accessor<Arrangement> provides an access to some of the private *Arrangement* functions. Users may use these functions to achieve more efficient programs when they have the exact topological information required by the specialized functions.

It is however highly recommended to be very careful when using the accessor functions that modify the arrangement. As we have just mentioned, these functions have very specific requirement on their input on one hand, and perform no preconditions on the other hand, so providing incorrect topological input may invalidate the arrangement.

#include <CGAL/Arr_accessor.h>

Types

Arr_accessor<Arrangement>:: Arrangement_2 — the type of the associated arrangement.

typedef typename Arrangement_2::Point_2

Point_2; — the point type.

typedef typename Arrangement_2::X_monotone_curve_2

X_monotone_curve_2;

the x-monotone curve type.

typedef typename Arrangement_2::Vertex_handle

Vertex_handle;

typedef typename Arrangement_2::Halfedge_handle

Halfedge_handle;

typedef typename Arrangement_2::Face_handle

Face_handle;

typedef typename Arrangement_2::Ccb_halfedge_circulator

Ccb_halfedge_circulator;

represents the boundary of a connected component (CCB).

Creation

Arr_accessor<Arrangement> acc(Arrangement_2& arr);

constructs an accessor attached to the given arrangement *arr*.

Accessing the notification functions

void *acc.notify_before_global_change()*

notifies the arrangement observer that a global change is going to take place (for the usage of the global functions that operate on arrangements).

void *acc.notify_after_global_change()*

notifies the arrangement observer that a global change has taken place (for the usage of the global functions that operate on arrangements).

advanced

Arrangement Predicates

Halfedge_handle *acc.locate_around_vertex(Vertex_handle v, X_monotone_curve_2 c) const*

locates a place for the curve *c* around the vertex *v* and returns a halfedge whose target is *v*, where c should be inserted between this halfedge and the next halfedge around *v* in a clockwise order.

int *acc.halfedge_distance(Halfedge_const_handle e1, Halfedge_const_handle e2) const*

counts the number of edges along the path from *e1* to *e2*. In case the two halfedges do not belong to the same connected component, the function returns (-1).

bool *acc.is_inside_new_face(Halfedge_handle pred1, Halfedge_handle pred2, X_monotone_curve_2 c) const*

determines whether a new halfedge we are about to create, which is to be associated with the curve *c* and directed from *pred1->target()* to *pred2->target()*, lies on the inner CCB of the new face that will be created, introducing this new edge.
Precondition: *pred1->target()* and *pred2->target()* are associated with *c*'s endpoints.
Precondition: *pred1* and *pred2* belong to the same connected component, such that a new face is created by connecting *pred1->target()* and *pred2->target()*.

bool *acc.point_is_in(Point_2 p, Halfedge_const_handle he) const*

determines whether a given point lies within the region bounded by a boundary of the connected component that *he* belongs to. Note that if the function returns *true*, then *p* is contained within *he->face()* (but not on its boundary), or inside one of the holes inside this face, or it may coincide with an isolated vertex in this face.

bool *acc.is_on_outer_boundary(Halfedge_const_handle he) const*

determines whether *he* lies on the outer boundary of its incident face.

bool *acc.is_on_inner_boundary(Halfedge_const_handle he) const*

determines whether *he* lies on the inner boundary of its incident face (that is, whether it lies on the boundary of one of the holes in this face).

Arrangement Modifiers

Vertex_handle *acc.create_vertex(Point_2 p)*

creates a new vertex an associates it with the point *p*. It is the user's responsibility that there is no existing vertex already associated with *p*.

Halfedge_handle *acc.insert_in_face_interior_ex(X_monotone_curve_2 c,*
Face_handle f,
Vertex_handle v1,
Vertex_handle v2,
Comparison_result res)

inserts the curve *c* as a new hole (inner component) of the face *f*, connecting the two isolated vertices *v1* and *v2*. *res* is the comparison result between these two end-vertices. The function returns a handle for one of the new halfedges corresponding to the inserted curve, directed from *v1* to *v2*.
Precondition: It is the user's responsibility that *v1* and *v2* are associated with *c*'s endpoints, that they lie of *f*'s interior and that and that they have no incident edges.

Halfedge_handle *acc.insert_from_vertex_ex(X_monotone_curve_2 c,*
Halfedge_handle pred,
Vertex_handle v,
Comparison_result res)

inserts the curve *c* into the arrangement, such that one of its endpoints corresponds to an arrangement, which is the target vertex of the halfedge *pred*, such that *c* is inserted to the circular list of halfedges around *pred->target()* right between *pred* and its successor. The other end-vertex is given by an isolated vertex *v*, where *res* is the comparison result between *pred->target()* and *v*. The function returns a handle for one of the new halfedges directed from *pred->target()* to *v*.
Precondition: It is the user's responsibility that *pred->target()* and *v* are associated with *c*'s endpoints and that and that *v* has no incident edges.

Halfedge_handle *acc.insert_at_vertices_ex(X_monotone_curve_2 c, Halfedge_handle pred1, Halfedge_handle pred2, Comparison_result res, bool& new_face)*

inserts the curve *c* into the arrangement, such that both *c*'s endpoints correspond to existing arrangement vertices, given by *pred1->target()* and *pred2->target()*. *res* is the comparison result between these two end-vertices. The function creates a new halfedge pair that connects the two vertices (with *pred1* and *pred2* indicate the exact place for these halfedges around the two target vertices) and returns a handle for the halfedge directed from *pred1->target()* to *pred2->target()*. The output flag *new_face* indicates whether a new face has been created following the insertion of the new curve.
Precondition: It is the user's responsibility that *pred1->target()* and *pred2->target()* are associated with *c*'s endpoints and that if a new face is created, then *is_inside_new_face (pred1, pred2, c)* is *true*.

void *acc.insert_isolated_vertex(Face_handle f, Vertex_handle v)*

inserts *v* as an isolated vertex inside *f*.
Precondition: It is the user's responsibility that *v->point()* is contained in the interior of the given face.

void *acc.move_hole(Face_handle f1, Face_handle f2, Ccb_halfedge_circulator hole)*

moves the given hole from the interior of the face *f1* inside the face *f2*.
Precondition: It is the user's responsibility that *hole* is currently contained in *f1* and should be moved to *f2*.

bool *acc.move_isolated_vertex(Face_handle f1, Face_handle f2, Vertex_handle v)*

moves the given isolated vertex from the interior of the face *f1* inside the face *f2*.
Precondition: It is the user's responsibility that *v* is indeed an isolated vertex currently contained in *f1* and should be moved to *f2*.

void *acc.relocate_in_new_face(Halfedge_handle he)*

relocates all holes and isolated vertices to their proper position immediately after a face has split due to the insertion of a new halfedge, namely after *insert_at_vertices_ex()* was invoked and indicated that a new face has been created. *he* is the halfegde returned by *insert_at_vertices_ex()*, such that *he->twin()->face* is the face that has just been split and *he->face()* is the newly created face.

void *acc.relocate_holes_in_new_face(Halfedge_handle he)*

relocates all holes in a new face, as detailed above.

void *acc.relocate_isolated_vertices_in_new_face(Halfedge_handle he)*

relocates all isolated vertices in a new face, as detailed above.

Vertex_handle *acc.modify_vertex_ex(Vertex_handle v, Point_2 p)*

modifies the point associated with the vertex v (the point may be geometrically different than the one currently associated with v). The function returns a handle to the modified vertex (same as v).
Precondition: It is the user's responsibility that no other arrangement vertex is already associated with p.

Halfedge_handle *acc.modify_edge_ex(Halfedge_handle e, X_monotone_curve_2 c)*

modifies the x-monotone curve associated with the edge e (the curve c may be geometrically different than the one currently associated with e). The function returns a handle to the modified edge (same as e).
Precondition: It is the user's responsibility that the interior of c is disjoint from all existing arrangement vertices and edges.

Halfedge_handle *acc.split_edge_ex(Halfedge_handle he,*
Point_2 p,
X_monotone_curve_2 c1,
X_monotone_curve_2 c2)

splits a given edge into two at the split point p, and associate the x-monotone curves *c1* and *c2* with the resulting edges, such that *c1* connects *he->source()* with p and *c2* connects p with *he->target()*. The function return a handle to the split halfedge directed from *he->source()* to the split point p.
Precondition: It is the user's responsibility that the endpoints of *c1* and *c2* correspond to p and to *he*'s end-vertices, as indicated above.

Halfedge_handle *acc.split_edge_ex(Halfedge_handle he,*
Vertex_handle v,
X_monotone_curve_2 c1,
X_monotone_curve_2 c2)

splits a given edge into two at by the vertex v, and associate the x-monotone curves *c1* and *c2* with the resulting edges, such that *c1* connects *he->source()* with v and *c2* connects v with *he->target()*. The function return a handle to the split halfedge directed from *he->source()* to v.
Precondition: It is the user's responsibility that the endpoints of *c1* and *c2* correspond to v and to *he*'s end-vertices, as indicated above. It is also assumed that v has no incident edges.

Face_handle *acc.remove_edge_ex(Halfedge_handle he, bool remove_source = true, bool remove_target = true)*

removes the edge *he* from the arrangement, such that if the edge removal causes the creation of a new hole, *he->target()* lies on the boundary of this hole. The flags *remove_source* and *remove_target* indicate whether the end-vertices of *he* should be removed as well, in case they have no other incident edges. If the operation causes two faces to merge, the merged face is returned. Otherwise, the face to which the edge was incident is returned.

advanced

CGAL::Arrangement_2<Traits,Dcel>::Vertex

Class

Definition

An object *v* of the class *Vertex* represents an arrangement vertex, that is — a 0-dimensional cell, associated with a point on the plane.

Inherits From

typename Dcel::Vertex

Creation

Vertex v; — default constructor.

Access Functions

All non-const methods listed below also have *const* counterparts that return constant handles, iterators or circulators:

bool *v.is_at_open_boundary() const*

checks whether the vertex lies at infinity and not associated with a point with bounded coordinates.

bool *v.is_isolated() const*

checks whether the vertex is isolated (i.e., has no incident edges).

typename Dcel::Size *v.degree() const*

returns the number of edges incident to *v*.

Halfedge_around_vertex_circulator *v.incident_halfedges()*

returns a circulator circulator that allows going over the halfedges incident to *v* (that have *v* as their target). The edges are traversed in a clockwise direction around *v*.
Precondition: *v* is *not* an isolated vertex.

Face_handle *v.face()* — returns a handle to the face that contains *v* in its interior.
Precondition: *v* is an isolated vertex.

typename Traits::Point_2 *v.point() const* — returns the point associated with the vertex.
Precondition: *v* is not a vertex at infinity.

Arr_parameter_space *v.parameter_space_in_x() const*

returns the placement of the *x*-coordinate in the parameter space, that is, either the left boundary-side, the interior, or the right boundary-side.

Arr_parameter_space *v.parameter_space_in_y() const*

returns the placement of the *y*-coordinate in the parameter space, that is, either the bottom boundary-side, the interior, or the top boundary-side.

CGAL::Arrangement_2<Traits,Dcel>::Halfedge

Class

Definition

An object *e* of the class *Halfedge* represents a halfedge in the arrangement. A halfedge is directed from its *source* vertex to its *target* vertex, and has an *incident face* lying to its right. Each halfedge has a *twin* halfedge directed in the opposite direction, where the pair of twin halfedges form together an arrangement edge, that is — a 1-dimensional cell, associated with planar *x*-monotone curve.

Halfedges are stored in doubly-connected lists and form chains. These chains define the inner and outer boundaries of connected components.

Inherits From

typename Dcel::Halfedge

Creation

Halfedge e;	default constructor.

Access Functions

All non-const methods listed below also have *const* counterparts that return constant handles, iterators or circulators:

bool	*e.is_fictitious() const*	
		returns whether the halfedge is fictitious (i.e., connects two vertices at infinity and is not associated with a valid curve).
Vertex_handle	*e.source()*	returns a handle for the source vertex of *e*.
Vertex_handle	*e.target()*	returns a handle for the target vertex of *e*.
Arr_halfedge_direction	*e.direction() const*	
		returns the direction of the halfedge: *ARR_LEFT_TO_RIGHT* if *e*'s source vertex is lexicographically smaller than it target (so the halfedge is directed from left to right), and *ARR_RIGHT_TO_LEFT* if it is lexicographically larger than the target (so the halfedge is directed from right to left).
Face_handle	*e.face()*	returns the face that *e* is incident to (The face lies to the left of *e*).
Halfedge_handle	*e.twin()*	returns the twin halfedge.
Halfedge_handle	*e.prev()*	returns *e*'s predecessor in the connected component it belongs to.

Halfedge_handle	*e.next()*	returns e's successor in the connected component it belongs to.
Ccb_halfedge_circulator	*e.ccb()*	returns a circulator that allows traversing the halfedges of the connected component boundary (CCB) that contains e. The circulator is initialized to point to e.

typename Traits::X_monotone_curve_2

e.curve() const

returns the x-monotone curve associated with e.
Precondition: e is not a fictitious halfedge.

CGAL::Arrangement_2<Traits,Dcel>::Face

Class

Definition

An object of the class *Face* represents an arrangement face, namely, a 2-dimensional arrangement cell. An arrangement that supports only bounded curves contains exactly one *unbounded* face, and a number of bounded faces. An arrangement that supports also unbounded curves has one or more unbounded faces. Such an arrangement has also exactly one fictitious face, which does not correspond to a real two-dimensional cell of the arrangement (and thus it is ignored in counting the number of faces of the arrangement.) Each bounded face has an outer boundary comprising a halfedge chain winding in counterclockwise orientation around it. Each unbounded face of an arrangement that has a fictitious face also has a boundary comprising a counterclockwise halfedge-chain. The edges on the boundary of a face incident to the fictitious face are fictitious, as they do not correspond to real curves. A face may also contain holes, which are defined by clockwise-oriented halfedge chains, and isolated vertices.

Inherits From

typename Dcel::Face

Creation

Face f;	default constructor.

Access Functions

All non-const methods listed below also have *const* counterparts that return constant handles, iterators or circulators:

bool	*f.is_fictitious() const*	returns a Boolean indicating whether this is the fictitious face, which contain the entire arrangement (and does not have an outer CCB). An arrangement that supports only bounded curves does not have a fictitious face at all.
bool	*f.is_unbounded() const*	returns a Boolean indicating whether the face is unbounded.
bool	*f.has_outer_ccb() const*	returns a Boolean indicating whether the face has an outer CCB. (The fictitious face and the unbounded face of an arrangement that does not have a fictitious face do not have outer CCBs.)

Ccb_halfedge_circulator

	f.outer_ccb()	returns a circulator that enables traversing the outer boundary of f. The edges along the CCB are traversed in a counterclockwise direction. *Precondition*: The face f has an outer CCB.
Hole_iterator	*f.holes_begin()*	returns an iterator for traversing all the holes (inner CCBs) of f.
Hole_iterator	*f.holes_end()*	returns a past-the-end iterator for the holes of f.

Isolated_vertex_iterator

f.isolated_vertices_begin()

returns an iterator for traversing all the isolated vertices contained in the interior of f.

Isolated_vertex_iterator

f.isolated_vertices_end()

returns a past-the-end iterator for the isolated vertices contained inside f.

CGAL::is_valid

Definition

The function *is_valid* checks the validity of a given arrangement.

#include <CGAL/Arrangement_2.h>

template<typename Traits, typename Dcel>
bool *is_valid(Arrangement_2<Traits, Dcel> arr)*

Invokes the member function *arr.is_valid()* to verify the topological correctness of the arrangement. Then it performs additional validity tests. It checks that all x-monotone curves associated with arrangement edges are pairwise disjoint in their interior. Then it makes sure that all holes and all isolated vertices are located within the proper arrangement faces. Note that the test carried out by this function may take a considerable amount of time; it is recommended to be used only for debugging purposes.

Requirements

The instantiated traits class must model the concept *ArranagmentXMonotoneTraits_2*.

Function

CGAL::insert

Definition

The function *insert* inserts one or more curves or x-monotone curves into a given arrangement, where no restrictions are imposed on the inserted curves. If an inserted curve is not x-monotone curve, it is subdivided into x-monotone subcurves (and perhaps isolated points), which are inserted into the arrangement.

#include <CGAL/Arrangement_2.h>

template<class Traits, class Dcel, class Curve, class PointLocation>
void *insert(Arrangement_2<Traits,Dcel>& arr, Curve c, PointLocation pl = walk_pl)*

Inserts the given curve *c* into the arrangement *arr*. *c* is subdivided into x-monotone subcurves (and perhaps isolated points). Each subcurve is in turn inserted into the arrangement by locating its left endpoint and computing its zone until reaching the right endpoint.

The given point-location object *pl* is used to locate the left endpoints of the x-monotone curves. By default, the function uses the "walk along line" point-location strategy — namely an instance of the class *Arr_walk_along_line_point_location<Arrangement_2<Traits,Dcel> >*.

Precondition: If provided, *pl* must be attached to the given arrangement *arr*.

template<typename Traits, typename Dcel>
void *insert(Arrangement_2<Traits,Dcel>& arr,*
typename Traits::X_monotone_curve_2 xc,
Object obj)

Inserts the*x-monotone (only)* curve *xc* into the arrangement *arr*. The object *obj*, which either wraps a *Vertex_const_handle*, a *Halfedge_const_handle*, or a *Face_const_handle*, represents the location of *xc*'s left endpoint in the arrangement. The zone of *xc* is computed starting from the feature represented by *obj*. As in the case above, the zone computation terminates, when the right endpoint is reached. Thus, point-location is not required.

template<class Traits, class Dcel, class InputIterator>
void *insert(Arrangement_2<Traits,Dcel>& arr, InputIterator first, InputIterator last)*

Aggregately inserts the curves or x-monotone curves in the range *[first,last)* into the arrangement *arr* using the sweep-line framework.

#include <CGAL/Arrangement_with_history_2.h>

template<typename Traits, typename Dcel, typename PointLocation>
typename Arrangement_with_history_2<Traits,Dcel>::Curve_handle

insert(Arrangement_with_history_2<Traits,Dcel>& arr,
typename Traits::Curve_2 c,
PointLocation pl = walk_pl)

Inserts the given curve *c* into the arrangement with history *arr*, and returns a handle to the inserted curve. *c* is subdivided into x-monotone subcurves (and perhaps isolated points). Each subcurve is in turn inserted into the arrangement by locating its left endpoint and computing its zone until reaching the right endpoint.

The given point-location object *pl* is used to locate the left endpoints of the x-monotone curves. By default, the function uses the "walk along line" point-location strategy — namely an instance of the class *Arr_walk_along_line_point_location<Arrangement_2<Traits,Dcel> >*.

Precondition: If provided, *pl* is attached to the given arrangement *arr*.

template<class Traits, class Dcel, InputIterator>
void *insert(Arrangement_with_history_2<Traits,Dcel>& arr, InputIterator first, InputIterator last)*

Aggregately inserts the curves in the range *[first,last)* into the arrangement with history *arr* using the sweep-line framework.

Requirements

- If the curve is x-monotone curve then The instantiated *Traits* class must model the *ArrangementXMonotoneTraits_2* concept. In case that the curve is not x-monotone then the instantiated *Traits* class must model the *ArrangementTraits_2* concept. That is, it should define the *Curve_2* type, and support its subdivision into x-monotone subcurves (and perhaps isolated points).
- The point-location object *pl*, must model the *ArrangementPointLocation_2* concept.

Function

CGAL::insert_non_intersecting_curve

Definition

The function *insert_non_intersecting_curve* inserts a given x-monotone curve into a given arrangement, where the interior of the given curve is disjoint from all existing arrangement vertices and edges. Under this assumption, it is possible to locate the endpoints of the given curve in the arrangement, and use one of the specialized insertion member-functions of the arrangement according to the results. The insertion operations creates a single new edge, that is, two twin halfedges, and the function returns a handle for the one directed lexicographically in increasing order (from left to right).

A given point-location object is used for answering the two point-location queries on the given curve endpoints. By default, the function uses the "walk along line" point-location strategy — namely, an instance of the class *Arr_walk_along_line_point_location<Arrangement_2<Traits,Dcel> >*.

#include <CGAL/Arrangement_2.h>

```
template<typename Traits, typename Dcel, typename PointLocation>
typename Arrangement_2<Traits,Dcel>::Halfedge_handle

        insert_non_intersecting_curve( Arrangement_2<Traits,Dcel>& arr,
                                       typename Traits::X_monotone_curve_2 xc,
                                       PointLocation pl = walk_pl)
```

Precondition: If provided, *pl* must be attached to the given arrangement *arr*.

Requirements

- The instantiated *Traits* class must model the restricted *ArrangementBasicTraits_2* concept, as no intersections are computed.
- The point-location object *pl* must model the *ArrangementPointLocation_2* concept.

CGAL::insert_non_intersecting_curves

Function

Definition

The function *insert_non_intersecting_curves* inserts a set of x-monotone curves in a given range into a given arrangement. The insertion is performed in an aggregated manner, using the sweep-line algorithm. The input curves should be pairwise disjoint in their interior and pairwise interior-disjoint from all existing arrangement vertices and edges.

#include <CGAL/Arrangement_2.h>

```
template<typename Traits, typename Dcel, InputIterator>
void    insert_non_intersecting_curves( Arrangement_2<Traits,Dcel>& arr,
                                        InputIterator first,
                                        InputIterator last)
```

Requirements

- The instantiated *Traits* class must model the *ArrangementBasicTraits_2* concept, as no intersections are computed.
- *InputIterator::value_type* must be *Traits::X_monotone_curve_2*

Function

CGAL::insert_point

Definition

The function *insert_point* inserts a given point into a given arrangement. It uses a given point-location object to locate the given point in the given arrangement. If the point conincides with an existing vertex, there is nothing left to do; if it lies on an edge, the edge is split at the point. Otherwise, the point is contained inside a face, and is inserted as an isolated vertex inside this face. By default, the function uses the "walk along line" point-location strategy — namely, an instance of the class *Arr_walk_along_line_point_location<Arrangement_2<Traits,Dcel> >*. In either case, the function returns a handle for the vertex associated with the point.

#include <CGAL/Arrangement_2.h>

template<typename Traits, typename Dcel, typename PointLocation>
typename Arrangement_2<Traits,Dcel>::Vertex_handle

insert_point(Arrangement_2<Traits,Dcel>& arr,
typename Traits::Point_2 p,
PointLocation pl = walk_pl)

Precondition: If provided, *pl* must be attached to the given arrangement *arr*.

Requirements

- The instantiated *Traits* class must model the *ArrangementXMonotoneTraits_2* concept. Not all expressions listed by this concept are required. In fact the traits class must model the *ArrangementBasicTraits_2* concept, and support the splitting functionality.
- The point-location object *pl*, must model the *ArrangementPointLocation_2* concept.

CGAL::zone

Function

Definition

The function *zone* compute the zone of the given x-monotone curve in the existing arrangement. Meaning, it output the arrangement's vertices, edges and faces that the x-monotone curve intersects. The order of the objects is the order that they are discovered when traversing the x-monotone curve from left to right.

A given point-location object is used for answering point-location queries during the insertion process. By default, the function uses the "walk along line" point-location strategy — namely an instance of the class *Arr_walk_along_line_point_location<Arrangement_2<Traits,Dcel> >*.

#include <CGAL/Arrangement_2.h>

```
template <class GeomTraits, class TopTraits, class OutputIterator, class PointLocation>
OutputIterator        zone( Arrangement_on_surface_2<GeomTraits, TopTraits>& arr,
                            typename GeomTraits::X_monotone_curve_2 c,
                            OutputIterator oi,
                            PointLocation pl)
```

Compute the zone of the given x-monotone curve c in the arrangement *arr*.

Precondition: If provided, *pl* must be attached to the given arrangement *arr*.

Requirements

- The instantiated *GeomTraits* class must model the *ArrangementXMonotoneTraits_2* concept.
- The point-location object *pl*, must model the *ArrangementPointLocation_2* concept.

Function

CGAL::do_intersect

Definition

The function *do_intersect* checks if a given curve or x-monotone curve intersects an existing arrangement's edges or vertices.

If the give curve is not an x-monotone curve then the function subdivides the given curve into x-monotone subcurves and isolated vertices . Each subcurve is in turn checked for intersection. The function uses the zone algorithm to check if the curve intersects the arrangement. First, the curve's left endpoint is located. Then, its zone is computed starting from its left endpoint location. The zone computation terminates when an intersection with an arrangement's edge/vertex is found or when the right endpoint is reached.

A given point-location object is used for locating the left endpoint of the given curve in the existing arrangement. By default, the function uses the "walk along line" point-location strategy — namely an instance of the class *Arr_walk_along_line_point_location<Arrangement_2<Traits,Dcel> >*.

#include <CGAL/Arrangement_2.h>

```
template <class GeomTraits, class TopTraits, class Curve, class PointLocation>
bool          do_intersect( Arrangement_on_surface_2<GeomTraits, TopTraits>& arr,
                            Curve c,
                            PointLocation pl)
```

Checks if the given curve or x-monotone curve c intersects edges or vertices of the existing arrangement *arr*.

Precondition: If provided, *pl* must be attached to the given arrangement *arr*.

Requirements

- If c is x-monotone then the instantiated *GeomTraits* class must model the *ArrangementXMonotoneTraits_2* concept. If c is a curve then the instantiated *GeomTraits* class must model the *ArrangementTraits_2* concept. That is, it should define the *Curve_2* type, and support its subdivision into x-monotone subcurves (and perhaps isolated points).
- The point-location object *pl*, must model the *ArrangementPointLocation_2* concept.

CGAL::remove_edge

Function

Definition

The function *remove_edge* removes an edge given by one of the twin halfedges that forms it, from a given arrangement. Once the edge is removed, if the vertices associated with its endpoints become isolated, they are removed as well. The call *remove_edge(arr, e)* is equivalent to the call *arr.remove_edge (e, true, true)*. However, this free function requires that *Traits* be a model of the refined concept *ArrangementXMonotoneTraits_2*, which requires merge operations on x-monotone curves. If one of the end-vertices of the given edge becomes redundant after the edge is removed (see *remove_vertex()* for the definition of a redundant vertex), it is removed, and its incident edges are merged. If the edge-removal operation causes two faces to merge, the merged face is returned. Otherwise, the face to which the edge was incident before the removal is returned.

#include <CGAL/Arrangement_2.h>

```
template<typename Traits, typename Dcel>
typename Arrangement_2<Traits,Dcel>::Face_handle

        remove_edge( Arrangement_2<Traits,Dcel>& arr,
                     typename Arrangement_2<Traits,Dcel>::Halfedge_handle e)
```

Requirements

- The instantiated traits class must model the concept *ArrangementXMonotoneTraits_2*.

CGAL::remove_vertex

Definition

The function *remove_vertex* attempts to removed a given vertex from a given arrangement. The vertex can be removed if it is either an isolated vertex, (and has no incident edge,) or if it is a *redundant* vertex. That is, it has exactly two incident edges, whose associated curves can be merged to form a single x-monotone curve. The function returns a boolean value that indicates whether it succeeded removing the vertex from the arrangement.

#include <CGAL/Arrangement_2.h>

```
template <typename Traits, typename Dcel>
bool        remove_vertex( Arrangement_2<Traits,Dcel>& arr,
                           typename Arrangement_2<Traits,Dcel>::Vertex_handle v)
```

Requirements

- The instantiated *Traits* class must model the *ArrangementXMonotoneTraits_2* concept. Not all expressions listed by this concept are required. In fact the traits class must model the *ArrangementBasicTraits_2* concept and support the merging functionality.

CGAL::overlay

Definition

The function *overlay* computes the overlay of two input arrangement objects, and returns the overlaid arrangement. All three arrangements can be instantiated with different geometric traits classes and different DCEL (encapsulated in the various topology-traits classes) classes. The geometry traits of the resulting arrangement is used to construct the resulting arrangement. This means that all the types (e.g., *Traits::Point_2*, *Traits::Curve_2*, and *Traits::Point_2*) of both input arrangements have to be convertible to the types in the resulting arrangement. A given overlay-traits object is used to properly construct the overlaid DCEL that represents the resulting arrangement.

#include <CGAL/Arr_overlay_2.h>

```
template <class GeomTraitsA, class GeomTraitsB, class GeomTraitsRes, class TopTraitsA, class TopTraitsB,
class TopTraitsRes, class OverlayTraits>
void    overlay( Arrangement_2<GeomTraitsA, TopTraitsA> arr1,
                 Arrangement_2<GeomTraitsB, TopTraitsB> arr2,
                 Arrangement_2<GeomTraitsRes, TopTraitsRes>& arr_res,
                 OverlayTraits& ovl_tr)
```

Computes the overlay of two arrangements *arr1* and *arr2*, and sets the output arrangement *res* to represent the overlaid arrangement.

Precondition: *res* does not refer to either *arr1* or *arr2* (that is, “self overlay” is not supported).

```
template <class GeomTraitsA, class GeomTraitsB, class GeomTraitsRes, class TopTraitsA, class TopTraitsB,
class TopTraitsRes>
void    overlay( Arrangement_2<GeomTraitsA, TopTraitsA> arr1,
                 Arrangement_2<GeomTraitsB, TopTraitsB> arr2,
                 Arrangement_2<GeomTraitsRes, TopTraitsRes>& arr_res)
```

Computes the (simple) overlay of two arrangements *arr1* and *arr2*, and sets the output arrangement *res* to represent the overlaid arrangement. It employs the default overlay-traits, which practically does nothing.

Precondition: *res* does not refer to either *arr1* or *arr2* (that is, “self overlay” is not supported).

#include <CGAL/Arrangement_with_history_2.h>

```
template<typename Traits, typename Dcel1, typename Dcel2, typename ResDcel, typename OverlayTraits>
void    overlay( Arrangement_with_history_2<Traits,Dcel1> arr1,
                 Arrangement_with_history_2<Traits,Dcel2> arr2,
                 Arrangement_with_history_2<Traits,ResDcel>& res,
                 OverlayTraits& ovl_tr)
```

Computes the overlay of two arrangements with history *arr1* and *arr2*, and sets the output arrangement with history *res* to represent the overlaid arrangement. The function also constructs a consolidated set of curves that induce *res*.

Precondition: *res* does not refer to either *arr1* or *arr2* (that is, "self overlay" is not supported).

template<typename Traits, typename Dcel1, typename Dcel2, typename ResDcel>
void overlay(Arrangement_with_history_2<Traits,Dcel1> arr1,
Arrangement_with_history_2<Traits,Dcel2> arr2,
Arrangement_with_history_2<Traits,ResDcel>`&` *res)*

Computes the (simple) overlay of two arrangements with history *arr1* and *arr2*, and sets the output arrangement with history *res* to represent the overlaid arrangement. The function also constructs a consolidated set of curves that induce *res*. It employs the default overlay-traits, which practically does nothing.

Precondition: *res* does not refer to either *arr1* or *arr2* (that is, "self overlay" is not supported).

Requirements

- The overlay-traits object *ovl_tr* must model the *OverlayTraits* concept, which is able to construct records of the *ResDcel* class on the basis of the *Dcel1* and *Dcel2* records that induce them.

See Also

OverlayTraits(page 2223)

OverlayTraits

A model for the OverlayTraits should be able to operate on records (namely, vertices, halfedges and faces) of two input DCEL classes, named *Dcel_A* and *Dcel_B*, and construct the records of an output DCEL class, referred to as *Dcel_R*.

Models for the concept are used by the global *overlay()* function to maintain the auxiliary data stored with the DCEL records of the resulting overlaid arrangement, based on the contents of the input records.

Types

OverlayTraits:: Vertex_handle_A	a constant handle a vertex in *Dcel_A*.
OverlayTraits:: Halfedge_handle_A	a constant handle to a halfedge in *Dcel_A*.
OverlayTraits:: Face_handle_A	a constant handle to a face *Dcel_A*.
OverlayTraits:: Vertex_handle_B	a constant handle to a vertex in *Dcel_B*.
OverlayTraits:: Halfedge_handle_B	a constant handle to a halfedge in *Dcel_B*.
OverlayTraits:: Face_handle_B	a constant handle to a face in *Dcel_B*.
OverlayTraits:: Vertex_handle_R	a handle to a vertex in *Dcel_R*.
OverlayTraits:: Halfedge_handle_R	a handle to a halfedge in *Dcel_R*.
OverlayTraits:: Face_handle_R	a handle to a faces in *Dcel_R*.

Functions

Whenever a vertex in the overlaid arrangement is created, one of the following functions is called in order to attach the appropriate auxiliary data to this vertex:

```
void    ovl_tr.create_vertex( Vertex_handle_A v1,
                              Vertex_handle_B v2,
                              Vertex_handle_R v) const
```

constructs the vertex *v* induced by the coinciding vertices *v1* and *v2*.

```
void    ovl_tr.create_vertex( Vertex_handle_A v1,
                              Halfedge_handle_B e2,
                              Vertex_handle_R v) const
```

constructs the vertex *v* induced by the vertex *v1* that lies on the halfedge *e2*.

```
void    ovl_tr.create_vertex( Vertex_handle_A v1,
                              Face_handle_B f2,
                              Vertex_handle_R v) const
```

constructs the vertex *v* induced by the vertex *v1* that lies inside the face *f2*.

void *ovl_tr.create_vertex(Halfedge_handle_A e1, Vertex_handle_B v2, Vertex_handle_R v) const*

constructs the vertex *v* induced by the vertex *v2* that lies on the halfedge *e1*.

void *ovl_tr.create_vertex(Face_handle_A f1, Vertex_handle_B v2, Vertex_handle_R v) const*

constructs the vertex *v* induced by the vertex *v2* that lies inside the face *f1*.

void *ovl_tr.create_vertex(Halfedge_handle_A e1, Halfedge_handle_B e2, Vertex_handle_R v) const*

constructs the vertex *v* induced by the intersection of the halfedges *e1* and *e2*.

Whenever an edge in the overlaid arrangement is created, one of the following functions is called in order to attach the appropriate auxiliary data to this vertex. Note that an edge is created after both its end-vertices are created, (and the corresponding *create_vertex()* methods were invoked). In all cases, the edge is represented by a halfedge *e* directed in lexicographic decreasing order (from right to left). The *create_edge()* method should attach auxiliary data to the twin halfedge (namely to *e->twin()*) as well:

void *ovl_tr.create_edge(Halfedge_handle_A e1, Halfedge_handle_B e2, Halfedge_handle_R e) const*

constructs the halfedge *e* induced by an overlap between the halfedges *e1* and *e2*.

void *ovl_tr.create_edge(Halfedge_handle_A e1, Face_handle_B f2, Halfedge_handle_R e) const*

constructs the halfedge *e* induced by the halfedge *e1* that lies inside the face *f2*.

void *ovl_tr.create_edge(Face_handle_A f1, Halfedge_handle_B e2, Halfedge_handle_R e) const*

constructs the halfedge *e* induced by the halfedge *e2* that lies inside the face *f1*.

The following function is invoked whenever a new face is created. It is guaranteed that all halfedges along the face boundary have already been created an have their auxiliary data fields attached to them:

void	*ovl_tr.create_face(Face_handle_A f1, Face_handle_B f2, Face_handle_R f) const*
	constructs the face *f* induced by the an overlap between the faces *f1* and *f2*.

Class

CGAL::Arr_default_overlay_traits<Arrangement>

Definition

An instance of *Arr_default_overlay_traits<Arrangement>* should be used for overlaying two arrangements of type *Arrangement* that store no auxiliary data with their DCEL records, where the resulting overlaid arrangement stores no auxiliary DCEL data as well. This class simply gives empty implementation for all traits-class functions.

#include <CGAL/Arr_default_overlay_traits.h>

CGAL::Arr_face_overlay_traits<Arr_A,Arr_B,Arr_R,OvlFaceData>

Class

Definition

An instance of *Arr_face_overlay_traits<Arr_A,Arr_B,Arr_R,OvlFaceData>* should be used for overlaying two arrangements of types *Arr_A* and *Arr_B*, which are instantiated using the same geometric traits-class and with the DCEL classes *Dcel_A* and *Dcel_B* respectively, in order to store their overlay in an arrangement of type *Arr_R*, which is instantiated using a third DCEL class *Dcel_R*. All three DCEL classes are assumed to be instantiations of the *Arr_face_extended_dcel* template with types *FaceData_A*, *FaceData_B* and *FaceData_R*, respectively.

This class gives empty implementation for all overlay traits-class functions, except the function that computes the overlay of two faces. In this case, it uses the functor *OvlFaceData*, which accepts a *FaceData_A* object and a *FaceData_B* object and computes a corresponding *FaceData_R* object, in order to set the auxiliary data of the overlay face.

#include <CGAL/Arr_default_overlay_traits.h>

Function

CGAL::read

Definition

The function *read* reads a given arrangement from a given input stream using a specific input format.

#include <CGAL/IO/Arr_iostream.h>

template<typename Traits, typename Dcel, typename Formatter>
std::istream& *read(Arrangement_2<Traits,Dcel>& arr, std::istream& is, Formatter& formatter)*

Reads the arrangement object *arr* from the given input stream *is* using a specific input format defined by formatter.

#include <CGAL/IO/Arr_with_history_iostream.h>

template<typename Traits, typename Dcel, typename WithHistoryFormatter>
std::istream& *read(Arrangement_with_history_2<Traits,Dcel>& arr,*
std::istream& is,
WithHistoryFormatter& formatter)

Reads the arrangement-with-history object *arr* from the given input stream *is* using a specific input format defined by formatter.

Requirements

- The instantiated *Formatter* class must model the *ArrangementInputFormatter* concept.
- The instantiated *WithHistoryFormatter* class must model the *ArrangementWithHistoryInputFormatter* concept.

See Also

write(page 2230)
operator<< page 2231
operator>> page 2229

CGAL::operator>>

Definition

Extracts an arrangement from a given input stream using the input format defined by the *Arr_text_formatter* class — that is, only the basic geometric and topological features of the arrangement are read and no auxiliary data is attached to the DCEL features.

#include <CGAL/IO/Arr_iostream.h>

template<class Traits, class Dcel>
std::istream& *std::istream& is >> Arrangement_2<Traits,Dcel>& arr*

Extracts an arrangement-with-history from a given input stream using the default input format.

#include <CGAL/IO/Arr_with_history_iostream.h>

template<class Traits, class Dcel>
std::istream& *std::istream& is >> Arrangement_with_history_2<Traits,Dcel>& arr*

Function

Function

CGAL::write

Definition

The function *write* writes a given arrangement into a given output stream using a specific output format.

#include <CGAL/IO/Arr_iostream.h>

template<typename Traits, typename Dcel, typename Formatter>
std::ostream& *write(Arrangement_2<Traits,Dcel> arr, std::ostream& os, Formatter& formatter)*

Writes the arrangement object *arr* into the given output stream *os* using a specific output format defined by *formatter*.

#include <CGAL/IO/Arr_with_history_iostream.h>

template<typename Traits, typename Dcel, typename WithHistoryFormatter>
std::ostream& *write(Arrangement_with_history_2<Traits,Dcel> arr,*
std::ostream& os,
WithHistoryFormatter& formatter)

Writes the arrangement-with-history object *arr* into the given output stream *os* using a specific output format defined by *formatter*.

Requirements

- The instantiated *Formatter* class must model the *ArrangementOutputFormatter* concept.
- The instantiated *WithHistoryFormatter* class must model the *ArrangementWithHistoryOutputFormatter* concept.

See Also

read(page 2228)
operator<< page 2231

CGAL::operator<<

Definition

The function *operator<<* inserts an object into a given output stream.

#include <CGAL/IO/Arr_iostream.h>

template<typename Traits, typename Dcel>
std::ostream& *std::ostream& os << Arrangement_2<Traits,Dcel> arr*

Inserts the arrangement object *arr* into the output stream *os* using the output format defined by the *Arr_text_formatter* class. Only the basic geometric and topological features of the arrangement are inserted. Auxiliary data that may be attached to the DCEL features is ignored.

#include <CGAL/IO/Arr_with_history_iostream.h>

template<typename Traits, typename Dcel>
std::ostream& *std::ostream& os << Arrangement_with_history_2<Traits,Dcel> arr*

Inserts the arrangement-with-history object *arr* into the output stream *os* using the output format defined by the *Arr_with_history_text_formatter* class. Only the basic geometric and topological features of the arrangement are inserted. Auxiliary data that may be attached to the DCEL features is ignored.

Inserts a polyline into a given *Qt_widget* stream. Only the basic geometric and topological features of the polylines are written. Auxiliary data that might be attached is lost.

#include <CGAL/IO/Qt_widget_Polyline_2.h>

template<typename SegmentTraits>
Qt_widget& *std::ostream& os << Polyline_2<SegmentTraits> polyline*

Inserts a conic arc into a given *Qt_widget* stream. Only the basic geometric and topological features of the conic arcs are written. Auxiliary data that might be attached is lost.

#include <CGAL/IO/Qt_widget_Conic_arc_2.h>

template<typename ConicArc>
Qt_widget& *std::ostream& os << _Conic_x_monotone_arc_2<ConicArc> cv*

ArrangementDcel

Definition

A doubly-connected edge-list (DCEL for short) data-structure. It consists of three containers of records: vertices V, halfedges E, and faces F. It maintains the incidence relation among them. The halfedges are ordered in pairs sometimes referred to as twins, such that each halfedge pair represent an edge.

A model of the ArrangementDcel concept must provide the following types and operations. (In addition to the requirements here, the local types *Vertex*,*Halfedge*, *Face Hole* and *Isolated_vertex* must be models of the concepts *ArrangementDcelVertex*(page 2236), *ArrangementDcelHalfedge*(page 2238), *ArrangementDcelFace*(page 2241), *ArrangementDcelHole*(page 2243), and *ArrangementDcelIsolatedVertex* (page 2244) respectively.)

Types

ArrangementDcel:: Vertex	the vertex type.
ArrangementDcel:: Halfedge	the halfedge type.
ArrangementDcel:: Face	the face type.
ArrangementDcel:: Hole	the hole type.
ArrangementDcel:: Isolated_vertex	the isolated vertex type.
ArrangementDcel:: Size	used to represent size values (e.g., *size_t*).
ArrangementDcel:: Vertex_iterator	a bidirectional iterator over the vertices. Its value-type is *Vertex*.
ArrangementDcel:: Halfedge_iterator	a bidirectional iterator over the halfedges. Its value-type is *Halfedge*.
ArrangementDcel:: Face_iterator	a bidirectional iterator over the faces. Its value-type is *Face*.

The non-mutable iterators *Vertex_const_iterator*, *Halfedge_const_iterator* and *Face_const_iterator* are also defined.

Creation

ArrangementDcel dcel; — constructs an empty DCEL with one unbounded face.

*Face** *dcel.assign(Self other, const Face *uf)*

assigns the contents of the *other* DCEL whose unbounded face is given by *uf*, to *dcel*. The function returns a pointer to the unbounded face of *dcel* after the assignment.

Access Functions

Size *dcel.size_of_vertices() const*

returns the number of vertices.

Size	*dcel.size_of_halfedges() const*	
		returns the number of halfedges (always even).
Size	*dcel.size_of_faces() const*	
		returns the number of faces.
Size	*dcel.size_of_holes() const*	
		returns the number of holes (the number of connected components).
Size	*dcel.size_of_isolated_vertices() const*	
		returns the number of isolated vertices.

The following operations have an equivalent *const* operations that return the corresponding non-mutable iterators:

Vertex_iterator	*dcel.vertices_begin()*	returns a begin-iterator of the vertices in *dcel*.
Vertex_iterator	*dcel.vertices_end()*	returns a past-the-end iterator of the vertices in *dcel*.
Halfedge_iterator	*dcel.halfedges_begin()*	
		returns a begin-iterator of the halfedges in *dcel*.
Halfedge_iterator	*dcel.halfedges_end()*	returns a past-the-end iterator of the halfedges in *dcel*.
Face_iterator	*dcel.faces_begin()*	returns a begin-iterator of the faces in *dcel*.
Face_iterator	*dcel.faces_end()*	returns a past-the-end iterator of the faces in *dcel*.

Modifiers

The following operations allocate a new element of the respective type. Halfedges are always allocated in pairs of opposite halfedges. The halfedges and their opposite pointers are automatically set.

*Vertex**	*dcel.new_vertex()*	creates a new vertex.
*Halfedge**	*dcel.new_edge()*	creates a new pair of twin halfedges.
*Face**	*dcel.new_face()*	creates a new face.
*Hole**	*dcel.new_hole()*	creates a new hole record.
*Isolated_vertex**	*dcel.new_isolated_vertex()*	
		creates a new isolated vertex record.

void	*dcel.delete_vertex(Vertex* v)*	
		deletes the vertex v.
void	*dcel.delete_edge(Halfedge* e)*	
		deletes the halfedge e as well as its twin.
void	*dcel.delete_face(Face* f)*	
		deletes the face f.

void *dcel.delete_hole(Hole* ho)*

deletes the hole *ho*.

void *dcel.delete_isolated_vertex(Isolated_vertex* iv)*

deletes the isolated vertex *iv*.

ArrangementDcelWithRebind

Definition

The concept ArrangementDcelWithRebind refines the *ArrangementDcel* concept by adding a policy clone idiom in form of a rebind struct-template.

Instantiate a dcel class with many different possible types without ad-hoc limitations on type of the dcel classes.

Refines

ArrangementDcel

Types

ArrangementDcelWithRebind:: template <class T> rebind

allows the instantiation of a model of the base concept *ArrangementDcel* with a different possible geometry-traits class without ad-hoc limitations on it.
Following the standard clone policy, the rebind struct-template must have a nested type named *other* that defines the type of the model replica.

Creation

ArrangementDcelWithRebind dcel;	constructs an empty DCEL with one unbouned face.

Has Models

Arr_default_dcel<Traits> (page 2247)
Arr_face_extended_dcel<Traits,FData,V,H,F> (page 2248)
Arr_extended_dcel<Traits,VData,HData,FData,V,H,F> (page 2249)

Concept

ArrangementDcelVertex

Definition

A vertex record in a DCEL data structure. A vertex is always associated with a point. However, the vertex record only stores a pointer to the associated point, and the actual *Point* object is stored elsewhere.

A vertex usually has several halfedges incident to it, such that it is possible to access one of these halfedges directly and to traverse all incident halfedges around the vertex. However, the DCEL may also contain isolated vertices that have no incident halfedges. In this case, the vertex stores an isolated vertex-information record, indicating the face that contains this vertex in its interior.

Types

ArrangementDcelVertex:: Halfedge	the corresponding DCEL halfedge type.
ArrangementDcelVertex:: Isolated_vertex	the corresponding DCEL isolated vertex-information type.
ArrangementDcelVertex:: Point	the point type associated with the vertex.

Creation

ArrangementDcelVertex *v*;		default constructor.
void	*v.assign(Self other)*	assigns *v* with the contents of the *other* vertex.

Access Functions

All functions below also have *const* counterparts, returning non-mutable pointers or references:

bool	*v.is_isolated() const*	returns whether the vertex is isolated (has no incident halfedges).
*Halfedge**	*v.halfedge()*	returns an incident halfedge that has *v* as its target. *Precondition*: *v* is *not* an isolated vertex.
*Isolated_vertex**	*v.isolated_vertex()*	returns the isolated vertex-information record. *Precondition*: *v* is an isolated vertex.
bool	*v.has_null_point() const*	returns whether the vertex is not associated with a valid point (i.e. it lies at infinity).
Point&	*v.point()*	returns the associated point. *Precondition*: *v*() is associated with a valid point.

Arr_parameter_space

v.parameter_space_in_x() const

returns the placement of the x-coordinate in the parameter space, that is, either the left boundary-side, the interior, or the right boundary-side.

Arr_parameter_space

v.parameter_space_in_y() const

returns the placement of the y-coordinate in the parameter space, that is, either the bottom boundary-side, the interior, or the top boundary-side.

Modifiers

void *v.set_halfedge(Halfedge* e)*

sets the incident halfedge, marking v as a regular vertex.

void *v.set_isolated_vertex(Isolated_vertex* iv)*

sets the isolated vertex-information record, marking v as an isolated vertex.

void *v.set_point(Point* p)* sets the associated point.

void *v.set_boundary(Arr_parameter_space inf_x, Arr_parameter_space inf_y)*

sets v as a vertex on a boundary side.
Precondition: Either *inf_x* or *inf_y* is not *ARR_INTERIOR*.

ArrangementDcelIsolatedVertex (page 2244)

Concept

ArrangementDcelHalfedge

Definition

A halfedge record in a DCEL data structure. Two halfedges with opposite directions always form an edge (a halfedge pair). The halfedges form together chains, defining the boundaries of connected components, such that all halfedges along a chain have the same incident face. Note that the chain the halfedge belongs to may form the outer boundary of a bounded face (an outer CCB) or the boundary of a hole inside a face (an inner CCB).

An edge is always associated with a curve, but the halfedge records only store a pointer to the associated curve, and the actual curve objects are stored elsewhere. Two opposite halfedges are always associated with the same curve.

Types

ArrangementDcelHalfedge:: Vertex	the corresponding DCEL vertex type.
ArrangementDcelHalfedge:: Face	the corresponding DCEL face type.
ArrangementDcelHalfedge:: Hole	the corresponding DCEL hole type.

ArrangementDcelHalfedge:: X_monotone_curve

the curve type associated with the edge.

Creation

ArrangementDcelHalfedge e;	default constructor.

void	*e.assign(Self other)*	assigns *e* with the contents of the *other* halfedge.

Access Functions

Arr_halfedge_direction

e.direction() const	returns *ARR_LEFT_TO_RIGHT* if *e*'s source vertex is lexicographically smaller than it target, and *ARR_RIGHT_TO_LEFT* if it is lexicographically larger than the target.

bool	*e.is_on_hole() const*	determines whether the *e* lies on an outer CCB of a bounded face, or on an inner CCB (a hole inside a face). The function returns *true* if *e* lies on a hole.

All functions below also have *const* counterparts, returning non-mutable pointers or references:

*Halfedge**	*e.opposite()*	returns the twin halfedge.
*Halfedge**	*e.prev()*	returns the previous halfedge along the chain.

*Halfedge**	*e.next()*	returns the next halfedge along the chain.
*Vertex**	*e.vertex()*	returns the target vertex.
*Face**	*e.face()*	returns the incident face. *Precondition*: *e* lies on the outer boundary of this face.
*Hole**	*e.hole()*	returns the hole (inner CCB) *e* belongs to. *Precondition*: *e* lies on a hole inside its incident face.
bool	*e.has_null_curve() const*	returns whether the vertex is not associated with a valid curve.
X_monotone_curve&	*e.curve()*	returns the associated curve. *Precondition*: *e* is associated with a valid curve.

Modifiers

void	*e.set_opposite(Halfedge* opp)*	sets the opposite halfedge.
void	*e.set_direction(Arr_halfedge_direction dir)*	sets the lexicographical order between *e*'s source and target vertices to be *dir*. The direction of the opposite halfedge is also set to the opposite direction.
void	*e.set_prev(Halfedge* prev)*	sets the previous halfedge of *e* along the chain, and updates the cross-pointer *prev->next()*.
void	*e.set_next(Halfedge* next)*	sets the next halfedge of *e* along the chain, and updates the cross-pointer *next->prev()*.
void	*e.set_vertex(Vertex* v)*	sets the target vertex.
void	*e.set_face(Face* f)*	sets the incident face, marking that *e* lies on the outer CCB of the face *f*.

void	*e.set_hole(Hole* ho)*	sets the incident hole, marking that *e* lies on an inner CCB.
void	*e.set_curve(X_monotone_curve* c)*	
		sets the associated curve of *e* and its opposite halfedge.

ArrangementDcelFace

Definition

A face record in a DCEL data structure. A face may either be unbounded, otherwise it has an incident halfedge along the chain defining its outer boundary. A face may also contain holes and isolated vertices in its interior.

Types

ArrangementDcelFace:: Vertex	the corresponding DCEL vertex type.
ArrangementDcelFace:: Halfedge	the corresponding DCEL halfedge type.
ArrangementDcelFace:: Hole_iterator	a bidirectional iterator over the holes in inside the face. Its value-type is *Halfedge**.
ArrangementDcelFace:: Isolated_vertex_iterator	a bidirectional iterator over the isolated vertices in inside the face. Its value-type is *Vertex**.

The non-mutable iterators *Hole_const_iterator*, and *Isolated_vertex_const_iterator* are also defined.

Creation

ArrangementDcelFace f;		default constructor.
void	f*.assign(Self other)*	assigns f with the contents of the *other* face.

Access Functions

All functions below also have *const* counterparts, returning non-mutable pointers or iterators:

bool	f*.is_unbounded() const*	returns whether the face is unbounded.
*Halfedge**	f*.halfedge()*	returns an incident halfedge along the outer boundary of the face. If f has no outer boundary, the function returns *NULL*.
size_t	f*.number_of_holes() const*	returns the number of holes inside f.
Hole_iterator	f*.holes_begin()*	returns a begin-iterator for the holes inside f.
Hole_iterator	f*.holes_end()*	returns a past-the-end iterator for the holes inside f.

size_t	*f.number_of_isolated_vertices() const*	
		returns the number of isolated vertices inside f.
Isolated_vertex_iterator		
	f.isolated_vertices_begin()	
		returns a begin-iterator for the isolated vertices inside f.
Isolated_vertex_iterator		
	f.isolated_vertices_end()	
		returns a past-the-end iterator for the isolated vertices inside f.

Modifiers

void	*f.set_unbounded(bool flag)*	
		sets the face as unbounded (if *flag* is *true*), or as a bounded face (if it is *false*).
void	*f.set_halfedge(Halfedge* e)*	
		sets the incident halfedge.
void	*f.add_hole(Halfedge* e)*	
		adds e as a hole inside f.
void	*f.erase_hole(Hole_iterator it)*	
		removes the hole that *it* points to from inside f.
void	*f.add_isolated_vertex(Vertex* v)*	
		adds v as an isolated vertex inside f.
void	*f.erase_isolated_vertex(Isolated_vertex_iterator it)*	
		removes the isolated vertex that *it* points to from inside f.

ArrangementDcelHole

Concept

Definition

A hole record in a DCEL data structure, which stores the face that contains the hole in its interior, along with an iterator for the hole in the holes' container of this face.

Types

ArrangementDcelHole:: Face	the corresponding DCEL face type.

typedef Face::Hole_iterator

Hole_iterator;

Creation

ArrangementDcelHole ho;	default constructor.

Access Functions

All functions below also have *const* counterparts, returning non-mutable pointers or iterators:

*Face**	*ho.face()*	returns the incident face, which contains *ho* in its interior.
Hole_iterator	*ho.iterator()*	returns an iterator for the hole.

Modifiers

void	*ho.set_face(Face* f)*	sets the incident face.
void	*ho.set_iterator(Hole_iterator it)*	sets the hole iterator.

Concept

ArrangementDcelIsolatedVertex

Definition

An isolated vertex-information record in a DCEL data structure, which stores the face that contains the isolated vertex in its interior, along with an iterator for the isolated vertex in the isolated vertices' container of this face.

Types

ArrangementDcelIsolatedVertex:: Face	the corresponding DCEL face type.

typedef Face::Isolated_vertex_iterator

Isolated_vertex_iterator;

Creation

ArrangementDcelIsolatedVertex iv;	default constructor.

Access Functions

All functions below also have *const* counterparts, returning non-mutable pointers or iterators:

*Face**	*iv.face()*	returns the incident face, which contains *iv* in its interior.
Isolated_vertex_iterator	*iv.iterator()*	returns an iterator for the isolated vertex.

Modifiers

void	*iv.set_face(Face* f)*	sets the incident face.
void	*iv.set_iterator(Isolated_vertex_iterator it)*	sets the isolated vertex iterator.

CGAL::Arr_dcel_base<V,H,F>

Definition

The *Arr_dcel_base<V,H,F>* class is an important ingredient in the definition of DCEL data structures. It serves as a basis class for any instance of the *Dcel* template parameter of the *Arrangement_2* template. In particular it is the basis class of the default *Dcel* template parameter, and the basis class of any extended DCEL. The template parameters V, H, and F must be instantiated with models of the concepts *ArrangementDcelVertex*, *ArrangementDcelHalfedge*, and *ArrangementDcelFace* respectively.

#include <CGAL/Arr_dcel_base.h>

Is Model for the Concepts

ArrangementDcel

Class Arr_vertex_base<Point>

Definition

The basic DCEL vertex type. Serves as a basis class for an extended vertex record with auxiliary data fields. The *Point* parameter is the type of points associated with the vertices.

Is Model for the Concepts

ArrangementDcelVertex

Class Arr_halfedge_base<Curve>

Definition

The basic DCEL halfedge type. Serves as a basis class for an extended halfedge record with auxiliary data fields. The *Curve* parameter is the type of x-monotone curves associated with the vertices.

Is Model for the Concepts

ArrangementDcelHalfedge

Class Arr_face_base

Definition

The basic DCEL face type. Serves as a basis class for an extended face record with auxiliary data fields.

Is Model for the Concepts

ArrangementDcelFace

CGAL::Arr_default_dcel<Traits>

Definition

The default DCEL class used by the *Arrangement_2* class-template is parameterized by a traits class, which is a model of the *ArrangementBasicTraits_2* concept. It simply uses the nested *Traits::Point_2* and *Traits::X_monotone_curve_2* to instantiate the base vertex and halfedge types, respectively. Thus, the default DCEL records store no other information, except for the topological incidence relations and the geometric data attached to vertices and edges.

CGAL::Arr_face_extended_dcel<Traits,FData,V,H,F>

Definition

The *Arr_face_extended_dcel<Traits,FData,V,H,F>* class-template extends the DCEL face-records, making it possible to store extra (non-geometric) data with the arrangement faces. The class should be instantiated by an *FData* type which represents the extra data stored with each face.

Note that all types of DCEL features (namely vertex, halfedge and face) are provided as template parameters. However, by default they are defined as follows:

V = Arr_vertex_base<typename Traits::Point_2>
H = Arr_halfedge_base<typename Traits::X_monotone_curve_2>
F = Arr_face_base

#include <CGAL/Arr_extended_dcel.h>

CGAL::Arr_extended_dcel<Traits,VData,HData,FData,V,H,F>

Class

Definition

The *Arr_extended_dcel<Traits,VData,HData,FData,V,H,F>* class-template extends the topological-features of the DCEL namely the vertex, halfedge, and face types. While it is possible to maintain extra (non-geometric) data with the curves or points of the arrangement by extending their types respectively, it is also possible to extend the vertex, halfedge, or face types of the DCEL through inheritance. As the technique to extend these types is somewhat cumbersome and difficult for inexperienced users, the *Arr_extended_dcel< Traits,VData,HData,FData,V,H,F>* class-template provides a convenient way to do that. Each one of the three features is extended with a corresponding data type provided as parameters. This class template is also parameterized with a traits class used to extract default values for the vertex, halfedge, and face base classes, which are the remaining three template parameters respectively. The default values follow:

V = Arr_vertex_base<typename Traits::Point_2>
H = Arr_halfedge_base<typename Traits::X_monotone_curve_2>
F = Arr_face_base

#include <CGAL/Arr_extended_dcel.h>

ArrangementBasicTraits_2

Definition

The concept ArrangementBasicTraits_2 defines the minimal set of geometric predicates needed for the construction and maintenance of objects of the class *Arrangement_2*, as well as performing simple queries (such as point-location queries) on such arrangements.

A model of this concept must define nested *Point_2* and *X_monotone_curve_2* types, which represent planar points and continuous *x*-monotone curves (a vertical segment is also considered to be *weakly* *x*-monotone), respectively. The *x*-monotone curves are assumed to be pairwise disjoint in their interiors, so they do not intersect except at their endpoints.

The *X_monotone_curve_2* curves of an arrangement are confined to an iso-rectangular area called the parameter space. The iso-rectangule can be unbounded, open, or closed. The set of predicates provided by a model the concept ArrangementBasicTraits_2 is sufficient for constructing arrangements of *x*-monotone curves that do not reach or approach the boundary of the parameter space. The nature of the input curves, whether they are expected to reach or approach the left, right, bottom, or top side of the boundary of the parameter space, are conveyed through the definition of four additional nested types, namely *Left_side_category*, *Right_side_category*, *Bottom_side_category*, and *Top_side_category*. Each such type must be convertible to the type *Arr_oblivious_side_tag*.

		determines whether *xc1* and *xc2* are geometrically equivalent (have the same graph).

ArrangementLandmarkTraits_2

Concept

Definition

The concept ArrangementLandmarkTraits_2 refines the general traits concept by adding operations needed for the landmarks point-location strategy, namely — approximating points and connecting points with a simple x-monotone curve.

A model of this concept must define the *Approximate_number_type*, which is used to approximate the coordinates of *Point_2* instances. It is recommended to define the approximated number type as the built-in *double* type.

returns an x-monotone curve connecting *p1* and *p2* (i.e., the two input points are its endpoints).

ArrangementXMonotoneTraits_2

Concept

Definition

The concept ArrangementXMonotoneTraits_2 refines the basic arrangement-traits concept. A model of this concept is able to handle x-monotone curves that intersect in their interior (and points that coincide with curve interiors). This is necessary for constructing arrangements of sets of intersecting x-monotone curves.

As the resulting structure, represented by the *Arrangement_2* class, stores pairwise interior-disjoint curves, the input curves are split at the intersection points before being inserted into the arrangement. A model of this refined concept therefore needs to compute the intersections (and possibly overlaps) between two x-monotone curves and to support curve splitting.

accepts two *mergeable* x-monotone curves *xc1* and *xc2* and asigns *xc* with the merged curve.
Precondition: *are_mergeable_2*(*xc1*, *xc2*) is true.

ArrangementTraits_2

Definition

The concept ArrangementTraits_2 allows the construction of arrangement of *general* planar curves. Models of this concept are used by the free *insert()* functions of the arrangement package and by the *Arrangement_with_history_2* class.

A model of this concept must define the nested *Curve_2* type, which represents a general planar curve that is not necessarily x-monotone and is not necessarily connected. Such curves are eventually subdivided into x-monotone subcurves and isolated points (represented by the *Point_2* and *X_monotone_curve_2* types, defined in the basic traits concept).

A model of the concept ArrangementTraits_2 that handles arbitrary curves, which are always x-monotone, such as a traits class that handles linear curves may define the nested types *Curve_2* and *X_monotone_curve_2* to be of equivalent types. Moreover, defining them as of equivalent types is advantageous, as it enables a generic simple implementation of the nested Functor *Make_x_monotone_2*.

On the other hand, a model of the ArrangementTraits_2 concept that handles arbitrary curves, which may be not x-monotone must define the *Curve_2* and *X_monotone_curve_2* nested types to be of different types to allow proper dispatching of the free functions that accept such curves, such as *intsert()*.

template <typename OutputIterator>
OutputIterator *fo(ArrTraits::Curve_2 c, OutputIterator oi)*

subdivides the input curve c into x-monotone subcurves and isolated points, and inserts the results into a container through the given output iterator. The value type of *OutputIterator* is *CGAL::Object*, where each *Object* wraps either an *ArrTraits::X_monotone_curve_2* object or a *ArrTraits::Point_2* object. The operator returns a past-the-end iterator for the output sequence.

CGAL::Arr_segment_traits_2<Kernel>

Definition

The traits class *Arr_segment_traits_2<Kernel>* is a model of the *ArrangementTraits_2* concept, which allows the construction and maintenance of arrangements of line segments. It should be parameterized with a CGAL-kernel model that is templated in turn with a number type. To avoid numerical errors and robustness problems, the number type should support exact rational arithmetic — that is, the number type should support the arithmetic operations $+$, $-$, $\times$ and $\div$ carried out without loss of precision.

For example, instantiating the traits template with kernels, such as *Cartesian<Quotient<MP_Float> >*, or *Homogeneous<Gmpz>*, ensures the exact and robust operation of the application. In particular, the *Cartesian<Gmpq>* achieves the fastest running times in most cases. Using other inexact number types (for example, instantiating the template with *Simple_cartesian<double>*) is at the user's own risk: Selecting an inexact number type usually leads to faster running time at the expense of possible robustness problems.

For optimal performance, we recommend instantiating the traits class with the default *Exact_predicates_exact_constructions_kernel* provided by CGAL. Using this kernel guarantees exactness and robustness, while it incurs only a minor overhead (in comparison to working with a fast, inexact number type) for most inputs.

Arr_segment_traits_2<Kernel> defines *Kernel::Point_2* as its point type. However, it does *not* define *Kernel::Segment_2* as its curve type, as one may expect. The reason is that the kernel segment is represented by its two endpoints only, while the traits class needs to store extra data with its segments, in order to efficiently operate on them. Nevertheless, the nested *X_monotone_curve_2* and *Curve_2* types (in this case both types refer to the same class, as *every* line segment is (weakly) x-monotone) can however be converted to the type *Kernel::Segment_2*.

Arr_segment_traits_2<Kernel> achieves faster running times than the *Arr_non_caching_segment_traits_2<Kernel>* traits-class, when arrangements with relatively many intersection points are constructed. It also allows for working with less accurate, yet computationally efficient number types, such as *Quotient<MP_Float>*, which represents floating-point numbers with an unbounded mantissa, but with a bounded exponent. Using this traits class is therefore highly recommended for almost all applications that rely on arrangements of line segments. On the other hand, *Arr_segment_traits_2<Kernel>* uses more space and stores extra data with each segment, so constructing arrangements of huge sets of non-intersecting segments (or segments that intersect very sparsely) could be more efficient with the *Arr_non_caching_segment_traits_2* traits-class.

While *Arr_segment_traits_2<Kernel>* models the concept *ArrangementDirectionalXMonotoneTraits_2*, the implementation of the *Arr_mergeable_2* operation does not enforce the input curves to have the same direction as a precondition. Moreover, *Arr_segment_traits_2<Kernel>* supports the merging of curves of opposite directions.

#include <CGAL/Arr_segment_traits_2.h>

Is Model for the Concepts

ArrangementTraits_2
ArrangementLandmarkTraits_2
ArrangementDirectionalXMonotoneTraits_2

Class

CGAL::Arr_non_caching_segment_basic_traits_2<Kernel>

Definition

The traits class *Arr_non_caching_segment_basic_traits_2<Kernel>* is a model of the *ArrangementTraits_2* concept that allow the construction and maintenance of arrangements of sets of pairwise interior-disjoint line segments. It is templated with a CGAL-Kernel model, and it is derived from it. This traits class is a thin layer above the parameterized kernel. It inherits the *Point_2* from the kernel and its *X_monotone_curve_2* type is defined as *Kernel::Segment_2*. Most traits-class functor are inherited from the kernel functor, and the traits class only supplies the necessary functors that are not provided by the kernel. The kernel is parameterized with a number type, which should support the arithmetic operations $+$, $-$ and $\times$ in an exact manner in order to avoid robustness problems. Using *Cartesian<MP_Float>* or *Cartesian<Gmpz>* are possible instantiations for the kernel. Using other (inexact) number types (for example, instantiating the template with *Simple_cartesian<double>*) is also possible, at the user's own risk.

#include <*CGAL/Arr_non_caching_segment_basic_traits_2.h*>

Is Model for the Concepts

ArrangementLandmarkTraits_2

CGAL::Arr_non_caching_segment_traits_2<Kernel>

Class

Definition

The traits class *Arr_non_caching_segment_traits_2<Kernel>* is a model of the *ArrangementTraits_2* concept that allows the construction and maintenance of arrangements of line segments. It is parameterized with a CGAL-Kernel type, and it is derived from it. This traits class is a thin layer above the parameterized kernel. It inherits the *Point_2* from the kernel and its *X_monotone_curve_2* and *Curve_2* types are both defined as *Kernel::Segment_2*. Most traits-class functor are inherited from the kernel functor, and the traits class only supplies the necessary functors that are not provided by the kernel. The kernel is parameterized with a number type, which should support exact rational arithmetic in order to avoid robustness problems, although other number types could be used at the user's own risk.

The traits-class implementation is very simple, yet may lead to a cascaded representation of intersection points with exponentially long bit-lengths, especially if the kernel is parameterized with a number type that does not perform normalization (e.g. *Quotient<MP_Float>*). The *Arr_segment_traits_2* traits class avoids this cascading problem, and should be the default choice for implementing arrangements of line segments. It is recommended to use *Arr_non_caching_segment_traits_2<Kernel>* only for very sparse arrangements of huge sets of input segments.

While *Arr_non_caching_segment_traits_2<Kernel>* models the concept *ArrangementDirectionalXMonotoneTraits_2*, the implementation of the *Arr_mergeable_2* operation does not enforce the input curves to have the same direction as a precondition. Moreover, *Arr_non_caching_segment_traits_2<Kernel>* supports the merging of curves of opposite directions.

Arr_segment_traits_2<Kernel>

Class

CGAL::Arr_linear_traits_2<Kernel>

Definition

The traits class *Arr_linear_traits_2<Kernel>* is a model of the *ArrangementTraits_2* concept that allows for the construction and maintenance of arrangements of linear objects which may be bounded (line segments) or unbounded (rays and lines). The traits class is parameterized with a CGAL-kernel model; see the reference page of *Arr_segment_traits_2<Kernel>* (page 2283) for further explanations and recommendations on choosing a kernel.

Arr_linear_traits_2<Kernel> defines *Kernel::Point_2* as its point type. The nested *X_monotone_curve_2* and *Curve_2* types defined by the traits class (as is the case with the various segment-traits classes, both types refer to the same class, as *every* linear object is (weakly) x-monotone), are constructible from a point, a line segment, a ray and from a line (objects of types *Kernel::Point_2*, *Kernel::Segment_2*, *Kernel::Ray_2* and *Kernel::Line_2*, respectively). On the other hand, when we are given a curve we can find out its actual type and convert it to the respective kernel object (say, to a *Kernel::Ray_2*).

#include <CGAL/Arr_linear_traits_2.h>

Is Model for the Concepts

ArrangementTraits_2
ArrangementLandmarkTraits_2

Class Arr_linear_traits_2<Kernel>::Curve_2

The *Curve_2* (and the *X_monotone_curve_2*) class nested within the linear-traits can represent all types of linear objects. The class supports the copy and default constructor and the assignment operator. In addition, the *operator<<* and *operator>>* for linear objects are defined for standard output and input streams.

Types

typedef typename Kernel::Point_2
Point_2;

typedef typename Kernel::Segment_2
Segment_2;

typedef typename Kernel::Ray_2
Ray_2;

typedef typename Kernel::Line_2
Line_2;

Creation

Arr_linear_traits_2<Kernel>::Curve_2 c(Point_2 p);

constructs an degenerate curve equivalent to the point *p*.

Arr_linear_traits_2<Kernel>::Curve_2 c(Segment_2 seg);

constructs an line segment.

Arr_linear_traits_2<Kernel>::Curve_2 c(Ray_2 ray);

constructs a ray.

Arr_linear_traits_2<Kernel>::Curve_2 c(Line_2 ln);

constructs a line.

Access Functions

bool	*c.is_point() const*	returns whether *c* is a point (a degenerate curve).
Point_2	*c.point() const*	returns a point object equivalent to *c*. *Precondition*: *c* is a point.
bool	*c.is_segment() const*	returns whether *c* is a segment (has two bounded endpoints).
Segment_2	*c.segment() const*	returns a segment object equivalent to *c*. *Precondition*: *c* is a segment.
bool	*c.is_ray() const*	returns whether *c* is a ray (has a bounded source point and its other end is unbounded).
Ray_2	*c.ray() const*	returns a ray object equivalent to *c*. *Precondition*: *c* is a ray.
bool	*c.is_line() const*	returns whether *c* is a line (has only unbounded ends).
Line_2	*c.line() const*	returns a line object equivalent to *c*. *Precondition*: *c* is a line.
Line_2	*c.supporting_line() const*	returns the supporting line of *c*. *Precondition*: *c* is not a point (a degenerate curve).
Point_2	*c.source() const*	returns *c*'s source point. *Precondition*: *c* is a point, a segment or a ray.
Point_2	*c.target() const*	returns *c*'s target point. *Precondition*: *c* is a point or a segment.

Class

CGAL::Arr_polyline_traits_2<SegmentTraits>

Definition

The traits class *Arr_polyline_traits_2<SegmentTraits>* is a model of the *ArrangementTraits_2* concept. It handles piecewise linear curves, commonly referred to as polylines. Each polyline is a chain of segments, where each two neighboring segments in the chain share a common endpoint. The traits class exploits the functionality of the *SegmentTraits* template-parameter to handle the segments that comprise the polyline curves.

The class instantiated for the template parameter *SegmentTraits* must be a model of the *ArrangementTraits_2* concept that handles line segments (e.g., *Arr_segment_traits_2<Kernel>* or *Arr_non_caching_segment_traits_2<Kernel>*, where the first alternative is recommended).

The number type used by the injected segment traits should support exact rational arithmetic (that is, the number type should support the arithmetic operations $+$, $-$, $\times$ and $\div$ that should be carried out without loss of precision), in order to avoid robustness problems, although other inexact number types could be used at the user's own risk.

#include <CGAL/Arr_polyline_traits_2.h>

Is Model for the Concepts

ArrangementTraits_2
ArrangementLandmarkTraits_2

Class Arr_polyline_traits_2<SegmentTraits>::Curve_2

The *Curve_2* class nested within the polyline traits is used to represent general continuous piecewise-linear curves (a polyline can be self-intersecting) and support their construction from any range of points.

The copy and default constructor as well as the assignment operator are provided for polyline curves. In addition, an *operator<<* for the curves is defined for standard output streams, and an *operator>>* for the curves is defined for standard input streams.

Types

Arr_polyline_traits_2<SegmentTraits>::Curve_2:: const_iterator

A bidirectional iterator that allows traversing the points that comprise a polyline curve.

Arr_polyline_traits_2<SegmentTraits>::Curve_2:: const_reverse_iterator

A bidirectional iterator that allows traversing the points that comprise a polyline curve.

Creation

Arr_polyline_traits_2<SegmentTraits>::Curve_2 pi;

default constructor that constructs an empty polyline.

template <class InputIterator>
Arr_polyline_traits_2<SegmentTraits>::Curve_2 pi(Iterator first, Iterator last);

constructs a polyline defined by the given range of points *[first, last)* (the value-type of *InputIterator* must be *SegmentTraits::Point_2*. If the range contains $(n+1)$ points labeled $(p_0, p_1, \ldots, p_n)$, the generated polyline consists of n segments, where the kth segment is defined by the endpoints $[p_{k-1}, p_k]$. The first point in the range is considered as the source point of the polyline while the last point is considered as its target.
Precondition: There are at least two points in the range.

Access Functions

size_t	*pi.points() const*	returns the number of points that comprise the polyline. Note that if there are n points in the polyline, it is comprised of $(n-1)$ segments.
const_iterator	*pi.begin() const*	returns an iterator pointing at the source point of the polyline.
const_iterator	*pi.end() const*	returns an iterator pointing after the end of the polyline.
const_iterator	*pi.rbegin() const*	returns an iterator pointing at the target point of the polyline.
const_iterator	*pi.rend() const*	returns an iterator pointing before the beginning of the polyline.
size_t	*pi.size() const*	returns the number of line segments comprising the polyline (equivalent to *pi.points() - 1*).
typename SegmentTraits::X_monotone_curve_2	*pi*[*size_t k*]	returns the kth segment of the polyline. *Precondition*: k is not greater or equal to *pi.size() - 1*.
Bbox_2	*pi.bbox() const*	return a bounding box of the polyline *pi*.

Operations

void *pi.push_back(Point_2 p)*

adds a new point to the polyline, which becomes the new target point of *pi*.

void	*pi.clear()*	resets the polyline.

Class Arr_polyline_traits_2<SegmentTraits>::X_monotone_curve_2

The *X_monotone_curve_2* class nested within the polyline traits is used to represent x-monotone piecewise linear curves. It inherits from the *Curve_2* type. It has a default constructor and a constructor from a range of points, just like the *Curve_2* class. However, there is precondition that the point range define an x-monotone polyline.

The points that define the x-monotone polyline are always stored in an ascending lexicographical xy-order, so their order may be reversed with respect to the input sequence. Also note that the x-monotonicity ensures that an x-monotone polyline is never self-intersecting (thus, a self-intersecting polyline will be subdivided to several interior-disjoint x-monotone subcurves).

CGAL::Arr_circle_segment_traits_2<Kernel>

Definition

The class *Arr_circle_segment_traits_2<Kernel>* is a model of the *ArrangementTraits_2* concept and can be used to construct and maintain arrangements of circular arcs and line segments.

The traits class must be instantiated with a geometric kernel, such that the supporting circles of the circular arcs are of type *Kernel::Circle_2* and the supporting lines of the line segments are of type *Kernel::Line_2*. Thus, the coordinates of the center of supporting circles, and its squared radius are of type *Kernel::FT*, which should be an exact rational number-type; similarly, the coefficients of each supporting line $ax+by+c=0$ are also of type *Kernel::FT*. Note however that the intersection point between two such arcs do not have rational coordinates in general. For this reason, we do not require the endpoints of the input arcs and segments to have rational coordinates.

The nested *Point_2* type defined by the traits class is therefore *different* than the *Kernel::Point_2* type. Its coordinates are of type *CoordNT*, which an instantiation of *CGAL::Sqrt_extension<NT,ROOT>* where *NT* = *ROOT* = *Kernel::FT*. Moreover, the third and fourth (hidden) template parameters of *CGAL::Sqrt_extension< NT,ROOT>* are set to *CGAL::Tag_true*, which enables efficient comparison among different extensions.

For more details see the documentation of *CGAL::Sqrt_extension<NT,ROOT>* . . . . page 220

While *Arr_circle_segment_traits_2<Kernel>* models the concept *ArrangementDirectionalXMonotoneTraits_2*, the implementation of the *Arr_mergeable_2* operation does not enforce the input curves to have the same direction as a precondition. Moreover, *Arr_circle_segment_traits_2<Kernel>* supports the merging of curves of opposite directions.

#include <CGAL/Arr_circle_segment_traits_2.h>

ArrangementTraits_2
ArrangementDirectionalXMonotoneTraits_2

Class Arr_circle_segment_traits_2<Kernel>::Point_2

The *Point_2* number-type nested within the traits class represents a Cartesian point whose coordinates are algebraic numbers of type *CoordNT*.

Types

Arr_circle_segment_traits_2<Kernel>::Point_2:: Rational

the *Kernel::FT* type.

Arr_circle_segment_traits_2<Kernel>::Point_2:: CoordNT

the algebraic number-type.

Creation

Arr_circle_segment_traits_2<Kernel>::Point_2 p;

default constructor.

Arr_circle_segment_traits_2<Kernel>::Point_2 p(Rational x, Rational y);

creates the point (x,y).

Arr_circle_segment_traits_2<Kernel>::Point_2 p(CoordNT x, CoordNT y);

creates the point (x,y).

Access Functions

CoordNT	*p.x() const*	returns the *x*-coordinate.
CoordNT	*p.y() const*	returns the *y*-coordinate.

Class Arr_circle_segment_traits_2<Kernel>::Curve_2

The *Curve_2* class nested within the traits class can represent arbitrary circular arcs, full circles and line segments and support their construction in various ways. The copy and default constructor as well as the assignment operator are provided. In addition, an *operator<<* for the curves is defined for standard output streams.

Creation

Arr_circle_segment_traits_2<Kernel>::Curve_2 cv(typename Kernel::Segment_2 seg);

constructs an curve corresponding to the line segment *seg*.

Arr_circle_segment_traits_2<Kernel>::Curve_2 cv(typename Kernel::Point_2 source, typename Kernel::Point_2 target)

constructs an curve corresponding to the line segment directed from *source* to *target*, both having rational coordinates.

Arr_circle_segment_traits_2<Kernel>::Curve_2 cv(typename Kernel::Line_2 line, Point_2 source, Point_2 target)

constructs an curve corresponding to the line segment supported by the given line, directed from *source* to *target*. Note that the two endpoints may have one-root coordinates.
Precondition: Both endpoints must lie on the given supporting line.

Arr_circle_segment_traits_2<Kernel>::Curve_2 cv(typename Kernel::Circle_2 circ);

constructs an curve corresponding to the given circle. *circ* has a center point with rational coordinates and its *squared* radius is rational.

Arr_circle_segment_traits_2<Kernel>::Curve_2 cv(typename Kernel::Point_2 c,
typename Kernel::FT r,
Orientation orient = COUNTERCLOCKWISE)

constructs an curve corresponding to a circle centered at the rational point *c* whose radius *r* is rational.

Arr_circle_segment_traits_2<Kernel>::Curve_2 cv(typename Kernel::Circle_2 circ,
Point_2 source,
Point_2 target)

constructs a circular arc supported by *circ*, which has a center point with rational coordinates and whose *squared* radius is rational, with the given endpoints. The orientation of the arc is the same as the orientation of *circ*.
Precondition: Both endpoints must lie on the given supporting circle.

Arr_circle_segment_traits_2<Kernel>::Curve_2 cv(typename Kernel::Point_2 c,
typename Kernel::FT r,
Orientation orient,
Point_2 source,
Point_2 target)

constructs a circular arc supported by a circle centered at the rational point *c* whose radius *r* is rational, directed from *source* to *target* with the given orientation.
Precondition: Both endpoints must lie on the supporting circle.

Arr_circle_segment_traits_2<Kernel>::Curve_2 cv(typename Kernel::Point_2 source,
typename Kernel::Point_2 mid,
typename Kernel::Point_2 target)

constructs an circular arc whose endpoints are *source* and *target* that passes through *mid*. All three points have rational coordinates.
Precondition: The three points must not be collinear.

Access Functions

bool	*cv.is_full() const*	indicates whether the curve represents a full circle.
Point_2	*cv.source() const*	returns the source point. *Precondition*: *cv* is not a full circle.

Point_2	*cv.target() const*	returns the target point. *Precondition*: *cv* is not a full circle.
Orientation	*cv.orientation() const*	returns the orientation of the curve (*COLLINEAR* in case of line segments).
bool	*cv.is_linear() const*	determines whether *cv* is a line segment.
bool	*cv.is_circular() const*	determines whether *cv* is a circular arc.

typename Kernel::Line_2

cv.supporting_line() const

returns the supporting line of *cv*.
Precondition: *cv* is a line segment.

typename Kernel::Circle_2

cv.supporting_circle() const

returns the supporting circle of *cv*.
Precondition: *cv* is a circular arc.

Class Arr_circle_segment_traits_2<Kernel>::X_monotone_curve_2

The *X_monotone_curve_2* class nested within the traits class can represent *x*-monotone and line segments (which are always weakly *x*-monotone). The copy and default constructor as well as the assignment operator are provided. In addition, an *operator<<* for the curves is defined for standard output streams.

Creation

Arr_circle_segment_traits_2<Kernel>::X_monotone_curve_2 xcv(typename Kernel::Point_2 source, typename Kernel::Point_2 target)

constructs an curve corresponding to the line segment directed from *source* to *target*, both having rational coordinates.

Arr_circle_segment_traits_2<Kernel>::X_monotone_curve_2 xcv(typename Kernel::Line_2 line, Point_2 source, Point_2 target)

constructs an curve corresponding to the line segment supported by the given line, directed from *source* to *target*. Note that the two endpoints may have one-root coordinates.
Precondition: Both endpoints must lie on the given supporting line.

Arr_circle_segment_traits_2<Kernel>::X_monotone_curve_2 xcv(typename Kernel::Circle_2 circ,

Point_2 source,
Point_2 target,
Orientation orient)

constructs a circular arc supported by *circ*, which has a center point with rational coordinates and whose *squared* radius is rational, with the given endpoints. The orientation of the arc is determined by *orient*.
Precondition: Both endpoints must lie on the given supporting circle.
Precondition: The circular arc is x-monotone.

Access Functions

Point_2	*xcv.source() const*	returns the source point of *xcv*.
Point_2	*xcv.target() const*	returns the target point of *xcv*.
bool	*xcv.is_directed_right() const*	returns true if *xcv* is directed right, false otherwise.
Point_2	*xcv.left() const*	returns the left (lexicographically smaller) endpoint of *xcv*.
Point_2	*xcv.right() const*	returns the right (lexicographically larger) endpoint of *xcv*.
Orientation	*xcv.orientation() const*	returns the orientation of the curve (*COLLINEAR* in case of line segments).
bool	*xcv.is_linear() const*	determines whether *xcv* is a line segment.
bool	*xcv.is_circular() const*	determines whether *xcv* is a circular arc.
typename Kernel::Line_2	*xcv.supporting_line() const*	returns the supporting line of *xcv*. *Precondition*: *xcv* is a line segment.
typename Kernel::Circle_2	*xcv.supporting_circle() const*	returns the supporting circle of *xcv*. *Precondition*: *xcv* is a circular arc.
Bbox_2	*xcv.bbox() const*	returns a bounding box of the arc *xcv*.

Definition

This class is a traits class for CGAL arrangements, built on top of a model of concept *CircularKernel*. It provides curves that can be of both types *CGAL::Line_arc_2<CircularKernel>* or *CGAL::Circular_arc_2<CircularKernel>*.

It uses the boost::variant.

Is Model for the Concepts

ArrangementTraits_2

CGAL::Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>

Class

Definition

The class *Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>* is a model of the *ArrangementTraits_2* concept and can be used to construct and maintain arrangements of bounded segments of algebraic curves of degree 2 at most, also known as *conic curves*.

A general conic curve C is the locus of all points (x,y) satisfying the equation: $rx^2+sy^2+txy+ux+vy+w=0$, where:

- If $4rs-t^2>0$, C is an ellipse. A special case occurs when $r=s$ and $t=0$, when C becomes a circle.
- If $4rs-t^2<0$, C is a hyperbola.
- If $4rs-t^2=0$, C is a parabola. A degenerate case occurs when $r=s=t=0$, when C is a line.

A *bounded conic arc* is defined as either of the following:

- A full ellipse (or a circle) C.
- The tuple $\langle C, p_s, p_t, o\rangle$, where C is the supporting conic curve, with the arc endpoints being p_s and p_t (the source and target points, respectively). The orientation o indicates whether we proceed from p_s to p_t in a clockwise or in a counterclockwise direction. Note that C may also correspond to a line or to pair of lines — in this case o may specify a *COLLINEAR* orientation.

A very useful subset of the set of conic arcs are line segments and circular arcs, as arrangements of circular arcs and line segments have some interesting applications (e.g. offsetting polygons, motion planning for a disc robot, etc.). Circular arcs and line segment are simpler objects and can be dealt with more efficiently than arbitrary arcs. For these reasons, it is possible to construct conic arcs from segments and from circles. Using these constructors is highly recommended: It is more straightforward and also speeds up the arrangement construction. However, in case the set of input curves contain only circular arcs and line segments, it is recommended to use the *Arr_circle_segment_2* class to achieve faster running times.

In our representation, all conic coefficients (namely r,s,t,u,v,w) must be rational numbers. This guarantees that the coordinates of all arrangement vertices (in particular, those representing intersection points) are algebraic numbers of degree 4 (a real number α is an algebraic number of degree d if there exist a polynomial p with *integer* coefficient of degree d such that $p(\alpha)=0$). We therefore require separate representations of the curve coefficients and the point coordinates. The *NtTraits* should be instantiated with a class that defines nested *Integer*, *Rational* and *Algebraic* number types and supports various operations on them, yielding certified computation results (for example, it can convert rational numbers to algebraic numbers and can compute roots of polynomials with integer coefficients). The other template parameters, *RatKernel* and *AlgKernel* should be geometric kernels templated with the *NtTraits::Rational* and *NtTraits::Algebraic* number types, respectively. It is recommended to instantiate the *CORE_algebraic_number_traits* class as the *NtTraits* parameter, with *Cartesian<NtTraits::Rational>* and *Cartesian<NtTraits::Algebraic>* instantiating the two kernel types, respectively. The number types in this case are provided by the CORE library, with its ability to exactly represent simple algebraic numbers.

The traits class inherits its point type from *AlgKernel::Point_2*, and defines a curve and x-monotone curve types, as detailed below.

While the *Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>* models the concept *ArrangementDirectionalXMonotoneTraits_2*, the implementation of the *Arr_mergeable_2* operation does not enforce the input curves to have the same direction as a precondition. Moreover, *Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>* supports the merging of curves of opposite directions.

#include <CGAL/Arr_conic_traits_2.h>

Is Model for the Concepts

ArrangementTraits_2
ArrangementLandmarkTraits_2
ArrangementDirectionalXMonotoneTraits_2

Types

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>:: Rational

the *NtTraits::Rational* type (and also the *RatKernel::FT* type).

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>:: Algebraic

the *NtTraits::Algebraic* type (and also the *AlgKernel::FT* type).

Class Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2

The *Curve_2* class nested within the conic-arc traits can represent arbitrary conic arcs and support their construction in various ways. The copy and default constructor as well as the assignment operator are provided for conic arcs. In addition, an *operator<<* for the curves is defined for standard output streams.

Creation

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 a(typename RatKernel::Segment_2 seg);

constructs an arc corresponding to the line segment *seg*.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 a(typename RatKernel::Circle_2 circ);

constructs an arc corresponding to the full circle *circ* (note that this circle has a center point with rational coordinates and rational squared radius).

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 a(typename RatKernel::Circle_2 circ,
Orientation o,
Point_2 ps,

Point_2 pt)

constructs a circular arc supported by the circle *circ*, going in the given orientation *o* from the source point *ps* to its target point *pt*.
Precondition: *ps* and *pt* both lie on the circle *circ*.
Precondition: *o* is not *COLLINEAR*.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 a(typename RatKernel::Point_2 p1, typename RatKernel::Point_2 p2, typename RatKernel::Point_2 p3)

constructs a circular arc going from *p1* (its source point) through *p2* to *p3* (its target point). Note that all three points have rational coordinates. The orientation of the arc is determined automatically.
Precondition: The three points are not collinear.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 a(Rational r, Rational s, Rational t, Rational u, Rational v, Rational w)

constructs a conic arc that corresponds to the full conic curve $rx^2 + sy^2 + txy + ux + vy + w = 0$.
Precondition: As a conic arc must be bounded, the given curve must be an ellipse, that is $4rs - t^2 > 0$.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 a(Rational r, Rational s, Rational t, Rational u, Rational v, Rational w, Orientation o, Point_2 ps, Point_2 pt)

constructs a conic arc supported by the conic curve $rx^2 + sy^2 + txy + ux + vy + w = 0$, going in the given orientation *o* from the source point *ps* to its target point *pt*.
Precondition: *ps* and *pt* both satisfy the equation of the supporting conic curve and define a bounded segment of this curve (e.g. in case of a hyperbolic arc, both point should be located on the same branch of the hyperbola).
Precondition: *o* is not *COLLINEAR* if the supporting conic is curves, and must be *COLLINEAR* if it is not curved (a line or a line-pair).

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 a(typename RatKernel::Point_2 p1,

typename RatKernel::Point_2 p2,
typename RatKernel::Point_2 p3,
typename RatKernel::Point_2 p4,
typename RatKernel::Point_2 p5)

constructs a conic arc going from *p1* (its source point) through *p2*, *p3* and *p4* (in this order) to *p5* (its target point). Note that all five points have rational coordinates. The orientation of the arc is determined automatically.
Precondition: No three points of the five are not collinear.
Precondition: The five points define a valid arc, in their given order.

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2 a(Rational r,
Rational s,
Rational t,
Rational u,
Rational v,
Rational w,
Orientation o,
Point_2 app_ps,
Rational r1,
Rational s1,
Rational t1,
Rational u1,
Rational v1,
Rational w1,
Point_2 app_pt,
Rational r2,
Rational s2,
Rational t2,
Rational u2,
Rational v2,
Rational w2)

constructs a conic arc supported by the conic curve $rx^2 + sy^2 + txy + ux + vy + w = 0$, going in the given orientation o from its source point to its target point. In this case only some approximations of the endpoints (*app_ps* and *app_pt*, respectively) is available, and their exact locations are given implicitly, specified by the intersections of the supporting conic curve with $r_1x^2 + s_1y^2 + t_1xy + u_1x + v_1y + w_1 = 0$ and $r_2x^2 + s_2y^2 + t_2xy + u_2x + v_2y + w_2 = 0$, respectively.
Precondition: The two auxiliary curves specifying the endpoints really intersect with the supporting conic curve, such that the arc endpoints define a bounded segment of the supporting curve (e.g. in case of a hyperbolic arc, both point should be located on the same branch of the hyperbola).
Precondition: o is not *COLLINEAR* if the supporting conic is curves, and must be *COLLINEAR* if it is not curved (a line or a line-pair).

Access Functions

bool	*a.is_valid() const*	indicates whether a is a valid conic arc. As the precondition to some of the constructor listed above are quite complicated, their violation does not cause the program to abort. Instead, the constructed arc is invalid (a defaultly constructed arc is also invalid). It is however recommended to check that a constructed arc is valid before inserting it to an arrangement, as this operation *will* cause the program to abort.
bool	*a.is_x_monotone() const*	determines whether the arc is x-monotone, namely each vertical line intersects it at most once. A vertical line segment is also considered (weakly) x-monotone.
bool	*a.is_y_monotone() const*	determines whether the arc is y-monotone, namely each horizontal line intersects it at most once. A horizontal line segment is also considered (weakly) x-monotone.
bool	*a.is_full_conic() const*	indicates whether the arc represents a full conic curve (en ellipse or a circle).

The six following methods return the coefficients of the supported conic, after their conversion to integer number (represented by the *Integer* type of the *NtTraits* class):

typename NtTraits::Integer	*a.r() const*	returns the coefficient of x^2.
typename NtTraits::Integer	*a.s() const*	returns the coefficient of t^2.
typename NtTraits::Integer	*a.t() const*	returns the coefficient of xy.
typename NtTraits::Integer	*a.u() const*	returns the coefficient of x.
typename NtTraits::Integer	*a.v() const*	returns the coefficient of y.
typename NtTraits::Integer	*a.w() const*	returns the free coefficient.

Point_2	*a.source() const*	returns the source point of the arc. *Precondition*: a is not a full conic curve.
Point_2	*a.target() const*	returns the target point of the arc. *Precondition*: a is not a full conic curve.
Orientation	*a.orientation() const*	returns the orientation of the arc.
Bbox_2	*a.bbox() const*	return a bounding box of the arc a.

Operations

void	*a.set_source(Point_2 ps)*	sets a new source point for the conic arc. *Precondition*: ps lies on the supporting conic of a.
void	*a.set_target(Point_2 pt)*	sets a new target point for the conic arc. *Precondition*: pt lies on the supporting conic of a.

Class Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>::X_monotone_curve_2

The *X_monotone_curve_2* class nested within the conic-arc traits is used to represent x-monotone conic arcs. It inherits from the *Curve_2* type, therefore supports the access methods and the operations listed above.

For efficiency reasons, we recommend users not to construct x-monotone conic arc directly, but rather use the *Make_x_monotone_2* functor supplied by the conic-arc traits class to convert conic curves to x-monotone curves.

Creation

Arr_conic_traits_2<RatKernel,AlgKernel,NtTraits>:: X_monotone_curve_2 xa(Curve_2 arc);

converts the given arc to an x-monotone arc.
Precondition: *arc* is x-monotone.

Access Functions

Point_2	*xa.left() const*	returns the left (lexicographically smaller) endpoint of *xa*.
Point_2	*xa.right() const*	returns the right (lexicographically larger) endpoint of *xa*.

CGAL::Arr_rational_function_traits_2<AlgebraicKernel_d_1>

Class

Definition

The traits class *Arr_rational_function_traits_2<AlgebraicKernel_d_1>* is a model of the *ArrangementTraits_2* concept. It handles bounded and unbounded arcs of rational functions, referred to as rational arcs (in particular, such an arc may correspond to the entire graph of a rational function), and enables the construction and maintenance of arrangements of such arcs.

A rational function $y = \frac{P(x)}{Q(x)}$ is defined by two polynomials P and Q of arbitrary degrees. If $Q(x) = 1$ then the function is a simple polynomial function. Usually the domain is $\mathbb{R}$ but the function may also be restricted to a bounded interval $[x_{\min}, x_{\max}]$ or defined over a ray $(-\infty, x_{\max}]$ or over $[x_{\min}, \infty)$. Rational functions are represented by the nested type *Curve_2*. Note that a rational function may be not continuous since roots of Q induce vertical asymptotes, which would contradict the notion of an x-monotone curve as it is introduced by the *ArrangementTraits_2* concept. Thus, continuous portions of rational functions are represented by the nested type *X_monotone_curve_2*, which is different from *Curve_2*. Constructors for both classes are provided by the traits. A *Curve_2* may be split up into several *X_monotone_curve_2* using *Make_x_monotone_2*.

The template parameter of the traits must be a model of the concept *AlgebraicKernel_d_1*. A rational function is then represented by two polynomials P and Q of type *AlgebraicKernel_d_1::Polynomial_1*. A point is represented by a rational function and its x-coordinate, which is of type *AlgebraicKernel_d_1::Algebraic_real_1*. Note that an explicit representation of the y-coordinate is only computed upon request, which can be a rather costly operation.

The constructed rational functions are cached by the traits class. The cache is local to each traits class object. It is therefore necessary to construct the curves using the constructor objects provided by member functions of the traits class. Moreover, a curve must only be used with its own traits. The cache is automatically cleaned up from time to time. The amortized clean up costs are constant. However, there is also a separate member function that cleans up the cache on demand.

While *Arr_rational_function_traits_2<AlgebraicKernel_d_1>* models the concept *ArrangementDirectionalXMonotoneTraits_2*, the implementation of the *Arr_mergeable_2* operation does not enforce the input curves to have the same direction as a precondition. Moreover, *Arr_rational_function_traits_2<AlgebraicKernel_d_1>* supports the merging of curves of opposite directions.

typedef AlgebraicKernel_d_1::Algebraic_real_1	*Algebraic_real_1;*
typedef AlgebraicKernel_d_1::Bound	*Bound;*

Creation

Arr_rational_function_traits_2<AlgebraicKernel_d_1> traits(const Algebraic_kernel_d_1 kernel);*

constructs an empty traits that uses the kernel pointed by *kernel* for performing algebraic operations.

Operations

Construct_curve_2	*traits.construct_curve_2_object() const*	
		Returns an instance of *Construct_curve_2*.
Construct_x_monotone_curve_2	*traits.construct_x_monotone_curve_2_object() const*	
		Returns an instance of *Construct_x_monotone_curve_2*.
void	*traits.cleanup_cache() const*	
		Deletes all curves from the cache that exist only there.
*const Algebraic_kernel_d_1**	*traits.algebraic_kernel_d_1() const*	
		Returns a pointer to the used algerbaic kernel object.

Class Arr_rational_function_traits_2<AlgebraicKernel_d_1>::Curve_2

The *Curve_2* class nested within the traits is used to represent rational functions which may be restricted to a certain x-range.

Is Model for the Concepts

ArrTraits::Curve_2

Types

typedef AlgebraicKernel_d_1::Polynomial_1	*Polynomial_1;*
typedef AlgebraicKernel_d_1::Algebraic_real_1	*Algebraic_real_1;*

Operations

Polynomial_1	*curve.numerator() const*	returns the numerator of the supporting rational function.
Polynomial_1	*curve.denominator() const*	returns the denominator of the supporting rational function.

bool	*curve.is_continuous() const*	returns whether *curve* is continuous, namely whether it does not contains any vertical asymptotes in its interior.
Arr_parameter_space	*curve.left_parameter_space_in_x() const*	
		returns whether the x-coordinate of *curve*'s left end is finite or whether it is $\pm\infty$.
Arr_parameter_space	*curve.right_parameter_space_in_x() const*	
		returns whether the x-coordinate of *curve*'s right end is finite or whether it is $\pm\infty$.
Algebraic_real_1	*curve.left_x() const*	returns the x-coordinate of the left end. *Precondition*: left_boundary_in_x()==ARR_INTERIOR
Algebraic_real_1	*curve.right_x() const*	returns the x-coordinate of the right end. *Precondition*: right_boundary_in_x()==ARR_INTERIOR

Class Arr_rational_function_traits_2<AlgebraicKernel_d_1>::X_monotone_curve_2

The *X_monotone_curve_2* class nested within the traits is used to represent x-monotone parts of rational functions. In particular, such an x-monotone curve may not contain a vertical asymptote in its interior x-range.

Is Model for the Concepts

		returns whether the y-coordinate of the right curve end is finite or whether it is $\pm\infty$.
Point_2	*xcurve.right() const*	returns the right point of the arc. *Precondition*: Both the x- and y-coordinates of The right point is finite.
Algebraic_real_1	*xcurve.right_x() const*	returns the x-coordinate of the right point. *Precondition*: The x-coordinate of the right point is finite.
bool	*xcurve.is_left_to_right() const*	returns whether the curve is oriented from left to right.

Class Arr_rational_function_traits_2<AlgebraicKernel_d_1>::Point_2

Is Model for the Concepts

ArrTraits::Point_2

Types

typedef AlgebraicKernel_d_1::Polynomial_1	*Polynomial_1;*
typedef AlgebraicKernel_d_1::Algebraic_real_1	*Algebraic_real_1;*
typedef AlgebraicKernel_d_1::Bound	*Bound;*

Operations

Polynomial_1	*point.numerator() const*	returns the numerator of the supporting rational function.
Polynomial_1	*point.denominator() const*	returns the denominator of the supporting rational function.
std::pair<double,double>	*point.to_double() const*	returns double-approximations of the x- and y-coordinates.
Algebraic_real_1	*point.x() const*	returns the x-coordinate of the point.

Algebraic_real_1 *point.y() const*

obtains the y-coordinates of the point. **Attention:** As described above, points are not stored by their y-coordinate in *Algebraic_real_1* representation. In fact, this representation must be computed on demand, and might become quite costly for points defined by high-degree polynomials. Therefore, it is recommended to avoid calls to this function as much as possible.

std::pair<Bound,Bound> *point.approximate_absolute_x(int a) const*

Computes a pair p approximating the x-coordinate with respect to the given absolute precision a.
Postcondition: $p.first \leq x \leq p.second$
Postcondition: $p.second - p.first \leq 2^{-a}$

std::pair<Bound,Bound> *point.approximate_absolute_y(int a) const*

Computes a pair p approximating the y-coordinate with respect to the given absolute precision a.
Postcondition: $p.first \leq y \leq p.second$
Postcondition: $p.second - p.first \leq 2^{-a}$

std::pair<Bound,Bound> *point.approximate_relative_x(int r) const*

Computes a pair p approximating the x-coordinate with respect to the given relative precision r.
Postcondition: $p.first \leq x \leq p.second$
Postcondition: $p.second - p.first \leq 2^{-r}|x|$

std::pair<Bound,Bound> *point.approximate_relative_y(int r) const*

Computes a pair p approximating the y-coordinate with respect to the given relative precision r.
Postcondition: $p.first \leq y \leq p.second$
Postcondition: $p.second - p.first \leq 2^{-r}|y|$

Class Arr_rational_function_traits_2<AlgebraicKernel_d_1>::Construct_curve_2

Functor to construct a *Curve_2*. To enable caching the class is not default constructible and must be obtained via the function *construct_curve_2_object()*, which is a member of the traits.

Precondition: Q has no real roots in the interior of I.

CGAL::Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>

Class

Definition

The traits class *Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>* is a model of the *ArrangementTraits_2* concept that handles planar Bézier curves. A planar *Bézier curve B* is a parametric curve defined by a sequence of *control points* $p_0, \ldots, p_n$ as follows:

$$B(t) = (X(t), Y(t)) = \sum_{k=0}^{n} p_k \cdot \frac{n!}{k!(n-k)!} \cdot t^k (1-t)^{n-k} \, .$$

where $t \in [0,1]$. The degree of the curve is therefore n — namely, $X(t)$ and $Y(t)$ are polynomials of degree n. Bézier curves have numerous applications in computer graphics and solid modelling. They are used, for example, in free-form sketches and for defining the true-type fonts.

In our representation, we assume that the coordinates of all control points are rational numbers (namely they are given as objects of the *RatKernel::Point_2* type), so both $X(t)$ and $Y(t)$ are polynomials with rational coefficients. The intersection points between curves are however algebraic numbers, and their exact computation is time-consuming. The traits class therefore contains a layer of geometric filtering that performs all computation in an approximate manner whenever possible, and it resorts to exact computations only when the approximate computation fails to produce an unambiguous result.

We therefore require separate representations of the control points and the intersection points. The *NtTraits* should be instantiated with a class that defines nested *Integer*, *Rational* and *Algebraic* number types and supports various operations on them, yielding certified computation results (for example, in can convert rational numbers to algebraic numbers and can compute roots of polynomials with integer coefficients). The other template parameters, *RatKernel* and *AlgKernel* should be geometric kernels templated with the *NtTraits::Rational* and *NtTraits::Algebraic* number types, respectively. It is recommended to instantiate the *CORE_algebraic_number_traits* class as the *NtTraits* parameter, with *Cartesian<NtTraits::Rational>* and *Cartesian<NtTraits::Algebraic>* instantiating the two kernel types, respectively. The number types in this case are provided by the CORE library, with its ability to exactly represent simple algebraic numbers.

While *Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>* models the concept *ArrangementDirectionalXMonotoneTraits_2*, the implementation of the *Arr_mergeable_2* operation does not enforce the input curves to have the same direction as a precondition. Moreover, *Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>* supports the merging of curves of opposite directions.

#include <CGAL/Arr_Bezier_curve_traits_2.h>

Is Model for the Concepts

ArrangementTraits_2
ArrangementDirectionalXMonotoneTraits_2

Types

Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>:: Rational

the *NtTraits::Rational* type (and also the *RatKernel::FT* type).

Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>:: Algebraic

the *NtTraits::Algebraic* type (and also the *AlgKernel::FT* type).

Class Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>::Curve_2

The *Curve_2* class nested within the Bézier traits class is used to represent a Bézier curve of arbitrary degree, which is defined by a sequence of rational control points. In addition to the methods listed below, the I/O operators *operator<<* and *operator>>* for standard output-streams are also supported. The copy constructor and assignment operator are supported as well.

Creation

Arr_Bezier_curve_traits_2<AlgKernel,NtTraits>::Curve_2 B;

default constructor.

template <class InputIterator>
Arr_Bezier_curve_traits_2<AlgKernel,NtTraits>::Curve_2 B(InputIterator pts_begin, InputIterator pts_end);

constructs a Bézier curve as defined by the given range of control points. The value-type of *InputIterator* is *RatKernel::Point_2*.
Precondition: The input range must contain at least two control points.

Access Functions

size_t *B.number_of_control_point() const*

returns the number of control points that define *B*.

typename RatKernel::Point_2

B.control_point(size_t k) const

returns the *k*th control point. Note that the first control point equals the curve source, while the last control point equals its target. The rest of the control points do not lie on the curve.
Precondition: *k* is smaller than the number of control points.

typename RatKernel::Point_2

B(Rational t) returns the point $B(t)$ on the curve that corresponds to the given rational parameter value.

typename AlgKernel::Point_2

B(Algebraic t) returns the point $B(t)$ on the curve that corresponds to the given algebraic parameter value.

Class Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>::Point_2

The *Point_2* class nested within the Bézier traits class is used to represent: (i) an endpoint of a Bézier curve, (ii) a vertical tangency point of a curve, used to subdivide it into x-monotone subcurve, and (iii) an intersection point between two curves. While, points of type (i) have rational coordinates and are given as part of the input, points of the two latter types have algebraic coordinates. However, to speed up the arrangement construction, such point are not computed in an exact manner, and instead are given in an approximate representation. Note that the exact coordinates of a point may only be accessed if it is exactly computed.

In addition to the methods listed below, the copy constructor and assignment operator for *Point_2* objects are also supported.

Creation

Arr_Bezier_curve_traits_2<AlgKernel,NtTraits>::Point_2 p;

default constructor.

Arr_Bezier_curve_traits_2<AlgKernel,NtTraits>::Point_2 p(Curve_2 B, Algebraic t_0);

constructs the point $B(t_0)$ on the given curve. As t_0 is an algebraic number, the point has algebraic coordinates.

Arr_Bezier_curve_traits_2<AlgKernel,NtTraits>::Point_2 p(Curve_2 B, Rational t_0);

constructs the point $B(t_0)$ on the given curve. As t_0 is a rational number, the point has rational coordinates.

Access Functions

std::pair<double, double>

p.approximate() const

returns the approximated coordinates of p.

bool	*p.is_exact() const*	returns whether the coordinates of p are computed in an exact manner.
Algebraic	*p.x() const*	returns the x-coordinate of p. *Precondition*: p is exactly computed.
Algebraic	*p.y() const*	returns the y-coordinate of p. *Precondition*: p is exactly computed.

bool *p.is_rational() const* returns whether the coordinates of p are rational numbers.

typename RatKernel::Point_2

typename RatKernel::Point_2 (p)

casts p to a point with rational coordinates.
Precondition: p has rational coordinates.

Class Arr_Bezier_curve_traits_2<RatKernel,AlgKernel,NtTraits>::X_monotone_curve_2

The *X_monotone_curve_2* class nested within the Bézier traits is used to represent x-monotone subcurves of Bézier curves. The subcurve is defined by a supporting Bézier curve $B(t)$ and a range of definition in the parameter space $[t_1, t_2] \subseteq [0, 1]$, where $B(t_1)$ is the subcurve source and $B(t_2)$ is its target. Note that as the point endpoints may only be approximated, the parameter range defining the subcurve may only be approximately known.

It is not possible to construct x-monotone subcurves directly. Instead, use the *Make_x_monotone_2* functor supplied by the traits class to subdivide a *Curve_2* object into x-monotone subcurves.

Access Functions

Curve_2 *b.supporting_curve() const*

returns the supporting Bézier curve of b.

Point_2 *b.source() const* returns the source point of b.
Point_2 *b.target() const* returns the target point of b.

Point_2 *b.left() const* returns the left (xy-lexicographically smaller) endpoint of b.
Point_2 *b.right() const* returns the right (xy-lexicographically smaller) endpoint of b.

std::pair<double, double>

b.parameter_range() const

return the approximate parameter range defining the subcurve b.

CGAL::Arr_algebraic_segment_traits_2<Coefficient>

Class

Definition

The traits class *Arr_algebraic_segment_traits_2<Coefficient>* is a model of the *ArrangementTraits_2* concept that handles planar algebraic curves of arbitrary degree, and x-monotone of such curves. A planar (real) *algebraic curve* is the vanishing set of a polynomial in two variables, that is, the curve is defined by the defining equation

$$f(x) := \sum_{i+j \leq n} a_{ij} x^i y^j = 0,$$

where n is the degree of the curve.

The traits class allows the construction of algebraic curves, by specifying their implicit equation. x-monotone and vertical segments of a curve can also be defined; unbounded curves and segments are supported. The template parameter *Coefficient* defines the innermost coefficient type of the polynomials. Currently, the types *leda::integer* and *CORE::BigInt* are supported as well as any instance of *CGAL::Sqrt_extension* that is instantiated with one of the integral types above.

Typedef from *Algebraic_kernel_1::Bound*

Class Arr_algebraic_segment_traits_2<Coefficient>::Curve_2

Models the *ArrangementTraits_2::Curve_2* concept. Represents algebraic curves. Internally, the type stores topological-geometric information about the particular curve. In order to use internal caching, instances should only be created using the *Construct_curve_2* functor of the traits class.

Polynomial_2	*C.polynomial() const*	returns the defining polynomial of the curve.

Class Arr_algebraic_segment_traits_2<Coefficient>::Point_2

Models the *ArrangementBasicTraits_2::Point_2* concept. Represents points in $\mathbb{R}^2$. Intersection points of algebraic curves are in general non-rational, so we need a data structure that is capable of representing arbitrary points with algebraic coordinates.

The traits class represents algebraic coordinates by the type *Algebraic_real_1*, which is a model of the *AlgebraicReal_1* concept. A point p is stored by a triple $(x, cv, arcno)$, where x is the x-coordinate of a point, cv is an instance of *Curve_2* that contains the point, (and has no vertical line at x), and $arcno$ is an *int*, denoting that p is met as the $arcno$-th point when shooting a vertical ray at x, starting from $-\infty$ (where counting starts with 0).

In addition to the methods listed below, the copy constructor and assignment operator for *Point_2* objects are also supported.

The functor *Construct_point_2* constructs *Point_2* instances.

Algebraic_real_1	*p.x() const*	returns the x-coordinate of p.
Algebraic_real_1	*p.y() const*	returns the y-coordinates of p. **Attention:** As described above, points are not stored by their y-coordinate in *Algebraic_real_1* representation. In fact, this representation must be computed on demand, and might become quite costly for points defined by high-degree polynomials. Therefore, it is recommended to avoid to call this function as much as possible.
Curve_2	*p.curve() const*	returns a *Curve_2* instance that $p$is part of.
int	*p.arcno() const*	returns the arc number of p.
std::pair<double,double>	*p.to_double() const*	returns double-approximations of the x- and y-coordinates.

Class Arr_algebraic_segment_traits_2<Coefficient>::X_monotone_curve_2

Models the *ArrangementBasicTraits_2::X_monotone_curve_2* concept. Represents terminal segments of an algebraic curves, that means vertical segments or x-monotone segments with no critical x-coordinate in the interior of their x-range. Terminal segments might either be bounded or unbounded. By definition, each interior point of a non-vertical segment has the same arc number (see the documentation of type *Point_2* above, which is called the *arc number* of the segment (note the arc number at the endpoints might differ). Such segments are represented internally by a 4-tuple $(p,q,cv,arcno)$, where p and q are the endpoints, cv is the *supporting curve* that the segment belongs to, and arcno is the arc number of the segment.

Arbitrary (weakly) x-monotone segments are presented by a range of *X_monotone_curve_2* instances, whose union equals the segment. The functor *Construct_x_monotone_segment_2* allows their construction. To construct all (maximal) terminal segments of a curve, use the *Make_x_monotone_2* functor supplied by the traits class.

Curve_2	*s.curve() const*	returns the supporting algebraic curve of s.
bool	*s.is_vertical() const*	returns whether s is a vertical segment.
bool	*s.is_finite(CGAL::Arr_curve_end ce) const*	
		returns whether s has a finite endpoint on the left (if *ce==CGAL::ARR_MIN_END*) or on the right (if *ce==CGAL::ARR_MAX_END*).
Point_2	*s.curve_end(CGAL::Arr_curve_end ce) const*	
		returns the left or right endpoint of $s$for *ce==CGAL::ARR_MIN_END* and *ce==CGAL::ARR_MAX_END*. *Precondition*: (The corresponding curve end is finite)
int	*s.arcno() const*	returns the arc number of the segment. *Precondition*: (The segment is non-vertical)
Algebraic_real_1	*s.x() const*	returns the x-coordinate of a vertical segment. *Precondition*: (The segment is vertical)

Object Creation Functors

Curves, points, and x-monotone segments are created by special functors. The functors are not default constructible; the only possibility to obtain them is by the corresponding accessing functions.

Class Arr_algebraic_segment_traits_2<Coefficient>::Construct_curve_2

Curve_2	*fo(Polynomial_2 p)*	Returns a *Curve_2* object that represents the curve defined by the polynomial p

Curve_2	*fo(std::string s)*	Returns a *Curve_2* object specified by *s*. The passed string represents the defining polynomial of the curve and must be given in a MAPLE-readable format using "x" as first and "y" as second variable, e.g., "(x^3*y-2*x)*(-6*x-y^3*x^6)" for integer coefficients, and "3/2*x*y^4-5/7*x^2+3/1" for rational coefficients.

Class Arr_algebraic_segment_traits_2<Coefficient>::Construct_point_2

Point_2 *fo(Algebraic_real_1 x, Curve_2 cv, int arcno)*

Returns a *Point_2* object that represents the *arcno*-th point in the fiber of *cv* at *x*-coordinate *x*, counted from the bottom, starting with zero.
Precondition: (*cv* must not have a vertical line at *x*, and $0 \leq$ *arcno* $< c$, where c is the number of points in the fiber of *cv* at *x*.)

Point_2 *fo(Algebraic_real_1 x, X_monotone_curve_2 xcv)*

Returns a *Point_2* object that represents the point on *xcv* at *x*-coordinate *x*
Precondition: (*x* is in the *x*-range of *xcv*.)

Point_2 *fo(Algebraic_real_1 x, Algebraic_real_1 y)*

Returns a *Point_2* object that represents (x,y)

Point_2 *fo(Coefficient x, Coefficient y)*

Returns a *Point_2* object that represents (x,y)

Point_2	*fo(Bound x, Bound y)*	Returns a *Point_2* object that represents (x,y)
Point_2	*fo(int x, int y)*	Returns a *Point_2* object that represents (x,y)

Class Arr_algebraic_segment_traits_2<Coefficient>::Construct_x_monotone_segment_2

template<class OutputIterator>
OutputIterator *fo(Curve_2 cv, Point_2 end_min, Point_2 end_max, OutputIterator out)*

Writes a sequence of *X_monotone_curve_2* objects (terminal segments) into *out*. These terminal segments compose an *x*-monotone (or vertical) segment of the curve *cv* that starts in *end_min*, and ends in *end_max*.
Precondition: (*end_min* must have a unique *x*-monotone segment to its right, or *end_max* must have a unique *x*-monotone segment to its left. Furthermore, *end_min* and *end_max* must be connected by an *x*-monotone segment of *cv*)

template<class OutputIterator>
OutputIterator *fo(Curve_2 cv, Point_2 p, Site_of_point site_of_p, OutputIterator out)*

Writes a sequence of *X_monotone_curve_2* objects into *out*. These segments form an *x*-monotone (or vertical) segment of the curve *cv*.
If *site_of_p==POINT_IN_INTERIOR*, the maximal segment is returned that contains *p* in its interior.
If *site_of_p==MIN_ENDPOINT*, the maximal segment is returned that contains *p* as its left endpoint.
If *site_of_p==MAX_ENDPOINT*, the maximal segment is returned that contains *p* as its left endpoint.
Precondition: (If *site_of_p==POINT_IN_INTERIOR*, *p* must be an interior point of an *x*-monotone or a vertical segment. If *site_of_p==MIN_ENDPOINT*, *p* must either have a unique *x*-monotone segment to the right, or a vertical segment from *p* upwards. If *site_of_p==MAX_ENDPOINT*, *p* must either have a unique *x*-monotone segment to the left, or a vertical segment from *p* downwards.)

template<class OutputIterator>
OutputIterator *fo(Point_2 p, Point_2 q, OutputIterator out)*

Writes a sequence of *X_monotone_curve_2* objects into *out*. These segments form a straight-line segment connecting the points *p* and *q*. If *p* and *q* share the same *x*-coordinate, the constructed vertical segment consists of only one *X_monotone_curve_2* object and can be computed efficiently. In the non-vertical case, the construction is only possible if *p* and *q* have both rational x- and y-coordinates.
Precondition: (*p* must not be equal to *q*.)

Accessing functor objects

Construct_curve_2 *traits.construct_curve_2_object() const*
Construct_point_2 *traits.construct_point_2_object() const*
Construct_x_monotone_segment_2

traits.construct_x_monotone_segment_2_object() const

Class

CGAL::Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>

Definition

The class *Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>* is a model of the *ArrangementTraits_2* concept and serves as a decorator class that allows the extension of the curves defined by the base traits-class (the *Tr* parameter), which serves as a geometric traits-class (a model of the *ArrangementTraits_2* concept), with extraneous (non-geometric) data fields.

The traits class inherits its point type from *Traits::Point_2*, and defines an extended *Curve_2* and *X_monotone_curve_2* types, as detailed below.

Each *Curve_2* object is associated with a single data field of type *CData*, and each *X_monotone_curve_2* object is associated with a single data field of type *XData*. When a curve is subdivided into x-monotone subcurves, its data field is converted using the conversion functor, which is specified by the *Cnv* template-parameter, and the resulting objects is copied to all *X_monotone_curve_2* objects induced by this curve. The conversion functor should provide an operator with the following prototype:
XData operator() (const CData& d) const;

By default, the two data types are the same, so the conversion operator is trivial:

CData = *XData*
Cnv = *_Default_convert_functor<CData,XData>*

In case two (or more) x-monotone curves overlap, their data fields are merged to a single field, using the merge functor functor, which is specified by the *Mrg* template-parameter. This functor should provide an operator with the following prototype:
XData operator() (const XData& d1, const XData& d2) const;
which returns a single data object that represents the merged data field of *d1* and *d2*. The x-monotone curve that represents the overlap is associated with the output of this functor.

#include <CGAL/Arr_curve_data_traits_2.h>

Is Model for the Concepts

ArrangementTraits_2

Types

typedef Tr	*Base_traits_2;*	the base traits-class.
typedef typename Base_traits_2::Curve_2	*Base_curve_2;*	the base curve.
typedef typename Base_traits_2::X_monotone_curve_2	*Base_x_monotone_curve_2;*	the base x-monotone curve curve.

typedef Mrg	*Merge;*	the merge functor.
typedef Cnv	*Convert;*	the conversion functor.

typedef CData	*Curve_data;*	the type of data associated with curves.
typedef XData	*X_monotone_curve_data;*	the type of data associated with x-monotone curves.

Inherits From

Base_traits_2

Class Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::Curve_2

The *Curve_2* class nested within the curve-data traits extends the *Base_traits_2::Curve_2* type with an extra data field of type *Data*.

Inherits From

Base_curve_2

Creation

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::Curve_2 cv;

default constructor.

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::Curve_2 cv(Base_curve_2 base);

constructs curve from the given *base* curve with uninitialized data field.

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::Curve_2 cv(Base_curve_2 base, Data data);

constructs curve from the given *base* curve with an attached *data* field.

Access Functions

Curve_data	*cv.data() const*	returns the data field (a non-const version, which returns a reference to the data object, is also available).
void	*cv.set_data(Curve_data data)*	sets the data field.

Class Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::X_monotone_curve_2

The *X_monotone_curve_2* class nested within the curve-data traits extends the *Base_traits_2::X_monotone_curve_2* type with an extra data field.

Inherits From

Base_x_monotone_curve_2

Creation

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::X_monotone_curve_2 xcv;

default constructor.

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::X_monotone_curve_2 xcv(Base_x_monotone_curve_2 base)

constructs an *x*-monotone curve from the given *base* curve with uninitialized data field.

Arr_curve_data_traits_2<Tr,XData,Mrg,CData,Cnv>::X_monotone_curve_2 xcv(Base_x_monotone_curve_2 base, X_monotone_curve_data data)

constructs an *x*-monotone curve from the given *base* *x*-monotone curve with an attached *data* field.

Access Functions

X_monotone_curve_data *xcv.data() const*

returns the field (a non-const version, which returns a reference to the data object, is also available).

void *xcv.set_data(X_monotone_curve_data data)*

sets the data field.

CGAL::Arr_consolidated_curve_data_traits_2<Traits,Data>

Class

Definition

The class *Arr_consolidated_curve_data_traits_2<Traits,Data>* is a model of the concept *ArrangementTraits_2*, and serves as a decorator class that enables the extension of the curve type defined by the *Traits* parameter. The traits class inherits its point type from *Traits::Point_2*, and defines the types *Curve_2* and *X_monotone_curve_2* extended with extraneous data fields of type *Data*.

Each *Curve_2* object is associated with a single data field of type *Data*, and each *X_monotone_curve_2* object is associated with a set of unique data objects. When a curve is subdivided into x-monotone subcurves, all resulting subcurves are associated with a list containing a single data object, copied from the inducing curve. When an x-monotone curve is split, its data set is duplicated, and inserted into the sets of both resulting subcurves. In case two (or more) x-monotone curves overlap, their data sets are consolidated, and are inserted into the set of the x-monotone curve that represents the overlap.

#include <CGAL/Arr_consolidated_curve_data_traits_2.h>

Is Model for the Concepts

ArrangementTraits_2

Inherits From

```
Arr_curve_data_traits_2<Traits,
                        _Unique_list<Data>,
                        _Consolidate_unique_lists<Data>,
                        Data>
```

Types

typedef Traits *Base_traits_2;* the base traits-class.

typedef typename Base_traits_2::Curve_2
Base_curve_2; the base curve.

typedef typename Base_traits_2::X_monotone_curve_2
Base_x_monotone_curve_2;
the base x-monotone curve curve.

Arr_consolidated_curve_data_traits_2<Traits,Data>:: typedef Data_container

a set of data objects that is associated with an x-monotone curve.

Arr_consolidated_curve_data_traits_2<Traits,Data>:: typedef Data_iterator

a non-mutable iterator for the data objects in the data container.

Class Arr_consolidated_curve_data_traits_2<Traits,Data>::Data_container

The *Data_container* class nested within the consolidated curve-data traits and associated with the *Traits::X_monotone_curve_2* type is maintained as a list with unique data objects. This representation is simple and efficient in terms of memory consumption. It also requires that the *Data* class supports only the equality operator. Note however that most set operations require linear time.

Creation

Arr_consolidated_curve_data_traits_2<Traits,Data>:: Data_container dset;

default constructor.

Arr_consolidated_curve_data_traits_2<Traits,Data>:: Data_container dset(Data data);

constructs set containing a single *data* object.

Access Functions

std::size_t	*dset.size() const*	returns the number of data objects in the set.
Data_iterator	*dset.begin() const*	returns an iterator pointing to the first data object.
Data_iterator	*dset.end() const*	returns a past-the-end iterator for the data objects.
Data	*dset.front() const*	returns the first data object inserted into the set. *Precondition*: The number of data objects is not 0.
Data	*dset.back() const*	returns the last data object inserted into the set. *Precondition*: The number of data objects is not 0.

Predicates

bool *dset == Data_container other*

check if the two sets contain the same data objects (regardless of order).

Data_iterator *dset.find(Data data)* find the given *data* object in the set and returns an iterator for this object, or *end()* if it is not found.

Modifiers

bool *dset.insert(Data data)*

inserts the given *data* object into the set. Returns *true* on success, or *false* if the set already contains the object.

bool	*dset.erase(Data data)*	
		erases the given *data* object from the set. Returns *true* on success, or *false* if the set does not contain the object.
void	*dset.clear()*	clears the set.

Concept

ArrangementInputFormatter

A model for the ArrangementInputFormatter concept supports a set of functions that enable reading an arrangement from an input stream using a specific format.

Types

ArrangementInputFormatter:: Arrangement_2 — the type of arrangement to input.

typedef typename Arrangement_2::Point_2
Point_2; — the point type.

typedef typename Arrangement_2::X_monotone_curve_2
X_monotone_curve_2; — the x-monotone curve type.

typedef typename Arrangement_2::Size
Size;

typedef typename Arrangement_2::Vertex_handle
Vertex_handle;

typedef typename Arrangement_2::Halfedge_handle
Halfedge_handle;

typedef typename Arrangement_2::Face_handle
Face_handle;

Creation

ArrangementInputFormatter inf; — default constructor.

ArrangementInputFormatter inf(std::istream& is);
constructs a formatter that reads from *is*.

void *inf.set_in(std::istream& is)*
directs *inf* to read from *is*.

Access Functions

std::istream& *inf.in()* — returns the stream that *inf* reads from.
Precondition: *inf* is directed to a valid output stream.

Formatted Input Functions

void	*inf.read_arrangement_begin()*	
		reads a message indicating the beginning of the arrangement.
void	*inf.read_arrangement_end()*	
		reads a message indicating the end of the arrangement.
Size	*inf.read_size(const char *label = NULL)*	
		reads a size value, which is supposed to be preceded by the given label.
void	*inf.read_vertices_begin()*	
		reads a message indicating the beginning of the vertex records.
void	*inf.read_vertices_end()*	
		reads a message indicating the end of the vertex records.
void	*inf.read_edges_begin()*	
		reads a message indicating the beginning of the edge records.
void	*inf.read_edges_end()*	reads a message indicating the end of the edge records.
void	*inf.read_faces_begin()*	
		reads a message indicating the beginning of the face records.
void	*inf.read_faces_end()*	reads a message indicating the end of the face records.
void	*inf.read_vertex_begin()*	
		reads a message indicating the beginning of a single vertex record.
void	*inf.read_vertex_end()*	reads a message indicating the end of a single vertex record.
std::size_t	*inf.read_vertex_index()*	
		reads and returns a vertex index.
void	*inf.read_point(Point_2& p)*	
		reads a point.

void	*inf.read_vertex_data(Vertex_handle v)*	
		reads an auxiliary vertex-data object and associates it with the vertex *v*.
void	*inf.read_edge_begin()*	
		reads a message indicating the beginning of a single edge record.
void	*inf.read_edge_end()*	reads a message indicating the end of a single edge record.
std::size_t	*inf.read_halfedge_index()*	
		reads and returns halfedge index.
void	*inf.read_x_monotone_curve(X_monotone_curve_2& c)*	
		reads an *x*-monotone curve.
void	*inf.read_halfegde_data(Halfedge_handle he)*	
		reads an auxiliary halfedge-data object and associates it with the halfedge *he*.
void	*inf.read_face_begin()*	reads a message indicating the beginning of a single face record.
void	*inf.read_face_end()*	reads a message indicating the end of a single face record.
void	*inf.read_outer_ccb_begin()*	
		reads a message indicating the beginning of the outer CCB of the current face.
void	*inf.read_outer_ccb_end()*	
		reads a message indicating the end of the outer CCB of the current face.
void	*inf.read_holes_begin()*	
		reads a message indicating the beginning of the container of holes inside the current face.
void	*inf.read_holes_end()*	reads a message indicating the end of the container of holes inside the current face.
void	*inf.read_inner_ccb_begin()*	
		reads a message indicating the beginning of an inner CCB of the current face.

void *inf.read_inner_ccb_end()*

reads a message indicating the end of an inner CCB of the current face.

void *inf.read_ccb_halfedges_begin()*

reads a message indicating the beginning a connected component boundary.

void *inf.read_ccb_halfedges_end()*

reads a message indicating the end of a connected component boundary.

void *inf.read_isolated_vertices_begin()*

reads a message indicating the beginning of the container of isolated vertices inside the current face.

void *inf.read_isolated_vertices_end()*

reads a message indicating the end of the container of isolated vertices inside the current face.

void *inf.read_face_data(Face_handle f)*

reads an auxiliary face-data object and associates it with the face f.

Arr_extended_dcel_text_formatter<Arrangement> (page 2340)

Concept

ArrangementOutputFormatter

A model for the ArrangementOutputFormatter concept supports a set of functions that enable writing an arrangement to an output stream using a specific format.

Types

ArrangementOutputFormatter:: Arrangement_2

the type of arrangement to output.

typedef typename Arrangement_2::Point_2

Point_2; the point type.

typedef typename Arrangement_2::X_monotone_curve_2

X_monotone_curve_2;

the x-monotone curve type.

typedef typename Arrangement_2::Size

Size;

typedef typename Arrangement_2::Vertex_const_handle

Vertex_const_handle;

typedef typename Arrangement_2::Halfedge_const_handle

Halfedge_const_handle;

typedef typename Arrangement_2::Face_const_handle

Face_const_handle;

Creation

ArrangementOutputFormatter outf; default constructor.

ArrangementOutputFormatter outf(std::ostream& os);

constructs a formatter that writes to *os*.

void *outf.set_out(std::ostream& os)*

directs *outf* to write to *os*.

Access Functions

std::ostream&	*outf.out()*	returns the stream that *outf* writes to. *Precondition*: *outf* is directed to a valid output stream.

Formatted Output Functions

void	*outf.write_arrangement_begin()*	
		writes a message indicating the beginning of the arrangement.
void	*outf.write_arrangement_end()*	
		writes a message indicating the end of the arrangement.
void	*outf.write_size(const char *label, Size size)*	
		writes a size value, preceded by a given label.
void	*outf.write_vertices_begin()*	
		writes a message indicating the beginning of the vertex records.
void	*outf.write_vertices_end()*	
		writes a message indicating the end of the vertex records.
void	*outf.write_edges_begin()*	
		writes a message indicating the beginning of the edge records.
void	*outf.write_edges_end()*	
		writes a message indicating the end of the edge records.
void	*outf.write_faces_begin()*	
		writes a message indicating the beginning of the face records.
void	*outf.write_faces_end()*	
		writes a message indicating the end of the face records.
void	*outf.write_vertex_begin()*	
		writes a message indicating the beginning of a single vertex record.
void	*outf.write_vertex_end()*	
		writes a message indicating the end of a single vertex record.

void *outf.write_vertex_index(std::size_t idx)*

writes a vertex index.

void *outf.write_point(Point_2 p)*

writes a point.

void *outf.write_vertex_data(Vertex_const_handle v)*

writes the auxiliary data associated with the vertex.

void *outf.write_edge_begin()*

writes a message indicating the beginning of a single edge record.

void *outf.write_edge_end()*

writes a message indicating the end of a single edge record.

void *outf.write_halfedge_index(std::size_t idx)*

writes a halfedge index.

void *outf.write_x_monotone_curve(X_monotone_curve_2 c)*

writes an *x*-monotone curve.

void *outf.write_halfegde_data(Halfedge_const_handle he)*

writes the auxiliary data associated with the halfedge.

void *outf.write_face_begin()*

writes a message indicating the beginning of a single face record.

void *outf.write_face_end()* writes a message indicating the end of a single face record.

void *outf.write_outer_ccb_begin()*

writes a message indicating the beginning of the outer CCB of the current face.

void *outf.write_outer_ccb_end()*

writes a message indicating the end of the outer CCB of the current face.

void *outf.write_holes_begin()*

writes a message indicating the beginning of the container of holes inside the current face.

void *outf.write_holes_end()*

writes a message indicating the end of the container of holes inside the current face.

void *outf.write_ccb_halfedges_begin()*

writes a message indicating the beginning a connected component's boundary.

void *outf.write_ccb_halfedges_end()*

writes a message indicating the end of a connected component's boundary.

void *outf.write_isolated_vertices_begin()*

writes a message indicating the beginning of the container of isolated vertices inside the current face.

void *outf.write_isolated_vertices_end()*

writes a message indicating the end of the container of isolated vertices inside the current face.

void *outf.write_face_data(Face_const_handle f)*

writes the auxiliary data associated with the face.

Has Models

Arr_text_formatter<Arrangement> (page 2338)
Arr_face_extended_text_formatter<Arrangement> (page 2339)
Arr_extended_dcel_text_formatter<Arrangement> (page 2340)

Class

CGAL::Arr_text_formatter<Arrangement>

Definition

Arr_text_formatter<Arrangement> defines the format of an arrangement in an input or output stream (typically a file stream), thus enabling reading and writing an *Arrangement* instance using a simple text format. The arrangement is assumed to store no auxiliary data with its DCEL records (and if there are such records they will not be written or read by the formatter).

The *Arr_text_formatter<Arrangement>* class assumes that the nested *Point_2* and the *Curve_2* types defined by the *Arrangement* template-parameter can both be written to an input stream using the << operator and read from an input stream using the >> operator.

#include <CGAL/IO/Arr_text_formatter.h>

Definition

Arr_extended_dcel_text_formatter<Arrangement> defines the format of an arrangement in an input or output stream (typically a file stream), thus enabling reading and writing an *Arrangement* instance using a simple text format. The *Arrangement* class should be instantiated with a DCEL class which in turn instantiates the *Arr_extended_dcel* template with the *VertexData*, *HalfedgeData* and *FaceData* types. The formatter supports reading and writing the data objects attached to the arrangement vertices, halfedges and faces.

The *Arr_extended_dcel_text_formatter<Arrangement>* class assumes that the nested *Point_2* and the *Curve_2* types defined by the *Arrangement* template-parameter, as well as the *VertexData*, *HalfedgeData* and *FaceData* types, can all be written to an input stream using the << operator and read from an input stream using the >> operator.

ArrangementPointLocation_2

Concept

Definition

A model of the ArrangementPointLocation_2 concept can be attached to an *Arrangement_2* instance and answer point-location queries on this arrangement. Namely, given a *Arrangement_2::Point_2* object, representing a point in the plane, it returns the arrangement cell containing it. In the general case, the query point is contained inside an arrangement face, but in degenerate situations it may lie on an edge or coincide with an arrangement vertex.

Types

ArrangementPointLocation_2:: Arrangement_2

the associated arrangement type.

ArrangementPointLocation_2:: Point_2 — equivalent to *Arrangement_2::Point_2*.

Creation

ArrangementPointLocation_2 pl; — default constructor.

ArrangementPointLocation_2 pl(Arrangement_2 arr);

constructs a point-location object *pl* attached to the given arrangement *arr*.

Query Functions

Object pl.locate(Point_2 q) const

locates the arrangement cell that contains the query point *q* and returns a handle for this cell. The function returns an *Object* instance that wraps either of the following types:

- *Arrangement_2::Face_const_handle*, in case *q* is contained inside an arrangement face;
- *Arrangement_2::Halfedge_const_handle*, in case *q* lies on an arrangement edge;
- *Arrangement_2::Vertex_const_handle*, in case *q* coincides with an arrangement vertex.

Precondition: *pl* is attached to a valid arrangement instance.

Operations

void *pl.attach(Arrangement_2 arr)*

attaches *pl* to the given arrangement *arr*.

void *pl.detach()*

detaches *pl* from the arrangement it is currently attached to.

Arr_landmarks_point_location<Arrangement,Generator>

ArrangementVerticalRayShoot_2

Definition

A model of the ArrangementVerticalRayShoot_2 concept can be attached to an *Arrangement_2* instance and answer vertical ray-shooting queries on this arrangement. Namely, given a *Arrangement_2::Point_2* object, representing a point in the plane, it returns the arrangement feature (edge or vertex) that lies strictly above it (or below it). By "strictly" we mean that if the query point lies on an arrangement edge (or on an arrangement vertex) this edge will *not* be the query result, but the feature lying above or below it. (An exception to this rule is the degenerate situation where the query point lies in the interior of a vertical edge.) Note that it may happen that the query point lies above the upper envelope (or below the lower envelope) of the arrangement, so that the vertical ray emanating from it may go to infinity without hitting any arrangement feature on its way. In this case the unbounded face is returned.

Types

ArrangementVerticalRayShoot_2:: Arrangement_2

the associated arrangement type.

ArrangementVerticalRayShoot_2:: Point_2 — equivalent to *Arrangement_2::Point_2*.

Creation

ArrangementVerticalRayShoot_2 rs; — default constructor.

ArrangementVerticalRayShoot_2 rs(Arrangement_2 arr);

constructs a ray-shooting object *rs* attached to the given arrangement *arr*.

Query Functions

Object *rs.ray_shoot_up(Point_2 q) const*

locates the arrangement feature that is first hit by an upward-directed vertical ray emanating from the query point q, and returns a handle for this feature. The function returns an *Object* instance that is a wrapper for one of the following types:

- *Arrangement_2::Halfedge_const_handle*, in case the vertical ray hits an arrangement edge;
- *Arrangement_2::Vertex_const_handle*, in case the vertical ray hits an arrangement vertex.
- *Arrangement_2::Face_const_handle* for the unbounded arrangement face, in case q lies above the upper envelope of the arrangement.

Precondition: *rs* is attached to a valid arrangement instance.

Object *rs.ray_shoot_down(Point_2 q) const*

locates the arrangement feature that is first hit by a downward-directed vertical ray emanating from the query point *q*, and returns a handle for this feature. The function returns an *Object* instance that is a wrapper for one of the following types:

- *Arrangement_2::Halfedge_const_handle*, in case the vertical ray hits an arrangement edge;
- *Arrangement_2::Vertex_const_handle*, in case the vertical ray hits an arrangement vertex.
- *Arrangement_2::Face_const_handle* for the unbounded arrangement face, in case *q* lies below the lower envelope of the arrangement.

Precondition: *rs* is attached to a valid arrangement instance.

Operations

void *rs.attach(Arrangement_2 arr)*

attaches *rs* to the given arrangement *arr*.

void *rs.detach()* detaches *rs* from the arrangement it is currently attached to.

CGAL::Arr_naive_point_location<Arrangement>

Class

Definition

The *Arr_naive_point_location<Arrangement>* class implements a naive algorithm that traverses all the vertices and halfedges in the arrangement in search for an answer to a point-location query. The query time is therefore linear in the complexity of the arrangement. Naturally, this point-location strategy could turn into a heavy time-consuming process when applied to dense arrangements.

#include <CGAL/Arr_naive_point_location.h>

Is Model for the Concepts

ArrangementPointLocation_2
ArrangementVerticalRayShoot_2

Class

CGAL::Arr_walk_along_line_point_location<Arrangement>

Definition

The *Arr_walk_along_line_point_location<Arrangement>* class implements a very simple point-location (and vertical ray-shooting) strategy that improves the naive one. The algorithm considers an imaginary vertical ray emanating from the query point, and simulates a walk along the zone of this ray, starting from the unbounded face until reaching the query point. In dense arrangements this walk can considerably reduce the number of traversed arrangement edges, with respect to the naïve algorithm.

The walk-along-a-line point-location object (just like the naïve one) does not use any auxiliary data structures. Thus, attaching it to an existing arrangement takes constant time, and any ongoing updates to this arrangement do not affect the point-location object. It is therefore recommended to use the "walk" point-location strategy for arrangements that are constantly changing, especially if the number of issued queries is not large.

#include <CGAL/Arr_walk_along_line_point_location.h>

Is Model for the Concepts

ArrangementPointLocation_2
ArrangementVerticalRayShoot_2

CGAL::Arr_trapezoid_ric_point_location<Arrangement>

Class

Definition

The *Arr_trapezoid_ric_point_location<Arrangement>* class implements the incremental randomized algorithm introduced by Mulmuley [Mul90] as presented by Seidel [Sei91] (see also [dBvKOS00, Chapter 6]). It subdivides each arrangement face to pseudo-trapezoidal cells, each of constant complexity, and constructs and maintains a linear-size search structure on top of these cells, such that each query can be answered in $O(\log n)$ time, where n is the complexity of the arrangement.

Constructing the search structures takes $O(n \log n)$ expected time and may require a small number of rebuilds [HKH12]. Therefore attaching a trapezoidal point-location object to an existing arrangement may incur some overhead in running times. In addition, the point-location object needs to keep its auxiliary data structures up-to-date as the arrangement goes through structural changes. It is therefore recommended to use this point-location strategy for static arrangements (or arrangement that do not alter frequently), and when the number of issued queries is relatively large.

This strategy supports arbitrary subdivisions, including unbounded ones.

#include <CGAL/Arr_trapezoid_ric_point_location.h>

Is Model for the Concepts

ArrangementPointLocation_2
ArrangementVerticalRayShoot_2

Creation

Arr_trapezoid_ric_point_location<Arrangement> pl(bool with_guarantees = true);

If with_guarantees is set to true, the cunstruction performs rebuilds in order to guarantee a resulting structure with linear size and logarithmic query time. Otherwise the structure has expected linear size and expected logarithmic query time.

Arr_trapezoid_ric_point_location<Arrangement> pl(Arrangement arr, bool with_guarantees = true);

Constructs a point location search structure for the given arrangement. If with_guarantees is set to true, the cunstruction performs rebuilds in order to guarantee a resulting structure with linear size and logarithmic query time. Otherwise the structure has expected linear size and expected logarithmic query time.

Modifiers

void *pl.with_guarantees(bool with_guarantees)*

If with_guarantees is set to true, the structure will guarantee linear size and logarithmic query time, that is, this function may cause a reconstruction of the data structure.

CGAL::Arr_landmarks_point_location<Arrangement,Generator>

The *Arr_landmarks_point_location<Arrangement,Generator>* class implements a Jump & Walk algorithm, where special points, referred to as "landmarks", are chosen in a preprocessing stage, their place in the arrangement is found, and they are inserted into a data-structure that enables efficient nearest-neighbor search (a KD-tree). Given a query point, the nearest landmark is located and a "walk" strategy is applied from the landmark to the query point.

There are various strategies to select the landmark set in the arrangement, where the strategy is determined by the *Generator* template parameter. The following landmark-generator classes are available:

Arr_landmarks_vertices_generator — The arrangement vertices are used as the landmarks set.

Arr_random_landmarks_generator — n random points in the bounding box of the arrangement are chosen as the landmarks set.

Arr_halton_landmarks_generator — n Halton points in the bounding box of the arrangement are chosen as the landmarks set.

Arr_middle_edges_landmarks_generator — The midpoint of each arrangement edge is computed, and the resulting set of points is used as the landmarks set. This generator can be applied only for arrangements of line segments.

Arr_grid_landmarks_generator — A set of n landmarks are chosen on a $\lceil\sqrt{n}\rceil \times \lceil\sqrt{n}\rceil$ grid that covers the bounding box of the arrangement.

The *Arr_landmarks_vertices_generator* class is the default generator and used if no *Generator* parameter is specified.

It is recommended to use the landmarks point-location strategy when the application frequently issues point-location queries on a rather static arrangement that the changes applied to it are mainly insertions of curves and not deletions of them.

#include <CGAL/Arr_landmarks_point_location.h>

Is Model for the Concepts

ArrangementPointLocation_2
ArrangementVerticalRayShoot_2

Function

CGAL::locate

Definition

The function *locate* performs a batched point-location operation on a given arrangement. It accepts a range of query points, and locates each point in the arrangement. The query results are returned through the output iterator. Each result is given as a pair of the query point and an object representing the arrangement feature that contains it, namely an *Object* that may be either *Face_const_handle*, *Halfedge_const_handle*, or *Vertex_const_hanlde*. The resulting pairs in the output sequence are sorted in increasing *xy*-lexicographical order of the query points. The function returns a past-the-end iterator of the output sequence.

#include <CGAL/Arr_batched_point_location.h>

```
template<typename Traits, typename Dcel, typename PointsIterator, typename OutputIterator>
OutputIterator          locate( Arrangement_2<Traits,Dcel> arr,
                                PointsIterator points_begin,
                                PointsIterator points_end,
                                OutputIterator oi)
```

Requirements

- *InputIterator::value_type* must be *Traits::Point_2*.
- *OutputIterator::value_type* must be *std::pair<Traits::Point_2,Object>*.

CGAL::decompose

Definition

The function *decompose* produces the symbolic vertical decomposition of a given arrangement, performing a batched vertical ray-shooting query from all arrangement vertices, such that every vertex is associated with a pair of objects, one corresponds to the arrangement feature that lies below it, and the other corresponds to the feature that lies above it. The output of this function can be readily used for inserting vertical walls and physically decomposing the arrangement into pseudo-trapezoids. To do this, it is convenient to process the vertices in an ascending *xy*-lexicographic order. The visible objects are therefore returned through an output iterator, which pairs each finite arrangement vertex with the two features it "sees", such that the vertices are given in ascending *xy*-lexicographic order.

#include <CGAL/Arr_vertical_decomposition_2.h>

template<typename Traits, typename Dcel, typename OutputIterator>
OutputIterator decompose(Arrangement_2<Traits,Dcel> arr, OutputIterator oi)

Produces the symbolic vertical decomposition of the *arr* arrangement. More precisely, it performs a batched vertical ray-shooting query from all arrangement vertices, such that every vertex is associated with a pair of objects, one corresponding to the arrangement feature that lies below it, while the other corresponds to the feature that lies above it. The query results are returned through the output iterator, which pairs each finite arrangement vertex with a pair of *Object*s, the first represents the feature below the vertex, and the second represents the feature that lies above it. Each *Object* may be one of the following:

- *Halfedge_const_handle*, if the vertex is located above (or below) an edge. The given halfedge is always directed from right to left. In case there is no concrete edge below (or above) the vertex, and the arrangement is unbounded, then the object returned is a *fictitious* halfedge.
- *Face_const_handle*, in case there is no edge below (or above) the vertex, and the arrangement is bounded.
- *Vertex_const_handle*, in case the vertex is located vertically above (or below) another arrangement vertex.
- An empty object, in case the vertex is the top end-vertex of a vertical edge, we define there is no feature below it. Similarly, if it is the bottom end-vertex of a vertical edge, we define that there is no feature above it.

The function returns a past-the-end iterator for its output sequence.

Requirements

OutputIterator::value_type must be *pair<Arrangement_2::Vertex_const_handle, pair<Object, Object> >*.

CGAL::Arr_observer<Arrangement>

Definition

Arr_observer<Arrangement> serves as an abstract base class for all observer classes that are attached to an arrangement instance of type *Arrangement* and receive notifications from the arrangement. This base class handles the attachment of the observer to a given arrangement instance or to the detachment of the observer from this arrangement instance. It also gives a default empty implementation to all notification functions that are invoked by the arrangement to notify the observer on local or global changes it undergoes. The notification functions are all virtual functions, so they can be overridden by the concrete observer classes that inherit from *Arr_observer<Arrangement>*.

In order to implement a concrete arrangement observer-class, one simply needs to derive from *Arr_observer< Arrangement>* and override the relevant notification functions. For example, if only face-split events are of interest, it is sufficient to override just *before_split_face()* (or just *after_split_face()*).

#include <CGAL/Arr_observer.h>

Types

Arr_observer<Arrangement>:: Arrangement_2 — the type of the associated arrangement.

typedef typename Arrangement_2::Point_2

Point_2; — the point type.

typedef typename Arrangement_2::X_monotone_curve_2

X_monotone_curve_2;

the x-monotone curve type.

typedef typename Arrangement_2::Vertex_handle

Vertex_handle;

typedef typename Arrangement_2::Halfedge_handle

Halfedge_handle;

typedef typename Arrangement_2::Face_handle

Face_handle;

typedef typename Arrangement_2::Ccb_halfedge_circulator

Ccb_halfedge_circulator;

represents the boundary of a connected component (CCB). In particular, holes are represented by a circulator for their outer CCB.

Creation

Arr_observer<Arrangement> obs; — constructs an observer that is unattached to any arrangement instance.

Arr_observer<Arrangement> obs(Arrangement_2& arr);

constructs an observer and attaches it to the given arrangement *arr*.

Modifiers

void — *obs.attach(Arrangement_2& arr)*

attaches the observer to the given arrangement *arr*.

void — *obs.detach()* — detaches the observer from its arrangement.

Notifications on Global Arrangement Operations

virtual void — *obs.before_assign(Arrangement_2 arr)*

issued just before the attached arrangement is assigned with the contents of another arrangement *arr*.

virtual void — *obs.after_assign()* — issued immediately after the attached arrangement has been assigned with the contents of another arrangement.

virtual void — *obs.before_clear()* — issued just before the attached arrangement is cleared.

virtual void — *obs.after_clear(Face_handle uf)*

issued immediately after the attached arrangement has been cleared, so it now consists only of a the unbounded face *uf*.

virtual void — *obs.before_global_change()*

issued just before a global function starts to modify the attached arrangement. It is guaranteed that no queries (especially no point-location queries) are issued until the termination of the global function is indicated by *after_global_change()*.

virtual void — *obs.after_global_change()*

issued immediately after a global function has stopped modifying the attached arrangement.

Notifications on Attachment or Detachment

virtual void *obs.before_attach(Arrangement_2 arr)*

issued just before the observer is attached to the arrangement instance *arr*.

virtual void *obs.after_attach()* issued immediately after the observer has been attached to an arrangement instance.

virtual void *obs.before_detach()* issued just before the observer is detached from its arrangement instance.

virtual void *obs.after_attach()* issued immediately after the observer has been detached from its arrangement instance.

Notifications on Local Changes in the Arrangement

virtual void *obs.before_create_vertex(Point_2 p)*

issued just before a new vertex that corresponds to the point *p* is created.

virtual void *obs.after_create_vertex(Vertex_handle v)*

issued immediately after a new vertex *v* has been created. Note that the vertex still has no incident edges and is not connected to any other vertex.

virtual void *obs.before_create_boundary_vertex(X_monotone_curve_2 cv, Arr_curve_end ind, Arr_parameter_space ps_x, Arr_parameter_space ps_y)*

issued just before a new vertex at infinity is created, *cv* is the curve incident to the surface boundary, *ind* is the relevant curve-end, *ps_x* is the boundary condition of the vertex in *x* and *ps_y* is the boundary condition of the vertex in *y*.

virtual void *obs.after_create_boundary_vertex(Vertex_handle v)*

issued immediately after a new vertex *v* has been created. Note that the vertex still has no incident edges and is not connected to any other vertex.

virtual void *obs.before_create_edge(X_monotone_curve_2 c, Vertex_handle v1, Vertex_handle v2)*

issued just before a new edge that corresponds to the *x*-monotone curve *c* and connects the vertices *v1* and *v2* is created.

virtual void *obs.after_create_edge(Halfedge_handle e)*

issued immediately after a new edge *e* has been created. The halfedge that is sent to this function is always directed from *v1* to *v2* (see above).

virtual void *obs.before_modify_vertex(Vertex_handle v, Point_2 p)*

issued just before a vertex *v* is modified to be associated with the point *p*.

virtual void *obs.after_modify_vertex(Vertex_handle v)*

issued immediately after an existing vertex *v* has been modified.

virtual void *obs.before_modify_edge(Halfedge_handle e, X_monotone_curve_2 c)*

issued just before an edge *e* is modified to be associated with the *x*-monotone curve *c*.

virtual void *obs.after_modify_edge(Halfedge_handle e)*

issued immediately after an existing edge *e* has been modified.

virtual void *obs.before_split_edge(Halfedge_handle e, Vertex_handle v, X_monotone_curve_2 c1, X_monotone_curve_2 c2)*

issued just before an edge *e* is split into two edges that should be associated with the *x*-monotone curves *c1* and *c2*. The vertex *v* corresponds to the split point, and will be used to separate the two resulting edges.

virtual void *obs.after_split_edge(Halfedge_handle e1, Halfedge_handle e2)*

issued immediately after an existing edge has been split into the two given edges *e1* and *e2*.

virtual void *obs.before_split_fictitious_edge(Halfedge_handle e, Vertex_handle v)*

issued just before a fictitious edge *e* is split into two. The vertex at infinity *v* corresponds to the split point, and will be used to separate the two resulting edges.

virtual void *obs.after_split_fictitious_edge(Halfedge_handle e1, Halfedge_handle e2)*

issued immediately after an existing fictitious edge has been split into the two given fictitious edges *e1* and *e2*.

virtual void *obs.before_split_face(Face_handle f, Halfedge_handle e)*

issued just before a face *f* is split into two, as a result of the insertion of the edge *e* into the arrangement.

virtual void *obs.after_split_face(Face_handle f1, Face_handle f2, bool is_hole)*

issued immediately after the existing face *f1* has been split, such that a portion of it now forms a new face *f2*. The flag *is_hole* designates whether *f2* forms a hole inside *f1*.

virtual void *obs.before_split_outer_ccb(Face_handle f,*
Ccb_halfedge_circulator h,
Halfedge_handle e)

issued just before outer ccb *h* inside a face *f* is split into two, as a result of the removal of the edge *e* from the arrangement.

virtual void *obs.after_split_outer_ccb(Face_handle f,*
Ccb_halfedge_circulator h1,
Ccb_halfedge_circulator h2)

issued immediately after outer ccb the face *f* has been split, resulting in the two holes *h1* and *h2*.

virtual void *obs.before_split_inner_ccb(Face_handle f,*
Ccb_halfedge_circulator h,
Halfedge_handle e)

issued just before inner ccb *h* inside a face *f* is split into two, as a result of the removal of the edge *e* from the arrangement.

virtual void *obs.after_split_inner_ccb(Face_handle f,*
Ccb_halfedge_circulator h1,
Ccb_halfedge_circulator h2)

issued immediately after inner ccb the face *f* has been split, resulting in the two holes *h1* and *h2*.

virtual void *obs.before_add_outer_ccb(Face_handle f, Halfedge_handle e)*

issued just before the edge *e* is inserted as a new outer ccb inside the face *f*.

virtual void *obs.after_add_outer_ccb(Ccb_halfedge_circulator h)*

issued immediately after a new outer ccb *h* has been created. The outer ccb always consists of a single pair of twin halfedges.

virtual void *obs.before_add_inner_ccb(Face_handle f, Halfedge_handle e)*

issued just before the edge *e* is inserted as a new inner ccb inside the face *f*.

virtual void *obs.after_add_inner_ccb(Ccb_halfedge_circulator h)*

issued immediately after a new inner ccb *h* has been created. The inner ccb always consists of a single pair of twin halfedges.

virtual void *obs.before_add_isolated_vertex(Face_handle f, Vertex_handle v)*

issued just before the vertex *v* is inserted as an isolated vertex inside the face *f*.

virtual void *obs.after_add_isolated_vertex(Vertex_handle v)*

issued immediately after the vertex *v* has been set as an isolated vertex.

virtual void *obs.before_merge_edge(Halfedge_handle e1, Halfedge_handle e2, X_monotone_curve_2 c)*

issued just before the two edges *e1* and *e2* are merged to form a single edge that will be associated with the *x*-monotone curve *c*.

virtual void *obs.after_merge_edge(Halfedge_handle e)*

issued immediately after two edges have been merged to form the edge *e*.

virtual void *obs.before_merge_fictitious_edge(Halfedge_handle e1, Halfedge_handle e2)*

issued just before the two fictitious edges *e1* and *e2* are merged to form a single fictitious edge.

virtual void *obs.after_merge_fictitious_edge(Halfedge_handle e)*

issued immediately after two fictitious edges have been merged to form the fictitious edge *e*.

virtual void *obs.before_merge_face(Face_handle f1, Face_handle f2, Halfedge_handle e)*

issued just before the two edges *f1* and *f2* are merged to form a single face, following the removal of the edge *e* from the arrangement.

virtual void *obs.after_merge_face(Face_handle f)*

issued immediately after two faces have been merged to form the face *f*.

virtual void *obs.before_merge_outer_ccb(Face_handle f, Ccb_halfedge_circulator h1, Ccb_halfedge_circulator h2, Halfedge_handle e)*

issued just before two outer ccbs *h1* and *h2* inside the face *f* are merged to form a single connected component, following the insertion of the edge *e* into the arrangement.

virtual void *obs.after_merge_outer_ccb(Face_handle f, Ccb_halfedge_circulator h)*

issued immediately after two outer ccbs have been merged to form a single outer ccb *h* inside the face *f*.

virtual void *obs.before_merge_inner_ccb(Face_handle f, Ccb_halfedge_circulator h1, Ccb_halfedge_circulator h2, Halfedge_handle e)*

issued just before two inner ccbs *h1* and *h2* inside the face *f* are merged to form a single connected component, following the insertion of the edge *e* into the arrangement.

virtual void *obs.after_merge_inner_ccb(Face_handle f, Ccb_halfedge_circulator h)*

issued immediately after two inner ccbs have been merged to form a single inner ccb *h* inside the face *f*.

virtual void *obs.before_move_outer_ccb(Face_handle from_f, Face_handle to_f, Ccb_halfedge_circulator h)*

issued just before the outer ccb *h* is moved from one face to another. This can happen if the face *to_f* containing the outer ccb has just been split from *from_f*.

virtual void *obs.after_move_outer_ccb(Ccb_halfedge_circulator h)*

issued immediately after the outer ccb *h* has been moved to a new face.

virtual void *obs.before_move_inner_ccb(Face_handle from_f, Face_handle to_f, Ccb_halfedge_circulator h)*

issued just before the inner ccb *h* is moved from one face to another. This can happen if the face *to_f* containing the inner ccb has just been split from *from_f*.

virtual void *obs.after_move_inner_ccb(Ccb_halfedge_circulator h)*

issued immediately after the inner ccb *h* has been moved to a new face.

virtual void *obs.before_move_isolated_vertex(Face_handle from_f, Face_handle to_f, Vertex_handle v)*

issued just before the isolated vertex *v* is moved from one face to another. This can happen if the face *to_f* containing the isolated vertex has just been split from *from_f*.

virtual void *obs.after_move_isolated_vertex(Vertex_handle v)*

issued immediately after the isolated vertex *v* has been moved to a new face.

virtual void *obs.before_remove_vertex(Vertex_handle v)*

issued just before the vertex *v* is removed from the arrangement.

virtual void *obs.after_remove_vertex()*

issued immediately after a vertex has been removed (and deleted) from the arrangement.

virtual void *obs.before_remove_edge(Halfedge_handle e)*

issued just before the edge e is removed from the arrangement.

virtual void *obs.after_remove_edge()*

issued immediately after an edge has been removed (and deleted) from the arrangement.

virtual void *obs.before_remove_outer_ccb(Face_handle f, Ccb_halfedge_circulator h)*

issued just before the outer ccb f is removed from inside the face f.

virtual void *obs.after_remove_outer_ccb(Face_handle f)*

issued immediately after a outer ccb has been removed (and deleted) from inside the face f.

virtual void *obs.before_remove_inner_ccb(Face_handle f, Ccb_halfedge_circulator h)*

issued just before the inner ccb f is removed from inside the face f.

virtual void *obs.after_remove_inner_ccb(Face_handle f)*

issued immediately after a inner ccb has been removed (and deleted) from inside the face f.

Concept

ArrangementOpenBoundaryTraits_2

Definition

Several predicates are required to handle x-monotone curves that approach infinity and thus approach the boundary of the parameter space. These predicates are sufficient to handle not only curves embedded in an unbounded parameter space, but also curves embedded in a bounded parameter space with open boundaries. Models of the concept ArrangementOpenBoundaryTraits_2 handle curves that approach the boundary of a parameter space. This concept refines the concept *ArrangementBasicTraits_2*. The arrangement template instantiated with a traits class that models this concept can handle x-monotone curves that are unbounded in any direction. The concept ArrangementOpenBoundaryTraits_2, nontheless, also supports planar x-monotone curves that reach the boundary of an open yet bounded parameter space.

An x-monotone curve may be *closed*, in which case its endpoints are representable as *Point_2* objects, or *open* at the boundary of the parameter space. It can have one open end and one closed end (e.g., a ray). The nature of the x-monotone curves, whether they are expected to be closed or not at any one of the four boundary-sides, is conveyed through the definition of the four nested types *Left_side_category*, *Right_side_category*, *Bottom_side_category*, and *Top_side_category*. If some curves handled by a model of the concept ArrangementOpenBoundaryTraits_2 are expected to be open on the left, the nested type *Left_side_category* must be convertible to *Arr_open_side_tag*. Similarly, if some curves handled by the concept are expected to be open on the right, open at the bottom, or open at the top, the corresponding nested type must be convertible to *Arr_open_side_tag*. A model of the concept ArrangementOpenBoundaryTraits_2 must have all the four categories convertible to *Arr_open_side_tag*.[22] In this case the DCEL of the arrangement instantiated with the model is initialized with an implicit bounding rectangle. When the parameter space is bounded, it is the exact geometric embedding of the implicit bounding rectangle.

ArrangementOpenBoundaryTraits_2:: Left_side_category

Must be convertible to either *Arr_oblivious_side_tag* or *Arr_open_side_tag*.

ArrangementOpenBoundaryTraits_2:: Bottom_side_category

Must be convertible to either *Arr_oblivious_side_tag* or *Arr_open_side_tag*.

ArrangementOpenBoundaryTraits_2:: Top_side_category

Must be convertible to either *Arr_oblivious_side_tag* or *Arr_open_side_tag*.

[22]We intend to introduce more concepts that require only a subset of the categories to be convertible to *Arr_open_side_tag*.

ArrangementOpenBoundaryTraits_2:: Right_side_category

Must be convertible to either *Arr_oblivious_side_tag* or *Arr_open_side_tag*.

Functor Types

ArrangementOpenBoundaryTraits_2:: Parameter_space_in_x_2

models the concept *ArrTraits::ParameterSpaceInX_2*. Required only if the traits class supports unbounded curves that approach the left or the right sides (the *Left_side_category* or the *Right_side_category* categories are convertible to *Arr_open_side_tag*).

ArrangementOpenBoundaryTraits_2:: Compare_y_near_boundary_2

models the concept *ArrTraits::CompareYNearBoundary_2*. Required only if the traits class supports unbounded curves that approach the left or the right sides (the *Left_side_category* or the *Right_side_category* categories are convertible to *Arr_open_side_tag*).

ArrangementOpenBoundaryTraits_2:: Parameter_space_in_y_2

models the concept *ArrTraits::ParameterSpaceInY_2*. Required only if the traits class supports unbounded curves that approach the bottom or the top sides (the *Bottom_side_category* or the *Top_side_category* categories are convertible to *Arr_open_side_tag*).

ArrangementOpenBoundaryTraits_2:: Compare_x_at_limit_2

models the concept *ArrTraits::CompareXAtLimit_2*. Required only if the traits class supports unbounded curves that approach the bottom or the top sides (the *Bottom_side_category* or the *Top_side_category* categories are convertible to *Arr_open_side_tag*).

ArrangementOpenBoundaryTraits_2:: Compare_x_near_limit_2

models the concept *ArrTraits::CompareXNearLimit_2*. Required only if the traits class supports unbounded curves that approach the bottom or the top sides (the *Bottom_side_category* or the *Top_side_category* categories are convertible to *Arr_open_side_tag*).

Arr_parameter_space

fo(ArrTraits::X_monotone_curve_2 xcv, Arr_curve_end ce)

Given an x-monotone curve *xcv* and an enumeration *ce* that specifies either the minimum or the maximum end of the curve, determines the location of the curve end along the x-dimension. The variable *xcv* identifies the parametric curve $C(t) = (X(t), Y(t))$ defined over an open or half-open interval with endpoints 0 and 1. The enumeration *ce* identifies an open end $d \in \{0,1\}$ of C. Formally, determines whether $\lim_{t \to d} X(t)$ evaluates to b_l, b_r, or a value in between, where b_l and b_r are the x-coordinates of the left and right boundaries of the parameter space, respectively. Returns *ARR_LEFT_BOUNDARY*, *ARR_RIGHT_BOUNDARY*, or *ARR_INTERIOR*, accordingly.
Precondition: If *ArrTraits::Left_side_category* is not convertible to *Arr_open_side_tag* then $ce \neq$ *ARR_MIN_END*.
Precondition: If *ArrTraits::Right_side_category* is not convertible to *Arr_open_side_tag* then $ce \neq$ *ARR_MAX_END*.
Postcondition: If *ce* = *ARR_MIN_END* then the result is either *ARR_LEFT_BOUNDARY* or *ARR_INTERIOR*.
Postcondition: If *ce* = *ARR_MAX_END* then the result is either *ARR_RIGHT_BOUNDARY* or *ARR_INTERIOR*.

CGAL::Arrangement_with_history_2<Traits,Dcel>

Definition

An object *arr* of the class *Arrangement_with_history_2<Traits,Dcel>* represents the planar subdivision induced by a set of input curves $\mathcal{C}$. The arrangement is represented as a doubly-connected edge-list (DCEL). As is the case for the *Arrangement_2<Traits,Dcel>*, each DCEL vertex is associated with a point and each edge is associated with an x-monotone curve whose interior is disjoint from all other edges and vertices. Each such x-monotone curve is a subcurve of some $C \in \mathcal{C}$ — or may represent an overlap among several curves in $\mathcal{C}$.

The *Arrangement_with_history_2<Traits,Dcel>* class-template extends the *Arrangement_2* class-template by keeping an additional container of input curves representing $\mathcal{C}$, and by maintaining a cross-mapping between these curves and the arrangement edges they induce. This way it is possible to determine the inducing curve(s) of each arrangement edge. This mapping also allows the traversal of input curves, and the traversal of edges induced by each curve.

The *Arrangement_with_history_2<Traits,Dcel>* template has two parameters:

- The *Traits* template-parameter should be instantiated with a model of the *ArrangementTraits_2* concept. The traits class defines the *Curve_2* type, which represents an input curve. It also defines the types of x-monotone curves and two-dimensional points, namely *X_monotone_curve_2* and *Point_2*, respectively, and supports basic geometric predicates on them.
- The *Dcel* template-parameter should be instantiated with a class that is a model of the *ArranagementDcelWithRebind* concept. The value of this parameter is by default *Arr_default_dcel<Traits>*.

Inherits From

Arrangement_2<Traits,Dcel>

#include <CGAL/Arrangement_with_history_2.h>

Types

typedef Arrangement_with_history_2<Traits_2,Dcel>

Self;	a private type used as an abbreviation of the *Arrangement_with_history_2<Traits,Dcel>* type hereafter.

Arrangement_with_history_2<Traits,Dcel>:: Traits_2

the traits class in use.

Arrangement_with_history_2<Traits,Dcel>:: Dcel

the DCEL representation of the arrangement.

typedef typename Traits_2::Point_2

Point_2;	the point type, as defined by the traits class.

typedef typename Traits_2::X_monotone_curve_2

X_monotone_curve_2;

the x-monotone curve type, as defined by the traits class.

typedef typename Traits_2::Curve_2

Curve_2; the curve type, as defined by the traits class.

In addition, the nested types *Vertex*, *Halfedge* and *Face* are defined, as well as all handle, iterator and circulator types, as defined by the *Arrangement_2* class-template (page 2187).

Arrangement_with_history_2<Traits,Dcel>:: Curve_handle

a handle for an input curve.

Arrangement_with_history_2<Traits,Dcel>:: Curve_iterator

a bidirectional iterator over the curves that induce the arrangement. Its value-type is *Curve_2*.

Arrangement_with_history_2<Traits,Dcel>:: Induced_edge_iterator

an iterator over the edges induced by an input curve. Its value type is *Halfedge_handle*.

Arrangement_with_history_2<Traits,Dcel>:: Originating_curve_iterator

an iterator for the curves that originate a given arrangement edge. Its value type is *Curve_handle*.

Creation

Arrangement_with_history_2<Traits,Dcel> arr;

constructs an empty arrangement containing one unbounded face, which corresponds to the whole plane.

Arrangement_with_history_2<Traits,Dcel> arr(Self other);

copy constructor.

*Arrangement_with_history_2<Traits,Dcel> arr(Traits_2 *traits);*

constructs an empty arrangement that uses the given *traits* instance for performing the geometric predicates.

Assignment Methods

Self&	*arr = other*	assignment operator.
void	*arr.assign(Self other)*	
		assigns the contents of another arrangement.
void	*arr.clear()*	clears the arrangement.

Access Functions

See the *Arrangement_2* reference pages (page 2187) for the full list.

• *Accessing the Input Curves:*

Size	*arr.number_of_curves() const*	
		returns the number of input curves that induce the arrangement.
Curve_iterator	*arr.curves_begin()*	returns the begin-iterator of the curves inducing the arrangement.
Curve_iterator	*arr.curves_end()*	returns the past-the-end iterator of the curves inducing the arrangement.
Size	*arr.number_of_induced_edges(Curve_handle ch) const*	
		returns the number of arrangement edges induced by the curve *ch*.
Induced_edge_iterator		
	arr.induced_edges_begin(Curve_handle ch) const	
		returns the begin-iterator of the edges induced by the curve *ch*.
Induced_edge_iterator		
	arr.induced_edges_end(Curve_handle ch) const	
		returns the past-the-end iterator of the edges induced by the curve *ch*.
Size	*arr.number_of_originating_curves(Halfedge_handle e) const*	
		returns the number of input curves that originate the edge *e*.

Originating_curve_iterator

arr.originating_curves_begin(Halfedge_handle e) const

returns the begin-iterator of the curves originating the edge *e*.

Originating_curve_iterator

arr.originating_curves_end(Halfedge_handle e) const

returns the past-the-end iterator of the curves originating the edge *e*.

Modifiers

See the *Arrangement_2* reference pages (page 2187) for the full list of functions for modifying arrangement vertices.

• *Modifying Arrangement Edges:*

The following functions override their counterparts in the *Arrangement_2* class, as they also maintain the cross-relationships between the input curves and the edges they induce.

Halfedge_handle *arr.split_edge(Halfedge_handle e, Point_2 p)*

splits the edge *e* into two edges (more precisely, into two halfedge pairs), at a given split point *p*. The function returns a handle for the halfedge whose source is the same as *e->source()* and whose target vertex is the split point.
Precondition: *p* lies in the interior of the curve associated with *e*.

Halfedge_handle *arr.merge_edge(Halfedge_handle e1, Halfedge_handle e2)*

merges the edges represented by *e1* and *e2* into a single edge. The function returns a handle for one of the merged halfedges.
Precondition: *e1* and *e2* share a common end-vertex, of degree 2, and the *x*-monotone curves associated with *e1* and *e2* are mergeable into a single *x*-monotone curves.

Face_handle *arr.remove_edge(Halfedge_handle e,*
bool remove_source = true,
bool remove_target = true)

removes the edge *e* from the arrangement. Since the *e* may be the only edge incident to its source vertex (or its target vertex), this vertex can be removed as well. The flags *remove_source* and *remove_target* indicate whether the endpoints of *e* should be removed, or whether they should be left as isolated vertices in the arrangement. If the operation causes two faces to merge, the merged face is returned. Otherwise, the face to which the edge was incident is returned.

enum Arr_parameter_space { *ARR_LEFT_BOUNDARY,*
ARR_RIGHT_BOUNDARY,
ARR_BOTTOM_BOUNDARY,
ARR_TOP_BOUNDARY,
ARR_INTERIOR}

CGAL::remove_curve

Function

Definition

The function *remove_curve* removes a given curve from a given arrangement.

#include <CGAL/Arrangement_with_history_2.h>

template <class Traits, class Dcel>
Size remove_curve(Arrangement_with_history_2<Traits,Dcel>& arr,
typename Arrangement_with_history_2<Traits,Dcel>::Curve_handle ch)

remove_curve removes a curve, specified by its handle *ch*, from the arrangement *arr*, by deleting all the edges it induces. The function returns the number of deleted edges.

Concept

ArrangementWithHistoryInputFormatter

A model for the ArrangementWithHistoryInputFormatter concept supports a set of functions that enable reading an arrangement-with-history instance from an input stream using a specific format.

Refines

ArrangementInputFormatter

Types

ArrangementWithHistoryInputFormatter:: Arr_with_history_2

the type of arrangement to input.

typedef typename Arrangement_2::Curve_2

Curve_2; the inducing curve type.

Formatted Input Functions

void *inf.read_curves_begin()*

reads a message indicating the beginning of the inducing curves.

void *inf.read_curves_end()*

reads a message indicating the end of the inducing curves.

void *inf.read_curve_begin()*

reads a message indicating the beginning of a single curve record.

void *inf.read_curve_end()* reads a message indicating the end of a single curve record.

void *inf.read_curve(Curve_2& c)*

reads a curve.

void *inf.read_induced_edges_begin()*

reads a message indicating the beginning of the set of edges induced by the current curve.

void *inf.read_induced_edges_end()*

reads a message indicating the end of the induced edges set.

Has Models

Arr_with_history_text_formatter<ArrFormatter> (page 2380)

ArrangementWithHistoryOutputFormatter

A model for the ArrangementWithHistoryOutputFormatter concept supports a set of functions that enable writing an arrangement-with-history instance to an output stream using a specific format.

Refines

ArrangementOutputFormatter

Types

ArrangementWithHistoryOutputFormatter:: Arr_with_history_2

the type of arrangement to output.

typedef typename Arrangement_2::Curve_2

Curve_2; — the inducing curve type.

Formatted Output Functions

void *outf.write_curves_begin()*

writes a message indicating the beginning of the inducing curves.

void *outf.write_curves_end()*

writes a message indicating the end of the inducing curves.

void *outf.write_curve_begin()*

writes a message indicating the beginning of a single curve record.

void *outf.write_curve_end()*

writes a message indicating the end of a single curve record.

void *outf.write_curve(Curve_2 c)*

writes a curve.

void *outf.write_induced_edges_begin()*

writes a message indicating the beginning of the set of edges induced by the current curve.

void *outf.write_induced_edges_end()*

writes a message indicating the end of the induced edges set.

Has Models

Arr_with_history_text_formatter<ArrFormatter> (page 2380)

Class

CGAL::Arr_with_history_text_formatter<ArrFormatter>

Definition

Arr_with_history_text_formatter<ArrFormatter> defines the format of an arrangement in an input or output stream (typically a file stream), thus enabling reading and writing an arrangement-with-history instance using a simple text format.

The *ArrFormatter* parameter servers as a base class for *Arr_with_history_text_formatter<ArrFormatter>* and must be a model of the *ArrangementInputFormatter* and the *ArrangementOutputFormatter* concepts. It is used to read or write the base arrangement, while the derived class is responsible for reading and writing the set of curves inducing the arrangement and maintaining the relations between these curves and the edges they induce.

#include <CGAL/IO/Arr_with_history_text_formatter.h>

Chapter 33

2D Intersection of Curves

Baruch Zukerman, Ron Wein, and Efi Fogel

Contents

33.1 Introduction

Let $\mathcal{C} = \{C_1, C_2, \ldots, C_n\}$ be a set of curves. We wish to compute all intersection points between two curves in the set in an output-sensitive manner, without having to go over all $O(n^2)$ curve pairs. To this end, we sweep an imaginary line l from $x = -\infty$ to $x = \infty$ over the plane. While sweeping the plane, we keep track of the order of curves intersecting it. This order changes at a finite number of *event points*, such that we only have to calculate the intersection points between two curves when they become contiguous. For more details on the *sweep-line algorithm* see, for example, [dBvKOS00, Chapter 2].

This chapter describes three functions implemented using the sweep-line algorithm: given a collection of input curves, compute all intersection points, compute the set of subcurves that are pairwise interior-disjoint induced by them, and checking whether there is at least one pair of curves among them that intersect in their interior.

The implementation is robust. It supports general curves and handles all degenerate cases, including overlapping curves, vertical segments, and tangency between curves. The robustness of the algorithm is guaranteed if the functions are instantiated with a traits class that employs certified computations. This traits class must be a model of the *ArrangementTraits_2* concept — see the Chapter 32 for more details.

The complexity of the sweep-line algorithm is $O((n+k)\log n)$ where n is the number of the input curves and k is the number of intersection points induced by these curves.

33.2 Example

The simple program listed below computes intersection points induced by a set of four input segments illustrated in figure 33.1.

```
#include <CGAL/Cartesian.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Quotient.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Sweep_line_2_algorithms.h>
#include <list>

typedef CGAL::Quotient<CGAL::MP_Float>                       NT;
typedef CGAL::Cartesian<NT>                                  Kernel;
typedef Kernel::Point_2                                      Point_2;
typedef CGAL::Arr_segment_traits_2<Kernel>                   Traits_2;
typedef Traits_2::Curve_2                                    Segment_2;

int main()
{
  // Construct the input segments.
  Segment_2 segments[] = {Segment_2 (Point_2 (1, 5), Point_2 (8, 5)),
                          Segment_2 (Point_2 (1, 1), Point_2 (8, 8)),
                          Segment_2 (Point_2 (3, 1), Point_2 (3, 8)),
                          Segment_2 (Point_2 (8, 5), Point_2 (8, 8))};

  // Compute all intersection points.
  std::list<Point_2>     pts;

  CGAL::compute_intersection_points (segments, segments + 4,
                                     std::back_inserter (pts));

  // Print the result.
  std::cout << "Found " << pts.size() << " intersection points: " <<
   std::endl;
  std::copy (pts.begin(), pts.end(),
             std::ostream_iterator<Point_2>(std::cout, "\n"));

  // Compute the non-intersecting sub-segments induced by the input
   segments.

33.3 Design and Implementation History

The current version of the sweep-line algorithm was written by Baruch Zukerman, based on previous implementations by Ester Ezra and Tali Zvi.

2D Intersection of Curves Reference Manual

Baruch Zukerman and Ron Wein

This chapter describes three functions implemented using the sweep-line algorithm: given a collection $\mathcal{C}$ of planar curves, compute all intersection points among them, obtain the set of maximal pairwise interior-disjoint subcurves of the curves in $\mathcal{C}$, or check whether there is at least one pair of curves in $\mathcal{C}$ that intersect in their interior.

The first two operations are performed in an output-sensitive manner.

Functions

33.4 Alphabetical List of Reference Pages

Function

CGAL::compute_intersection_points

#include <CGAL/Sweep_line_2_algorithms.h>

template <class InputIterator, class OutputIterator, class Traits>
OutputIterator compute_intersection_points(InputIterator curves_begin,
InputIterator curves_end,
OutputIterator points,
bool report_endpoints = false,
Traits traits = Default_traits())

given a range of curves, compute all intersection points between two (or more) input curves. When the flag *report_endpoints* is *true*, this function reports all the curve endpoints as well. If a curve endpoint is also an intersection point, it is reported once (regardless of the value of the *report_endpoints* flag). The *Traits* type must be a model of the *ArrangementTraits_2* concept, such that the value-type of *InputIterator* is *Traits::Curve_2*, and the value-type of *OutputIterator* is *Traits::Point_2*. The output points are reported in an increasing *xy*-lexicographical order.

CGAL::compute_subcurves

#include <CGAL/Sweep_line_2_algorithms.h>

template <class InputIterator, class OutputIterator, class Traits>
OutputIterator *compute_subcurves(InputIterator curves_begin,*
InputIterator curves_end,
OutputIterator subcurves,
bool multiple_overlaps = false,
Traits traits = Default_traits())

given a range of curves, compute all x-monotone subcurves that are pairwise disjoint in their interior, as induced by the input curves. If the flag *multiple_overlaps* is *true*, then a subcurve that represents an overlap of k input curves is reported k times; otherwise, each subcurve is reported only once. The *Traits* type must be a model of the *ArrangementTraits_2* concept, such that the value-type of *InputIterator* is *Traits::Curve_2*, and the value-type of *OutputIterator* is *Traits::X_monotone_curve_2*.

Function

Function

CGAL::do_curves_intersect

#include <CGAL/Sweep_line_2_algorithms.h>

template <class InputIterator, class Traits>
bool *do_curves_intersect(InputIterator curves_begin, InputIterator curves_end, Traits traits = Default_traits())*

given a range of curves, check whether there is at least one pair of curves that intersect in their interior. The function returns *true* if such a pair is found, and *false* if all curves are pairwise disjoint in their interior.The *Traits* type must be a model of the *ArrangementTraits_2* concept, such that the value-type of *InputIterator* is *Traits::Curve_2*.

Chapter 34

2D Snap Rounding

Eli Packer

Contents

34.1 Introduction

Snap Rounding (SR, for short) is a well known method for converting arbitrary-precision arrangements of segments into a fixed-precision representation [GGHT97, GM98, Hob99]. In the study of robust geometric computing, it can be classified as a finite precision approximation technique. Iterated Snap Rounding (ISR, for short) is a modification of SR in which each vertex is at least half-the-width-of-a-pixel away from any non-incident edge [HP02]. This package supports both methods. Algorithmic details and experimental results are given in [HP02].

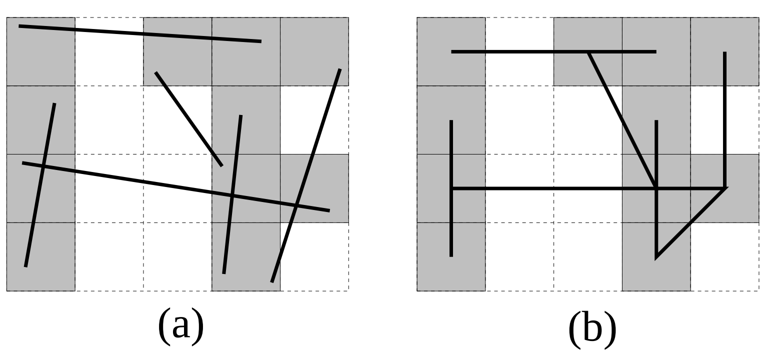

Figure 34.1: An arrangement of segments before (a) and after (b) SR (hot pixels are shaded)

34.2 What is Snap Rounding/Iterated Snap Rounding

Given a finite collection $\mathcal{S}$ of segments in the plane, the arrangement of $\mathcal{S}$ denoted $\mathcal{A}(\mathcal{S})$ is the subdivision of the plane into vertices, edges, and faces induced by $\mathcal{S}$. A *vertex* of the arrangement is either a segment endpoint or the intersection of two segments. Given an arrangement of segments whose vertices are represented with arbitrary-precision coordinates, the SR procedure *snap_rounding_2<Traits,InputIterator,OutputContainer>* proceeds as follows. We tile the plane with a grid of unit squares, *pixels*, each centered at a point with integer coordinates. A pixel is *hot* if it contains a vertex of the arrangement. Each vertex of the arrangement is replaced by the center of the hot pixel containing it and each edge e is replaced by the polygonal chain through the centers of the hot pixels met by e, in the same order as they are met by e. Figure 34.1 demonstrates the results of SR.

In a snap-rounded arrangement, the distance between a vertex and a non-incident edge can be extremely small compared with the width of a pixel in the grid used for rounding. ISR is a modification of SR which makes a vertex and a non-incident edge well separated (the distance between each is at least half-the-width-of-a-pixel). However, the guaranteed quality of the approximation in ISR degrades. Figure 34.2 depicts the results of SR and ISR on the same input. Conceptually, the ISR procedure is equivalent to repeated application of SR, namely we apply SR to the original set of segments, then we use the output of SR as input to another round of SR and so on until all the vertices are well separated from non-incident edges. Algorithmically we operate differently, as this repeated application of SR would have resulted in an efficient overall process. The algorithmic details are given in [HP02].

34.3 Terms and Software Design

Our package supports both schemes, implementing the algorithm described in [HP02]. Although the paper only describes an algorithm for ISR, it is easy to derive an algorithm for SR, by performing only the first rounding level for each segment.

The input to the program is a set S of n segments, $S = \{s_1, \ldots, s_n\}$ and the output is a set G of n polylines, with a polyline g_i for each input segments s_i. An input segment is given by the coordinates of its endpoints. An output polyline is given by the ordered set of vertices $v_0, \ldots, v_k$ along the polyline. The polyline consists of the segments $(v_0 v_1), \ldots, (v_{k-1} v_k)$.

There are three template parameters: *Traits* is the underlying geometry, i.e., the number type used and the coordinate representation. *InputIterator* is the type of the iterators that point to the first and after-the-last elements of the input. Finally, *OutputContainer* is the type of the output container.

Since the algorithm requires kernel functionalities such as the rounding to the center of a pixel, a special traits class must be provided. The precise description of the requirements is given by the concept *SnapRoundingTraits_2*. The class *Snap_rounding_traits_2* is a model of this concept.

34.4 Four Line Segment Example

The following example generates an ISR representation of an arrangement of four line segments. In particular it produces a list of points that are the vertices of the resulting polylines in a plane tiled with one-unit square pixels.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>
```

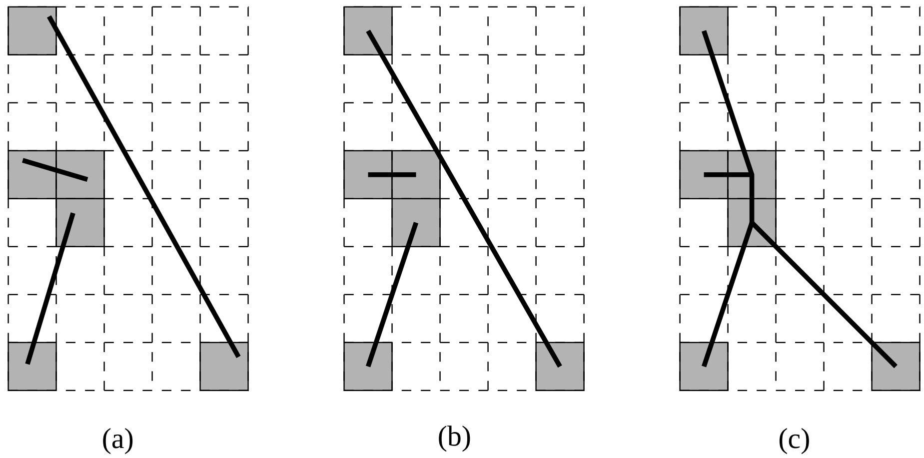

Figure 34.2: An arrangement of segments before (a), after SR (b) and ISR (c) (hot pixels are shaded).

```
#include <CGAL/MP_Float.h>
#include <CGAL/Snap_rounding_traits_2.h>
#include <CGAL/Snap_rounding_2.h>

typedef CGAL::Quotient<CGAL::MP_Float>          Number_type;
typedef CGAL::Cartesian<Number_type>            Kernel;
typedef CGAL::Snap_rounding_traits_2<Kernel>    Traits;
typedef Kernel::Segment_2                       Segment_2;
typedef Kernel::Point_2                         Point_2;
typedef std::list<Segment_2>                    Segment_list_2;
typedef std::list<Point_2>                      Polyline_2;
typedef std::list<Polyline_2>                   Polyline_list_2;

int main()
{
  Segment_list_2 seg_list;
  Polyline_list_2 output_list;

  seg_list.push_back(Segment_2(Point_2(0, 0), Point_2(10, 10)));
  seg_list.push_back(Segment_2(Point_2(0, 10), Point_2(10, 0)));
  seg_list.push_back(Segment_2(Point_2(3, 0), Point_2(3, 10)));
  seg_list.push_back(Segment_2(Point_2(7, 0), Point_2(7, 10)));

  // Generate an iterated snap-rounding representation, where the centers
    of
  // the hot pixels bear their original coordinates, using 5 kd trees:

   CGAL::snap_rounding_2<Traits,Segment_list_2::const_iterator,Polyline_list_2>
    (seg_list.begin(), seg_list.end(), output_list, 1.0, true, false, 5);

  int counter = 0;
  Polyline_list_2::const_iterator iter1;
  for (iter1 = output_list.begin(); iter1 != output_list.end(); ++iter1)
   {
    std::cout << "Polyline number " << ++counter << ":\n";
    Polyline_2::const_iterator iter2;
```

```
    for (iter2 = iter1->begin(); iter2 != iter1->end(); ++iter2)
      std::cout << "    (" << iter2->x() << ":" << iter2->y() << ")\n";
  }

  return(0);
}
```

File: `examples/Snap_rounding_2/snap_rounding.cpp`

This program generates four polylines, one for each input segment. The exact output follows:

```
Polyline number 1:
    (0/4:0/4)
    (12/4:12/4)
    (20/4:20/4)
    (28/4:28/4)
    (40/4:40/4)
Polyline number 2:
    (0/4:40/4)
    (12/4:28/4)
    (20/4:20/4)
    (28/4:12/4)
    (40/4:0/4)
Polyline number 3:
    (12/4:0/4)
    (12/4:12/4)
    (12/4:28/4)
    (12/4:40/4)
Polyline number 4:
    (28/4:0/4)
    (28/4:12/4)
    (28/4:28/4)
    (28/4:40/4)
```

The package is supplied with a graphical demo program that opens a window, allows the user to edit segments dynamically, applies a selected snap-rounding procedures, and displays the result onto the same window (see *<CGAL_ROOT>/demo/Snap_rounding_2/demo.cpp*).

2D Snap Rounding Reference Manual

Eli Packer

Snap Rounding is a method for converting arbitrary-precision arrangements of segments into a fixed-precision representation.

34.5 Alphabetical List of Reference Pages

Function

CGAL::snap_rounding_2

Definition

Snap Rounding (SR, for short) is a well known method for converting arbitrary-precision arrangements of segments into a fixed-precision representation [GGHT97, GM98, Hob99]. In the study of robust geometric computing, it can be classified as a finite precision approximation technique. Iterated Snap Rounding (ISR, for short) is a modification of SR in which each vertex is at least half-the-width-of-a-pixel away from any non-incident edge [HP02]. This package supports both methods. Algorithmic details and experimental results are given in [HP02].

Given a finite collection $\mathcal{S}$ of segments in the plane, the arrangement of $\mathcal{S}$ denoted $\mathcal{A}(\mathcal{S})$ is the subdivision of the plane into vertices, edges, and faces induced by $\mathcal{S}$. A *vertex* of the arrangement is either a segment endpoint or the intersection of two segments. Given an arrangement of segments whose vertices are represented with arbitrary-precision coordinates, SR proceeds as follows. We tile the plane with a grid of unit squares, *pixels*, each centered at a point with integer coordinates. A pixel is *hot* if it contains a vertex of the arrangement. Each vertex of the arrangement is replaced by the center of the hot pixel containing it and each edge e is replaced by the polygonal chain through the centers of the hot pixels met by e, in the same order as they are met by e.

In a snap-rounded arrangement, the distance between a vertex and a non-incident edge can be extremely small compared with the width of a pixel in the grid used for rounding. ISR is a modification of SR which makes a vertex and a non-incident edge well separated (the distance between each is at least half-the-width-of-a-pixel). However, the guaranteed quality of the approximation in ISR degrades. For more details on ISR see [HP02].

The traits used here must support (arbitrary-precision) rational number type as this is a basic requirement of SR.

#include <CGAL/Snap_rounding_2.h>

```
template < class Traits, class InputIterator, class OutputContainer >
void                  snap_rounding_2( InputIterator begin,
                                       InputIterator end,
                                       OutputContainer& output_container,
                                       typename Traits::FT pixel_size,
                                       bool do_isr = true,
                                       bool int_output = true,
                                       unsigned int number_of_kd_trees = 1)
```

The first two parameters denote the first and after-the-last iterators of the input segments. The third parameter is a reference to a container of the output polylines. Since a polyline is composed of a sequence of points, a polyline is a container itself. The fifth parameter determines whether to apply ISR or SR.

The fourth parameter denotes the pixel size w. The plane will be tiled with square pixels of width w such that the origin is the center of a pixel. The sixth parameter denotes the output representation. If the value of the sixth parameter is *true* then the centers of pixels constitute the integer grid, and hence the vertices of the output polylines will be integers. For example, the coordinates of the center of the pixel to the right of the pixel containing the origin will be $(1,0)$ regardless of the pixel width. If the value of the sixth parameter is *false*, then the centers of hot pixels (and hence the vertices of the output polylines) will bear their original coordinates, which may not necessarily be integers. In the latter case, the coordinates of the center of the pixel to the right of the pixel containing the origin, for example, will be $(w,0)$.

The seventh (and last) parameter is briefly described next; for a detailed description see [HP02].

advanced

A basic query used in the algorithm is to report the hot pixels of size w that a certain segment s intersects. An alternative way to do the same is to query the hot pixels' centers contained in a Minkowski sum of s with a pixel of width w centered at the origin; we denote this Minkowski sum by $M(s)$. Since efficiently implementing this kind of query is difficult, we use an orthogonal range-search structure instead. We query with the bounding box $B(M(s))$ of $M(s)$ in a two-dimensional kd-tree which stores the centers of hot pixels. Since $B(M(s))$ in general is larger than $M(s)$, we still need to filter out the hot pixels which do not intersect s.

While this approach is easy to implement with CGAL, it may incur considerable overhead since the area of $B(M(s))$ may be much larger than the area of $M(s)$, possibly resulting in many redundant hot pixels to filter out. Our heuristic solution, which we describe next, is to use a cluster of kd-trees rather than just one. The cluster includes several kd-trees, each has the plane, and hence the centers of hot pixels, rotated by a different angle in the first quadrant of the plane; for our purpose, a rotation by angles outside this quadrant is symmetric to a rotation by an angle in the first quadrant.

Given a parameter c, the angles of rotation are $(i-1)\frac{\pi}{2c}, i = 1,\ldots,c$, and we construct a kd-tree corresponding to each of these angles. Then for a query segment s, we choose the kd-tree for which the area of $B(M(s))$ is the smallest, in order to (potentially) get less hot pixels to filter out. Since constructing many kd-trees may be costly, our algorithm avoids building a kd-tree which it expects to be queried a relatively small number of times (we estimate this number in advance). How many kd-trees should be used? It is difficult to provide a simple answer for that. There are inputs for which the time to build more than one kd-tree is far greater than the time saved by having to filter out less hot pixels (sparse arrangements demonstrate this behavior), and there are inputs which benefit from using several kd-trees. Thus, the user can control the number of kd-trees with the parameter *number_of_kd_trees*. Typically, but not always, one kd-tree (the default) is sufficient.

advanced

Precondition: *pixel_size* must have a positive value and *number_of_kd_trees* must be a positive integer.

SnapRoundingTraits_2

Definition

The concept SnapRoundingTraits_2 lists the set of requirements that must be fulfilled by an instance of the *Traits* template-parameter of the function *snap_rounding_2<Traits,InputIterator,OutputContainer>()*. This concept provides the types of the geometric primitives used in this class and some function object types for the required predicates on those primitives.

Refines

This concept refines the standard concepts DefaultConstructible, Assignable and CopyConstructible. It also refines the concept *SweepLineTraits_2* (page **??**). An instance of this concept is used as the traits class for the *Sweep_line_2.get_intersection_points()* operation. The requirements listed below are induced by compnents of the *snap_rounding_2()* function other than the call to *Sweep_line_2.get_intersection_points()*. Naturally, some of them may already be listed in *SweepLineTraits_2*.

Types

SnapRoundingTraits_2:: FT	The number type. This type must fulfill the requirements on *FieldNumberType*
SnapRoundingTraits_2:: Point_2	The point type.
SnapRoundingTraits_2:: Segment_2	The segment type.
SnapRoundingTraits_2:: Iso_rectangle_2	The iso-rectangle type.
SnapRoundingTraits_2:: Construct_vertex_2	Function object. Must provide the operator *Point_2 operator()(Segment_2 seg, int i)*, which returns the source or target of *seg*. If *i* modulo 2 is 0, the source is returned, otherwise the target is returned.
SnapRoundingTraits_2:: Construct_segment_2	Function object. Must provide the operator *Segment_2 operator()(Point_2 p, Point_2 q)*, which introduces a segment with source *p* and target *q*. The segment is directed from the source towards the target.
SnapRoundingTraits_2:: Construct_iso_rectangle_2	Function object. Must provide the operator *Iso_rectangle_2 operator()(Point_2 left, Point_2 right, Point_2 bottom, Point_2 top)*, which introduces an iso-oriented rectangle fo whose minimal *x* coordinate is the one of *left*, the maximal *x* coordinate is the one of *right*, the minimal *y* coordinate is the one of *bottom*, the maximal *y* coordinate is the one of *top*.
SnapRoundingTraits_2:: To_double	Function object. Must provide the operator *double operator()(FT)*, which computes an approximation of a given number of type *FT*. The precision of this operation is of not high significance, as it is only used in the implementation of the heuristic technique to exploit a cluster of kd-trees rather than just one.

SnapRoundingTraits_2:: Compare_x_2	Function object. Must provide the operator *Comparison_result operator()(Point_2 p, Point_2 q)* which returns *SMALLER, EQUAL* or *LARGER* according to the x-ordering of points p and q.
SnapRoundingTraits_2:: Compare_y_2	Function object. Must provide the operator *Comparison_result operator()(Point_2 p, Point_2 q)* which returns *SMALLER, EQUAL* or *LARGER* according to the y-ordering of points p and q.
SnapRoundingTraits_2:: Snap_2	Rounds a point to a center of a pixel (unit square) in the grid used by the Snap Rounding algorithm. Note that no conversion to an integer grid is done yet. Must have the syntax *void operator()(Point_2 p,FT pixel_size,FT &x,FT &y)* where p is the input point, *pixel_size* is the size of the pixel of the grid, and x and y are the x and y-coordinates of the rounded point respectively.
SnapRoundingTraits_2:: Integer_grid_point_2	Convert coordinates into an integer representation where one unit is equal to pixel size. For instance, if a point has the coordinates $(3.7,5.3)$ and the pixel size is 0.5, then the new point will have the coordinates of $(7,10)$. Note, however, that the number type remains the same here, although integers are represented. Must have the syntax *Point_2 operator()(Point_2 p,NT pixel_size)* where p is the converted point and *pixel_size* is the size of the pixel of the grid.

SnapRoundingTraits_2:: Minkowski_sum_with_pixel_2

Returns the vertices of a polygon, which is the Minkowski sum of a segment and a square centered at the origin with edge size *pixel edge*. Must have the syntax *void operator()(std::list<Point_2>& vertices_list, Segment_2 s, NT unit_square)* where *vertices_list* is the list of the vertices of the Minkowski sum polygon, s is the input segment and *unit_square* is the edge size of the pixel.

Creation

This concept refines the standard concepts DefaultConstructible, Assignable and CopyConstructible.

Operations

The following functions construct the required function objects occasionally referred as functors listed above.

Construct_vertex_2	*traits.construct_vertex_2_object()*
Construct_segment_2	*traits.construct_segment_2_object()*
Construct_iso_rectangle_2	*traits.construct_iso_rectangle_2_object()*
Compare_x_2	*traits.compare_x_2_object()*
Compare_y_2	*traits.compare_y_2_object()*
Snap_2	*traits.snap_2_object()*
Integer_grid_point_2	*traits.integer_grid_point_2_object()*
Minkowski_sum_with_pixel_2	*traits.minkowski_sum_with_pixel_2_object()*

Has Models

CGAL::Snap_rounding_traits<Kernel>

See Also

CGAL::Snap_rounding_2<Traits>

CGAL::Snap_rounding_traits_2<Kernel>

The class *Snap_rounding_traits_2<Kernel>* is a model of the *SnapRoundingTraits_2* concept, and is the only traits class supplied with the package. This class should be instantiated with an exact geometric kernel that conforms to the CGAL kernel-concept, such as the *Cartesian<gmpq>* kernel.

This geometric kernel must provide an (arbitrary-precision) rational number type (*FT*), *Point_2*, *Segment_2* and *Iso_rectangle_2*. It should be possible to cast numbers of the number type *FT* to double-precision representation. That is, the function *CGAL::to_double(FT)* must be supported.

The *CGAL::to_double()* function is used to implement the operation that rounds the coordinates of a point to a center of a pixel. This operation is one of the traits-concept requirement. The coordinates are converted to double, rounded down to the nearest grid point, and finally adjusted to lie on a center of a pixel. Notice that if *CGAL::to_double()* returns the closet value, then when it rounds up a given coordinate, the resulting ISR, may be imprecise, and the distance between some vertex and a non-incident edge can be slightly less than the guaranteed half-the width-of-a-pixel.

#include <CGAL/Snap_rounding_traits_2.h>

Chapter 35

Envelopes of Curves in 2D

Ron Wein

Contents

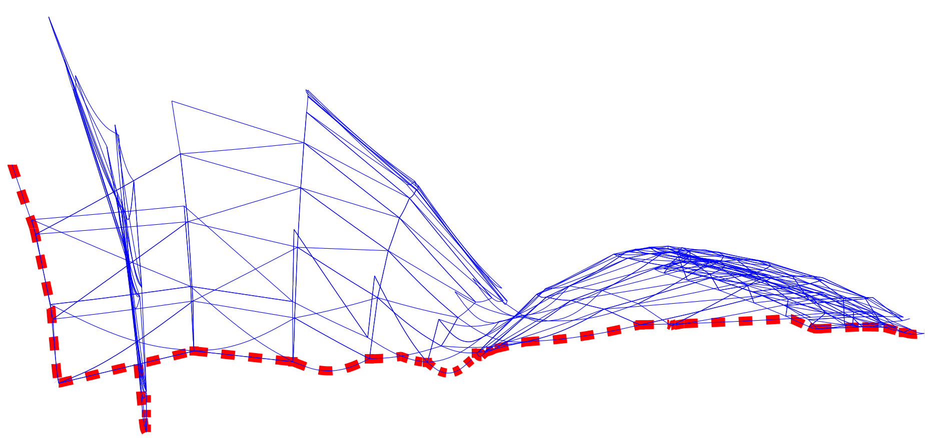

Figure 35.1: The lower envelope of a set of line segments and hyperbolic arc.

35.1 Introduction

A continuous curve C in $\mathbb{R}^2$ is called *x-monotone*, if every vertical line intersects it at a single point at most. For example, the circle $x^2+y^2=1$ is *not* xy-monotone as the vertical line $x=0$ intersects it at $(0,-1)$ and at $(0,1)$;

however, it is possible to split the circle into an upper part and a lower part, such that both of these parts are x-monotone. We consider vertical segments as *weakly* x-monotone, to properly handle inputs that contain such vertical curves.

An x-monotone curve can be represented as a univariate function $y = C(x)$, defined over some continuous range $R_C \subseteq \mathbb{R}$. Given a set $\mathcal{C} = \{C_1, C_2, \ldots, C_n\}$ of x-monotone curves, their *lower envelope* is defined as the point-wise minimum of all curves. Namely, the lower envelope of the set $\mathcal{C}$ can be defined as the following function:

$$\mathcal{L}_{\mathcal{C}}(x) = \min_{1 \leq k \leq n} \overline{C}_k(x) \ ,$$

where we define $\overline{C}_k(x) = C_k(x)$ for $x \in R_{C_k}$, and $\overline{C}_k(x) = \infty$ otherwise.

Similarly, the *upper envelope* of $\mathcal{C}$ is the point-wise maximum of the x-monotone curves in the set:

$$\mathcal{U}_{\mathcal{C}}(x) = \max_{1 \leq k \leq n} \underline{C}_k(x) \ ,$$

where in this case $\underline{C}_k(x) = -\infty$ for $x \notin R_{C_k}$.

Given a set of x-monotone curves $\mathcal{C}$, the *minimization diagram* of $\mathcal{C}$ is a subdivision of the x-axis into cells, such that the identity of the curves that induce the lower envelope over a specific cell of the subdivision (an edge or a vertex) is the same. In non-degenerate situations, an edge — which represents a continuous interval on the x-axis — is induced by a single curve (or by no curves at all, if there are no x-monotone curves defined over the interval), and a vertex is induced by a single curve and corresponds to one of its endpoints, or by two curves and corresponds to their intersection point. The *maximization diagram* is symmetrically defined for upper envelopes. In the rest of this chapter, we refer to both these diagrams as *envelope diagrams*.

Lower and upper envelopes can be efficiently computed using a divide-and-conquer approach. First, note that the envelope diagram for a single x-monotone curve C_k is trivial to compute: we project the boundary of its range of definition R_{C_k} onto the x-axis and label the features it induces accordingly. Given a set $\mathcal{D}$ of (non necessarily x-monotone) curves in $\mathbb{R}^2$, we subdivide each curve into a finite number of weakly x-monotone curves, and obtain the set $\mathcal{C}$. Then, we split the set into two disjoint subsets $\mathcal{C}_1$ and $\mathcal{C}_2$, and we compute their envelope diagrams recursively. Finally, we merge the diagrams in linear time by traversing both diagrams in parallel.

35.2 The Envelope Diagram

The package basically contains two sets of free functions: *lower_envelope_x_monotone_2 (begin, end, diag)* (similarly *upper_envelope_x_monotone_2()*) construct the envelope diagram for a given range of x-monotone curves, while *lower_envelope_2 (begin, end, diag)* (similarly *upper_envelope_2()*) construct the envelope diagram for a range of *arbitrary* (not necessarily x-monotone) curves. In this section we explain more on the structure of the envelope diagram these functions output.

A minimization diagram or a maximization diagram is represented by a model of the concept *EnvelopeDiagram_1*. This concept defines the structure of the subdivision of the x-axis into 0-dimensional cells called *vertices*, and 1-dimensional cells called *edges*. The important property of this subdivision is that the identity of the curves that induce the lower envelope (or the upper envelope) over each cell is fixed.

Figure 35.2 shows the lower envelope of a set of eight line segments, and sketches the structure of their minimization diagram. Each diagram vertex v is associated with a point p_v on the envelope, which corresponds to either a curve endpoint or to an intersection point of two (or more) curves. The vertex is therefore associated with a set of x-monotone curves that induce the envelope over p_v. Each vertex is incident to two edges, one lying to its left and the other to its right.

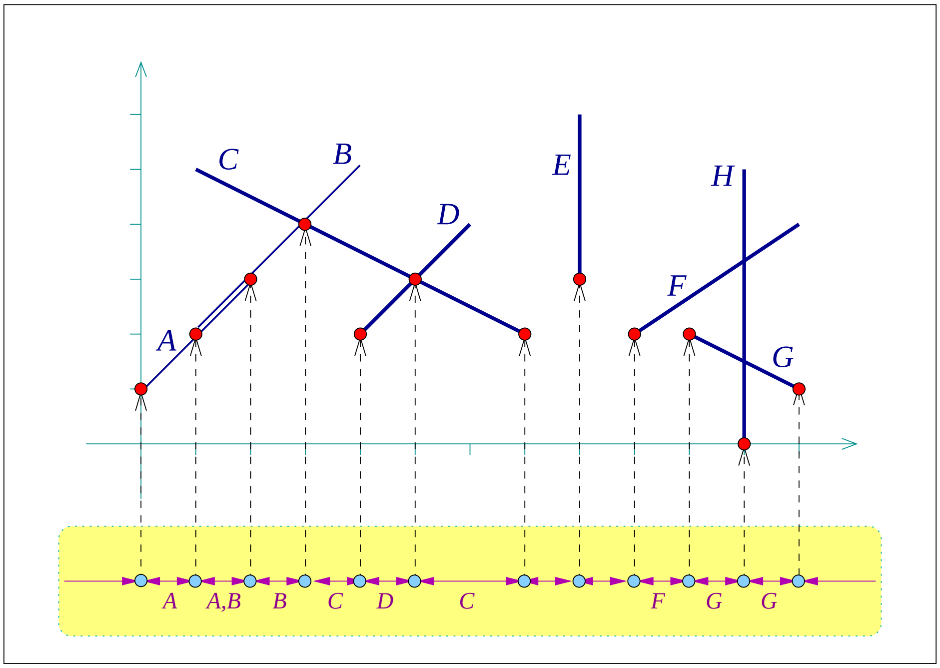

Figure 35.2: The lower envelope of eight line segments, labeled $A, \ldots, H$, as constructed in *envelope_segments.cpp*. The minimization diagram is shown at the bottom, where each diagram vertex points to the point associated with it, and the labels of the segment that induce a diagram edge are displayed below this edge. Note that there exists one edge that represents an overlap (i.e., there are two segments that induce it), and there are also a few edges that represent empty intervals.

An edge in the envelope diagram represents a continuous portion of the x-axis, and is associated with a set of x-monotone curves that induce the envelope over this interval. Note that this set may be empty if no x-monotone curves are defined over this interval. In degenerate situations where curves overlap, there may be more than a single curve that induces the envelope over the interval the edge represents. An envelop diagram of a set of curves either consists of a single unbounded edge (in case the curve set is empty or if the envelope contains a single unbounded curve that is below or above all other curves), or at least one vertex and two unbounded edges, while each additional vertex comes along with an additional edge. It is possible to directly access the *leftmost* edge, representing the unbounded interval that starts at $-\infty$, and the *rightmost* edge, representing the unbounded interval that ends at ∞. (In the example depicted in Figure 35.2 we have only bounded curves, so the leftmost and rightmost edges represent empty intervals. This is not the case when we deal, for example, with envelopes of sets of lines.)

Any model of the concept must define a geometric traits class, which in turn defines the *Point_2* and *X_monotone_curve_2* types defined with the diagram features. The geometric traits class must be a model of the *ArrangementXMonotoneTraits_2* concept in case we construct envelopes of x-monotone curves. If we are interested in handling arbitrary (not necessarily x-monotone) curves, the traits class must be a model of the *ArrangementTraits_2* concept. This concepts refined the *ArrangementXMonotoneTraits_2* concept; a traits class that models this concepts must also defines a *Curve_2* type, representing an arbitrary planar curve, and provide a functor for subdividing such curves into x-monotone subcurves.

35.3 Examples

35.3.1 Example for Envelope of Line Segments

The following example demonstrates how to compute and traverse the minimization diagram of line segments, as illustrated in Figure 35.2. We use the curve-data traits instantiated by the *Arr_segment_traits_2* class, in order to attach a label (a *char* in this case) to each input segment. We use these labels when we print the minimization diagram:

```
#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_curve_data_traits_2.h>
#include <CGAL/Envelope_diagram_1.h>
#include <CGAL/envelope_2.h>

#include <list>
#include <iostream>

typedef CGAL::Gmpq                                        Number_type;
typedef CGAL::Cartesian<Number_type>                      Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>                Segment_traits_2;
typedef Segment_traits_2::X_monotone_curve_2              Segment_2;
typedef CGAL::Arr_curve_data_traits_2<Segment_traits_2,
                                       char>              Traits_2;
typedef Traits_2::Point_2                                 Point_2;
typedef Traits_2::X_monotone_curve_2
    Labeled_segment_2;
typedef CGAL::Envelope_diagram_1<Traits_2>                Diagram_1;

int main ()
{
  // Consrtuct the input segments and label them 'A' ... 'H'.
  std::list<Labeled_segment_2>   segments;

  segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (0, 1),
                                                     Point_2 (2, 3)),
    'A'));
  segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (1, 2),
                                                     Point_2 (4, 5)),
    'B'));
  segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (1, 5),
                                                     Point_2 (7, 2)),
    'C'));
  segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (4, 2),
                                                     Point_2 (6, 4)),
    'D'));
  segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (8, 3),
                                                     Point_2 (8, 6)),
    'E'));
  segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (9, 2),
                                                     Point_2 (12, 4)),
```

```
    'F'));
  segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (10, 2),
                                                    Point_2 (12, 1)),
    'G'));
  segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (11, 0),
                                                    Point_2 (11, 5)),
    'H'));

  // Compute the minimization diagram that represents their lower
    envelope.
  Diagram_1              min_diag;

  lower_envelope_x_monotone_2 (segments.begin(), segments.end(),
                               min_diag);

  // Print the minimization diagram.
  Diagram_1::Edge_const_handle     e = min_diag.leftmost();
  Diagram_1::Vertex_const_handle   v;
  Diagram_1::Curve_const_iterator  cit;

  while (e != min_diag.rightmost())
  {
    std::cout << "Edge:";
    if (! e->is_empty())
    {
      for (cit = e->curves_begin(); cit != e->curves_end(); ++cit)
        std::cout << ' ' << cit->data();
    }
    else
      std::cout << " [empty]";
    std::cout << std::endl;

    v = e->right();
    std::cout << "Vertex (" << v->point() << "):";
    for (cit = v->curves_begin(); cit != v->curves_end(); ++cit)
      std::cout << ' ' << cit->data();
    std::cout << std::endl;

    e = v->right();
  }
  CGAL_assertion (e->is_empty());
  std::cout << "Edge: [empty]" << std::endl;

  return (0);
}
```

35.3.2 Example for Computing the Convex Hull with Envelopes

The next example computes the convex hull of a set of input points by constructing envelopes of unbounded curves, in our case lines that are dual to the input points. Here use the *Arr_linear_traits_2* class to compute the lower envelope of the set of dual lines. We read a set of points $\mathcal{P} = p_1, \ldots, p_n$ from an input file, and construct the corresponding dual lines $\mathcal{P}^* = p_1^*, \ldots, p_n^*$, where the line p^* dual to a point $p = (p_x, p_y)$ is given by $y = p_x x - p_y$. We then compute the convex hull of the point-set $\mathcal{P}$, using the fact that the lines that form the lower envelope of $\mathcal{P}^*$ are dual to the points along the *upper* part of $\mathcal{P}$'s convex hull, and the lines that form the upper envelope of $\mathcal{P}^*$ are dual to the points along the *lower* part of the convex hull; see, e.g., [dBvKOS00, Section 11.4] for more details. Note that the leftmost edge of the minimization diagram is associated with the same line as the rightmost edge of the maximization diagram, and vice-verse. We can therefore skip the rightmost edges of both diagrams:

```
#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_linear_traits_2.h>
#include <CGAL/Arr_curve_data_traits_2.h>
#include <CGAL/Envelope_diagram_1.h>
#include <CGAL/envelope_2.h>
#include <vector>

typedef CGAL::Gmpq                                          Number_type;
typedef CGAL::Cartesian<Number_type>                        Kernel;
typedef CGAL::Arr_linear_traits_2<Kernel>                   Linear_traits_2;
typedef Linear_traits_2::Point_2                            Point_2;
typedef Linear_traits_2::Line_2                             Line_2;
typedef CGAL::Arr_curve_data_traits_2<Linear_traits_2,
                                      unsigned int>         Traits_2;
typedef Traits_2::X_monotone_curve_2                        Dual_line_2;
typedef CGAL::Envelope_diagram_1<Traits_2>                  Diagram_1;

int main (int argc, char* argv[])
{
  // Read the points from the input file.
  const char* filename = (argc > 1) ? argv[1] : "ch_points.dat";
  std::ifstream in_file(filename);
  if (!in_file.is_open()) {
    std::cerr << "Failed to open " << filename << " ..." << std::endl;
    return -1;
  }

  // Read the points from the file, and construct their dual lines.
  std::list<Dual_line_2>  dual_lines;

  unsigned int            n;
  in_file >> n;
  std::vector<Point_2>    points;
  points.resize(n);

  for (unsigned int k = 0; k < n; ++k) {
    int px, py;
    in_file >> px >> py;
    points[k] = Point_2 (px, py);

    // The line dual to the point (p_x, p_y) is y = p_x*x - p_y,
    // or: p_x*x - y - p_y = 0:
    Line_2 line = Line_2 (Number_type(px), Number_type(-1),
   Number_type(-py));
```

```
    // Generate the x-monotone curve based on the line and the point
      index.
    dual_lines.push_back (Dual_line_2 (line, k));
  }
  in_file.close();

  // Compute the lower envelope of dual lines, which corresponds to the
      upper
  // part of the convex hull, and their upper envelope, which corresponds
      to
  // the lower part of the convex hull.
  Diagram_1              min_diag;
  Diagram_1              max_diag;
  lower_envelope_x_monotone_2(dual_lines.begin(), dual_lines.end(),
    min_diag);
  upper_envelope_x_monotone_2(dual_lines.begin(), dual_lines.end(),
    max_diag);

  // Output the points along the boundary convex hull in counterclockwise
  // order. We start by traversing the minimization diagram from left to
  // right, then the maximization diagram from right to left.
  std::cout << "The convex hull of " << points.size() << " input
    points:";
  Diagram_1::Edge_const_handle  e = min_diag.leftmost();
  while (e != min_diag.rightmost()) {
    std::cout << " (" << points[e->curve().data()] << ')';
    e = e->right()->right();
  }

  // Handle the degenerate case of a vertical convex hull edge:
  if (e->curve().data() != max_diag.leftmost()->curve().data())
    std::cout << " (" << points[e->curve().data()] << ')';

  e = max_diag.leftmost();
  while (e != max_diag.rightmost()) {
    std::cout << " (" << points[e->curve().data()] << ')';
    e = e->right()->right();
  }
  std::cout << std::endl;

  return 0;
}
```

File: examples/Envelope_2/convex_hull.cpp

35.3.3 Example for Envelope of Non-Linear Curves

We conclude by an example of envelopes of non-linear curves. We use the *Arr_circle_segment_traits_2* class to construct the lower and the upper envelopes of a set of four circles, as depicted in Figure 35.3. Note that unlike

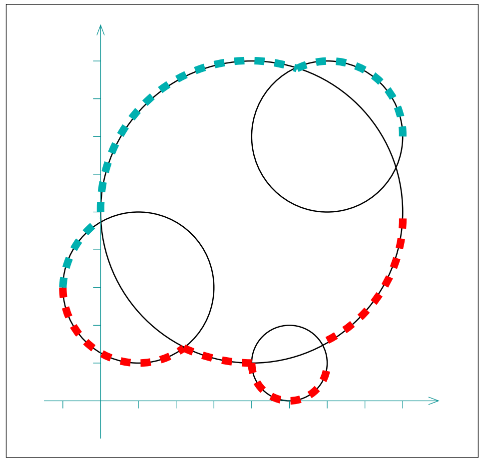

Figure 35.3: A set of four circles, as constructed in *ex_envelope_circles.cpp*. The lower envelope and the upper envelope are shown using thick dashed lines of different colors respectively.

the two previous examples, here our curves are not x-monotone, so we use the functions that compute envelopes of arbitrary curves:

```
#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_circle_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Envelope_diagram_1.h>
#include <CGAL/envelope_2.h>

typedef CGAL::Gmpq                                          Number_type;
typedef CGAL::Cartesian<Number_type>                        Kernel;
typedef Kernel::Point_2                                     Kernel_point_2;
typedef Kernel::Circle_2                                    Circle_2;
typedef CGAL::Arr_circle_segment_traits_2<Kernel>           Traits_2;
typedef Traits_2::Curve_2                                   Curve_2;
typedef CGAL::Envelope_diagram_1<Traits_2>                  Diagram_1;

/*! Print the given envelope diagram. */
void print_diagram (const Diagram_1& diag)
{
  Diagram_1::Edge_const_handle     e = diag.leftmost();
  Diagram_1::Vertex_const_handle   v;

  while (e != diag.rightmost())
  {
    std::cout << "Edge: ";
    if (! e->is_empty())
    {
      Circle_2      circ = e->curve().supporting_circle();
      std::cout << " (x - " << CGAL::to_double(circ.center().x()) << ")^2
  +"
                << " (y - " << CGAL::to_double(circ.center().y()) << ")^2
```

```
    = "
                << CGAL::to_double(circ.squared_radius()) << std::endl;
    }
    else
      std::cout << " [empty]" << std::endl;

    v = e->right();
    std::cout << "Vertex (" << CGAL::to_double(v->point().x()) << ' '
              << CGAL::to_double(v->point().y()) << ')' << std::endl;

    e = v->right();
  }
  CGAL_assertion (e->is_empty());
  std::cout << "Edge: [empty]" << std::endl;

  return;
}

/*! The main program. */
int main ()
{
  // Create four input circles.
  Curve_2          circles[4];

  circles[0] = Circle_2 (Kernel_point_2 (1, 3), CGAL::square(2));

Envelopes of Curves in 2D
Reference Manual

Ron Wein

Introduction

This package consists of functions that compute the lower (or upper) envelope of a set of arbitrary curves in 2D. The output is represented as an envelope diagram, namely a subdivision of the x-axis into intervals, such that the identity of the curves that induce the envelope over each interval is unique.

Functions

Concepts

Classes

35.4 Alphabetical List of Reference Pages

CGAL::lower_envelope_2

#include <CGAL/envelope_2.h>

template<class InputIterator, class EnvelopeDiagram>
void *lower_envelope_2(InputIterator begin, InputIterator end, EnvelopeDiagram& diag)*

Computes the lower envelope of a set of curves in $\mathbb{R}^2$, as given by the range *[begin, end)*. The lower envelope is represented using the output minimization diagram *diag*, which must be a model of the *EnvelopeDiagram_1* concept.

Precondition: The value-type of *InputIterator* is *EnvelopeDiagram::Traits_2::Curve_2*.

Function

Function

CGAL::upper_envelope_2

#include <CGAL/envelope_2.h>

template<class InputIterator, class EnvelopeDiagram>
void *upper_envelope_2(InputIterator begin, InputIterator end, EnvelopeDiagram& diag)*

Computes the upper envelope of a set of curves in $\mathbb{R}^2$, as given by the range *[begin, end)*. The upper envelope is represented using the output maximization diagram *diag*, which must be a model of the *EnvelopeDiagram_1* concept.
Precondition: The value-type of *InputIterator* is *EnvelopeDiagram::Traits_2::Curve_2*.

CGAL::lower_envelope_x_monotone_2

#include <CGAL/envelope_2.h>

template<class InputIterator, class EnvelopeDiagram>
void lower_envelope_x_monotone_2(InputIterator begin,
InputIterator end,
EnvelopeDiagram& diag)

Computes the lower envelope of a set of x-monotone curves in $\mathbb{R}^2$, as given by the range *[begin, end)*. The lower envelope is represented using the output minimization diagram *diag*, which must be a model of the *EnvelopeDiagram_1* concept.
Precondition: The value-type of *InputIterator* is *EnvelopeDiagram::X_monotone_curve_2*.

Function

CGAL::upper_envelope_x_monotone_2

#include <CGAL/envelope_2.h>

template<class InputIterator, class EnvelopeDiagram>
void *upper_envelope_x_monotone_2(InputIterator begin, InputIterator end, EnvelopeDiagram& diag)*

Computes the upper envelope of a set of x-monotone curves in $\mathbb{R}^2$, as given by the range *[begin, end)*. The upper envelope is represented using the output maximization diagram *diag*, which must be a model of the *EnvelopeDiagram_1* concept.
Precondition: The value-type of *InputIterator* is *EnvelopeDiagram::X_monotone_curve_2*.

EnvelopeDiagram_1

Concept

Definition

This concept defines the representation of an envelope diagram of a set of planar curve. The *envelope diagram* is a subdivision of the x-axis into 0-dimensional cells (*vertices*) and 1-dimensional cells (*edges*), such that the identity of the curves that induce the lower envelope (or the upper envelope) over each cell is fixed.

A vertex in an envelope diagram is therefore associated with a point on the envelope, and corresponds to either a curve endpoint or to an intersection point of two (or more) curves. Therefore each vertex is associated with a set of x-monotone curves that induce the envelope over this point. Each vertex is incident to two edges, one lying to its left and the other to its right.

An edge in the envelope diagram represents a continuous portion of the x-axis, and is associated with a (possibly empty) set of curves that induce the envelope over this portion of the x-axis. An edge may be bounded by two vertices, one to its left and the other to its right. However, the diagram contains two unbounded edges, its *leftmost* edge, representing the interval $(-\infty, x_l)$, and its *rightmost* edge, representing the interval (x_r, ∞), where x_l and x_r are the x-coodinates of the leftmost and the rightmost vertices in the diagram, respectively. Note that a diagram may contain no vertices at all, in which case it comprises a single edge.

Note that any model of the EnvelopeDiagram_1 concept must define a geometric traits class, which in turn defines the *Point_2* and *X_monotone_curve_2* types defined with the diagram features.

Types

EnvelopeDiagram_1:: Traits_2	the geometric traits class.
typedef Traits_2::Point_2 Point_2;	the point type.
typedef Traits_2::X_monotone_curve_2 X_monotone_curve_2;	the x-monotone curve type.
EnvelopeDiagram_1:: Size	the size type (convertible to *size_t*).
EnvelopeDiagram_1:: Curve_const_iterator	an iterator for the x-monotone curves that induce a diagram feature. Its value-type is *X_monotone_curve_2*.
EnvelopeDiagram_1:: Vertex	the vertex type, a model of the concept *EnvelopeDiagramVertex*.
EnvelopeDiagram_1:: Edge	the edge type, a model of the concept *EnvelopeDiagramEdge*.
EnvelopeDiagram_1:: Vertex_handle	a handle to a diagram vertex.
EnvelopeDiagram_1:: Vertex_const_handle	a non-mutable handle to a diagram vertex.

EnvelopeDiagram_1:: Edge_handle	a handle to a diagram edge.
EnvelopeDiagram_1:: Edge_const_handle	a non-mutable handle to a diagram edge.

Creation

EnvelopeDiagram_1 diag;

constructs an empty diagram containing one unbounded edge, which corresponds to the entire plane and has no x-monotone curves that are associated with it.

EnvelopeDiagram_1 diag(Self other);

copy constructor.

Access Functions

Edge_const_handle *diag.leftmost() const*

returns the leftmost edge of the diagram (a non-const version is also available).

Edge_const_handle *diag.rightmost() const*

returns the rightmost edge of the diagram (a non-const version is also available).

Modifiers

void *diag.set_leftmost(Edge_const_handle e)*

sets the leftmost edge of the diagram to be e.

void *diag.set_rightmost(Edge_const_handle e)*

sets the rightmost edge of the diagram to be e.

Vertex_handle *diag.new_vertex(Point_2 p)*

creates a new diagram vertex, associated with the point p.

Edge_handle *diag.new_edge()*

creates a new diagram edge.

void *diag.delete_vertex(Vertex_handle v)*

deletes the given vertex v.

void *diag.delete_edge(Edge_handle e)*

deletes the given edge e.

EnvelopeDiagramVertex

Concept

Definition

A vertex record in an envelope diagram. It is always associated with a point on the lower (upper) envelope of a non-empty set of curves. A vertex is also associated with a set of x-monotone curves that induce the envelope over this point. It is incident to two edges, one lying to its left and the other to its right.

Types

EnvelopeDiagramVertex:: Size	the size type (convertible to *size_t*).
EnvelopeDiagramVertex:: Edge	the corresponding diagram-edge type.
EnvelopeDiagramVertex:: Point_2	the point type associated with the vertex.
EnvelopeDiagramVertex:: X_monotone_curve_2	the x-monotone curve type.

Creation

EnvelopeDiagramVertex v;	default constructor.
EnvelopeDiagramVertex v(other);	copy constructor.
EnvelopeDiagramVertex v(Point_2 p);	constructs a vertex associated with the given point p.

Access Functions

Point_2	*v.point() const*	returns the point associated with v.
Size	*v.number_of_curves() const*	returns the number of x-monotone curves associated with v.
Curve_const_iterator	*v.curves_begin() const*	return an iterator for the first x-monotone curve associated with v.
Curve_const_iterator	*v.curves_end() const*	return a past-the-end iterator for the x-monotone curves associated with v.
Edge_const_handle	*v.left() const*	returns the edge lying to v's left.
Edge_const_handle	*v.right() const*	returns the edge lying to v's right.

Modifiers

void	*v.set_point(Point_2 p)*	
		associates the point p with v.
void	*v.clear_curves()*	clears the set of curves associated with v.
void	*v.add_curve(X_monotone_curve_2 cv)*	
		adds the x-monotone curve cv to the set of curves associated with v.
void	*v.add_curves(Curve_const_iterator begin, Curve_const_iterator end)*	
		adds the given range of x-monotone curves to the set of curves associated with v.
void	*v.set_left(Edge_const_handle e)*	
		sets the edge lying to the left of v to be e.
void	*v.set_right(Edge_const_handle e)*	
		sets the edge lying to the right of v to be e.

EnvelopeDiagramEdge

Concept

Definition

An edge record in an envelope diagram, which represents a continuous portion of the x-axis. It is associated with a (possibly empty) set of curves that induce the envelope over this portion of the x-axis. Note that all curves in this set overlap over the interval represented by the edge.

Types

EnvelopeDiagramEdge:: Size — the size type (convertible to *size_t*).

EnvelopeDiagramEdge:: Vertex — the corresponding diagram-vertex type.

EnvelopeDiagramEdge:: X_monotone_curve_2 — the x-monotone curve type.

Creation

EnvelopeDiagramEdge e; — default constructor.

EnvelopeDiagramEdge e(other); — copy constructor.

Access Functions

Size	*e.number_of_curves() const*	returns the number of x-monotone curves associated with e.
bool	*e.is_empty() const*	returns whether e represents an empty interval — namely, whether the set of x-monotone curves associated with it is empty.
X_monotone_curve_2	*e.curve() const*	returns a representative x-monotone curve associated with e. *Precondition*: e does not represent an empty interval.
Curve_const_iterator	*e.curves_begin() const*	return an iterator for the first x-monotone curve associated with e.
Curve_const_iterator	*e.curves_end() const*	return a past-the-end iterator for the x-monotone curves associated with e.
Vertex_const_handle	*e.left() const*	returns the vertex lying to e's left. *Precondition*: e is not the leftmost edge in the diagram.

Vertex_const_handle	*e.right() const*	returns the vertex lying to *e*'s right. *Precondition*: *e* is not the rightmost edge in the diagram.

Modifiers

void	*e.clear_curves()*	clears the set of curves associated with *e*.
void	*e.add_curve(X_monotone_curve_2 cv)*	
		adds the *x*-monotone curve *cv* to the set of curves associated with *e*.
void	*e.add_curves(Curve_const_iterator begin, Curve_const_iterator end)*	
		adds the given range of *x*-monotone curves to the set of curves associated with *e*.
void	*e.set_left(Vertex_const_handle v)*	
		sets the vertex lying to the left of *e* to be *v*.
void	*e.set_right(Vertex_const_handle v)*	
		sets the vertex lying to the right of *e* to be *v*.

CGAL::Envelope_diagram_1<Traits>

Class

Definition

This class is the default envelope-diagram class used by envelope functions to represent the minimization or the maximization diagram of a set of curves. It represents the diagram as a doubly-linked list of interleaved vertices and edges. Thus, all operations provided by the envelope diagram take constant time, and the space needed to store the diagram class is linear in the complexity of the envelope.

The envelope-diagram class is parameterized by a traits class, which is a model of the *ArrangementXMonotoneTraits_2* concept, in case we handle only envelopes of x-monotone curves, or of the refined *ArrangementTraits_2* concept in case we handle arbitrary planar curves.

Chapter 36

Envelopes of Surfaces in 3D

Dan Halperin, Michal Meyerovitch, Ron Wein, and Baruch Zukerman

Contents

36.1 Introduction

A continuous surface S in $\mathbb{R}^3$ is called *xy-monotone*, if every line parallel to the z-axis intersects it at a single point at most. For example, the sphere $x^2+y^2+z^2=1$ is *not* xy-monotone as the z-axis intersects it at $(0,0,-1)$ and at $(0,0,1)$; however, if we use the xy-plane to split it to an upper hemisphere and a lower hemisphere, these two hemispheres are xy-monotone.

An xy-monotone surface can therefore be represented as a bivariate function $z = S(x,y)$, defined over some continuous range $R_S \subseteq \mathbb{R}^2$. Given a set $\mathcal{S} = \{S_1, S_2, \ldots, S_n\}$ of xy-monotone surfaces, their *lower envelope* is defined as the point-wise minimum of all surfaces. Namely, the lower envelope of the set $\mathcal{S}$ can be defined as the following function:

$$\mathcal{L}_{\mathcal{S}}(x,y) = \min_{1 \le k \le n} \overline{S}_k(x,y) ,$$

where we define $\overline{S}_k(x,y) = S_k(x,y)$ for $(x,y) \in R_{S_k}$, and $\overline{S}_k(x,y) = \infty$ otherwise.

Similarly, the *upper envelope* of $\mathcal{S}$ is the point-wise maximum of the xy-monotone surfaces in the set:

$$\mathcal{U}_{\mathcal{S}}(x,y) = \max_{1 \le k \le n} \underline{S}_k(x,y) ,$$

where in this case $\underline{S}_k(x,y) = -\infty$ for $(x,y) \notin R_{S_k}$.

Given a set of xy-monotone surfaces $\mathcal{S}$, the *minimization diagram* of $\mathcal{S}$ is a subdivision of the xy-plane into cells, such that the identity of the surfaces that induce the lower diagram over a specific cell of the subdivision (be it a face, an edge, or a vertex) is the same. In non-degenerate situation, a face is induced by a single surface (or by no surfaces at all, if there are no xy-monotone surfaces defined over it), an edge is induced by a single surface and corresponds to its projected boundary, or by two surfaces and corresponds to their projected intersection curve, and a vertex is induced by a single surface and corresponds to its projected boundary point, or by three surfaces and corresponds to their projected intersection point. The *maximization diagram* is symmetrically defined for upper envelopes. In the rest of this chapter, we refer to both these diagrams as *envelope diagrams*.

It is easy to see that an envelope diagram is no more than a planar arrangement (see Chapter 32), represented using an extended DCEL structure, such that every DCEL record (namely each face, halfedge and vertex) stores an additional container of it originators: the xy-monotone surfaces that induce this feature.

Lower and upper envelopes can be efficiently computed using a divide-and-conquer approach. First note that the envelope diagram for a single xy-monotone curve S_k is trivial to compute: we project the boundary of its range of definition R_{S_k} onto the xy-plane, and label the faces it induces accordingly. Given a set $\mathcal{D}$ of (non necessarily xy-monotone) surfaces in $\mathbb{R}^3$, we subdivide each surface into a finite number of weakly xy-monotone surfaces,[1] and obtain the set $\mathcal{S}$. Then, we split the set into two disjoint subsets $\mathcal{S}_1$ and $\mathcal{S}_2$, and we compute their envelope diagrams recursively. Finally, we merge the diagrams, and we do this by overlaying them and then applying some post-processing on the resulting diagram. The post-processing stage is non-trivial and involves the projection of intersection curves onto the xy-plane — see [Mey06] for more details.

36.2 The Envelope-Traits Concept

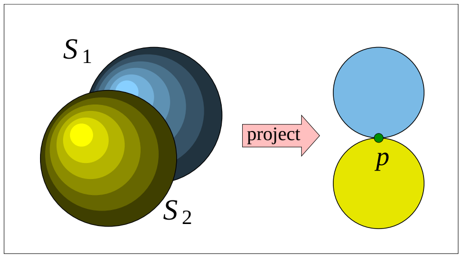
The implementation of the envelope-computation algorithm is generic and can handle arbitrary surfaces. It is parameterized with a traits class, which defines the geometry of surfaces it handles, and supports all the necessary functionality on these surfaces, and on their projections onto the xy-plane. The traits class must model the *EnvelopeTraits_3* concept, the details of which are given below.

As the representation of envelope diagrams is based on 2D arrangements, and the envelop-computation algorithm employs overlay of planar arrangements, the *EnvelopeTraits_3* refines the *ArrangementXMonotoneTraits_2* concept. Namely, a model of this concept must define the planar types *Point_2* and *X_monotone_curve_2* and support basic operations on them, as listed in Section 32.6. Moreover, it must define the spacial types *Surface_3* and *Xy_monotone_surface_3* (in practice, these two types may be the same). Any model of the envelope-traits concept must also support the following operations on these spacial types:

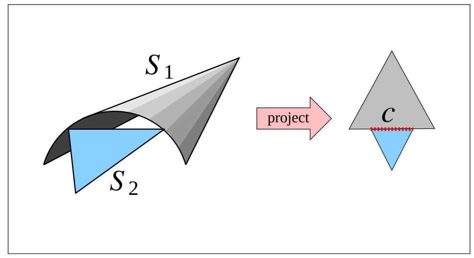
- Subdivide a given surface into continuous xy-monotone surfaces. It is possible to disregard xy-monotone surfaces that do not contribute to the surface envelope at this stage (for example, if we are given a sphere, it is possible to return just its lower hemisphere if we are interested in the lower envelope; the upper hemisphere is obviously redundant).
- Given an xy-monotone surface S, construct all planar curves that form the boundary of the vertical projection S's boundary onto the xy-plane.

  This operation is used at the bottom of the recursion to build the minimization diagram of a single xy-monotone surface.
- Construct all geometric entities that comprise the projection (onto the xy-plane) of the intersection between two xy-monotone surfaces S_1 and S_2. These entities may be:

[1] We consider *vertical* surfaces, namely patches of planes that are perpendicular to the xy-plane, as *weakly* xy-monotone, to handle degenerate inputs properly.



(a)



(b)

Figure 36.1: (a) The spheres S_1 and S_2 have only one two-dimensional point p in their common xy-definition range. They do not necessarily intersect over this point, and the envelope-construction algorithm needs to determine their relative z-order over p. (b) The z-order of the surfaces S_1 and S_2 should be determined over the x-monotone curve c. The comparison is performed over the *interior* of c, excluding its endpoints.

– A planar curve, which is the projection of an 3D intersection curve of S_1 and S_2 (for example, the intersection curve between two spheres is a 3D circle, which becomes an ellipse when projected onto the xy-plane). In many cases it is also possible to indicate the multiplicity of the intersection: if it is odd, the two surfaces intersect transversely and change their relative z-positions on either side of the intersection curve; if it the multiplicity is even, they maintain their relative z-position. Providing the multiplicity information is optional. When provided, it is used by the algorithm to determine the relative order of S_1 and S_2 on one side of their intersection curve when their order on the other side of that curve is known, thus improving the performance of the algorithm.

– A point, induces by the projection of a tangency point of S_1 and S_2, *or* by the projection of a vertical intersection curve onto the xy-plane.

Needless to say, the set of intersection entities may be empty in case S_1 and S_2 do not intersect.

- Given two xy-monotone surfaces S_1 and S_2, and a planar point $p = (x_0, y_0)$ that lies in their common xy-definition range, determine the z-order of S_1 and S_2 over p, namely compare $S_1(x_0, y_0)$ and $S_2(x_0, y_0)$. This operation is used only in degenerate situations, in order to determine the surface inducing the envelope over a vertex (see Figure 36.1(a) for an illustration of a situation when this operation is used).

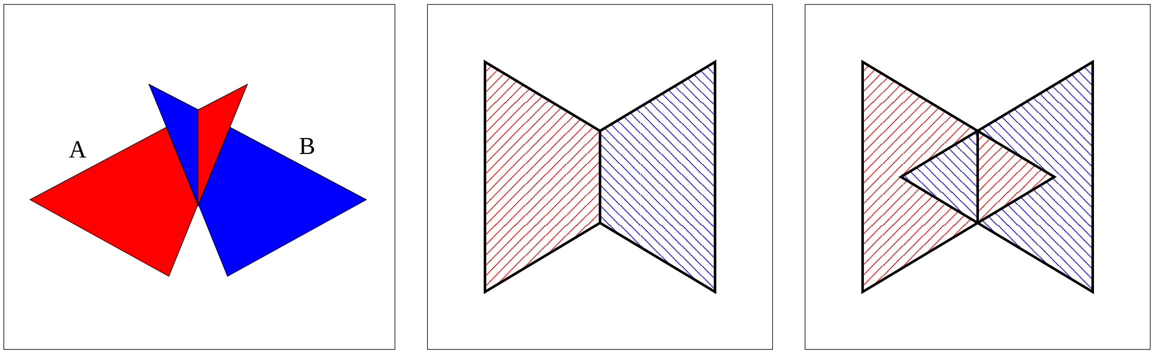
- Given two xy-monotone surfaces S_1 and S_2, and a planar x-monotone curve c, which is a part of their projected intersection, determine the z-order of S_1 and S_2 immediately above (or, similarly, immediately below) the curve c. Note that c is a planar x-monotone curve, and we refer to the region above (or below) it in the *plane*. If c is a vertical curve, we regard the region to its left as lying above it, and the region to its right as lying below it.

  This operation is used by the algorithm to determine the surface that induce the envelope over a face incident to c.

- Given two xy-monotone surfaces S_1 and S_2, and a planar x-monotone curve c, which fully lies in their common xy-definition range, and such that S_1 and S_2 do not intersect over the interior of c, determine the relative z-order of s_1 and s_2 over the interior of c. Namely, we compare $S_1(x_0, y_0)$ and $S_2(x_0, y_0)$ for some point (x_0, y_0) on c.

  This operation is used by the algorithm to determine which surface induce the envelope over an edge associated with the x-monotone curve c, or of a face incident to c, in situations where the previous predicate cannot be used, as c is *not* an intersection curve of S_1 and S_2 (see Figure 36.1(b) for an illustration of a situation where this operation is used).

The package currently contains a traits class for named *Env_triangle_traits_3<Kenrel>* handling 3D triangles, and another named *Env_sphere_traits_3<ConicTraits>* for 3D spheres, based on geometric operations on conic curves (ellipses). In addition, the package includes a traits-class decorator that enables users to attach external (non-geometric) data to surfaces. The usage of the various traits classes is demonstrated in the next section.



(a) (b) (c)

Figure 36.2: (a) Two triangles in $\mathbb{R}^3$, as given in *envelope_triangles.cpp*. (b) Their lower envelope. (c) Their upper envelope.

36.3 Examples

36.3.1 Example for Envelope of Triangles

The following example shows how to use the envelope-traits class for 3D triangles and how to traverse the envelope diagram. It constructs the lower and upper envelopes of the two triangles, as depicted in Figure 36.2(a) and prints the triangles that induce each face and each edge in the output diagrams. For convenience, we use the traits-class decorator *Env_surface_data_traits_3* to label the triangles. When printing the diagrams, we just output the labels of the triangles:

```
#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Env_triangle_traits_3.h>
#include <CGAL/Env_surface_data_traits_3.h>
#include <CGAL/envelope_3.h>
#include <iostream>
#include <list>

typedef CGAL::Gmpq                                                Number_type;
typedef CGAL::Cartesian<Number_type>                              Kernel;
typedef CGAL::Env_triangle_traits_3<Kernel>                       Traits_3;
typedef Kernel::Point_3                                           Point_3;
typedef Traits_3::Surface_3                                       Triangle_3;
typedef CGAL::Env_surface_data_traits_3<Traits_3, char>           Data_traits_3;
typedef Data_traits_3::Surface_3                                  Data_triangle_3;
typedef CGAL::Envelope_diagram_2<Data_traits_3>
    Envelope_diagram_2;

/* Auxiliary function - print the features of the given envelope diagram.
    */
void print_diagram (const Envelope_diagram_2& diag)
{
  // Go over all arrangement faces.
  Envelope_diagram_2::Face_const_iterator            fit;
  Envelope_diagram_2::Ccb_halfedge_const_circulator  ccb;
```

```
  Envelope_diagram_2::Surface_const_iterator         sit;

  for (fit = diag.faces_begin(); fit != diag.faces_end(); ++fit)
  {
    // Print the face boundary.
    if (fit->is_unbounded())
    {
      std::cout << "[Unbounded face]";
    }
    else
    {
      // Print the vertices along the outer boundary of the face.
      ccb = fit->outer_ccb();
      std::cout << "[Face]  ";
      do
      {
        std::cout << '(' << ccb->target()->point() << ")  ";
        ++ccb;
      } while (ccb != fit->outer_ccb());
    }

    // Print the labels of the triangles that induce the envelope on this
     face.
    std::cout << "-->  " << fit->number_of_surfaces()
              << " triangles:";

    for (sit = fit->surfaces_begin(); sit != fit->surfaces_end(); ++sit)
      std::cout << ' ' << sit->data();
    std::cout << std::endl;
  }

  // Go over all arrangement edges.
  Envelope_diagram_2::Edge_const_iterator            eit;

  for (eit = diag.edges_begin(); eit != diag.edges_end(); ++eit)
  {
    // Print the labels of the triangles that induce the envelope on this
     edge.
    std::cout << "[Edge]  (" << eit->source()->point()
              << ")  (" << eit->target()->point()
              << ")  -->  " << eit->number_of_surfaces()
              << " triangles:";

    for (sit = eit->surfaces_begin(); sit != eit->surfaces_end(); ++sit)
      std::cout << ' ' << sit->data();
    std::cout << std::endl;
  }

  return;
}

/* The main program: */
int main ()
{
```

```
  // Construct the input triangles, makred A and B.
  std::list<Data_triangle_3>   triangles;

  triangles.push_back (Data_triangle_3 (Triangle_3 (Point_3 (0, 0, 0),
                                                     Point_3 (0, 6, 0),
                                                     Point_3 (5, 3, 4)),
                                         'A'));
  triangles.push_back (Data_triangle_3 (Triangle_3 (Point_3 (6, 0, 0),
                                                     Point_3 (6, 6, 0),
                                                     Point_3 (1, 3, 4)),
                                         'B'));

  // Compute and print the minimization diagram.
  Envelope_diagram_2      min_diag;

  CGAL::lower_envelope_3 (triangles.begin(), triangles.end(),
                          min_diag);

  std::cout << std::endl << "The minimization diagram:" << std::endl;
  print_diagram (min_diag);

  // Compute and print the maximization diagram.
  Envelope_diagram_2      max_diag;

  CGAL::upper_envelope_3 (triangles.begin(), triangles.end(),
                          max_diag);

  std::cout << std::endl << "The maximization diagram:" << std::endl;
  print_diagram (max_diag);

  return (0);
}
```

36.3.2 Example for Envelope of Spheres

The next example demonstrates how to instantiate and use the envelope-traits class for spheres, based on the *Arr_conic_traits_2* class that handles the projected intersecion curves. The program reads a set of spheres from an input file and constructs their lower envelope:

```
#include <CGAL/basic.h>

#ifndef CGAL_USE_CORE
#include <iostream>
int main()
{
  std::cout << "Sorry, this example needs CORE ..." << std::endl;
  return 0;
}
#else
```

```
#include <CGAL/Cartesian.h>
#include <CGAL/CORE_algebraic_number_traits.h>
#include <CGAL/Arr_conic_traits_2.h>
#include <CGAL/Env_sphere_traits_3.h>
#include <CGAL/envelope_3.h>
#include <CGAL/Timer.h>
#include <iostream>
#include <list>

typedef CGAL::CORE_algebraic_number_traits            Nt_traits;
typedef Nt_traits::Rational                           Rational;
typedef Nt_traits::Algebraic                          Algebraic;
typedef CGAL::Cartesian<Rational>                     Rat_kernel;
typedef Rat_kernel::Point_3                           Rat_point_3;
typedef CGAL::Cartesian<Algebraic>                    Alg_kernel;

typedef CGAL::Arr_conic_traits_2<Rat_kernel, Alg_kernel, Nt_traits>
                                                      Conic_traits_2;

typedef CGAL::Env_sphere_traits_3<Conic_traits_2>     Traits_3;
typedef Traits_3::Surface_3                           Sphere_3;
typedef CGAL::Envelope_diagram_2<Traits_3>            Envelope_diagram_2;

int main(int argc, char **argv)
{
  // Get the name of the input file from the command line, or use the
   default
  // fan_grids.dat file if no command-line parameters are given.
  const char * filename = (argc > 1) ? argv[1] : "spheres.dat";

  // Open the input file.
  std::ifstream     in_file(filename);

  if (! in_file.is_open())
  {
    std::cerr << "Failed to open " << filename << " ..." << std::endl;
    return 1;
  }

  // Read the spheres from the file.
  // The input file format should be (all coordinate values are
   integers):
  // <n>                          // number of spheres.
  // <x_1> <y_1> <x_1> <R_1>      // center and squared radious of
   sphere #1.
  // <x_2> <y_2> <x_2> <R_2>      // center and squared radious of
   sphere #2.
  //   :     :     :     :
  // <x_n> <y_n> <x_n> <R_n>      // center and squared radious of
   sphere #n.
  int                     n = 0;
  std::list<Sphere_3>     spheres;
  int                     x = 0, y = 0, z = 0, sqr_r = 0;
```

```
  int                     i;

  in_file >> n;
  for (i = 0; i < n; ++i)
  {
    in_file >> x >> y >> z >> sqr_r;
    spheres.push_back(Sphere_3(Rat_point_3(x, y, z), Rational(sqr_r)));
  }
  in_file.close();

  // Compute the lower envelope.
  Envelope_diagram_2    min_diag;
  CGAL::Timer           timer;

  std::cout << "Constructing the lower envelope of "
            << n << " spheres." << std::endl;

  timer.start();
  CGAL::lower_envelope_3(spheres.begin(), spheres.end(), min_diag);
  timer.stop();

  // Print the dimensions of the minimization diagram.
  std::cout << "V = " << min_diag.number_of_vertices()
            << ",  E = " << min_diag.number_of_edges()
            << ",  F = " << min_diag.number_of_faces() << std::endl;

  std::cout << "Construction took " << timer.time()
            << " seconds." << std::endl;

  return 0;
}

#endif
```

File: examples/Envelope_3/envelope_spheres.cpp

36.3.3 Example for Envelope of Planes

The next example demonstrates how to instantiate and use the envelope-traits class for planes, based on the *Arr_linear_traits_2* class that handles infinite linear objects such as lines and rays.

```
#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Env_plane_traits_3.h>
#include <CGAL/envelope_3.h>
#include <iostream>
#include <list>

typedef CGAL::Gmpq                                              Number_type;
typedef CGAL::Cartesian<Number_type>                            Kernel;
typedef Kernel::Plane_3                                         Plane_3;
```

```
typedef CGAL::Env_plane_traits_3<Kernel>                    Traits_3;
typedef Traits_3::Surface_3                                 Surface_3;
typedef CGAL::Envelope_diagram_2<Traits_3>
    Envelope_diagram_2;

/* Auxiliary function - print the features of the given envelope diagram.
     */
void print_diagram (const Envelope_diagram_2& diag)
{
  // Go over all arrangement faces.
  Envelope_diagram_2::Face_const_iterator            fit;
  Envelope_diagram_2::Ccb_halfedge_const_circulator  ccb;
  Envelope_diagram_2::Surface_const_iterator         sit;

  for (fit = diag.faces_begin(); fit != diag.faces_end(); ++fit)
  {
    // Print the face boundary.

    // Print the vertices along the outer boundary of the face.
    ccb = fit->outer_ccb();
    std::cout << "[Face]  ";
    do
    {
      if(!ccb->is_fictitious())
        std::cout << '(' << ccb->curve() << ") ";
      ++ccb;
    } while (ccb != fit->outer_ccb());

    // Print the planes that induce the envelope on this face.
    std::cout << "-->  " << fit->number_of_surfaces()
              << " planes:";

    for (sit = fit->surfaces_begin(); sit != fit->surfaces_end(); ++sit)
      std::cout << ' ' << sit->plane();
    std::cout << std::endl;
  }

  return;
}

/* The main program: */
int main ()
{
  // Construct the input planes.
  std::list<Surface_3>   planes;

  planes.push_back (Surface_3(Plane_3(0, -1, 1, 0)));
  planes.push_back (Surface_3(Plane_3(-1, 0, 1, 0)));
  planes.push_back (Surface_3(Plane_3(0, 1 , 1, 0)));
  planes.push_back (Surface_3(Plane_3(1, 0, 1,  0)));

  // Compute and print the minimization diagram.
  Envelope_diagram_2      min_diag;
```

```
  CGAL::lower_envelope_3 (planes.begin(), planes.end(), min_diag);

  std::cout << std::endl << "The minimization diagram:" << std::endl;
  print_diagram (min_diag);

  // Compute and print the maximization diagram.
  Envelope_diagram_2      max_diag;

  CGAL::upper_envelope_3 (planes.begin(), planes.end(), max_diag);

  std::cout << std::endl << "The maximization diagram:" << std::endl;
  print_diagram (max_diag);

  return (0);
}
```

Envelopes of Surfaces in 3D Reference Manual

Dan Halperin, Michal Meyerovitch, Ron Wein and Baruch Zukerman

Introduction

This package consists of functions that compute the lower (or upper) envelope of a set of arbitrary surfaces in 3D. The output is represented as an 2D envelope diagram — a planar subdivision such that the identity of the surfaces that induce the envelope over each diagram cell is unique.

Functions

Concepts

Classes

36.4 Alphabetical List of Reference Pages

CGAL::lower_envelope_3

#include <CGAL/envelope_3.h>

template<class InputIterator, class Traits>
void lower_envelope_3(InputIterator begin, InputIterator end, Envelope_diagram_2<Traits>& diag)

Computes the lower envelope of a set of surfaces in $\mathbb{R}^3$, as given by the range *[begin, end)*. The lower envelope is represented using the output minimization diagram *diag*.
Precondition: The value-type of *InputIterator* is *Traits::Surface_3*.

Function

Function

CGAL::upper_envelope_3

#include <CGAL/envelope_3.h>

template<class InputIterator, class Traits>
void *upper_envelope_3(InputIterator begin, InputIterator end, Envelope_diagram_2<Traits>& diag)*

Computes the upper envelope of a set of surfaces in $\mathbb{R}^3$, as given by the range *[begin, end)*. The upper envelope is represented using the output maximization diagram *diag*.
Precondition: The value-type of *InputIterator* is *Traits::Surface_3*.

CGAL::lower_envelope_xy_monotone_3

#include <CGAL/envelope_3.h>

template<class InputIterator, class Traits>
void *lower_envelope_xy_monotone_3(InputIterator begin, InputIterator end, Envelope_diagram_2<Traits>& diag)*

Computes the lower envelope of a set of *xy*-monotone surfaces in $\mathbb{R}^3$, as given by the range *[begin, end)*. The lower envelope is represented using the output minimization diagram *diag*.
Precondition: The value-type of *InputIterator* is *Traits::Xy_monotone_surface_3*.

Function

Function

CGAL::upper_envelope_xy_monotone_3

#include <CGAL/envelope_3.h>

```
template<class InputIterator, class Traits>
void    upper_envelope_xy_monotone_3( InputIterator begin,
                                      InputIterator end,
                                      Envelope_diagram_2<Traits>& diag)
```

Computes the upper envelope of a set of *xy*-monotone surfaces in $\mathbb{R}^3$, as given by the range *[begin, end)*. The lower envelope is represented using the output maximization diagram *diag*.

Precondition: The value-type of *InputIterator* is *Traits::Xy_monotone_surface_3*.

EnvelopeTraits_3

Concept

Definition

This concept defines the minimal set of geometric predicates and operations needed to compute the envelope of a set of arbitrary surfaces in $\mathbb{R}^3$. It refines the *ArrangementXMonotoneTraits_2* concept. In addition to the *Point_2* and *X_monotone_curve_2* types and the *Has_boundary_category* category tag listed in the base concept, it also lists the *Surface_3* and *Xy_monotone_surface_3* types, which represent arbitrary surfaces and *xy*-monotone surfaces, respectively, and some constructions and predicates on these types. Note however, that these operations usually involve the projection of 3D objects onto the *xy*-plane.

Refines

ArrangementXMonotoneTraits_2

Types

EnvelopeTraits_3:: Surface_3	represents an arbitrary surface in $\mathbb{R}^3$.
EnvelopeTraits_3:: Xy_monotone_surface_3	represents a weakly *xy*-monotone surface in $\mathbb{R}^3$.

Functor Types

EnvelopeTraits_3:: Make_xy_monotone_3

provides the operator (templated by the *OutputIterator* type) :

- *OutputIterator operator() (Surface_3 S, bool is_lower, OutputIterator oi)*
  which subdivides the given surface *S* into *xy*-monotone parts and inserts them into the output iterator. The value of *is_lower* indicates whether we compute the lower or the upper envelope, so that *xy*-monotone surfaces that are irrelevant to the lower-envelope (resp. upper-envelope) computation may be discarded. The value-type of *OutputIterator* is *Xy_monotone_surface_3*. The operator returns a past-the-end iterator for the output sequence.

EnvelopeTraits_3:: Construct_projected_boundary_2

provides the operator (templated by the *OutputIterator* type) :

- *OutputIterator operator() (Xy_monotone_surface_3 s, OutputIterator oi)*
  which computes all planar *x*-monotone curves and possibly isolated planar points that form the projection of the boundary of the given *xy*-monotone surface *s* onto the *xy*-plane, and inserts them into the output iterator. The value-type of *OutputIterator* is *Object*, where *Object* wraps either a *Point_2*, or a *pair<X_monotone_curve_2, Oriented_side>*. In the former case, the object represents an isolated point of the projected boundary. In the latter, more general, case the object represents an *x*-monotone boundary curve along with an enumeration value which is either *ON_NEGATIVE_SIDE* or *ON_POSITIVE_SIDE*, indicating whether whether the projection of the surface onto the *xy*-plane lies below or above this *x*-monotone curve, respectively. In degenerate case, namely when the surface itself is vertical, and its projection onto the plane is 1-dimensional, the *Oriented_side* value is *ON_ORIENTED_BOUNDARY*. The operator returns a past-the-end iterator for the output sequence.

EnvelopeTraits_3:: Construct_projected_intersections_2

provides the operator (templated by the *OutputIterator* type) :

- *OutputIterator operator() (Xy_monotone_surface_3 s1, Xy_monotone_surface_3 s2, OutputIterator oi)*
  which computes the projection of the intersections of the *xy*-monotone surfaces *s1* and *s2* onto the *xy*-plane, and inserts them into the output iterator. The value-type of *OutputIterator* is *Object*, where each *Object* either wraps a *pair<X_monotone_curve_2,Multiplicity>* instance, which represents a projected intersection curve with its multiplicity (in case the multiplicity is undefined or not known, it should be set to 0) or an *Point_2* instance, representing the projected image of a degenerate intersection (the projection of an isolated intersection point, or of a vertical intersection curve). The operator returns a past-the-end iterator for the output sequence.

EnvelopeTraits_3:: Compare_z_at_xy_3

provides the operators :

- *Comparison_result operator() (Point_2 p, Xy_monotone_surface_3 s1, Xy_monotone_surface_3 s2)*
  which determines the relative z-order of the two given *xy*-monotone surfaces at the *xy*-coordinates of the point p, with the precondition that both surfaces are defined over p. Namely, it returns the comparison result of $s_1(p)$ and $s_2(p)$.

- *Comparison_result operator() (X_monotone_curve_2 c, Xy_monotone_surface_3 s1, Xy_monotone_surface_3 s2)*
  which determines the relative z-order of the two given *xy*-monotone surfaces over the interior of a given x-monotone curve c, with the precondition that c is fully contained in the *xy*-definition range of both s_1 and s_2, and that the surfaces do not intersect over c. The functor should therefore return the comparison result of $s_1(p')$ and $s_2(p')$ for some point p' in the interior of c.

- *Comparison_result operator() (Xy_monotone_surface_3 s1, Xy_monotone_surface_3 s2)*
  which determines the relative z-order of the two given unbounded *xy*-monotone surfaces, which are defined over the entire *xy*-plane and have no boundary, with the precondition that the surfaces do not intersect at all. The functor should therefore return the comparison result of $s_1(p)$ and $s_2(p)$ for some planar point $p \in \mathbb{R}^2$. This operator is required iff the category tag *Has_boundary_category* is defined as *Tag_true*.

EnvelopeTraits_3:: Compare_z_at_xy_above_3

provides the operator :

- *Comparison_result operator() (X_monotone_curve_2 c, Xy_monotone_surface_3 s1, Xy_monotone_surface_3 s2)*
  which determines the relative z-order of the two given *xy*-monotone surfaces immediately above their projected intersection curve c (a planar point p is *above* an x-monotone curve c if it is in the x-range of c, and lies to its left when the curve is traversed from its *xy*-lexicographically smaller endpoint to its larger endpoint). We have the precondition that both surfaces are defined "above" c, and their relative z-order is the same for some small enough neighborhood of points above c.

EnvelopeTraits_3:: Compare_z_at_xy_below_3

provides the operator :

- *Comparison_result operator() (X_monotone_curve_2 c, Xy_monotone_surface_3 s1, Xy_monotone_surface_3 s2)*
  which determines the relative z-order of the two given xy-monotone surfaces immediately below their projected intersection curve c (a planar point p is *below* an x-monotone curve c if it is in the x-range of c, and lies to its right when the curve is traversed from its xy-lexicographically smaller endpoint to its larger endpoint). We have the precondition that both surfaces are defined "below" c, and their relative z-order is the same for some small enough neighborhood of points below c.

CGAL::Env_plane_traits_3<Kernel>
CGAL::Env_surface_data_traits_3<Traits,XyData,SData,Cnv>

Class

CGAL::Env_triangle_traits_3<Kernel>

Definition

The traits class *Env_triangle_traits_3<Kernel>* models the *EnvelopeTraits_3* concept, and is used for the construction of lower and upper envelopes of triangles in the space. It is parameterized by a CGAL-kernel, which is parameterized in turn by a number type. The number type should support exact rational arithmetic, to avoid numerical errors and robustness problems. In particular, the number type should support the arithmetic operations $+$, $-$, $\times$, and $\div$ without loss of precision. For optimal performance, we recommend instantiating the traits class with the predefined *Exact_predicates_exact_constructions_kernel* provided by CGAL. Using this kernel guarantees exactness and robustness, while it incurs only a minor overhead (in comparison to working with a fast, inexact number type) for most inputs.

Note that when we project the boundary of a triangle, or the intersection of two triangles, onto the *xy*-plane, we obtain line segments. Indeed, *Env_triangle_traits_3<Kernel>* inherits from the *Arr_segment_traits_2<Kernel>* traits class, and extends it by adding operations on 3D objects, namely spacial triangles. Note that the traits class does *not* define *Kernel::Triangle_3* as its surface (and *xy*-monotone surface) type, as one may expect. This is because the traits class needs to store extra data with the triangles in order to efficiently operate on them. Nevertheless, the nested *Xy_monotone_surface_3* and *Surface_3* types are however constructible from a *Kernel::Triangle_3* instance and are also convertible to a *Kernel::Triangle_3* object. Both types, *Xy_monotone_surface_3* and *Surface_3*, refer to the same class, as *every* triangle is (weakly) *xy*-monotone).

CGAL::Env_sphere_traits_3<ConicTraits>

Class

Definition

The traits class *Env_sphere_traits_3<ConicTraits>* models the *EnvelopeTraits_3* concept, and is used for the construction of lower and upper envelopes of spheres. Note that when projecting the intersection curve of two spheres (a circle in 3D) onto the *xy*-plane, the resulting curve is an ellipse. The traits class is therefore parameterized by an arrangement-traits class that is capable of handling conic curves — namely an instantiation of the *Arr_conic_traits_2* class-template — and inherits from it.

The conic-traits class defines a nested type named *Rat_kernel*, which is a geometric kernel parameterized by an exact rational type. *Env_sphere_traits_3<ConicTraits>* defines its *Surface_3* type to be constructible from *Rat_kernel::Sphere_3*. Namely, it can handle spheres whose center points have rational coordinates (i.e., of the type *Rat_kernel::FT*), and whose squared radius is also rational. The *Surface_3* type is also convertible to a *Rat_kernel::Sphere_3* object.

The *Xy_monotone_surface_3* type is the same as the nested *Surface_3* type. The traits-class simply ignores the upper hemisphere when it computes lower envelopes, and ignores the lower hemisphere when it computes upper envelopes.

ConicTraits

Class

CGAL::Env_surface_data_traits_3<Traits,XyData,SData,Cnv>

Definition

The class *Env_surface_data_traits_3<Traits,XyData,SData,Cnv>* is a model of the *EnvelopeTraits_3* concept and serves as a decorator class that allows the extension of the surfaces defined by the base traits-class (the *Traits* parameter), which serves as a geometric traits-class (a model of the *EnvelopeTraits_3* concept), with extraneous (non-geometric) data fields.

The traits-class decorator extends the *Surface_3* and the *Xy_monotone_surface_3* types as detailed below. Each *Surface_3* object is associated with a single data field of type *SData*, and each *Xy_monotone_surface_3* object is associated with a single data field of type *XyData*. When a surface is subdivided into *xy*-monotone surfaces, its data field is converted using the conversion functor, which is specified by the *Cnv* template-parameter, and the resulting objects is copied to all *Xy_monotone_surface_3* objects induced by this surface. The conversion functor should provide an operator with the following prototype:
XyData operator() (const SData& d) const;

By default, the two data types are the same, so the conversion operator is trivial and just copies the data object:

SData = XyData
Cnv = _Default_convert_functor<SData,XyData>

#include <CGAL/Env_surface_data_traits_3.h>

constructs an *xy*-monotone surface from the given *base* surface with uninitialized data field.

Arr_surface_data_traits_3<Tr,XData,Mrg,CData,Cnv>::Xy_monotone_surface_3 xys(Base_xy_monotone_surface_3 base, Xy_monotone_surface_data data)

constructs an *x*-monotone surface from the given *base* *x*-monotone surface with an attached *data* field.

Access Functions

Xy_monotone_surface_data *xys.data() const*

returns the field (a non-const version, which returns a reference to the data object, is also available).

void *xys.set_data(Xy_monotone_surface_data data)*

sets the data field.

CGAL::Env_plane_traits_3<Kernel>

Definition

The traits class *Env_plane_traits_3<Kernel>* models the *EnvelopeTraits_3* concept, and is used for the construction of lower and upper envelopes of planes and half planes in the space. It is parameterized by a CGAL-kernel model, which is parameterized in turn by a number type. The number type should support exact rational arithmetic, to avoid numerical errors and robustness problems. In particular, the number type should support the arithmetic operations $+$, $-$, $\times$, and $\div$ without loss of precision. For optimal performance, we recommend instantiating the traits class with the predefined *Exact_predicates_exact_constructions_kernel* provided by CGAL. Using this kernel guarantees exactness and robustness, while it incurs only a minor overhead (in comparison to working with a fast, inexact number type) for most inputs.

Note that an entire plane has no boundaries, and the projection of a half-plane is an (unbounded) line. Naturally, rays and segments may occur as a result of overlaying projections of several half planes. Indeed, *Env_plane_traits_3<Kernel>* inherits from the *Arr_linear_traits_2<Kernel>* traits class, and extends it by adding operations on planes and half planes. The nested *Xy_monotone_surface_3* and *Surface_3* types refer to the same type. They are constructible from a *Kernel::Plane_3* in case of an entire plane, or from *Kernel::Plane_3* and *Kernel::Line_2* in case of a half-plane. The line orientation determines which half is considered.

#include <CGAL/Env_plane_traits_3.h>

CGAL::Envelope_diagram_2<EnvTraits>

Definition

The class-template *Envelope_diagram_2<EnvTraits>* represents the minimization diagram that corresponds to the lower envelope of a set of curves, or the maximization diagram that corresponds to their upper envelope. It is parameterized by a traits class that must be a model of the *EnvelopeTraits_3* concept, and is basically a planar arrangement of x-monotone curves, as defined by this traits class. These x-monotone curves are the projections of boundary curves of xy-monotone surfaces, or the intersection curves between such surfaces, onto the xy-plane. Thus, it is possible to traverse the envelope diagram using the methods inherited from the *Arrangement_2* class.

The envelope diagram extends the arrangement features (namely the vertices, halfedges, and faces), such that each feature stores a container of originators — namely, the xy-monotone surfaces (instances of the type *EnvTraits::Xy_monotone_surface_3*) that induce the lower envelope (or the upper envelope, in case of a maximization diagram) over this feature. The envelope diagram provides access methods to these originators.

Precondition: The number of surfaces is not 0.

Part IX

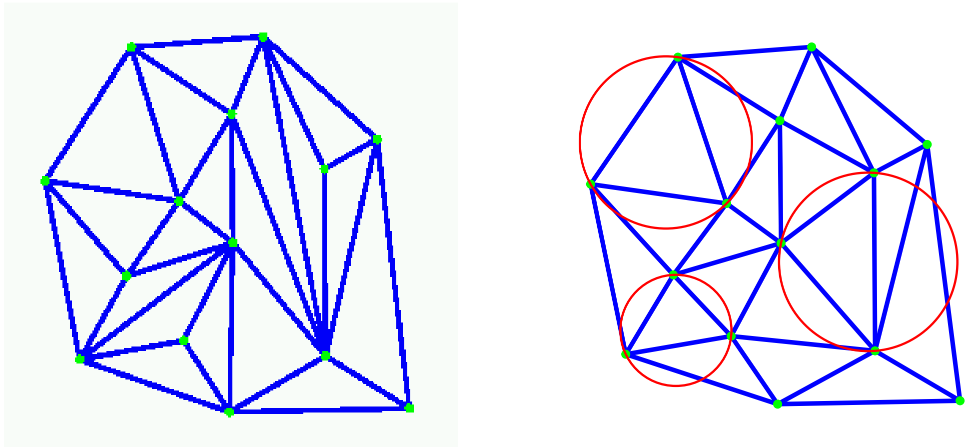
Triangulations and Delaunay Triangulations

Chapter 37

2D Triangulations

Mariette Yvinec

Contents



This chapter describes the two dimensional triangulations of CGAL. Section 37.1 recalls the main definitions about triangulations. Sections 37.2 discusses the way two-dimensional triangulations are represented in CGAL. Section 37.3 presents the overall software design of the 2D triangulations package. The next sections present the different two dimensional triangulations classes available in CGAL : basic triangulations (section 37.4), Delaunay triangulations (Section 37.5), regular triangulations (Section 37.6), constrained triangulations (Section 37.7), and constrained Delaunay triangulations (Section 37.8). Section 37.9 describes a class which implements a constrained or constrained Delaunay triangulation with an additional data structure to describe how the constraints are refined by the edges of the triangulations. Section 37.10 describes a hierarchical data structure for fast point location queries. At last, Section 37.11 explains how the user can benefit from the flexibility of CGAL triangulations using customized classes for faces and vertices.

37.1 Definitions

A two dimensional triangulation can be roughly described as a set T of triangular facets such that :
- two facets either are disjoint or share a lower dimensional face (edge or vertex).
- the set of facets in T is connected for the adjacency relation.
- the domain U_T which is the union of facets in T has no singularity.

More precisely, a triangulation can be described as a simplicial complex. Let us first record a few definitions.

A simplicial complex is a set T of simplices such that
- any face of a simplex in T is a simplex in T
- two simplices in T either are disjoint or share a common sub-face.

The dimension d of a simplicial complex is the maximal dimension of its simplices.
A simplicial complex T is pure if any simplex of T is included in a simplex of T with maximal dimension.
Two simplexes in T with maximal dimension d are said to be adjacent if they share a $d-1$ dimensional sub-face.
A simplicial complex is connected if the adjacency relation defines a connected graph over the set of simplices of T with maximal dimension.
The union U_T of all simplices in T is called the domain of T. A point p in the domain of T is said to singular if its surrounding in U_T is neither a topological ball nor a topological disc.

Then, a two dimensional triangulation can be described as a two dimensional simplicial complex that is pure, connected and without singularity.

Each facet of a triangulation can be given an orientation which in turn induces an orientation on the edges incident to that facet. The orientation of two adjacent facets are said to be consistent if they induce opposite orientations on their common incident edge. A triangulation is said to be orientable if the orientation of each facet can be chosen in such a way that all pairs of incident facets have consistent orientations.

The data structure underlying CGAL triangulations allows to represent the combinatorics of any orientable two dimensional triangulations without boundaries. On top of this data structure, the 2D triangulations classes take care of the geometric embedding of the triangulation and are designed to handle planar triangulations. The plane of the triangulation may be embedded in a higher dimensional space.

The triangulations of CGAL are complete triangulations which means that their domain is the convex hull of their vertices. Because any planar triangulation can be completed, this is not a real restriction. For instance, a triangulation of a polygonal region can be constructed and represented as a subset of a constrained triangulation in which the region boundary edges have been input as constrained edges (see Section 37.7, 37.8 and 37.9).

Strictly speaking, the term *face* should be used to design a face of any dimension, and the two-dimensional faces of a triangulation should be properly called *facets*. However, following a common usage, we hereafter often call *faces*, the facets of a two dimensional triangulation.

37.2 Representation

The Set of Faces

A 2D triangulation of CGAL can be viewed as a planar partition whose bounded faces are triangular and cover the convex hull of the set of vertices. The single unbounded face of this partition is the complementary of the convex hull. In many applications, such as Kirkpatrick's hierarchy or incremental Delaunay construction, it is convenient to deal with only triangular faces. Therefore, a fictitious vertex, called the *infinite vertex* is added to the triangulation as well as *infinite edges* and *infinite faces* incident to it.. Each infinite edge is incident to the infinite vertex and to a vertex of the convex hull. Each infinite face is incident to the infinite vertex and to a convex hull edge.

Therefore, each edge of the triangulation is incident to exactly two faces and the set of faces of a triangulation is topologically equivalent to a two-dimensional sphere. This extends to lower dimensional triangulations arising in degenerate cases or when the triangulations as less than three vertices. Including the infinite faces, a one dimensional triangulation is a ring of edges and vertices topologically equivalent to a 1-sphere. A zero dimensional triangulation, whose domain is reduced to a single point, is represented by two vertices that is topologically equivalent to a 0-sphere.

Note that the *infinite vertex* has no significant coordinates and that no geometric predicate can be applied on it nor on an infinite face.

A Representation Based on Faces and Vertices

Because a triangulation is a set of triangular faces with constant-size complexity, triangulations are not implemented as a layer on top of a planar map. CGAL uses a proper internal representation of triangulations based on faces and vertices rather than on edges. Such a representation saves storage space and results in faster algorithms [BDTY00].

The basic elements of the representation are vertices and faces. Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces.

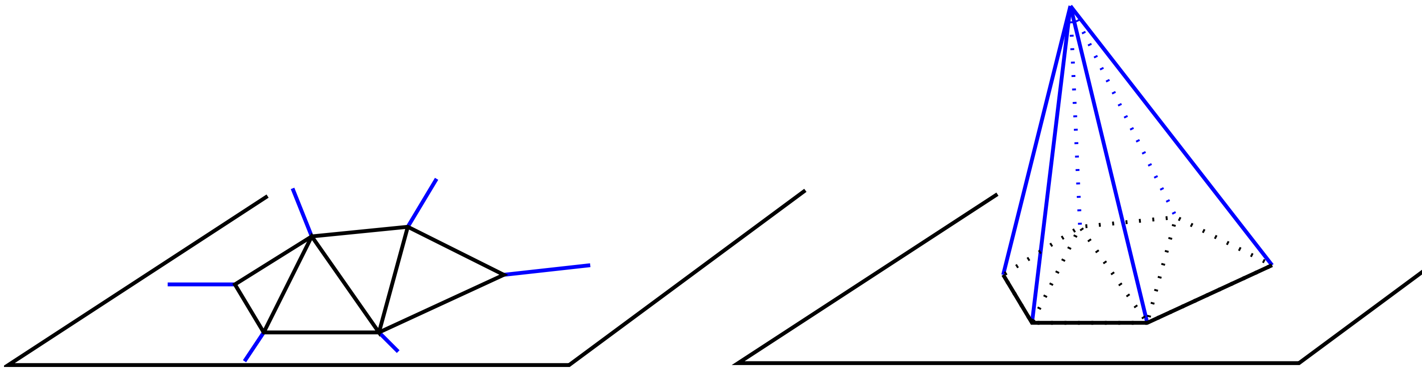


Figure 37.1: Infinite vertex and infinite faces

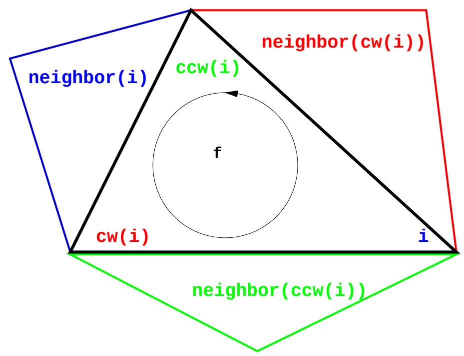

Figure 37.2: Vertices and neighbors.

The three vertices of a face are indexed with 0, 1 and 2 in counterclockwise order. The neighbors of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. See Figure 37.2, the functions *ccw(i)* and *cw(i)* shown on this figure compute respectively $i+1$ and $i-1$ modulo 3.

The edges are not explicitly represented, they are only implicitly represented through the adjacency relations of two faces. Each edge has two implicit representations: the edge of a face f which is opposed to the vertex indexed i, can be represented as well as an edge of the *neighbor(i)* of f.

37.3 Software Design

The triangulations classes of CGAL provide high-level geometric functionalities such as location of a point in the triangulation, insertion, removal, or displacement of a point. They are build as a layer on top of a data structure called the triangulation data structure. The triangulation data structure can be thought of as a container for the faces and vertices of the triangulation. This data structure also takes care of all the combinatorial aspects of the triangulation.

This separation between the geometric aspect and the combinatorial part is reflected in the software design by the fact that the triangulation classes have two template parameters:

- the first parameter stands for a **geometric traits** class providing the geometric primitives (points, segments

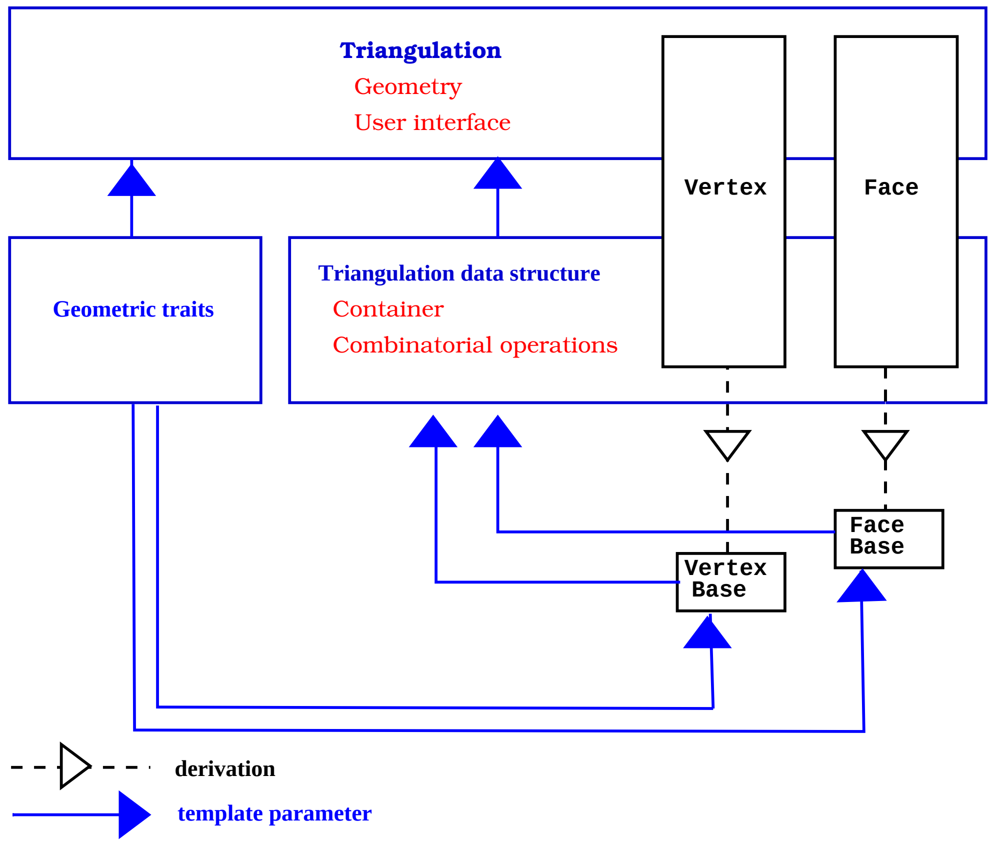

Figure 37.3: The triangulations software design.

and triangles) of the triangulation and the elementary operations (predicate or constructions) on those objects.

- the second parameter stands for a **triangulation data structure** class. The concept of triangulation data structure is described in Section 38.2 of Chapter 38. The triangulation data structure defines the types used to represent the faces and vertices of the triangulation, as well as additional types (handles, iterators and circulators) to access and visit the faces and vertices.

  CGAL provides the class *Triangulation_data_structure_2<Vb,Fb>* as a default model of triangulation data structure. The class *Triangulation_data_structure_2<Vb,Fb>* has two template parameters standing for a vertex class and a face class. CGAL defines concepts for these template parameters and provide default models for these concepts. The vertex and base classes are templated by the geometric traits which allows them to have some knowledge of the geometric primitives of the triangulation. Those default vertex and face base classes can be replaced by user customized base classes in order, for example, to deal with additional properties attached to the vertices or faces of a triangulation. See section 37.11 for more details on the way to make use of this flexibility.

The Figure 37.3 summarizes the design of the triangulation package, showing the three layers (base classes, triangulation data structure and triangulation) forming this design.

The top triangulation level, responsible for the geometric embedding of the triangulation comes in different flavors according to the different kind of triangulations: basic, Delaunay, regular, constrained or constrained Delaunay. Each kind of triangulations correspond to a different class. Figure 37.4 summarizes the derivation dependencies of CGAL 2D triangulations classes. Any 2D triangulation class is parametrized by a geometric

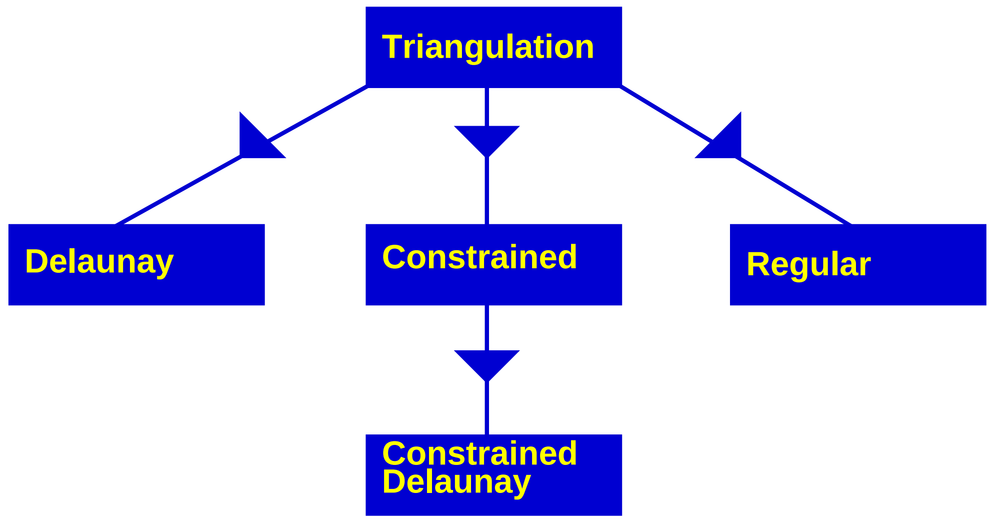

Figure 37.4: The derivation tree of 2D triangulations.

traits and a triangulation data structure. While a unique concept *TriangulationDataStructure_2* describes the triangulation data structure requirements for any triangulation class, the concept of geometric traits actually depends on the triangulation class. In general, the requirements for the vertex and face base classes are described by the basic concepts *TriangulationVertexBase_2* and *TriangulationFaceBase_2*. However, some triangulation classes requires base classes implementing refinements of the basic concepts.

37.4 Basic Triangulations

37.4.1 Description

The class *Triangulation_2<Traits,Tds>* serves as a base class for the other 2D triangulations classes and implements the user interface to a triangulation.

The vertices and faces of the triangulations are accessed through *handles*, *iterators* and *circulators*. A handle is a model of the concept *Handle* which basically offers the two dereference operators * and -> . A circulator is a type devoted to visit circular sequences. Handles are used whenever the accessed element is not part of a sequence. Iterators and circulators are used to visit all or parts of the triangulation.

The iterators and circulators are all bidirectional and non mutable. The circulators and iterators are convertible to the handles with the same value type, so that when calling a member function, any handle type argument can be replaced by an iterator or a circulator with the same value type.

The triangulation class allows to visit the vertices and neighbors of a face in clockwise or counterclockwise order.

There are circulators to visit the edges or faces incident to a given vertex or the vertices adjacent to it. Another circulator type allows to visit all the faces traversed by a given line. Circulators step through infinite features as well as through finite ones.

The triangulation class offers some iterators to visit all the faces, edges or vertices and also iterators to visit selectively the finite faces, edges or vertices.

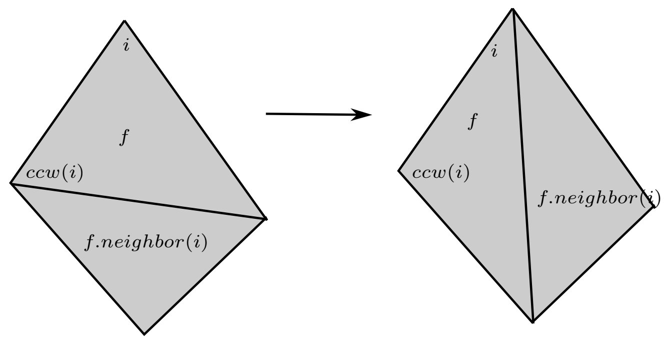

Figure 37.5: Flip.

The triangulation class provides methods to test the infinite character of any feature, and also methods to test the presence in the triangulation of a particular feature (edge or face) given its vertices.

The triangulation class provides a method to locate a given point with respect to a triangulation. In particular, this method reports whether the point coincides with a vertex of the triangulation, lies on an edge, in a face or outside of the convex hull. In case of a degenerate lower dimensional triangulation, the query point may also lie outside the triangulation affine hull.

The triangulation class also provides methods to locate a point with respect to a given finite face of the triangulation or with respect to its circumcircle. The faces of the triangulation and their circumcircles have the counterclockwise orientation.

The triangulation can be modified by several functions: insertion of a point, removal of a vertex, displacement of a vertex, flipping of an edge. The flipping of an edge is possible when the union of the two incident faces forms a convex quadrilateral (see Figure 37.5).

Implementation

Locate is implemented by a line walk. The walk begins at a vertex of the face which is given as an optional argument or at an arbitrary vertex of the triangulation if no optional argument is given. It takes time $O(n)$ in the worst case, but only $O(\sqrt{n})$ on average if the vertices are distributed uniformly at random. The class *Triangulation_hierarchy_2<Traits,Tds>*, described in section 37.10, implements a data structure designed to offer an alternate more efficient point location algorithm.

Insertion of a point is done by locating a face that contains the point, and splitting this face into three new faces. If the point falls outside the convex hull, the triangulation is restored by flips. Apart from the location, insertion takes a time $O(1)$. This bound is only an amortized bound for points located outside the convex hull.

Removal of a vertex is done by removing all adjacent triangles, and re-triangulating the hole. Removal takes a time at most proportional to d^2, where d is the degree of the removed vertex, which is $O(1)$ for a random vertex.

Displacement of a vertex is done by: first, verifying if the triangulation embedding remains planar after the displacement; if yes the vertex is directly placed at the new location; otherwise, a point is inserted at the new location and the vertex at the obsolete location is removed.

The face, edge, and vertex iterators on finite features are derived from their counterparts visiting all (finite and infinite) features which are themselves derived from the corresponding iterators of the triangulation data structure.

Geometric Traits

The geometric traits of a triangulation is required to provide the geometric objects (points, segments and triangles) building up the triangulation together with the geometric predicates on those objects. The required predicates are:
- comparison of the x or y coordinates of two points.
- the orientation test which computes the order type of three given point.

The concept *TriangulationTraits_2* describes the requirements for the geometric traits class of a triangulation. The CGAL kernel classes are models for this concept. The CGAL library also provides dedicated models of *TriangulationTraits_2* using the kernel geometric objects and predicates. These classes are themselves templated with a CGAL kernel and extract the required types and predicates from the kernel. The traits class *Triangulation_euclidean_traits_2<R>* is designed to deal with ordinary two dimensional points. The class *Projection_traits_xy_3<R>* is a geometric traits class to build the triangulation of a terrain. Such a triangulation is a two-dimensional triangulation embedded in three dimensional space. The data points are three-dimensional points. The triangulation is build according to the projections of those points on the xy plane and then lifted up to the original three-dimensional data points. This is especially useful to deal with GIS terrains. Instead of really projecting the three-dimensional points and maintaining a mapping between each point and its projection (which costs space and is error prone), the traits class supplies geometric predicates that ignore the z-coordinates of the points. See Section 37.5 for an example. CGAL provides also the geometric traits classes *Projection_traits_yz_3<R>* and *Projection_traits_xz_3<R>* to deal with projections on the yz plane and xz-plane, respectively.

37.4.2 Example of a Basic Triangulation

The following program creates a triangulation of 2D points using the default kernel *Exact_predicate_inexact_constructions_kernel* as geometric traits and the default triangulation data structure. The input points are read from a file and inserted in the triangulation. Finally points on the convex hull are written to `cout`.

```
#include <fstream>

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_2.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_2<K>         Triangulation;
typedef Triangulation::Vertex_circulator Vertex_circulator;
typedef Triangulation::Point             Point;

int main() {
  std::ifstream in("data/triangulation_prog1.cin");
  std::istream_iterator<Point> begin(in);
  std::istream_iterator<Point> end;

  Triangulation t;
  t.insert(begin, end);

  Vertex_circulator vc = t.incident_vertices(t.infinite_vertex()),
    done(vc);
  if (vc != 0) {
    do { std::cout << vc->point() << std::endl;
    }while(++vc != done);
```

```
  }
  return 0;
}
```

File: examples/Triangulation_2/triangulation_prog1.cpp

37.5 Delaunay Triangulations

37.5.1 Description

The class *Delaunay_triangulation_2<Traits,Tds>* is designed to represent the Delaunay triangulation of a set of data points in the plane. A Delaunay triangulation fulfills the following *empty circle property* (also called *Delaunay property*): the circumscribing circle of any facet of the triangulation contains no data point in its interior. For a point set with no subset of four co-circular points the Delaunay triangulation is unique, it is dual to the Voronoi diagram of the set of points.

The class *Delaunay_triangulation_2<Traits,Tds>* derives from the class *Triangulation_2<Traits,Tds>*.

The class *Delaunay_triangulation_2<Traits,Tds>* inherits the types defined by the basic class *Triangulation_2< Traits,Tds>*. Additional types, provided by the traits class, are defined to represent the dual Voronoi diagram.

The class *Delaunay_triangulation_2<Traits,Tds>* overwrites the member functions that insert, move, or remove a point in the triangulation to maintain the Delaunay property. It also has a member function (*Vertex_handle nearest_vertex(const Point& p)*) to answer nearest neighbor queries and member functions to construct the elements (vertices and edges) of the dual Voronoi diagram.

Geometric traits

The geometric traits has to be a model of the concept *DelaunayTriangulationTraits_2* which refines the concept *TriangulationTraits_2*. In particular this concept provides the *side_of_oriented_circle* predicate which, given four points *p,q,r,s* decides the position of the point *s* with respect to the circle passing through *p*, *q* and *r*. The *side_of_oriented_circle* predicate actually defines the Delaunay triangulation. Changing this predicate allows to build variant of Delaunay triangulations for different metrics such that L_1 or L_∞ metric or any metric defined by a convex object. However, the user of an exotic metric must be careful that the constructed triangulation has to be a triangulation of the convex hull which means that convex hull edges have to be Delaunay edges. This is granted for any smooth convex metric (like L_2) and can be ensured for other metrics (like L_∞) by the addition to the point set of well chosen sentinel points.

The CGAL kernel classes and the class *Triangulation_euclidean_traits_2<R>* are models of the concept *DelaunayTriangulationTraits_2* for the euclidean metric. The traits class for terrains, *Projection_traits_xy_3<R>*,
Projection_traits_yz_3<R>, and
Projection_traits_xz_3<R>
are also models of *DelaunayTriangulationTraits_2* except that they do not fulfill the requirements for the duality functions and nearest vertex queries.

Implementation

The insertion of a new point in the Delaunay triangulation is performed using first the insertion member function of the basic triangulation and second performing a sequence of flips to restore the Delaunay property. The number of flips that have to be performed is $O(d)$ if the new vertex has degree d in the updated Delaunay triangulation. For points distributed uniformly at random, each insertion takes time $O(1)$ on average, once the point has been located in the triangulation.

Removal calls the removal in the triangulation and then re-triangulates the hole created in such a way that the Delaunay criterion is satisfied. Removal of a vertex of degree d takes time $O(d^2)$. The degree d is $O(1)$ for a random vertex in the triangulation. When the degree of the removed vertex is small (≤ 7) a special procedure is used that allows to increase global removal time by a factor of 2 for random points [Dev09].

The displacement of a vertex v at a point p to a new location p', first checks whether the triangulation embedding remains planar or not after moving v to p'. If yes, it moves v to p' and simply performs a sequence of flips to restore the Delaunay property, which is $O(d)$ where d is the degree of the vertex after the displacement. Otherwise, the displacement is done by inserting a vertex at the new location, and removing the obsolete vertex. The complexity is $O(n)$ in the worst case, but only $O(1+\delta\sqrt{n})$ for evenly distributed vertices in the unit square, where δ is the Euclidean distance between the new and old locations.

After having performed a point location, the nearest neighbor of a point is found in time $O(n)$ in the worst case, but in time $O(1)$ for vertices distributed uniformly at random and any query point.

37.5.2 Example: a Delaunay Terrain

The following code creates a Delaunay triangulation with the usual Euclidean metric for the vertical projection of a terrain model. The points have elevation, that is they are 3D points, but the predicates used to build the Delaunay triangulation are computed using only the x and y coordinates of these points.

The class *Projection_traits_xy_3<K>* is part of the 2D and 3D Linear Geometric Kernel, and replaces the class *Triangulation_euclidean_traits_xy_3<K>* which is deprecated.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Projection_traits_xy_3.h>
#include <CGAL/Delaunay_triangulation_2.h>

#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Projection_traits_xy_3<K>  Gt;
typedef CGAL::Delaunay_triangulation_2<Gt> Delaunay;

typedef K::Point_3   Point;

int main()
{
  std::ifstream in("data/terrain.cin");
  std::istream_iterator<Point> begin(in);
  std::istream_iterator<Point> end;

  Delaunay dt;
  dt.insert(begin, end);
  std::cout << dt.number_of_vertices() << std::endl;
  return 0;
}
```

File: examples/Triangulation_2/terrain.cpp

37.5.3 Example: Voronoi Diagram

The following code computes the edges of Voronoi diagram of a set of data points and counts the number of finite edges and the number of rays of this diagram

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>

#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Delaunay_triangulation_2<K>  Triangulation;
typedef Triangulation::Edge_iterator  Edge_iterator;
typedef Triangulation::Point          Point;

int main( )
{
  std::ifstream in("data/voronoi.cin");
  std::istream_iterator<Point> begin(in);
  std::istream_iterator<Point> end;
  Triangulation T;
  T.insert(begin, end);

  int ns = 0;
  int nr = 0;
  Edge_iterator eit =T.edges_begin();
  for ( ; eit !=T.edges_end(); ++eit) {
    CGAL::Object o = T.dual(eit);
    if (CGAL::object_cast<K::Segment_2>(&o)) {++ns;}
    else if (CGAL::object_cast<K::Ray_2>(&o)) {++nr;}
  }
  std::cout << "The Voronoi diagram has " << ns << " finite edges "
            << " and " << nr << " rays" << std::endl;
  return 0;
}
```

File: examples/Triangulation_2/voronoi.cpp

37.5.4 Example: Print Voronoi Diagram Edges Restricted to a rectangle

The following code computes the Delaunay triangulation of a set of points and prints the Voronoi edges restricted to a given rectangle.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <iterator>
```

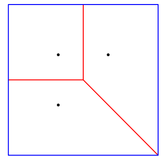

Figure 37.6: Voronoi diagram (in red) of the black points restricted to the blue rectangle.

```
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point_2;
typedef K::Iso_rectangle_2 Iso_rectangle_2;
typedef K::Segment_2 Segment_2;
typedef K::Ray_2 Ray_2;
typedef K::Line_2 Line_2;
typedef CGAL::Delaunay_triangulation_2<K>  Delaunay_triangulation_2;

//A class to recover Voronoi diagram from stream.
//Rays, lines and segments are cropped to a rectangle
//so that only segments are stored
struct Cropped_voronoi_from_delaunay{
  std::list<Segment_2> m_cropped_vd;
  Iso_rectangle_2 m_bbox;

  Cropped_voronoi_from_delaunay(const Iso_rectangle_2&
   bbox):m_bbox(bbox){}

  template <class RSL>
  void crop_and_extract_segment(const RSL& rsl){
    CGAL::Object obj = CGAL::intersection(rsl,m_bbox);
    const Segment_2* s=CGAL::object_cast<Segment_2>(&obj);
    if (s) m_cropped_vd.push_back(*s);
  }

  void operator<<(const Ray_2& ray)    { crop_and_extract_segment(ray); }
  void operator<<(const Line_2& line)  { crop_and_extract_segment(line);
   }
  void operator<<(const Segment_2& seg){ crop_and_extract_segment(seg); }
};

int main(){
  //consider some points
  std::vector<Point_2> points;
  points.push_back(Point_2(0,0));
  points.push_back(Point_2(1,1));
  points.push_back(Point_2(0,1));

  Delaunay_triangulation_2 dt2;
  //insert points into the triangulation
  dt2.insert(points.begin(),points.end());
  //construct a rectangle
  Iso_rectangle_2 bbox(-1,-1,2,2);
  Cropped_voronoi_from_delaunay vor(bbox);
  //extract the cropped Voronoi diagram
```

```
  dt2.draw_dual(vor);
  //print the cropped Voronoi diagram as segments
  std::copy(vor.m_cropped_vd.begin(),vor.m_cropped_vd.end(),
    std::ostream_iterator<Segment_2>(std::cout,"\n"));
}
```

File: examples/Triangulation_2/print_cropped_voronoi.cpp

37.6 Regular Triangulations

37.6.1 Description

Let $PW = \{(p_i, w_i) | i = 1, \ldots, n\}$ be a set of weighted points where each p_i is a point and each w_i is a scalar called the weight of point p_i. Alternatively, each weighted point (p_i, w_i) can be regarded as a sphere (or a circle, depending on the dimensionality of p_i) with center p_i and radius $r_i = \sqrt{w_i}$.

The power diagram of the set PW is a space partition in which each cell corresponds to a sphere (p_i, w_i) of PW and is the locus of points p whose power with respect to (p_i, w_i) is less than its power with respect to any other sphere in PW. In the two-dimensional space, the dual of this diagram is a triangulation whose domain covers the convex hull of the set $P = \{p_i | i = 1, \ldots, n\}$ of center points and whose vertices form a subset of P. Such a triangulation is called a regular triangulation. Three points p_i, p_j and p_k of P form a triangle in the regular triangulation of PW iff there is a point p of the plane with equal powers with respect to (p_i, w_i), (p_j, w_j) and (p_k, w_k) and such that this power is less than the power of p with respect to any other sphere in PW.

Let us defined the power product of two weighted points (p_i, w_i) and (p_j, w_j) as:

$$\Pi(p_i, w_i, p_j, w_j) = p_i p_j^2 - w_i - w_j.$$

$\Pi(p_i, w_i, p_j, 0)$ is simply the power of point p_j with respect to the sphere (p_i, w_i), and two weighted points are said to be orthogonal if their power product is null. The power circle of three weighted points (p_i, w_i), (p_j, w_j) and (p_k, w_k) is defined as the unique circle (π, ω) orthogonal to (p_i, w_i), (p_j, w_j) and (p_k, w_k).

The regular triangulation of the sets PW satisfies the following *regular property* (which just reduces to the Delaunay property when all the weights are null): a triangle $p_i p_j p_k$ is a face of the regular triangulation of PW iff the power product of any weighted point (p_l, w_l) of PW with the power circle of (p_i, w_i), (p_j, w_j) and (p_k, w_k) is positive or null. We call power test of (p_i, w_i), (p_j, w_j), (p_k, w_k), and (p_l, w_l), the predicates which amount to compute the sign of the power product of (p_l, w_l) with respect to the power circle of (p_i, w_i), (p_j, w_j) and (p_k, w_k). This predicate amounts to computing the sign of the following determinant

$$\begin{vmatrix} 1 & x_i & y_i & x_i^2 + y_i^2 - w_i \\ 1 & x_j & y_j & x_j^2 + y_j^2 - w_j \\ 1 & x_k & y_k & x_k^2 + y_k^2 - w_k \\ 1 & x_l & y_l & x_l^2 + y_l^2 - w_l \end{vmatrix}$$

A pair of neighboring faces $p_i p_j p_k$ and $p_i p_j p_l$ is said to be locally regular (with respect to the weights in PW) if the power test of (p_i, w_i), (p_j, w_j), (p_k, w_k), and (p_l, w_l) is positive. A classical result of computational geometry establishes that a triangulation of the convex hull of P such that any pair of neighboring faces is regular with respect to PW, is a regular triangulation of PW.

Alternatively, the regular triangulation of the weighted points set PW can be obtained as the projection on the two dimensional plane of the convex hull of the set of three dimensional points $P' = \{(p_i, p_i^2 - w_i) | i = 1, \ldots, n\}$.

The class *Regular_triangulation_2<Traits, Tds>* is designed to maintain the regular triangulation of a set of $2d$ weighted points. It derives from the class *Triangulation_2<Traits, Tds>*. The functions *insert* and *remove* are overwritten to handle weighted points and maintain the regular property. The function *move* is not overwritten and thus does not preserve the regular property. The vertices of the regular triangulation of a set of weighted points *PW* correspond only to a subset of *PW*. Some of the input weighted points have no cell in the dual power diagrams and therefore do not correspond to a vertex of the regular triangulation. Such a point is called a hidden point. Because hidden points can reappear later on as vertices when some other point is removed, they have to be stored somewhere. The regular triangulation store those points in special vertices, called hidden vertices. A hidden point can reappear as vertex of the triangulation only when the two dimensional face that hides it is removed from the triangulation. To deal with this feature, each face of a regular triangulation stores a list of hidden vertices. The points in those vertices are reinserted in the triangulation when the face is removed.

Regular triangulation have member functions to construct the vertices and edges of the dual power diagrams.

The Geometric Traits

The geometric traits of a regular triangulation must provide a weighted point type and a power test on these weighted points. The concept *RegularTriangulationTraits_2*, is a refinement of the concept *TriangulationTraits_2*. CGAL provides the class *Regular_triangulation_euclidean_traits_2<Rep,Weight>* which is a model for the traits concept *RegularTriangulationTraits_2*. The class *Regular_triangulation_euclidean_traits_2<Rep,Weight>* derives from the class *Triangulation_euclidean_traits_2<Rep>* and uses a *Weighted_point* type derived from the type *Point_2* of *Triangulation_euclidean_traits_2<Rep>*.

Note that, since the type *Weighted_point* is not defined in CGAL kernels, plugging a filtered kernel such as *Exact_predicates_exact_constructions_kernel* in *Regular_triangulation_euclidean_traits_2<K,Weight>* will in fact not provide exact predicates on weighted points. To solve this, there is also another model of the traits concept, *Regular_triangulation_filtered_traits_2<FK>*, which is providing filtered predicates (exact and efficient). The argument *FK* must be a model of the *Kernel* concept, and it is also restricted to be a instance of the *Filtered_kernel* template.

The Vertex Type and Face Type of a Regular Triangulation

The base vertex type of a regular triangulation includes a Boolean data member to mark the hidden state of the vertex. Therefore CGAL defines the concept *RegularTriangulationVertexBase_2* which refine the concept *TriangulationVertexBase_2* and provides a default model for this concept.

The base face type of a regular triangulation is required to provide a list of hidden vertices, designed to store the points hidden by the face. It has to be a model of the concept *RegularTriangulationFaceBase_2*. CGAL provides the templated class *Regular_triangulation_face_base_2<Traits>* as a default base class for faces of regular triangulations.

37.6.2 Example: a Regular Triangulation

The following code creates a regular triangulation of a set of weighted points and output the number of vertices and the number of hidden vertices.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Regular_triangulation_euclidean_traits_2.h>
#include <CGAL/Regular_triangulation_filtered_traits_2.h>
#include <CGAL/Regular_triangulation_2.h>
```

```
#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Regular_triangulation_filtered_traits_2<K>  Traits;
typedef CGAL::Regular_triangulation_2<Traits> Regular_triangulation;

int main()
{
   Regular_triangulation rt;
   std::ifstream in("data/regular.cin");

   Regular_triangulation::Weighted_point wp;
   int count = 0;
   while(in >> wp){
       count++;
     rt.insert(wp);
   }
   rt.is_valid();
   std::cout << "number of inserted points : " << count << std::endl;
   std::cout << "number of vertices :  " ;
   std::cout << rt.number_of_vertices() << std::endl;
   std::cout << "number of hidden vertices :  " ;
   std::cout << rt.number_of_hidden_vertices() << std::endl;
   return 0;
}
```

File: examples/Triangulation_2/regular.cpp

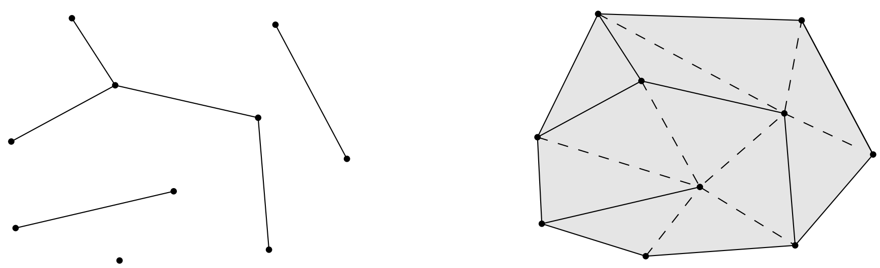
37.7 Constrained Triangulations

A constrained triangulation is a triangulation of a set of points that has to include among its edges a given set of segments joining the points. The corresponding edges are called *constrained edges*.

The endpoints of constrained edges are of course vertices of the triangulation. However the triangulation may include include other vertices as well. There are three versions of constrained triangulations.

- In the basic version, the constrained triangulation does not handle intersecting constraints, and the set of input constraints is required to be a set of segments that do not intersect except possibly at their endpoints. Any number of constrained edges are allowed to share the same endpoint. Vertical constrained edges or constrained edges with null length are allowed.
- The two other versions support intersecting input constraints. In those versions, input constraints are allowed to be intersecting, overlapping or partially overlapping segments. The triangulation introduces additional vertices at each point that is the proper intersection points of two constraints. A single constraint intersecting other constraints will then appear as several edges in the triangulation. The two versions dealing with intersecting constraints differ in the way intersecting constraints are dealt with.
  - One of them is designed to be robust when predicates are evaluated exactly but constructions (i. e. intersection computations) are approximate.

– The other one is designed to be used with exact arithmetic (meaning exact evaluation of predicates and exact computation of intersections.) This last version finds its full efficiency when used in conjunction with a constraint hierarchy data structure (which allows one to avoid the cascading of intersection computations) as provided in the class *Constrained_triangulation_plus_2*. See section 37.9.



A constrained triangulation is represented in the CGAL library as an object of the class *Constrained_triangulation_2<Traits,Tds,Itag>*. The third parameter *Itag* is the intersection tag which serves to choose how intersecting constraints are dealt with. This parameter has to be instantiated by one of the following classes :
CGAL::No_intersection_tag when input constraints do not intersect
CGAL::Exact_predicates_tag if the geometric traits provides exact predicates but approximate constructions
CGAL::Exact_intersections_tag when an exact predicates and exact constructions are provided.

The class *Constrained_triangulation_2<Traits,Tds, Itag>* inherits from *Triangulation_2<Traits,Tds>*. It defines an additional type *Constraint* to represent the constraints. A constraint is represented as a pair of points.

A constrained triangulation can be created from a list of constrained edges. The class *Constrained_triangulation_2<Traits,Tds,Itag>* overrides the insertion and removal of a point to take care of the information about constrained edges. The class also allows inline insertion of a new constraint, given by its two endpoints or the removal of a constraint. In current version, function *move* is not overwritten and thus does not take care of the constraints.

The Geometric Traits

The geometric traits of a constraint triangulation has to be a model of the concept *TriangulationTraits_2*. When intersections of input constraints are supported, the geometric traits class has to be a model of the concept *ConstrainedTriangulationTraits_2* which refines the concept *TriangulationTraits_2* providing additional function object types to compute the intersection of two segments.

The Base Face of a Constrained Triangulation

The information about constrained edges is stored in the faces of the triangulation. The base face of a Constrained Triangulation has to be a model for the concept *ConstrainedTriangulationFaceBase_2* which refines the concept *TriangulationFaceBase_2*. The concept *ConstrainedTriangulationFaceBase_2* requires member functions the get and set the constrained status of the edges.

CGAL provides a default base face class for constrained triangulations. This class, named *Constrained_triangulation_face_base_2<Traits>*, derives from the class *Triangulation_face_base_2<Traits>* and adds three Boolean data members to store the status of its edges.

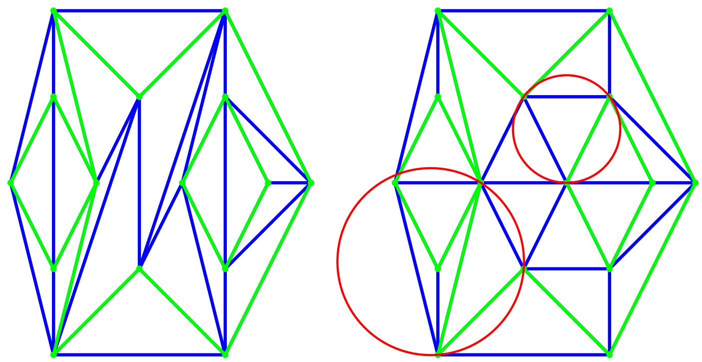


Figure 37.7: Constrained and Constrained Delaunay triangulation: the constraining edges are the green edges, a constrained triangulation is shown on the left, the constrained Delaunay triangulation with two examples of circumcircles is shown on the right.

37.8 Constrained Delaunay Triangulations

A constrained Delaunay triangulation is a triangulation with constrained edges which tries to be as much Delaunay as possible. As constrained edges are not necessarily Delaunay edges, the triangles of a constrained Delaunay triangulation do not necessarily fulfill the empty circle property but they fulfill a weaker *constrained empty circle property*. To state this property, it is convenient to think of constrained edges as blocking the view. Then, a triangulation is constrained Delaunay iff the circumscribing circle of any facet encloses no vertex visible from the interior of the facet. As in the case of constrained triangulations, three different versions of Delaunay constrained triangulations are provided. The first version handle set of constraints which do not intersect except possibly at the endpoints. The two other versions handle intersecting input constraints. One of them is designed to be designed to be robust when used in conjunction with a geometric traits providing exact predicates and approximate constructions (such as a *CGAL::Filtered_Kernel* or any kernel providing filtered exact predicates). The third version is designed to be used with an exact arithmetic number type.

The CGAL class *Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>* is designed to represent constrained Delaunay triangulations.

As in the case of constraints triangulation, the third parameter *Itag* is the intersection tag and serves to choose how intersecting constraints are dealt with. It can be instantiated with one of the following class : *CGAL::No_intersection_tag*, *CGAL::Exact_predicates_tag*, *CGAL::Exact_intersections_tag* (see Section 37.7.

A constrained Delaunay triangulation is not a Delaunay triangulation but it is a constrained triangulation. Therefore the class *Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>* derives from the class *Constrained_triangulation_2<Traits,Tds,Itag>*.

The constrained Delaunay triangulation has member functions to override the insertion and removal of a point or of a constraint. Each of those member function takes care to restore the constrained empty circle property.

The Geometric Traits

The geometric traits of a constrained Delaunay triangulation is required to provide the *side_of_oriented_circle* predicate as the geometric traits of a Delaunay triangulation and has to a model of the concept *DelaunayTriangulationTraits_2*. When intersecting input constraints are supported the geometric traits is further required to provide function objects to compute constraints intersections. Then the geometric traits has to be at the same time a model of the concept *ConstrainedTriangulationTraits_2*.

The Face Base Class

Information about the status (constrained or not) of the edges of the triangulation has to be stored in the face class and the base face class of a constrained Delaunay triangulation has to be a model of *ConstrainedTriangulationFaceBase_2*.

37.8.1 Example: a Constrained Delaunay Triangulation

The following code inserts a set of intersecting constraint segments into a triangulation and counts the number of constrained edges of the resulting triangulation.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>

#include <cassert>
#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_vertex_base_2<K>                     Vb;
typedef CGAL::Constrained_triangulation_face_base_2<K>           Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb>              TDS;
typedef CGAL::Exact_predicates_tag                               Itag;
typedef CGAL::Constrained_Delaunay_triangulation_2<K, TDS, Itag> CDT;
typedef CDT::Point          Point;

int
main( )
{
  CDT cdt;
  std::cout << "Inserting a grid of 5x5 constraints " << std::endl;
  for (int i = 1; i < 6; ++i)
    cdt.insert_constraint( Point(0,i), Point(6,i));
  for (int j = 1; j < 6; ++j)
    cdt.insert_constraint( Point(j,0), Point(j,6));

  assert(cdt.is_valid());
  int count = 0;
  for (CDT::Finite_edges_iterator eit = cdt.finite_edges_begin();
       eit != cdt.finite_edges_end();
       ++eit)
    if (cdt.is_constrained(*eit)) ++count;
  std::cout << "The number of resulting constrained edges is  ";
  std::cout <<  count << std::endl;
  return 0;
}
```

37.8.2 Example: Triangulating a Polygonal Domain

The following code inserts two nested polygons into a constrained Delaunay triangulation and counts the number of facets that are inside the domain delimited by these polygons. Note that the following code does not work if the boundaries of the polygons intersect.

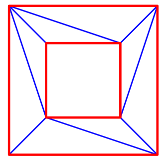

Figure 37.8: Triangulation (in blue) of the domain delimited by the red polygons.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_face_base_with_info_2.h>
#include <CGAL/Polygon_2.h>
#include <iostream>

struct FaceInfo2
{
  FaceInfo2(){}
  int nesting_level;

  bool in_domain(){
    return nesting_level%2 == 1;
  }
};

typedef CGAL::Exact_predicates_inexact_constructions_kernel       K;
typedef CGAL::Triangulation_vertex_base_2<K>                      Vb;
typedef CGAL::Triangulation_face_base_with_info_2<FaceInfo2,K>    Fbb;
typedef CGAL::Constrained_triangulation_face_base_2<K,Fbb>        Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb>               TDS;
typedef CGAL::Exact_predicates_tag                                Itag;
typedef CGAL::Constrained_Delaunay_triangulation_2<K, TDS, Itag>  CDT;
typedef CDT::Point                                                Point;
typedef CGAL::Polygon_2<K>
   Polygon_2;

void
mark_domains(CDT& ct,
             CDT::Face_handle start,
             int index,
             std::list<CDT::Edge>& border )

37.9 Constrained Triangulations Plus

The class *Constrained_triangulation_plus_2<Tr>* provides a constrained triangulation with an additional data structure called the constraint hierarchy that keeps track of the input constraints and of their refinement in the triangulation. The class *Constrained_triangulation_plus_2<Tr>* inherits from its template parameter Tr, which has to be instantiated by a constrained or constrained Delaunay triangulation. According to its intersection tag, the base class will support intersecting input constraints or not. When intersections of input constraints are supported, the base class constructs a triangulation of the arrangement of the constraints, introducing new vertices at each proper intersection points and refining the input constraints into sub-constraints which appear as edges (more precisely as constrained edges) of the triangulation. The data structure maintains for each input constraint the sequence of intersection vertices added on this constraint. The constraint hierarchy also allows the user to retrieve the set of constrained edges of the triangulation, and for each constrained edge, the set of input constraints that overlap it.

The class *Constrained_triangulation_plus_2<Tr>* is especially useful when the base constrained triangulation class handles intersections of constraints and uses an exact number type, i.e. when its intersection tag is *CGAL::Exact_intersections_tag*. Indeed in this case, the *Constrained_triangulation_plus_2<Tr>* is specially designed to avoid cascading in the computations of intersection points.

37.9.1 Example: Building a Triangulated Arrangement of Segments

The following code inserts a set of intersecting constraint segments into a triangulation and counts the number of constrained edges of the resulting triangulation.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/intersections.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Constrained_triangulation_plus_2.h>

#include <cassert>
#include <iostream>

typedef CGAL::Exact_predicates_exact_constructions_kernel K;

typedef CGAL::Triangulation_vertex_base_2<K>              Vb;
typedef CGAL::Constrained_triangulation_face_base_2<K>    Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb>       TDS;
typedef CGAL::Exact_intersections_tag                     Itag;
typedef CGAL::Constrained_Delaunay_triangulation_2<K,TDS,Itag> CDT;
typedef CGAL::Constrained_triangulation_plus_2<CDT>       CDTplus;
typedef CDTplus::Point                                    Point;

int
main( )
{
  CDTplus cdt;
  std::cout  << "Inserting a grid 5 x 5 of constraints " << std::endl;
  for (int i = 1; i < 6; ++i)
    cdt.insert_constraint( Point(0,i), Point(6,i));
  for (int j = 1; j < 6; ++j)
    cdt.insert_constraint( Point(j,0), Point(j,6));

  assert(cdt.is_valid());
  int count = 0;
  for (CDTplus::Subconstraint_iterator scit = cdt.subconstraints_begin();
       scit != cdt.subconstraints_end();
       ++scit)  ++count;
  std::cout << "The number of resulting constrained edges is  "
            <<  count << std::endl;
  return 0;
}
```

File: examples/Triangulation_2/constrained_plus.cpp

37.10 The Triangulation Hierarchy

The class *Triangulation_hierarchy_2<Tr>* implements a triangulation augmented with a data structure to answer efficiently point location queries. The data structure is a hierarchy of triangulations. The triangulation at the lowest level is the original triangulation where operations and point location are to be performed. Then at each succeeding level, the data structure stores a triangulation of a small random sample of the vertices of the triangulation at the preceding level. Point location is done through a top down nearest neighbor query. The nearest neighbor query is first performed naively in the top level triangulation. Then, at each following level, the nearest neighbor at that level is found through a linear walk performed from the nearest neighbor found at the preceding level. Because the number of vertices in each triangulation is only a small fraction of the number of vertices of the preceding triangulation, the data structure remains small and achieves fast point location queries on real data. As proved in [Dev98], this structure has an optimal behavior when it is built for Delaunay triangulations. However it can be used as well for other triangulations and the class *Triangulation_hierarchy_2<Tr>* is templated by a parameter which is to be instantiated by one of the CGAL triangulation classes.

The class *Triangulation_hierarchy_2<Tr>* inherits from the triangulation type passed as template parameter *Tr*. The *insert*, *move*, and *remove* member functions are overwritten to update the data structure at each operation. The locate queries are also overwritten to take advantage of the data structure for a fast processing.

The Vertex of a Triangulation Hierarchy

The base vertex class of a triangulation hierarchy has to be a model of the concept *TriangulationHierarchyVertexBase_2* which extends the concept *TriangulationVertexBase_2*. This extension adds access and setting member functions for two pointers to the corresponding vertices in the triangulations of the next and preceding levels.

CGAL provides the class *Triangulation_hierarchy_vertex_base_2<Vb>* which is a model for the concept *TriangulationHierarchyVertexBase_2*. This class is templated by a parameter *Vb* which is to be instantiated by a model of the concept *TriangulationVertexBase_2*. The class *Triangulation_hierarchy_vertex_base_2<Vb>* inherits from its template parameter *Vb*. This design allows to use for *Vb* either the default vertex class or a user customized vertex class with additional functionalities.

37.10.1 Examples For the Use of a Triangulation Hierarchy

The following program is example for the standard use of a triangulation hierarchy to enhance the efficiency of a Delaunay triangulation. The program outputs the number of vertices at the different levels of the hierarchy.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_hierarchy_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/algorithm.h>
#include <cassert>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_vertex_base_2<K>              Vbb;
```

```
typedef CGAL::Triangulation_hierarchy_vertex_base_2<Vbb> Vb;
typedef CGAL::Triangulation_face_base_2<K>               Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb>      Tds;
typedef CGAL::Delaunay_triangulation_2<K,Tds>            Dt;
typedef CGAL::Triangulation_hierarchy_2<Dt>              Triangulation;
typedef Triangulation::Point                             Point;
typedef CGAL::Creator_uniform_2<double,Point>            Creator;

int main( )
{
  std::cout << "insertion of 1000 random points" << std::endl;
  Triangulation t;
  CGAL::Random_points_in_square_2<Point,Creator> g(1.);
  CGAL::cpp0x::copy_n( g, 1000, std::back_inserter(t));

  //verbose mode of is_valid ; shows the number of vertices at each
   level
  std::cout << "The number of vertices at successive levels" <<
   std::endl;
  assert(t.is_valid(true));

  return 0;
}
```

File: examples/Triangulation_2/hierarchy.cpp

The following program shows how to use a triangulation hierarchy in conjunction with a constrained triangulation plus.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_hierarchy_2.h>
#include <CGAL/Constrained_triangulation_plus_2.h>

#include <cassert>
#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_vertex_base_2<K>             Vbb;
typedef CGAL::Triangulation_hierarchy_vertex_base_2<Vbb> Vb;
typedef CGAL::Constrained_triangulation_face_base_2<K>   Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb>      TDS;
typedef CGAL::Exact_predicates_tag                       Itag;
typedef CGAL::Constrained_Delaunay_triangulation_2<K,TDS,Itag> CDT;
typedef CGAL::Triangulation_hierarchy_2<CDT>             CDTH;
typedef CGAL::Constrained_triangulation_plus_2<CDTH>     Triangulation;

typedef Triangulation::Point                             Point;

int
main( )
{
```

```
  Triangulation cdt;
  std::cout << "Inserting a grid 5 x 5 of  constraints " << std::endl;
    for (int i = 1; i < 6; ++i)
    cdt.insert_constraint( Point(0,i), Point(6,i));
    for (int j = 1; j < 6; ++j)
    cdt.insert_constraint( Point(j,0), Point(j,6));

  int count = 0;
  for (Triangulation::Subconstraint_iterator scit =
    cdt.subconstraints_begin();
        scit != cdt.subconstraints_end();
        ++scit)  ++count;
  std::cout << "The number of resulting constrained edges is  ";
  std::cout <<  count << std::endl;

  //verbose mode of is_valid ; shows the number of vertices at each
    level
  std::cout << "The number of vertices at successive levels" <<
    std::endl;
  assert(cdt.is_valid(true));

  return 0;
}
```

File: examples/Triangulation_2/constrained_hierarchy_plus.cpp

37.11 Flexibility

37.11.1 Using Customized Vertices and Faces

To be able to adapt to various needs, a highly flexible design has been selected for 2D triangulations. We have already seen that the triangulation classes have two parameters: a geometric traits class and a triangulation data structure class which the user can instantiate with his own customized classes.

The most useful flexibility however comes from the fact that the triangulation data structure itself has two template parameters to be instantiated by classes for the vertices and faces of the triangulation. Using his own customized classes to instantiate these parameters, the user can easily build up a triangulation with additional information or functionality in the vertices and faces.

A Cyclic Dependency

To insure flexibility, the triangulation data structure is templated by the vertex and face base classes. Also since incidence and adjacency relations are stored in vertices and faces, the base classes have to know the types of handles on vertices and faces provided by the triangulation data structure. Thus the vertex and base classes have to be themselves parameterized by the triangulation data structure, and there is a cyclic dependency on template parameter.

Previously, this cyclic dependency was avoided by using only *void** pointers in the interface of base classes. These *void** were converted to appropriate types at the triangulation data structure levels. This solution had

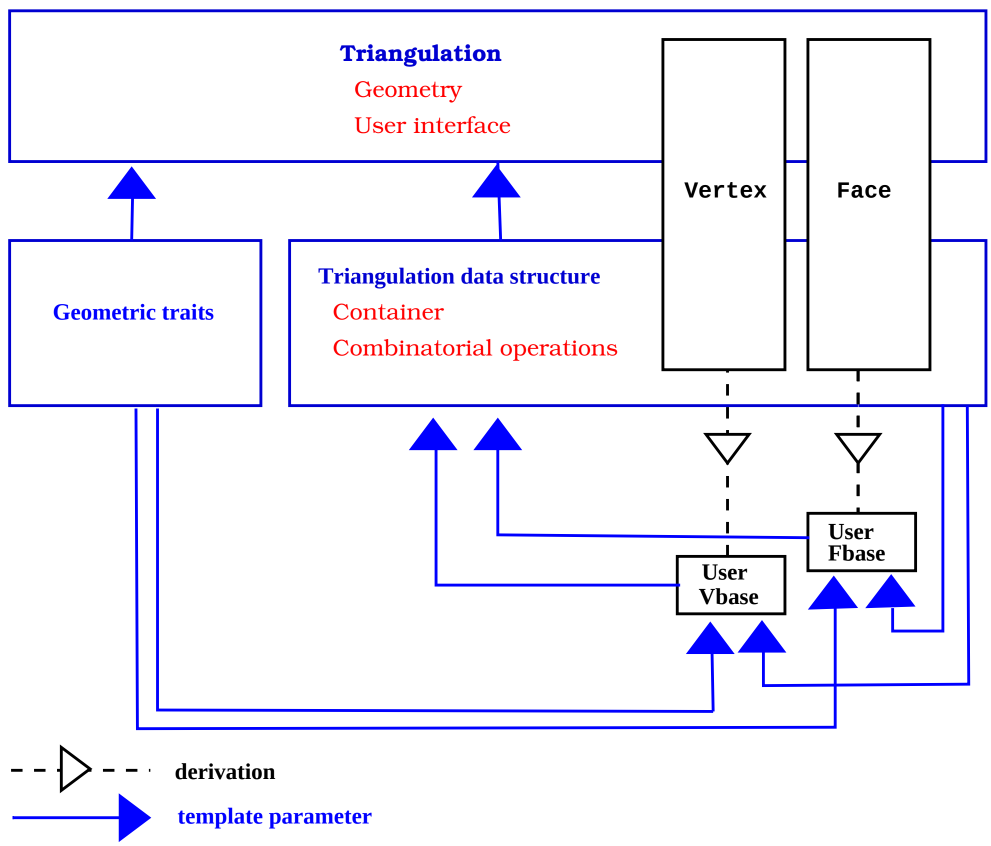

Figure 37.9: The cyclic dependency in triangulations software design.

some drawbacks : mainly the user could not add in the vertices or faces of the triangulation a functionality related to types defined by the triangulation data structure, for instance a handle to a vertex, and he was lead to use himself *void** pointers). The new solution to resolve the template dependency is based on a rebind mechanism similar to the mechanism used in the standard allocator class std::allocator. The rebind mechanism is described in Section 38.3 of Chapter 38. For now, we will just notice that the design requires the existence in the vertex and face base classes of a nested template class *Rebind_TDS* defining a type *Other* used by the rebinding mechanism.

The two following examples show how the user can put in use the flexibility offered by the base classes parameters.

Adding Colors

The first example corresponds to a case where the user wishes to add in the vertices or faces of the triangulation an additional information that does not depend on types provided by the triangulation data structure. In that case, predefined classes *Triangulation_vertex_base_with_info_2<Info,Traits,Vb>* or *Triangulation_face_base_with_info_2<Info,Traits,Vb>* can be used. Those classes have a template parameter *Info* devoted to handle additional information. The following examples shows how to add a *CGAL::Color* in the triangulation faces.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/IO/Color.h>
#include <CGAL/Triangulation_2.h>
#include <CGAL/Triangulation_face_base_with_info_2.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Triangulation_face_base_with_info_2<CGAL::Color,K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb> Tds;
typedef CGAL::Triangulation_2<K,Tds> Triangulation;

typedef Triangulation::Face_handle Face_handle;
typedef Triangulation::Finite_faces_iterator Finite_faces_iterator;
typedef Triangulation::Point  Point;

int main() {
  Triangulation t;
  t.insert(Point(0,1));
  t.insert(Point(0,0));
  t.insert(Point(2,0));
  t.insert(Point(2,2));

  Finite_faces_iterator fc = t.finite_faces_begin();
  for( ; fc != t.finite_faces_end(); ++fc)  fc->info() = CGAL::BLUE;

  Point p(0.5,0.5);
  Face_handle fh = t.locate(p);
  fh->info() = CGAL::RED;

  return 0;
}
```

File: examples/Triangulation_2/colored_face.cpp

Adding Handles

The second example shows how the user can still derive and plug in his own vertex or face class when he would like to have additional functionalities depending on types provided by the triangulation data structure.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_2.h>
#include <cassert>

/* A vertex class with an additionnal handle */
template < class Gt, class Vb = CGAL::Triangulation_vertex_base_2<Gt> >
class My_vertex_base
  : public  Vb
{
  typedef Vb                                   Base;
public:
  typedef typename Vb::Vertex_handle           Vertex_handle;
  typedef typename Vb::Face_handle             Face_handle;
  typedef typename Vb::Point                   Point;

  template < typename TDS2 >
  struct Rebind_TDS {
    typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
    typedef My_vertex_base<Gt,Vb2>                           Other;
  };

private:
  Vertex_handle  va_;

public:
  My_vertex_base() : Base() {}
  My_vertex_base(const Point & p) : Base(p) {}
  My_vertex_base(const Point & p, Face_handle f) : Base(f,p) {}
  My_vertex_base(Face_handle f) : Base(f) {}

  void set_associated_vertex(Vertex_handle va) { va_ = va;}
  Vertex_handle get_associated_vertex() {return va_ ; }
};

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef My_vertex_base<K> Vb;
typedef CGAL::Triangulation_data_structure_2<Vb> Tds;
typedef CGAL::Triangulation_2<K,Tds> Triangulation;

typedef Triangulation::Vertex_handle Vertex_handle;
typedef Triangulation::Finite_faces_iterator Finite_faces_iterator;
typedef Triangulation::Point   Point;

int main() {
  Triangulation t;
  Vertex_handle v0 = t.insert(Point(0,1));
  Vertex_handle v1 = t.insert(Point(0,0));
  Vertex_handle v2 = t.insert(Point(2,0));
```

```
  Vertex_handle v3 = t.insert(Point(2,2));

  // associate vertices as you like
  v0->set_associated_vertex(v1);
  v1->set_associated_vertex(v2);
  v2->set_associated_vertex(v3);
  v3->set_associated_vertex(v0);
  assert( v0->get_associated_vertex() == v1);

  return 0;
}
```

File: examples/Triangulation_2/adding_handles.cpp

37.11.2 Setting Information While Inserting a Range of Points

The most efficient method to insert (weighted) points in a Delaunay (or regular) triangulation is to provide an iterator range over (weighted) points to the insert function. However, an iterator range of (weighted) points does not allow to set different information to each vertex. To solve this problem, in the case the vertex type of the triangulation is a model of the concept *TriangulationVertexBaseWithInfo_2* (such as *Triangulation_vertex_base_with_info_2*), we provide three examples doing the same operation: set an unsigned integer as the information of each vertex. The value of this unsigned integer is the initial order of the corresponding point given in the range.

Using an Iterator Over Pairs

Each point and its information are gathered into a pair. We provide the *insert* function of the triangulation with a range of such pairs.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_vertex_base_with_info_2.h>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel         K;
typedef CGAL::Triangulation_vertex_base_with_info_2<unsigned, K>    Vb;
typedef CGAL::Triangulation_data_structure_2<Vb>                    Tds;
typedef CGAL::Delaunay_triangulation_2<K, Tds>
   Delaunay;
typedef Delaunay::Point
   Point;

int main()
{
  std::vector< std::pair<Point,unsigned> > points;
  points.push_back( std::make_pair(Point(0,0),0)   );
  points.push_back( std::make_pair(Point(1,0),1)   );
  points.push_back( std::make_pair(Point(0,1),2)   );
  points.push_back( std::make_pair(Point(14,4),3)  );
  points.push_back( std::make_pair(Point(2,2),4)   );
  points.push_back( std::make_pair(Point(-4,0),5)  );
```

```
  Delaunay T;
  T.insert( points.begin(),points.end() );

  CGAL_assertion( T.number_of_vertices() == 6 );

  // check that the info was correctly set.
  Delaunay::Finite_vertices_iterator vit;
  for (vit = T.finite_vertices_begin(); vit != T.finite_vertices_end();
   ++vit)
    if( points[ vit->info() ].first != vit->point() ){
      std::cerr << "Error different info" << std::endl;
      exit(EXIT_FAILURE);
    }
  std::cout << "OK" << std::endl;

  return 0;
}
```

Using the Boost Zip Iterator

Information and points are in separate containers. We use *boost::zip_iterator* to provide an iterator gathering them.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_vertex_base_with_info_2.h>
#include <boost/iterator/zip_iterator.hpp>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel         K;
typedef CGAL::Triangulation_vertex_base_with_info_2<unsigned, K>    Vb;
typedef CGAL::Triangulation_data_structure_2<Vb>                    Tds;
typedef CGAL::Delaunay_triangulation_2<K, Tds>
   Delaunay;
typedef Delaunay::Point
   Point;

int main()
{

  std::vector<unsigned> indices;
  indices.push_back(0);
  indices.push_back(1);
  indices.push_back(2);
  indices.push_back(3);
  indices.push_back(4);
  indices.push_back(5);
```

```
  std::vector<Point> points;
  points.push_back(Point(0,0));
  points.push_back(Point(1,0));
  points.push_back(Point(0,1));
  points.push_back(Point(1,47));
  points.push_back(Point(2,2));
  points.push_back(Point(-1,0));

  Delaunay T;
  T.insert( boost::make_zip_iterator(boost::make_tuple(
   points.begin(),indices.begin() )),
             boost::make_zip_iterator(boost::make_tuple(
   points.end(),indices.end() ) )  );

  CGAL_assertion( T.number_of_vertices() == 6 );

  // check that the info was correctly set.
  Delaunay::Finite_vertices_iterator vit;
  for (vit = T.finite_vertices_begin(); vit != T.finite_vertices_end();
   ++vit)
    if( points[ vit->info() ] != vit->point() ){
      std::cerr << "Error different info" << std::endl;
      exit(EXIT_FAILURE);
    }

  return 0;
}
```

File: examples/Triangulation_2/info_insert_with_zip_iterator_2.cpp

Using the Boost Transform Iterator

We define a functor *Auto_count* used together with *boost::transform_iterator* to set the order of each point in the range. Note that this is correct because the iterator is dereferenced only once per point during the insertion.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_vertex_base_with_info_2.h>
#include <boost/iterator/transform_iterator.hpp>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel         K;
typedef CGAL::Triangulation_vertex_base_with_info_2<unsigned, K>    Vb;
typedef CGAL::Triangulation_data_structure_2<Vb>                    Tds;
typedef CGAL::Delaunay_triangulation_2<K, Tds>
   Delaunay;
typedef Delaunay::Point
   Point;
```

```
//a functor that returns a std::pair<Point,unsigned>.
//the unsigned integer is incremented at each call to
//operator()
struct Auto_count : public std::unary_function<const
    Point&,std::pair<Point,unsigned> >{
  mutable unsigned i;
  Auto_count() : i(0){}
  std::pair<Point,unsigned> operator()(const Point& p) const {
    return std::make_pair(p,i++);
  }
};

int main()
{
  std::vector<Point> points;
  points.push_back(Point(0,0));
  points.push_back(Point(1,0));
  points.push_back(Point(0,1));
  points.push_back(Point(4,10));
  points.push_back(Point(2,2));
  points.push_back(Point(-1,0));

  Delaunay T;
  T.insert( boost::make_transform_iterator(points.begin(),Auto_count()),
            boost::make_transform_iterator(points.end(),  Auto_count() )
    );

  CGAL_assertion( T.number_of_vertices() == 6 );

  // check that the info was correctly set.
  Delaunay::Finite_vertices_iterator vit;
  for (vit = T.finite_vertices_begin(); vit != T.finite_vertices_end();
    ++vit)
    if( points[ vit->info() ] != vit->point() ){
      std::cerr << "Error different info" << std::endl;
      exit(EXIT_FAILURE);
    }
  std::cout << "OK" << std::endl;

  return 0;
}
```

37.12 Design and Implementation History

The code of this package is the result of a long development process. Here follows a tentative list of people who added their stone to this package : Jean-Daniel Boissonnat, Hervé Brönnimann, Olivier Devillers, Andreas Fabri, Frédéric Fichel, Julia Flötotto, Monique Teillaud and Mariette Yvinec.

2D Triangulations Reference Manual

Mariette Yvinec

A triangulation is a 2-dimensional simplicial complex which is pure connected and without singularities. Thus a triangulation can be viewed as a collection of triangular faces, such that two faces either have an empty intersection or share an edge or a vertex.

The basic elements of the representation are vertices and faces. Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces. The edges are not explicitly represented, they are only represented through the adjacency relations of two faces.

The triangulation classes of CGAL depend on two template parameters. The first template parameter stands for a geometric traits class which is assumed to provide the geometric objects (points, segments and triangles) forming the triangulation and the geometric predicates on those objects. The second template parameter stands for a model of triangulation data structure acting as a container for faces and vertices while taking care of the combinatorial aspects of the triangulation. The concepts and models relative to the triangulation data structure are described in Chapter 38.3.4.

Concept

ConstrainedDelaunayTriangulationTraits_2

Definition

The concept ConstrainedDelaunayTriangulationTraits_2 defines the requirements for the geometric traits class of a constrained Delaunay triangulation that supports intersections of input constraints. This is the case when the template parameter *Itag* of (*Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>*) is instantiated by one of the tag classes *Exact_intersections_tag* or *Exact_predicates_tag*). The concept ConstrainedDelaunayTriangulationTraits_2 refines both the concept *DelaunayTriangulationTraits_2* and the concept *ConstrainedTriangulationTraits_2*.

ConstrainedTriangulationFaceBase_2

Concept

Definition

In a constrained triangulation, the information about constrained edges is stored in the faces of the triangulation. The base face of a constrained triangulation has to be a model of the concept ConstrainedTriangulationFaceBase_2 which refines the concept *TriangulationFaceBase_2* providing functionalities to deal with constraints.

Refines

TriangulationFaceBase_2

Types

Defines the same types as the *TriangulationFaceBase_2* concept

Access Functions

bool *f.is_constrained(int i)*

returns true if the edge between f and its neighbor *f.neighbor(i)* is constrained. *Precondition*: $0 \leq i \leq 2$.

advanced

Modifiers

void *f.set_constraint(int i, bool b)*

sets the edge between f and its neighbor *f.neighbor(i)* as a constrained or unconstrained edge according to b.

void *f.set_constraints(bool c0, bool c1, bool c2)*

sets the status (constrained or unconstrained) of the three edges of f.

void	*f.reorient()*	Changes the orientation of f by exchanging *vertex(0)* with *vertex(1)* and *neighbor(0)* with *neighbor(1)* and the corresponding constrained status.
void	*f.ccw_permute()*	performs a counterclockwise permutation of the vertices, neighbors and constrained status of f.
void	*f.cw_permute()*	performs a clockwise permutation of the vertices and neighbors and constrained status of f.

Miscellaneous

bool	*f.is_valid()*	tests the validity of face f as a face of a plain triangulation and additionally checks if the edges of f are consistently marked as constrained or unconstrained edges in face f and its neighbors.

ConstrainedTriangulationTraits_2

Concept

Definition

The concept ConstrainedTriangulationTraits_2 defines the requirements for the geometric traits class of a constrained triangulation (*Constrained_Triangulation_2<Traits,Tds,Itag>*) that supports intersections of input constraints (i. e. when the template parameter *Itag* is instantiated by one of the tag classes *Exact_intersections_tag* or *Exact_predicates_tag*). This concept refines the concept *TriangulationTraits_2*, adding requirements for function objects to compute the intersection points of two constraints. When *Exact_predicates_tag* is used, the traits class is also required to provide additional types to compute the squared distance between a point and a line

Refines

TriangulationTraits_2

Types

ConstrainedTriangulationTraits_2:: Intersect_2

A function object whose operator() computes the intersection of two segments :
Object_2 operator()(Segment_2 s1, Segment_2 s2); Returns the intersection of *s1* and *s2*.

When the constrained triangulation is instantiated with the intersection tag *Exact_predicates_tag*, the used algorithm needs to be able to compare some distances between points and lines and the following types are further required.

ConstrainedTriangulationTraits_2:: RT A number type supporting the comparison operator <.

ConstrainedTriangulationTraits_2:: Line_2 The line type.

ConstrainedTriangulationTraits_2:: Construct_line_2

A function object whose operator() constructs a line from two points :
Line_2 operator()(Point_2 p1, Point_2 p2).

ConstrainedTriangulationTraits_2:: Compute_squared_distance_2

A function object with an operator() designed to compute the squared distance between a line and a point :
RT operator()(Line_2 l, Point_2 p); Return the squared distance between *p* and *l*.

Access to constructor object

Intersect_2 *traits.intersect_2_object()*

Construct_line_2 *traits.construct_line_2_object()*

required when the intersection tag is *Exact_predicates_tag*.

Compute_squared_distance_2

traits.compute_squared_distance_2_object()

required when the intersection tag is *Exact_predicates_tag*.

CGAL::Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>

Definition

A constrained Delaunay triangulation is a triangulation with constrained edges which tries to be as much Delaunay as possible. Constrained edges are not necessarily Delaunay edges, therefore a constrained Delaunay triangulation is not a Delaunay triangulation. A constrained Delaunay is a triangulation whose faces do not necessarily fulfill the empty circle property but fulfill a weaker property called the *constrained empty circle*. To state this property, it is convenient to think of constrained edges as blocking the view. Then, a triangulation is constrained Delaunay if the circumscribing circle of any of its triangular faces includes in its interior no vertex that is visible from the interior of the triangle. The class *Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>* is designed to represent constrained Delaunay triangulations.

As in the case of constrained triangulations, three different versions of Delaunay constrained triangulations are offered depending on whether the user wishes to handle intersecting input constraints or not. The desired version can be selected through the instantiation of the third template parameter *Itag* which can be one of the following :
CGAL::No_intersection_tag if intersections of input constraints are disallowed,
CGAL::Exact_predicates_tag allows intersections between input constraints and is to be used when the traits class provides exact predicates but approximate constructions of the intersection points,
CGAL::Exact_intersections_tag allows intersections between input constraints and is to be used in conjunction with an exact arithmetic type.

The template parameters *Tds* has to be instantiate with a model of *TriangulationDataStructure_2*. The geometric traits of a constrained Delaunay triangulation is required to provide the *side_of_oriented_circle* test as the geometric traits of a Delaunay triangulation and the *Traits* parameter has to be instantiated with a model *DelaunayTriangulationTraits_2*. When intersection of input constraints are supported, the geometric traits class is required to provide additional function object types to compute the intersection of two segments. and has then to be also a model of the concept *ConstrainedTriangulationTraits_2*.

A constrained Delaunay triangulation is not a Delaunay triangulation but it is a constrained triangulation. Therefore the class *Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>* derives from the class *Constrained_triangulation_2<Traits,Tds>*. Also, information about the status (constrained or not) of the edges of the triangulation is stored in the faces. Thus the nested *Face* type of a constrained triangulation offers additional functionalities to deal with this information. These additional functionalities induce additional requirements on the base face class plugged into the triangulation data structure of a constrained Delaunay triangulation. The base face of a constrained Delaunay triangulation has to be a model of the concept *ConstrainedTriangulationFaceBase_2*.

CGAL provides a default for the template parameters. If *Gt* is the geometric traits parameter, the default for *ConstrainedTriangulationFaceBase_2* is the class *CGAL::Constrained_triangulation_face_base_2<Gt>* and the default for the triangulation data structure parameter is the class *CGAL::Triangulation_data_structure_2< CGAL::Triangulation_vertex_base_2<Gt>, CGAL::Constrained_triangulation_face_base_2<Gt> >*. The default intersection tag is *CGAL::No_intersection_tag*.

#include <CGAL/Constrained_Delaunay_triangulation_2.h>

Inherits From

Constrained_triangulation_2<Traits,Tds,Itag>

Types

All types used in this class are inherited from the base class *Constrained_triangulation_2<Traits,Tds,Itag>*.

Creation

Constrained_Delaunay_triangulation_2<Traits,Tds,Itag> cdt(Traits t = Traits());

Introduces an empty constrained Delaunay triangulation *cdt*.

Constrained_Delaunay_triangulation_2<Traits,Tds,Itag> cdt(Constrained_Delaunay_triangulation_2 cdt1);

Copy constructor, all faces and vertices are duplicated and the constrained status of edges is copied.

template<class InputIterator>
Constrained_Delaunay_triangulation_2<Traits,Tds,Itag> cdt(InputIterator first, InputIterator last, Traits t=Traits())

A templated constructor which introduces and builds a constrained triangulation with constrained edges in the range $[first, last)$.
Precondition: The *value_type* of *first* and *last* is *Constraint*.

Insertion and Removal

The following member functions overwrite the corresponding members of the base class to include a step restoring the Delaunay constrained property after modification of the triangulation.

Vertex_handle *cdt.insert(Point p, Face_handle f = Face_handle())*

Inserts point p in the triangulation. If present f is used as an hint for the location of p.

Vertex_handle *cdt.insert(Point p, Locate_type& lt, Face_handle loc, int li)*

Same as above except that the location of the point p to be inserted is assumed to be given by *(lt,loc,i)*.

Vertex_handle *cdt.push_back(Point p)*

Equivalent to *insert(p)*.

template < class InputIterator >
std::ptrdiff_t *cdt.insert(InputIterator first, InputIterator last)*

Inserts the points in the range $[first, last)$. Returns the number of inserted points.
Precondition: The *value_type* of *first* and *last* is *Point*.

void *cdt.insert_constraint(Point a, Point b)*

Inserts segment ab as a constrained edge in the triangulation.

void *cdt.push_back(Constraint c)*

Inserts constraints *c* as above.

void *cdt.insert_constraint(Vertex_handle va, Vertex_handle vb)*

Inserts the line segment whose endpoints are the vertices *va* and *vb* as a constrained edge e in the triangulation.

void *cdt.remove(Vertex_handle & v)*

Removes vertex v.
Precondition: Vertex *v* is not incident to a constrained edge.

void *cdt.remove_incident_constraints(Vertex_handle v)*

Make the edges incident to vertex *v* unconstrained edges.

void *cdt.remove_constraint(Face_handle f, int i)*

Edge *(f,i)* is no longer constrained.

Queries

The following template member functions query the set of faces in conflict with a point *p*. The notion of conflict refers here to a constrained Delaunay setting which means the following. Constrained edges are considered as visibility obstacles and a point *p* is considered to be in conflict with a face *f* iff it is visible from the interior of *f* and included in the circumcircle of *f*.

template <class OutputItFaces, class OutputItBoundaryEdges>
std::pair<OutputItFaces,OutputItBoundaryEdges>

cdt.get_conflicts_and_boundary(Point p,
OutputItFaces fit,
OutputItBoundaryEdges eit,
Face_handle start) const

OutItFaces is an output iterator with *Face_handle* as value type. *OutItBoundaryEdges* stands for an output iterator with *Edge* as value type. This members function outputs in the container pointed to by *fit* the faces which are in conflict with point *p*. It outputs in the container pointed to by *eit* the boundary of the zone in conflict with *p*. The boundary edges of the conflict zone are output in counterclockwise order and each edge is described through its incident face which is not in conflict with *p*. The function returns in a std::pair the resulting output iterators.
Precondition: dimension()==2

template <class OutputItFaces>
OutputItFaces *cdt.get_conflicts(Point p, OutputItFaces fit, Face_handle start) const*

Same as above except that only the faces in conflict with *p* are output. The function returns the resulting output iterator.
Precondition: dimension()==2

template <class OutputItBoundaryEdges>
OutputItBoundaryEdges

cdt.get_boundary_of_conflicts(Point p, OutputItBoundaryEdges eit, Face_handle start) const

OutputItBoundaryEdges stands for an output iterator with *Edge* as value type. This functions outputs in the container pointed to by *eit*, the boundary of the zone in conflict with *p*. The boundary edges of the conflict zone are output in counter-clockwise order and each edge is described through the incident face which is not in conflict with *p*. The function returns the resulting output iterator.

Checking

bool *cdt.is_valid()* Checks if the triangulation is valid and if each constrained edge is consistently marked constrained in its two incident faces.

advanced

Flips

bool *cdt.is_flipable(Face_handle f, int i)*

Determines if edge *(f,i)* can be flipped. Returns true if edge *(f,i)* is not constrained and the circle circumscribing f contains the vertex of *f->neighbor(i)* opposite to edge *(f,i)*.

void *cdt.flip(Face_handle& f, int i)*

Flip *f* and *f->neighbor(i)*.

void *cdt.propagating_flip(List_edges & edges)*

Makes the triangulation constrained Delaunay by flipping edges. List edges contains an initial list of edges to be flipped. The returned triangulation is constrained Delaunay if the initial list contains at least all the edges of the input triangulation that failed to be constrained Delaunay. (An edge is said to be constrained Delaunay if it is either constrained or locally Delaunay.)

CGAL::Constrained_triangulation_2<Traits,Tds,Itag>

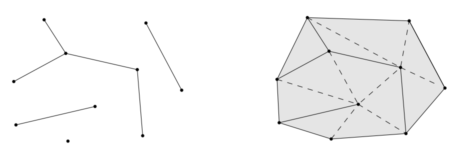
Definition

A constrained triangulation is a triangulation of a set of points which has to include among its edges a given set of segments joining the points. The given segments are called *constraints* and the corresponding edges in the triangulation are called *constrained edges*.

The endpoints of constrained edges are of course vertices of the triangulation. However the triangulation may include other vertices as well. There are three versions of constrained triangulations

- In the basic version, the constrained triangulation does not handle intersecting constraints, and the set of input constraints is required to be a set of segments that do not intersect except possibly at their endpoints. Any number of constrained edges are allowed to share the same endpoint. Vertical constrained edges are allowed as well as constrained edges with null length.
- The two other versions support intersecting input constraints. In those versions, input constraints are allowed to be intersecting, overlapping or partially overlapping segments. The triangulation introduce additional vertices at each point which is a proper intersection point of two constraints. A single constraint intersecting other constraints will then appear as the union of several constrained edges of the triangulation. The two versions dealing with intersecting constraints, slightly differ in the way intersecting constraints are dealt with.
  - One of them is designed to be robust when predicates are evaluated exactly but constructions (i. e. intersection computations) are approximate.
  - The other one is designed to be used with an exact arithmetic (meaning exact evaluation of predicates and exact computation of intersections.) This last version finds its full efficiency when used in conjunction with a constraint hierarchy data structure as provided in the class *Constrained_triangulation_plus_2*. See section 37.9.



The class *Constrained_triangulation_2<Traits,Tds,Itag>* of the CGAL library implements constrained triangulations. The template parameter *Traits* stands for a geometric traits class. It has to be a model of the concept *TriangulationTraits_2*. When intersection of input constraints are supported, the geometric traits class is required to provide additional function object types to compute the intersection of two segments. It has then to be a model of the concept *ConstrainedTriangulationTraits_2*. The template parameter *Tds* stands for a triangulation data structure class that has to be a model of the concept *TriangulationDataStructure_2*. The third parameter *Itag* is the intersection tag which serves to choose between the different strategies to deal with constraints intersections. CGAL provides three valid types for this parameter :
CGAL::No_intersection_tag disallows intersections of input constraints,
CGAL::Exact_predicates_tag is to be used when the traits class provides exact predicates but approximate constructions of the intersection points.
CGAL::Exact_intersections_tag is to be used in conjunction with an exact arithmetic type.

The information about constrained edges is stored in the faces of the triangulation. Thus the nested *Face* type of a constrained triangulation offers additional functionalities to deal with this information. These additional functionalities induce additional requirements on the base face class plugged into the triangulation data structure of a constrained Delaunay triangulation. The base face of a constrained Delaunay triangulation has to be a model of the concept *ConstrainedTriangulationFaceBase_2*.

CGAL provides default instantiations for the template parameters *Tds* and *Itag*, and for the *ConstrainedTriangulationFaceBase_2*. If *Gt* is the geometric traits parameter, the default for *ConstrainedTriangulationFaceBase_2* is the class *CGAL::Constrained_triangulation_face_base_2<Gt>* and the default for the triangulation data structure parameter is the class *CGAL::Triangulation_data_structure_2 < CGAL::Triangulation_vertex_base_2<Gt>, CGAL::Constrained_triangulation_face_base_2<Gt> >*. The default intersection tag is *CGAL::No_intersection_tag*.

#include <CGAL/Constrained_triangulation_2.h>

Inherits From

Triangulation_2<Traits,Tds>

Types

typedef std::pair<Point,Point>

Constraint; — The type of input constraints

typedef Itag *Intersection_tag;* — The intersection tag which decides how intersections between input constraints are dealt with.

Creation

Constrained_triangulation_2<Traits,Tds,Itag> ct;

default constructor.

Constrained_triangulation_2<Traits,Tds,Itag> ct(Constrained_triangulation_2 ct1);

Copy constructor, all faces and vertices are duplicated and the constrained status of edges is copied.

template<class InputIterator>
Constrained_triangulation_2<Traits,Tds,Itag> ct(InputIterator first, InputIterator last, Traits t=Traits());

A templated constructor which introduces and builds a constrained triangulation with constrained edges in the range $[first, last)$.
Precondition: The *value_type* of *first* and *last* is *Constraint*.

Queries

bool *ct.is_constrained(Edge e)*

Returns true if edge *e* is a constrained edge.

bool *ct.are_there_incident_constraints(Vertex_handle v)*

Returns true if at least one of the edges incident to vertex *v* is constrained.

template<class OutputItEdges>
OutputItEdges *ct.incident_constraints(Vertex_handle v, OutputItEdges out) const*

OutputItEdges is an output iterator with *Edge* as value type. Outputs the constrained edges incident to *v* in the sequence pointed to by *out* and returns the resulting output iterator.

Insertion and removal

Vertex_handle *ct.insert(Point p, Face_handle f = Face_handle())*

Inserts point *p* and restores the status (constrained or not) of all the touched edges. If present *f* is used as an hint for the location of *p*.

Vertex_handle *ct.insert(Point p, Locate_type& lt, Face_handle loc, int li)*

Same as above except that the location of the point *p* to be inserted is assumed to be given by *(lt,loc,i)*.

Vertex_handle *ct.push_back(Point p)*

Equivalent to *insert(p)*.

template < class InputIterator >
std::ptrdiff_t *ct.insert(InputIterator first, InputIterator last)*

Inserts the points in the range [*first*, *last*). Returns the number of inserted points.
Precondition: The *value_type* of *first* and *last* is *Point*.

void *ct.insert_constraint(Point a, Point b)*

Inserts points *a* and *b*, and inserts segment *ab* as a constraint. Removes the faces crossed by segment *ab* and creates new faces instead. If a vertex *c* lies on segment *ab*, constraint *ab* is replaced by the two constraints *ac* and *cb*. Apart from the insertion of *a* and *b*, the algorithm runs in time proportional to the number of removed triangles.
Precondition: The relative interior of segment *ab* does not intersect the relative interior of another constrained edge.

void *ct.push_back(Constraint c)*

Inserts constraints *c* as above.

void *ct.insert_constraint(Vertex_handle va, Vertex_handle vb)*

Inserts the line segment *s* whose endpoints are the vertices *va* and *vb* as a constrained edge *e*. The triangles intersected by *s* are removed and new ones are created.

void *ct.remove(Vertex_handle v)*

Removes a vertex *v*.
Precondition: Vertex *v* is not incident to a constrained edge.

void *ct.remove_incident_constraints(Vertex_handle v)*

Make the edges incident to vertex *v* unconstrained edges.

void *ct.remove_constrained_edge(Face_handle f, int i)*

Make edge *(f,i)* no longer constrained.

advanced

bool *ct.is_valid(bool verbose = false, int level = 0) const*

Checks the validity of the triangulation and the consistency of the constrained marks in edges.

advanced

I/O

ostream & *ostream& os << Constrained_triangulation_2<Traits,Tds> Ct*

Writes the triangulation as for *CGAL::Triangulation_2< Traits,Tds>* and, for each face f, and integers i=0,1,2, write “C” or “N” depending whether edge *(f,i)* is constrained or not.

istream& *istream& is >> Constrained_triangulation_2<Traits,Tds> Ct& t*

Reads a triangulation from stream *is* and assigns it to *t*. Data in the stream must have the same format *operator<<* uses. Note that *t* is first cleared.

Class

CGAL::Constrained_triangulation_plus_2<Tr>

The class *Constrained_triangulation_plus_2<Tr>* implements a constrained triangulation with an additional data structure called the constraint hierarchy that keeps track of the input constraints and of their refinement in the triangulation.

The class *Constrained_triangulation_plus_2<Tr>* inherits from its template parameter Tr, which has to be instantiated by a constrained or constrained Delaunay triangulation.

According to its intersection tag, the base class will support intersecting input constraints or not. When intersections of input constraints are supported, the base class constructs a triangulation of the arrangement of the constraints, introducing new vertices at each proper intersection point and refining the input constraints into sub-constraints which are edges (more precisely constrained edges) of the triangulation. In this context, the constraint hierarchy keeps track of the input constraints and of their refinement in the triangulation. This data structure maintains for each input constraints the sequence of intersection vertices added on this constraint. The constraint hierarchy also allows the user to retrieve the set of constrained edges of the triangulation, and for each constrained edge, the set of input constraints that overlap it.

#include <CGAL/Constrained_triangulation_plus_2.h>

Inherits From

Tr which is either a *CGAL::Constrained_triangulation_2<Traits,Tds>* or a *CGAL::Constrained_Delaunay_triangulation_2<Traits,Tds>*.

Types

typedef Tr	*Triangulation;*	the triangulation base class.
typedef Itag	*Intersection_tag;*	the intersection tag.s

Constrained_triangulation_plus_2<Tr>:: Constraint_iterator

An iterator to visit all the input constraints. The order of visit is arbitrary. The value type of this iterator is a pair *std::pair<Vertex_handle, Vertex_handle>* corresponding to the endpoints of the constraint.

Constrained_triangulation_plus_2<Tr>:: Subconstraint_iterator

An iterator to visit all the sub-constraints of the triangulation. The order of visit is arbitrary. The value type of this iterator is a pair *std::pair<Vertex_handle, Vertex_handle>* corresponding to the vertices of the sub-constraint.

Constrained_triangulation_plus_2<Tr>:: Vertices_in_constraint_iterator

An iterator on the vertices of the chain of triangulation edges representing a constraint. The value type of this iterator is *Vertex_handle*.

typedef	*Context;*	This type is intended to describe a constraint enclosing a sub-constraint and the position of the sub-constraint in this constraint. It provides three member functions *vertices_begin()*, *vertices_end()* and *current()* returning iterators of the type *Vertices_in_constraint_iterator* on the sequence of vertices of the enclosing constraint. These iterators point respectively on the first vertex of the enclosing constraint, past the last vertex and on the first vertex of the sub-constraint.
typedef	*Context_iterator;*	An iterator on constraints enclosing a given sub-constraint. The value type of this iterator is *Context*.

Creation

Constrained_triangulation_plus_2<Tr> ctp(Geom_traits gt=Geom_traits());

Introduces an empty triangulation.

Constrained_triangulation_plus_2<Tr> ctp(Constrained_triangulation_plus_2 ct);

Copy constructor.

Constrained_triangulation_plus_2<Tr> ctp(std::list<Constraint>& lc, Geom_traits t = Geom_traits());

Introduces and builds a constrained triangulation from the list of constraints *lc*.

template<class InputIterator>
Constrained_triangulation_plus_2<Tr> ctp(InputIterator first,
InputIterator last,
Geom_traits gt= Geom_traits())

Introduces and builds a constrained triangulation from the constraints in the range $[first, last)$.
Precondition: The *value_type* of *first* and *last* is *Constraint*.

Assignment

Constrained_triangulation_plus_2

ctp = Constrained_triangulation_plus_2 tr

Assignment. All the vertices and faces are duplicated. The constraint hierarchy is also duplicated.

void *ctp.swap(Constrained_triangulation_plus_2 tr)*

The triangulations *tr* and *ctp* are swapped. This operation should be preferred to *ctp = tr* or to *t(tr)* if *tr* is deleted after that.

Insertion and Removal

The class *Constrained_triangulation_plus_2<Tr>* overwrites the following insertion and removal member functions for points and constraints.

Vertex_handle *ctp.insert(Point p, Face_handle start = Face_handle())*

Inserts point *p* as a vertex of the triangulation.

Vertex_handle *ctp.insert(Point p, Locate_type lt, Face_handle loc, int li)*

inserts a point *p* whose location is assumed to be given by *(lt,loc,li)*.

Vertex_handle *ctp.push_back(Point p)*

Equivalent to *insert(p)*.

template < class InputIterator >
size_type *ctp.insert(InputIterator first, InputIterator last)*

Inserts the points in the range $[first, last)$. Returns the number of inserted points.
Precondition: The *value_type* of *first* and *last* is *Point*.

void *ctp.insert_constraint(Point a, Point b)*

Inserts the constraint segment ab in the triangulation.

void *ctp.push_back(Constraint c)*

Inserts the constraint *c*.

void *ctp.insert_constraint(Vertex_handle va, Vertex_handle vb)*

Inserts a constraint whose endpoints are the vertices pointed by *va* and *vb* in the triangulation.

void *ctp.remove_constraint(Vertex_handle va, Vertex_handle vb)*

Removes the constraint joining the vertices pointed by *va* and *vb*.
Precondition: *va* and *vb* have to refer to the endpoint vertices of an input constraint.

Queries

Constraint_iterator *ctp.constraints_begin() const*

Returns a *Constraint_iterator* pointing on the first constraint.

Constraint_iterator *ctp.constraints_end() const*

Returns a *Constraint_iterator* pointing past the last constraint.

Subconstraint_iterator

ctp.subconstraints_begin() const

Returns a *Subconstraint_iterator* pointing on the first sub-constraint.

Subconstraint_iterator

ctp.subconstraints_end() const

Returns a *Subconstraint_iterator* pointing past the last sub-constraint.

int *ctp.number_of_enclosing_constraints(Vertex_handle va, Vertex_handle vb)*

Returns the number of constraints enclosing the sub-constraint *(va,vb)*.
Precondition: *va* and *vb* refer to the vertices of a constrained edge of the triangulation.

Context *ctp.context(Vertex_handle va, Vertex_handle vb)*

Returns the *Context* relative to one of the constraint enclosing the sub-constraint *(va,vb)*.
Precondition: *va* and *vb* refer to the vertices of a constrained edge of the triangulation.

Context_iterator *ctp.contexts_begin(Vertex_handle va, Vertex_handle vb)*

Returns an iterator pointing on the first *Context* of the sequence of *Contexts* corresponding to the constraints enclosing the sub-constraint*(va,vb)*.
Precondition: *va* and *vb* refer to the vertices of a constrained edge of the triangulation.

Context_iterator *ctp.contexts_end(Vertex_handle va, Vertex_handle vb)*

Returns an iterator past the last *Context* of the sequence of *Contexts* corresponding to the constraints enclosing the *(va,vb)*.
Precondition: *va* and *vb* refer to the vertices of a constrained edge of the triangulation.

Vertices_in_constraint_iterator

ctp.vertices_in_constraint_begin(Vertex_handle va, Vertex_handle vb)

Returns an iterator on the first vertex on the constraint *(va,vb)*
Precondition: *va* and *vb* refer to the vertices of an input constraint.

Vertices_in_constraint_iterator

ctp.vertices_in_constraint_end(Vertex_handle va, Vertex_handle vb)

Returns an iterator past the last vertex on the constraint *(va,vb)*
Precondition: *va* and *vb* refer to the vertices of an input constraints.

DelaunayTriangulationTraits_2

Definition

In addition to the requirements of the concept *TriangulationTraits_2* described page 2541, the concept DelaunayTriangulationTraits_2 provide a predicate to check the empty circle property. The corresponding predicate type is called type *Side_of_oriented_circle_2*.

The additional types *Line_2*, *Ray_2* and the constructor objects *Construct_ray_2 Construct_circumcenter_2*, *Construct_bisector_2*, *Construct_midpoint* are used to build the dual Voronoi diagram and are required only if the dual functions are called. The additional predicate type *Compare_distance_2* is required if calls to *nearest_vertex(..)* are issued.

Refines

TriangulationTraits_2

Types

DelaunayTriangulationTraits_2:: Line_2 — The line type. This type is required only if some dual functions are called.

DelaunayTriangulationTraits_2:: Ray_2 — The type for ray. This type is required only if some dual functions are called.

DelaunayTriangulationTraits_2:: Side_of_oriented_circle_2

Predicate type. Provides the operator :
Oriented_side operator()(Point p, Point q, Point r, Point s) which takes four points p,q,r,s as arguments and returns *ON_POSITIVE_SIDE*, *ON_NEGATIVE_SIDE* or, *ON_ORIENTED_BOUNDARY* according to the position of points s with respect to the oriented circle through p,q and r.

DelaunayTriangulationTraits_2:: Compare_distance_2

Predicate type. Provides the operator :
Comparison_result operator()(Point_2 p, Point_2 q, Point_2 r) which returns *SMALLER*, *EQUAL* or *LARGER* according to the distance between p and q being smaller, equal or larger than the distance between p and r. This type is only require if *nearest_vertex* queries are issued.

DelaunayTriangulationTraits_2:: Construct_circumcenter_2

Constructor object. Provides the operator :
Point_2 operator()(Point_2 p, Point_2 q, Point_2 r) which returns the circumcenter of the three points *p, q* and *r*. This type is required only if functions relative to the dual Voronoi diagram are called.

DelaunayTriangulationTraits_2:: Construct_bisector_2

Constructor object. Provides the operator : *Line_2 operator()(Point_2 p, Point_2 q)* which constructs the bisector line of points p and q. This type is required only if functions relative to the dual Voronoi diagram are called.

DelaunayTriangulationTraits_2:: Construct_ray_2

A constructor object to build a ray from a point and a line. Provides :
Ray_2 operator() (Point_2 p, Line_2 l);

Creation

DelaunayTriangulationTraits_2 traits;	default constructor.
DelaunayTriangulationTraits_2 traits(dtt);	copy constructor
DelaunayTriangulationTraits_2 traits = traits2	Assignment operator.

Access to predicate and constructor objects

Side_of_oriented_circle_2 *traits.side_of_oriented_circle_2_object()*

The following functions are required only if member functions of the Delaunay triangulation relative to the dual Voronoi diagram are called.

Compare_distance_2	*traits.compare_distance_2_object()*
Construct_circumcenter_2	*traits.construct_circumcenter_2_object()*
Construct_bisector_2	*traits.construct_bisector_2_object()*
Construct_direction_2	*traits.construct_direction_2_object()*
Construct_ray_2	*traits.construct_ray_2_object()*

TriangulationTraits_2

Class

CGAL::Delaunay_triangulation_2<Traits,Tds>

Definition

The class *Delaunay_triangulation_2<Traits,Tds>* is designed to represent the Delaunay triangulation of a set of points in a plane. A Delaunay triangulation of a set of points is a triangulation of the sets of points that fulfills the following *empty circle property* (also called *Delaunay property*): the circumscribing circle of any facet of the triangulation contains no point of the set in its interior. For a point set with no case of co-circularity of more than three points, the Delaunay triangulation is unique, it is the dual of the Voronoi diagram of the points.

#include <CGAL/Delaunay_triangulation_2.h>

Parameters

The template parameter *Tds* is to be instantiated with a model of *TriangulationDataStructure_2*. CGAL provides a default instantiation for this parameter, which is the class *CGAL::Triangulation_data_structure_2 < CGAL::Triangulation_vertex_base_2<Traits>, CGAL::Triangulation_face_base_2<Traits> >*.

The geometric traits *Traits* is to be instantiated with a model of *DelaunayTriangulationTraits_2*. The concept *DelaunayTriangulationTraits_2* refines the concept *TriangulationTraits_2*, providing a predicate type to check the empty circle property.

Changing this predicate type allows to build Delaunay triangulations for different metrics such that L_1 or L_∞ or any metric defined by a convex object. However, the user of an exotic metric must be careful that the constructed triangulation has to be a triangulation of the convex hull which means that convex hull edges have to be Delaunay edges. This is granted for any smooth convex metric (like L_2) and can be ensured for other metrics (like L_∞) by the addition to the point set of well chosen sentinel points The concept of *DelaunayTriangulationTraits_2* is described page 2513.

When dealing with a large triangulations, the user is advised to encapsulate the Delaunay triangulation class into a triangulation hierarchy, which means to use the class *Triangulation_hierarchy_2<Tr>* with the template parameter instantiated with *Delaunay_triangulation_2<Traits,Tds>* . The triangulation hierarchy will then offer the same functionalities but be much more for efficient for locations and insertions.

Inherits From

Triangulation_2<Traits,Tds>

Types

Inherits all the types defined in *Triangulation_2<Traits,Tds>*.

Creation

Delaunay_triangulation_2<Traits,Tds> dt(Traits gt = Traits());

default constructor.

Delaunay_triangulation_2<Traits,Tds> dt(tr);

copy constructor. All the vertices and faces are duplicated.

Insertion and Removal

The following insertion and removal functions overwrite the functions inherited from the class *Triangulation_2<Traits,Tds>* to maintain the Delaunay property.

In the degenerate case when there are co-circular points, the Delaunay triangulation is known not to be uniquely defined. In this case, CGAL chooses a particular Delaunay triangulation using a symbolic perturbation scheme [DT03].

Vertex_handle *dt.insert(Point p, Face_handle f=Face_handle())*

inserts point *p*. If point *p* coincides with an already existing vertex, this vertex is returned and the triangulation is not updated. Optional parameter *f* is used to initialize the location of *p*.

Vertex_handle *dt.insert(Point p, Locate_type& lt, Face_handle loc, int li)*

inserts a point *p*, the location of which is supposed to be given by *(lt,loc,li)*, see the description of member function *locate* in class *Triangulation_2<Traits,Tds>*.

Vertex_handle *dt.push_back(Point p)*

equivalent to *insert(p)*.

template < class PointInputIterator >
std::ptrdiff_t *dt.insert(PointInputIterator first, PointInputIterator last)*

inserts the points in the range $[first, last)$. Returns the number of inserted points. Note that this function is not guaranteed to insert the points following the order of *PointInputIterator*, as *spatial_sort* is used to improve efficiency.
Precondition: The *value_type* of *first* and *last* is *Point*.

template < class PointWithInfoInputIterator >

std::ptrdiff_t *dt.insert(PointWithInfoInputIterator first, PointWithInfoInputIterator last)*

inserts the points in the iterator range $[first, last)$. Returns the number of inserted points. Note that this function is not guaranteed to insert the points following the order of *PointWithInfoInputIterator*, as *spatial_sort* is used to improve efficiency. Given a pair *(p,i)*, the vertex *v* storing *p* also stores *i*, that is *v.point() == p* and *v.info() == i*. If several pairs have the same point, only one vertex is created, and one of the objects of type *Vertex::Info* will be stored in the vertex.
Precondition: *Vertex* must be model of the concept *TriangulationVertexBaseWithInfo_2*. The *value_type* of *first* and *last* is *std::pair<Point,Vertex::Info>*.

void *dt.remove(Vertex_handle v)*

removes the vertex from the triangulation.

Note that the other modifier functions of *Triangulation_2<Traits,Tds>* are not overwritten. Thus a call to *insert_in_face insert_in_edge*, *insert_outside_convex_hull*, *insert_outside_affine_hull* or *flip* on a valid Delaunay triangulation might lead to a triangulation which is no longer a Delaunay triangulation.

Displacement

Vertex_handle *dt.move_if_no_collision(Vertex_handle v, Point p)*

if there is not already another vertex placed on *p*, the triangulation is modified such that the new position of vertex *v* is *p*, and *v* is returned. Otherwise, the triangulation is not modified and the vertex at point *p* is returned.
Precondition: Vertex *v* must be finite.

Vertex_handle *dt.move(Vertex_handle v, Point p)*

same as above if there is no collision. Otherwise, *v* is deleted and the vertex placed on *p* is returned.
Precondition: Vertex *v* must be finite.

Queries

Vertex_handle *dt.nearest_vertex(Point p, Face_handle f=Face_handle())*

returns any nearest vertex of *p*. The implemented function begins with a location step and *f* may be used to initialize the location.

template <class OutputItFaces, class OutputItBoundaryEdges>

std::pair<OutputItFaces,OutputItBoundaryEdges>

dt.get_conflicts_and_boundary(Point p,
OutputItFaces fit,
OutputItBoundaryEdges eit,
Face_handle start) const

OutputItFaces is an output iterator with *Face_handle* as value type. *OutputItBoundaryEdges* stands for an output iterator with *Edge* as value type. This members function outputs in the container pointed to by *fit* the faces which are in conflict with point *p* i. e. the faces whose circumcircle contains *p*. It outputs in the container pointed to by *eit* the the boundary of the zone in conflict with *p*. The boundary edges of the conflict zone are output in counter-clockwise order and each edge is described through its incident face which is not in conflict with *p*. The function returns in a std::pair the resulting output iterators.
Precondition: dimension()==2

template <class OutputItFaces>
OutputItFaces *dt.get_conflicts(Point p, OutputItFaces fit, Face_handle start) const*

same as above except that only the faces in conflict with *p* are output. The function returns the resulting output iterator.
Precondition: dimension()==2

template <class OutputItBoundaryEdges>
OutputItBoundaryEdges

dt.get_boundary_of_conflicts(Point p,
OutputItBoundaryEdges eit,
Face_handle start) const

OutputItBoundaryEdges stands for an output iterator with *Edge* as value type. This function outputs in the container pointed to by *eit*, the boundary of the zone in conflict with *p*. The boundary edges of the conflict zone are output in counterclockwise order and each edge is described through the incident face which is not in conflict with *p*. The function returns the resulting output iterator.

Voronoi diagram

The following member functions provide the elements of the dual Voronoi diagram.

Point *dt.dual(Face_handle f) const*

Returns the center of the circle circumscribed to face f.
Precondition: f is not infinite

Object *dt.dual(Edge e) const* returns a segment, a ray or a line supported by the bisector of the endpoints of *e*. If faces incident to *e* are both finite, a segment whose endpoints are the duals of each incident face is returned. If only one incident face is finite, a ray whose endpoint is the dual of the finite incident face is returned. Otherwise both incident faces are infinite and the bisector line is returned.

Object *dt.dual(Edge_circulator ec) const*

Idem

Object *dt.dual(Edge_iterator ei) const*

Idem

template < class Stream>
Stream&

dt.draw_dual(Stream & ps) output the dual Voronoi diagram to stream *ps*.

Predicates

Oriented_side *dt.side_of_oriented_circle(Face_handle f, Point p) const*

Returns the side of *p* with respect to the circle circumscribing the triangle associated with *f*

advanced

Miscellaneous

The checking function *is_valid()* is also overwritten to additionally test the empty circle property.

bool *dt.is_valid(bool verbose = false, int level = 0) const*

tests the validity of the triangulation as a *Triangulation_2* and additionally tests the Delaunay property. This method is mainly useful for debugging Delaunay triangulation algorithms designed by the user.

advanced

See Also

CGAL::Triangulation_2<Traits,Tds>,
TriangulationDataStructure_2,
DelaunayTriangulationTraits_2,
Triangulation_hierarchy_2<Tr>.

Implementation

Insertion is implemented by inserting in the triangulation, then performing a sequence of Delaunay flips. The number of flips is $O(d)$ if the new vertex is of degree d in the new triangulation. For points distributed uniformly at random, insertion takes time $O(1)$ on average.

Removal calls the removal in the triangulation and then re-triangulates the hole in such a way that the Delaunay criterion is satisfied. Removal of a vertex of degree d takes time $O(d^2)$. The degree d is $O(1)$ for a random vertex in the triangulation.

After a point location step, the nearest neighbor is found in time $O(n)$ in the worst case, but in time $O(1)$ for vertices distributed uniformly at random and any query point.

Enum

CGAL::Triangulation_2<Traits,Tds>::Locate_type

Definition

The enum *Locate_type* is defined by the *Triangulation_2<Traits,Tds>* class to specify which case occurs when locating a point in the triangulation.

enum Locate_type { *VERTEX=0, EDGE, FACET, OUTSIDE_CONVEX_HULL, OUTSIDE_AFFINE_HULL*};

The locate type is :
VERTEX when the located point coincides with a vertex of the triangulation
EDGE when the point is in the relative interior of an edge
FACE when the point is in the interior of a facet
OUTSIDE_CONVEX_HULL when the point is outside the convex hull but in the affine hull of the current triangulation
OUTSIDE_AFFINE_HULL when the point is outside the affine hull of the current triangulation.

CGAL::Triangulation_2<Traits,Tds>.

RegularTriangulationFaceBase_2

Definition

The regular triangulation of a set of weighted points does not necessarily have one vertex for each of the input points. Some of the input weighted points have no cell in the dual power diagrams and therefore do not correspond to a vertex of the regular triangulation. Those weighted points are said to be *hidden* points. A point which is hidden at a given time may appear later as a vertex of the regular triangulation upon removal on some other weighted point. Therefore, hidden points have to be stored somewhere. The regular triangulation store those hidden points in special vertices called *hidden* vertices.

A hidden point can appear as vertex of the triangulation only when the two dimensional face where its point component is located (the face which hides it) is removed. Therefore we decided to store in each face of a regular triangulation the list of hidden vertices whose points are located in the face. Thus points hidden by a face are easily reinserted in the triangulation when the face is removed.

The base face of a regular triangulation has to be a model of the concept RegularTriangulationFaceBase_2 , which refines the concept *TriangulationFaceBase_2* by adding in the face a list to store hidden vertices.

Refines

TriangulationFaceBase_2

Types

typedef std::list<Vertex_handle>

	Vertex_list;	An std list of hidden vertices.

Access Functions

Vertex_list&	*rfb.vertex_list()*	Returns a reference to the list of vertices hidden by the face.

RegularTriangulationTraits_2

Definition

The concept RegularTriangulationTraits_2 describe the requirements for the traits class of regular triangulations. It refines the concept *TriangulationTraits_2* providing the type *Weighted_point_2* and the *power-test* predicate on those weighted points. A weighted point is basically a point augmented with a scalar weight. It can be seen as a circle when the weight is interpreted as a square radius. The *power-test* on weighted points is the fundamental test to build regular triangulations as the *side_of_oriented_circle* test is the fundamental test of Delaunay triangulations.

Refines

TriangulationTraits_2

Types

RegularTriangulationTraits_2:: Bare_point — Another name for the point type.

RegularTriangulationTraits_2:: Weighted_point_2

The weighted point type, it has to be a model of the concept *WeightedPoint*.

RegularTriangulationTraits_2:: Power_test_2 — A predicate object type. Must provide the operators:
— *Oriented_side operator() (Weighted_point_2 p, Weighted_point_2 q, Weighted_point_2 r, Weighted_point_2 s)* which is the power test for points *p*, *q*, *r* and *s*.
Precondition: the bare points corresponding to *p*, *q*, *r* are not collinear.
— *Oriented_side operator() (Weighted_point_2 p, Weighted_point_2 q, Weighted_point_2 r)* which is the degenerated power test for collinear points *p*, *q*, *r*.
Precondition: the bare points corresponding to *p*, *q*, *r* are collinear and *p != q*.
— *Oriented_side operator() (Weighted_point_2 p, Weighted_point_2 q)* which is the degenerated power test for weighted points *p* and *q* whose corresponding bare-points are identical.
Precondition: the bare points corresponding to *p* and *q* are identical.

The following type/predicate is required if a call to *nearest_power_vertex* is issued:

RegularTriangulationTraits_2:: Compare_power_distance_2

A predicate object type. Must provide the operator:
Comparison_result operator()(Bare_point p, Weighted_point_2 q, Weighted_point_2 r), which compares the power distance between *p* and *q* to the power distance between *p* and *r*.

RegularTriangulationTraits_2:: Construct_weighted_circumcenter_2

A constructor object which constructs the weighted circumcenter of three weighted points. Provides the operator *Bare_point operator() (Weighted_point_2 p, Weighted_point_2 q, Weighted_point_2 r);*

RegularTriangulationTraits_2:: Construct_radical_axis_2

A constructor type which constructs the radical axis of two weighted points. Provides the operator : *Line_2 operator() (Weighted_point_2 p, Weighted_point_2 q);*

Creation

RegularTriangulationTraits_2 traits; default constructor.

RegularTriangulationTraits_2 traits(RegularTriangulatioTraits_2);

copy constructor.

RegularTriangulationTraits_2&

traits = RegularTriangulationTraits_2

assignment operator

Access to predicate and constructors objects

Power_test_2	*traits.power_test_2_object()*
Compare_power_distance_2	*traits.compare_power_distance_2_object()*

TriangulationVertexBase_2 CGAL::Regular_triangulation_vertex_base_2

CGAL::Regular_triangulation_2<Traits,Tds>

Definition

The class *Regular_triangulation_2<Traits,Tds>* is designed to maintain the regular triangulation of a set of weighted points.

Let $PW = \{(p_i, w_i), i = 1, \ldots, n\}$ be a set of weighted points where each p_i is a point and each w_i is a scalar called the weight of point p_i. Alternatively, each weighted point (p_i, w_i) can be regarded as a two dimensional sphere with center p_i and radius $r_i = \sqrt{w_i}$.

The power diagram of the set PW is a planar partition such that each cell corresponds to sphere (p_i, w_i) of PW and is the locus of points p whose power with respect to (p_i, w_i) is less than its power with respect to any other sphere (p_j, w_j) in PW. The dual of this diagram is a triangulation whose domain covers the convex hull of the set $P = \{p_i, i = 1, \ldots, n\}$ of center points and whose vertices are a subset of P. Such a triangulation is called a regular triangulation. The three points p_i, p_j and p_k of P form a triangle in the regular triangulation of PW iff there is a point p of the plane whose powers with respect to (p_i, w_i), (p_j, w_j) and (p_k, w_k) are equal and less than the power of p with respect to any other sphere in PW.

Let us defined the power product of two weighted points (p_i, w_i) and (p_j, w_j) as:

$$\Pi(p_i, w_i, p_j, w_j) = p_i p_j^2 - w_i - w_j.$$

$\Pi(p_i, w_i, p_j, 0)$ is simply the power of point p_j with respect to the sphere (p_i, w_i), and two weighted points are said to be orthogonal if their power product is null. The power circle of three weighted points (p_i, w_i), (p_j, w_j) and (p_k, w_k) is defined as the unique circle (π, ω) orthogonal to (p_i, w_i), (p_j, w_j) and (p_k, w_k).

The regular triangulation of the sets PW satisfies the following *regular property* (which just reduces to the Delaunay property when all the weights are null): a triangle $p_i p_j p_k$ of the regular triangulation of PW is such that the power product of any weighted point (p_l, w_l) of PW with the power circle of (p_i, w_i), (p_j, w_j) is (p_k, w_k) is positive or null. We call power test of the weighted point (p_l, w_l) with respect to the face $p_i p_j p_k$, the predicates testing the sign of the power product of (p_l, w_l) with respect to the power circle of (p_i, w_i), (p_j, w_j) is (p_k, w_k). This power product is given by the following determinant

$$\begin{vmatrix} 1 & x_i & y_i & x_i^2 + y_i^2 - w_i \\ 1 & x_j & y_j & x_j^2 + y_j^2 - w_j \\ 1 & x_k & y_k & x_k^2 + y_k^2 - w_k \\ 1 & x_l & y_l & x_l^2 + y_l^2 - w_l \end{vmatrix}$$

A pair of neighboring faces $p_i p_j p_k$ and $p_i p_j p_l$ is said to be locally regular (with respect to the weights in PW) if the power test of (p_l, w_l) with respect to $p_i p_j p_k$ is positive. A classical result of computational geometry establishes that a triangulation of the convex hull of P such that any pair of neighboring faces is regular with respect to PW, is a regular triangulation of PW.

Alternatively, the regular triangulation of the weighted points set PW can be obtained as the projection on the two dimensional plane of the convex hull of the set of three dimensional points $P' = \{(p_i, p_i^2 - w_i), i = 1, \ldots, n\}$.

The vertices of the regular triangulation of a set of weighted points PW form only a subset of the set of center points of PW. Therefore the insertion of a weighted point in a regular triangulation does not necessarily imply the creation of a new vertex. If the new inserted point does not appear as a vertex in the regular triangulation, it is said to be hidden.

Hidden points are stored in special vertices called hidden vertices. A hidden point is considered as hidden by the facet of the triangulation where its point component is located : in fact, the hidden point can appear as vertex of the triangulation only if this facet is removed. Each face of a regular triangulation stores the list of hidden vertices whose points are located in the facet. When a facet is removed, points hidden by this facet are reinserted in the triangulation.

#include <CGAL/Regular_triangulation_2.h>

Parameters

The geometric traits parameter *Traits* has to be instantiated with a model of the concept *RegularTriangulationTraits_2*. The concept *RegularTriangulationTraits_2* refines the concept *TriangulationTraits_2* by adding the type *Weighted_point_2* to describe weighted points and the type *Power_test_2* to perform power tests on weighted points.

The *Tds* parameter has to be instantiated by a model of *TriangulationDataStructure_2*. The face base of a regular triangulation has to be a model of the concept *RegularTriangulationFaceBase_2*. while the vertex base class has to be a model of *RegularTriangulationVertexBase_2*. CGAL provides a default instantiation for the *Tds* parameter by the class *CGAL::Triangulation_data_structure_2 < CGAL::Reugular_triangulation_vertex_base_2<Traits>, CGAL::Regular_Triangulation_face_base_2<Traits> >*.

Inherits From

Triangulation_2<Traits,Tds>

Types

typedef Traits::Distance	*Distance;*
typedef Traits::Line	*Line;*
typedef Traits::Ray	*Ray;*
typedef Traits::Bare_point	*Bare_point;*
typedef Traits::Weighted_point	*Weighted_point;*

Regular_triangulation_2<Traits,Tds>:: All_vertices_iterator

An iterator that allows to enumerate the vertices that are not hidden.

Regular_triangulation_2<Traits,Tds>:: Finite_vertices_iterator

An iterator that allows to enumerate the finite vertices that are not hidden.

Regular_triangulation_2<Traits,Tds>:: Hidden_vertices_iterator

An iterator that allows to enumerate the hidden vertices.

Creation

Regular_triangulation_2<Traits,Tds> rt(Traits gt = Traits());

Introduces an empty regular triangulation *rt*.

Regular_triangulation_2<Traits,Tds> rt(Regular_triangulation_2 rt);

Copy constructor.

Insertion and Removal

Vertex_handle *rt.insert(Weighted_point p, Face_handle f=Face_handle())*

inserts weighted point *p* in the regular triangulation. If the point *p* does not appear as a vertex of the triangulation, the returned vertex is a hidden vertex. If given the parameter *f* is used as an hint for the place to start the location process of point *p*.

Vertex_handle *rt.insert(Weighted_point p, Locate_type lt, Face_handle loc, int li)*

insert a weighted point *p* whose bare-point is assumed to be located in *lt,loc,li*.

Vertex_handle *rt.push_back(Point p)* Equivalent to *insert(p)*.

template < class InputIterator >
std::ptrdiff_t *rt.insert(InputIterator first, InputIterator last)*

inserts the weighted points in the range $[first, last)$. It returns the difference of the number of vertices between after and before the insertions (it may be negative due to hidden points). Note that this function is not guaranteed to insert the weighted points following the order of *InputIterator*, as *spatial_sort* is used to improve efficiency.
Precondition: The *value_type* of *first* and *last* is *Weighted_point*.

template < class WeightedPointWithInfoInputIterator >
std::ptrdiff_t *rt.insert(WeightedPointWithInfoInputIterator first,*

WeightedPointWithInfoInputIterator last)

inserts the weighted points in the iterator range [*first*, *last*). It returns the difference of the number of vertices between after and before the insertions (it may be negative due to hidden points). Note that this function is not guaranteed to insert the weighted points following the order of *WeightedPointWithInfoInputIterator*, as *spatial_sort* is used to improve efficiency. Given a pair *(p,i)*, the vertex *v* storing *p* also stores *i*, that is *v.point() == p* and *v.info() == i*. If several pairs have the same point, only one vertex is created, one of the objects of type *Vertex::Info* will be stored in the vertex.
Precondition: *Vertex* must be model of the concept *TriangulationVertexBaseWithInfo_2*. The *value_type* of *first* and *last* is *std::pair<Weighted_point,Vertex::Info>*.

void *rt.remove(Vertex_handle v)* removes the vertex from the triangulation.

Queries

template <class OutputItFaces, class OutputItBoundaryEdges, class OutputItHiddenVertices>
CGAL::Triple<OutputItFaces,OutputItBoundaryEdges,OutputItHiddenVertices>

rt.get_conflicts_and_boundary_and_hidden_vertices(Weighted_point p,
OutputItFaces fit,
OutputItBoundaryEdges eit,
OutputItHiddenVertices vit,
Face_handle start) const

OutputItFaces is an output iterator with *Face_handle* as value type. *OutputItBoundaryEdges* stands for an output iterator with *Edge* as value type. *OutputItHiddenVertices* is an output iterator with *Vertex_handle* as value type. This member function outputs in the container pointed to by *fit* the faces which are in conflict with point *p* i. e. the faces whose power circles have negative power wrt. *p*. It outputs in the container pointed to by *eit* the boundary of the zone in conflict with *p*. It inserts the vertices that would be hidden by *p* into the container pointed to by *vit*. The boundary edges of the conflict zone are output in counter-clockwise order and each edge is described through its incident face which is not in conflict with *p*. The function returns in a CGAL::Triple the resulting output iterators.
Precondition: dimension()==2

template <class OutputItFaces, class OutputItBoundaryEdges>
std::pair<OutputItFaces,OutputItBoundaryEdges>

rt.get_conflicts_and_boundary(Weighted_point p,
OutputItFaces fit,
OutputItBoundaryEdges eit,

Face_handle start) const

same as above except that only the faces in conflict with *p* and the boundary edges of the conflict zone are output via the corresponding output iterators. The function returns in a std::pair the resulting output iterators.
Precondition: dimension()==2

template <class OutputItFaces, class OutputItHiddenVertices>
std::pair<OutputItFaces,OutputItHiddenVertices>

rt.get_conflicts_and_hidden_vertices(Weighted_point p,
OutputItFaces fit,
OutputItHiddenVertices vit,
Face_handle start) const

same as above except that only the faces in conflict with *p* and the vertices that would be hidden by *p* are output via the corresponding output iterators. The function returns in a std::pair the resulting output iterators.
Precondition: dimension()==2

template <class OutputItBoundaryEdges, class OutputItHiddenVertices>
std::pair<OutputItBoundaryEdges,OutputItHiddenVertices>

rt.get_boundary_of_conflicts_and_hidden_vertices(Weighted_point p,
OutputItBoundaryEdges eit,
OutputItHiddenVertices vit,
Face_handle start) const

same as above except that only the vertices that would be hidden by *p* and the boundary of the zone in conflict with *p* are output via the corresponding output iterators. The boundary edges of the conflict zone are output in counterclockwise order and each edge is described through the incident face which is not in conflict with *p*. The function returns in a std::pair the resulting output iterators.

template <class OutputItFaces>
OutputItFaces

rt.get_conflicts(Point p, OutputItFaces fit, Face_handle start) const

same as above except that only the faces in conflict with *p* are output. The function returns the resulting output iterator.
Precondition: dimension()==2

template <class OutputItBoundaryEdges>

OutputItBoundaryEdges

rt.get_boundary_of_conflicts(Point p, OutputItBoundaryEdges eit, Face_handle start) const

same as above except that only the boundary edges of the conflict zone are output in counterclockwise order where each edge is described through the incident face which is not in conflict with p. The function returns the resulting output iterator.

template <class OutputItHiddenVertices>
OutputItHiddenVertices

rt.get_hidden_vertices(Point p, OutputItHiddenVertices vit, Face_handle start) const

same as above except that only the vertices that would be hidden by p are output. The function returns the resulting output iterator.

Vertex_handle *rt.nearest_power_vertex(Bare_point p)*

Returns the vertex of the triangulation which is nearest to p with respect to the power distance. This means that the power of the query point p with respect to the weighted point in the nearest vertex is smaller than the power of p with respect to the weighted point in any other vertex. Ties are broken arbitrarily. The default constructed handle is returned if the triangulation is empty.

Access functions

int *rt.number_of_vertices() const*

returns the number of finite vertices that are not hidden.

int *rt.number_of_hidden_vertices() const*

returns the number of hidden vertices.

Hidden_vertices_iterator *rt.hidden_vertices_begin() const*

starts at an arbitrary hidden vertex.

Hidden_vertices_iterator *rt.hidden_vertices_end() const*

past the end iterator for the sequence of hidden vertices.

Finite_vertices_iterator *rt.finite_vertices_begin() const*

starts at an arbitrary unhidden finite vertex

Finite_vertices_iterator *rt.finite_vertices_end() const*

Past-the-end iterator

All_vertices_iterator *rt.all_vertices_end() const*

starts at an arbitrary unhidden vertex.

All_vertices_iterator *rt.all_vertices_begin() const*

past the end iterator.

Dual power diagram

The following member functions provide the elements of the dual power diagram.

Point *rt.weighted_circumcenter(Face_handle f) const*

returns the center of the circle orthogonal to the three weighted points corresponding to the vertices of face f.
Precondition: f is not infinite

Point *rt.dual(Face_handle f) const*

same as weighted_circumcenter

Object *rt.dual(Edge e) const* If both incident faces are finite, returns a segment whose endpoints are the duals of each incident face. If only one incident face is finite, returns a ray whose endpoint is the dual of the finite incident face and supported by the line which is the bisector of the edge's endpoints. If both incident faces are infinite, returns the line which is the bisector of the edge's endpoints otherwise.

Object *rt.dual(Edge_circulator ec) const*

Idem

Object *rt.dual(Edge_iterator ei) const*

Idem

template < class Stream>
Stream& *rt.draw_dual(Stream & ps)*

output the dual power diagram to stream *ps*.

Predicates

Oriented_side *rt.power_test(Face_handle f, Weighted_point p) const*

Returns the power test of p with respect to the power circle associated with f

advanced

Miscellaneous

bool *rt.is_valid(bool verbose = false, int level = 0) const*

Tests the validity of the triangulation as a *Triangulation_2* and additionally test the regularity of the triangulation. This method is useful to debug regular triangulation algorithms implemented by the user.

TriangulationFaceBase_2

Concept

Definition

The concept TriangulationFaceBase_2 describes the requirements for the base face class of a triangulation data structure that is itself plugged into a basic triangulation or a Delaunay triangulation.

This concept refines the concept *TriangulationDSFaceBase_2* and could add geometric information. In fact, currently the triangulations of CGAL do not store any geometric information in the faces and, thus this concept is just equal to *TriangulationDSFaceBase_2* and only provided for symmetry with the vertex case.

Concept

TriangulationHierarchyVertexBase_2

Definition

The vertex of a triangulation included in a triangulation hierarchy has to provide some pointers to the corresponding vertices in the triangulations of the next and preceding levels. Therefore, the concept *TriangulationHierarchyVertexBase_2* refines the concept *TriangulationVertexBase_2*, adding handles to the corresponding vertices in the next and previous level triangulations.

Refines

TriangulationVertexBase_2

Operations

Vertex_handle	*v.up()*	returns the corresponding vertex (if any) of the next level triangulation;
Vertex_handle	*v.down()*	returns the corresponding vertex of the previous level triangulation;
void	*v.set_up(Vertex_handle u)*	sets the handle pointing to to the corresponding vertex of the next level triangulation;
void	*v.set_down(Vertex_handle d)*	sets the handle pointing to the corresponding vertex of the previous level triangulation;

TriangulationTraits_2

Definition

The concept TriangulationTraits_2 describes the set of requirements to be fulfilled by any class used to instantiate the first template parameter of the class *Triangulation_2<Traits,Tds>*. This concept provides the types of the geometric primitives used in the triangulation and some function object types for the required predicates on those primitives.

Types

TriangulationTraits_2:: Point_2	The point type.
TriangulationTraits_2:: Segment_2	The segment type.
TriangulationTraits_2:: Triangle_2	The triangle type.
TriangulationTraits_2:: Construct_segment_2	A constructor object for *Segment_2*. Provides : *Segment_2 operator()(Point_2 p,Point_2 q)*, which constructs a segment from two points.
TriangulationTraits_2:: Construct_triangle_2	A constructor object for *Triangle_2*. Provides : *Triangle_2 operator()(Point_2 p,Point_2 q,Point_2 r)*, which constructs a triangle from three points.
TriangulationTraits_2:: Less_x_2	Predicate object. Provides the operator : *bool operator()(Point p, Point q)* which returns *true* if p is before q according to the x-ordering of points.
TriangulationTraits_2:: Less_y_2	Predicate object. Provides the operator : *bool operator()(Point p, Point q)* which returns *true* if p is before q according to the y-ordering of points.
TriangulationTraits_2:: Compare_x_2	Predicate object. Provides the operator : *Comparison_result operator()(Point p, Point q)* which returns *SMALLER, EQUAL* or *LARGER* according to the x-ordering of points p and q.
TriangulationTraits_2:: Compare_y_2	Predicate object. Provides the operator : *Comparison_result operator()(Point p, Point q)* which returns (*SMALLER, EQUAL* or *LARGER*) according to the y-ordering of points p and q.
TriangulationTraits_2:: Orientation_2	Predicate object. Provides the operator : *Orientation operator()(Point p, Point q, Point r)* which returns *LEFT_TURN*, *RIGHT_TURN* or *COLLINEAR* depending on r being, with respect to the oriented line pq, on the left side , on the right side or on the line.

TriangulationTraits_2:: Side_of_oriented_circle_2

Predicate object. Must provide the operator *Oriented_side operator()(Point p, Point q, Point r, Point s)* which takes four points p,q,r,s as arguments and returns *ON_POSITIVE_SIDE*, *ON_NEGATIVE_SIDE* or, *ON_ORIENTED_BOUNDARY* according to the position of points s with respect to the oriented circle through through p,q and r. This type is required only if the function *side_of_oriented_circle(Face_handle f, Point p)* is called.

TriangulationTraits_2:: Construct_circumcenter_2

Constructor object. Provides the operator :
Point operator()(Point p, Point q, Point r)
which returns the circumcenter of the three points *p, q* and r. This type is required only if the function *Point circumcenter(Face_handle f)*is called.

Creation

Only a default constructor, copy constructor and an assignment operator are required. Note that further constructors can be provided.

TriangulationTraits_2 traits; — default constructor.

TriangulationTraits_2 traits(gtr); — Copy constructor

TriangulationTraits_2 $traits = gtr$ — Assignment operator.

Predicate functions

The following functions give access to the predicate and constructor objects.

Construct_segment_2	*traits.construct_segment_2_object()*
Construct_triangle_2	*traits.construct_triangle_2_object()*
Comparison_x_2	*traits.compare_x_2_object()*
Comparison_y_2	*traits.compare_y_2_object()*
Orientation_2	*traits.orientation_2_object()*
Side_of_oriented_circle_2	*traits.side_of_oriented_circle_2_object()*

Required only if *side_of_oriented_circle* is called called.

Construct_circumcenter_2

traits.construct_circumcenter_2_object()

Required only if *circumcenter* is called.

Concept

TriangulationVertexBase_2

Definition

The concept TriangulationVertexBase_2 describes the requirements for the vertex base class of a triangulation data structure to be plugged in a basic, Delaunay or constrained triangulations.

The concept TriangulationVertexBase_2 refines the concept *TriangulationDSVertexBase_2* adding geometric information : the vertex base of a triangulation stores a point.

Refines

TriangulationDSVertexBase_2

Types

TriangulationVertexBase_2:: Point	Must be the same as the point type *TriangulationTraits_2::Point_2* defined by the geometric traits class of the triangulation.

Creation

TriangulationVertexBase_2 v(Point p); constructs a vertex embedded in point p.

TriangulationVertexBase_2 v(Point p, Face_handle f);

constructs a vertex embedded in point p and pointing on face f.

Access Functions

Point *v.point() const* returns the point.

Setting

void *v.set_point(Point p)*

sets the point.

I/O

istream& *istream& is >> & v*

Inputs the non-combinatorial information given by the vertex: the point and other possible information.

ostream&

ostream& os << *v*

Outputs the non combinatorial operation given by the vertex: the point and other possible information.

CGAL::Triangulation_vertex_base_with_info_2

CGAL::Triangulation_2<Traits,Tds>

Definition

The class *Triangulation_2<Traits,Tds>* is the basic class designed to handle triangulations of set of points A in the plane.

Such a triangulation has vertices at the points of A and its domain covers the convex hull of A. It can be viewed as a planar partition of the plane whose bounded faces are triangular and cover the convex hull of A. The single unbounded face of this partition is the complementary of the convex hull of A.

In many applications, it is convenient to deal only with triangular faces. Therefore, we add to the triangulation a fictitious vertex, called the *infinite vertex* and we make each convex hull edge incident to an *infinite* face having as third vertex the *infinite vertex*. In that way, each edge is incident to exactly two faces and special cases at the boundary of the convex hull are simpler to deal with.

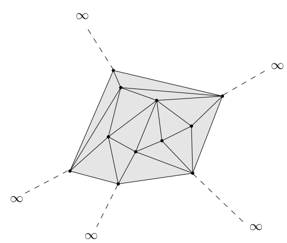

Figure 37.10: The infinite vertex.

The class *Triangulation_2<Traits,Tds>* implements this point of view and therefore considers the triangulation of the set of points as a set of triangular, finite and infinite faces. Although it is convenient to draw a triangulation as in figure 37.10, note that the *infinite vertex* has no significant coordinates and that no geometric predicate can be applied on it or on an infinite face.

A triangulation is a collection of vertices and faces that are linked together through incidence and adjacency relations. Each face give access to its three incident vertices and to its three adjacent faces. Each vertex give access to one of its incident faces.

The three vertices of a face are indexed with 0, 1 and 2 in counterclockwise order. The neighbor of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by i is opposite to the vertex with the same index.

The triangulation class offer two functions *int cw(int i)* and *int ccw(int i)* which given the index of a vertex in a face compute the index of the next vertex of the same face in clockwise or counterclockwise order. Thus, for example the neighbor *neighbor(cw(i))* is the neighbor of f which is next to *neighbor(i)* turning clockwise around f. The face *neighbor(cw(i))* is also the first face encountered after f when turning clockwise around vertex i of f (see Figure 37.11).

#include <CGAL/Triangulation_2.h>

Parameters

The class *Triangulation_2<Traits,Tds>* has two template parameters. The first one *Traits* is the geometric traits, it is to be instantiated by a model of the concept *TriangulationTraits_2*.

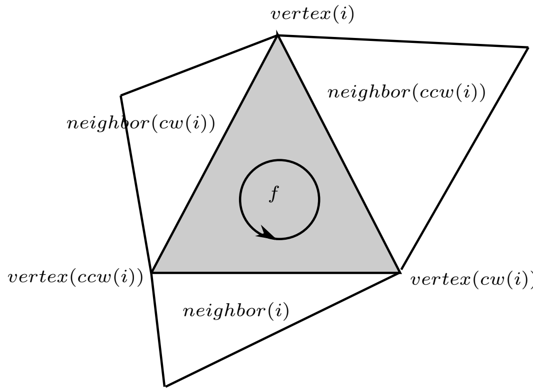

Figure 37.11: Vertices and neighbors.

The second parameter is the triangulation data structure, it has to be instantiated by a model of the concept *TriangulationDataStructure_2*. By default, the triangulation data structure is instantiated by *CGAL::Triangulation_data_structure_2 < CGAL::Triangulation_vertex_base_2<Gt>, CGAL::Triangulation_face_base_2<Gt> >*.

Inherits From

Triangulation_cw_ccw_2 This class provides the functions *cw(i)* and *ccw(i)*.

Types

typedef Traits	*Geom_traits;*	the traits class.
typedef Tds	*Triangulation_data_structure;*	the triangulation data structure type.
typedef Traits::Point_2	*Point;*	the point type
typedef Traits::Segment_2	*Segment;*	the segment type
typedef Traits::Triangle_2	*Triangle;*	the triangle type
typedef Tds::Vertex	*Vertex;*	the vertex type.
typedef Tds::Face	*Face;*	the face type.
typedef Tds::Edge	*Edge;*	the edge type.
typedef Tds::size_type	*size_type;*	Size type (an unsigned integral type)
typedef Tds::difference_type	*difference_type;*	Difference type (a signed integral type)

The vertices and faces of the triangulations are accessed through *handles*, *iterators* and *circulators*. The handles are models of the concept *Handle* which basically offers the two dereference operators * and ->. The iterators and circulators are all bidirectional and non mutable. The circulators and iterators are convertible to handles with the same value type, so that whenever a handle appear in the parameter list of a function, an appropriate iterator or circulator can be passed as well.

The edges of the triangulation can also be visited through iterators and circulators, the edge circulators and iterators are also bidirectional and non mutable.

In the following, we called *infinite* any face or edge incident to the infinite vertex and the infinite vertex itself. Any other feature (face, edge or vertex) of the triangulation is said to be *finite*. Some iterators (the *All* iterators

) allows to visit finite or infinite feature while others (the *Finite* iterators) visit only finite features. Circulators visit infinite features as well as finite ones.

typedef Tds::Vertex_handle	*Vertex_handle;*	handle to a vertex
typedef Tds::Face_handle	*Face_handle;*	handle to a face

typedef Tds::Face_iterator	*All_faces_iterator;*	iterator over all faces.
typedef Tds::Edge_iterator	*All_edges_iterator;*	iterator over all edges
typedef Tds::Vertex_iterator	*All_vertices_iterator;*	iterator over all vertices

Triangulation_2<Traits,Tds>:: Finite_faces_iterator	iterator over finite faces.
Triangulation_2<Traits,Tds>:: Finite_edges_iterator	iterator over finite edges.
Triangulation_2<Traits,Tds>:: Finite_vertices_iterator	iterator over finite vertices.
Triangulation_2<Traits,Tds>:: Point_iterator	iterator over the points corresponding the finite vertices of the triangulation.

Triangulation_2<Traits,Tds>:: Line_face_circulator	circulator over all faces intersected by a line.

Triangulation_2<Traits,Tds>:: Face_circulator	circulator over all faces incident to a given vertex.
Triangulation_2<Traits,Tds>:: Edge_circulator	circulator over all edges incident to a given vertex.
Triangulation_2<Traits,Tds>:: Vertex_circulator	circulator over all vertices incident to a given vertex.

The triangulation class also defines the following enum type to specify which case occurs when locating a point in the triangulation.

enum Locate_type { *VERTEX=0, EDGE, FACE, OUTSIDE_CONVEX_HULL, OUTSIDE_AFFINE_HULL*}*;*

The locate type is *OUTSIDE_CONVEX_HULL* when the point is outside the convex hull but in the affine hull of the current triangulation.
The locate type is *OUTSIDE_AFFINE_HULL* when the point is outside the affine hull of the current triangulation.

Creation

Triangulation_2<Traits,Tds> t; default constructor.

Triangulation_2<Traits,Tds> t(Traits gt = Traits());

Introduces an empty triangulation *t*.

Triangulation_2<Traits,Tds> t(Triangulation_2 tr);

Copy constructor. All the vertices and faces are duplicated. After the copy, *t* and *tr* refer to different triangulations : if *tr* is modified, *t* is not.

Triangulation_2	$t = tr$	Assignment. All the vertices and faces are duplicated. After the assignment, *t* and *tr* refer to different triangulations : if *tr* is modified, *t* is not.
void	*t.swap(Triangulation_2& tr)*	
		The triangulations *tr* and *t* are swapped. *t.swap(tr)* should be preferred to *t = tr* or to *t(tr)* if *tr* is deleted after that.
void	*t.clear()*	Deletes all faces and finite vertices resulting in an empty triangulation.

Access Functions

Geom_traits	*t.geom_traits() const*	Returns a const reference to the triangulation traits object.
TriangulationDataStructure_2		
	t.tds() const	Returns a const reference to the triangulation data structure.

advanced

Non const access

The responsibility of keeping a valid triangulation belongs to the user when using advanced operations allowing a direct manipulation of the *tds*.

TriangulationDataStructure_2&

	t.tds()	Returns a reference to the triangulation data structure.

This method is mainly a help for users implementing their own triangulation algorithms.

advanced

int	*t.dimension() const*	Returns the dimension of the convex hull.
size_type	*t.number_of_vertices() const*	
		Returns the number of finite vertices.
size_type	*t.number_of_faces() const*	
		Returns the number of finite faces.
Face_handle	*t.infinite_face() const*	a face incident to the *infinite_vertex*.
Vertex_handle	*t.infinite_vertex()*	the *infinite_vertex*.
Vertex_handle	*t.finite_vertex() const*	a vertex distinct from the *infinite_vertex*.

Predicates

The class *Triangulation_2<Traits,Tds>* provides methods to test the finite or infinite character of any feature, and also methods to test the presence in the triangulation of a particular feature (edge or face).

bool *t.is_infinite(Vertex_handle v) const*

true iff *v* is the *infinite_vertex*.

bool *t.is_infinite(Face_handle f) const* *true* iff face *f* is infinite.

bool *t.is_infinite(Face_handle f, int i) const*

true iff edge *(f,i)* is infinite.

bool *t.is_infinite(Edge e) const* *true* iff edge *e* is infinite.

bool *t.is_infinite(Edge_circulator ec) const*

true iff edge **ec* is infinite.

bool *t.is_infinite(Edge_iterator ei) const*

true iff edge **ei* is infinite.

bool *t.is_edge(Vertex_handle va, Vertex_handle vb)*

true if there is an edge having *va* and *vb* as vertices.

bool *t.is_edge(Vertex_handle va, Vertex_handle vb, Face_handle& fr, int & i)*

as above. In addition, if *true* is returned, the edge with vertices *va* and *vb* is the edge *e=(fr,i)* where *fr* is a handle to the face incident to *e* and on the right side of *e* oriented from *va* to *vb*.

bool *t.includes_edge(Vertex_handle va, Vertex_handle & vb, Face_handle& fr, int & i)*

true if the line segment from *va* to *vb* includes an edge *e* incident to *va*. If *true*, *vb* becomes the other vertex of *e*, *e* is the edge *(fr,i)* where *fr* is a handle to the face incident to *e* and on the right side *e* oriented from *va* to *vb*.

bool *t.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)*

true if there is a face having *v1*, *v2* and *v3* as vertices.

bool *t.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3, Face_handle &fr)*

as above. In addition, if *true* is returned, fr is a handle to the face with *v1*, *v2* and *v3* as vertices.

Queries

The class *Triangulation_2<Traits,Tds>* provides methods to locate a given point with respect to a triangulation. It also provides methods to locate a point with respect to a given finite face of the triangulation.

Face_handle *t.locate(Point query, Face_handle f = Face_handle())*

If the point *query* lies inside the convex hull of the points, a face that contains the query in its interior or on its boundary is returned.
If the point *query* lies outside the convex hull of the triangulation but in the affine hull, the returned face is an infinite face which is a proof of the point's location :
- for a two dimensional triangulation, it is a face (∞, p, q) such that *query* lies to the left of the oriented line *pq* (the rest of the triangulation lying to the right of this line).
- for a degenerate one dimensional triangulation it is the (degenerate one dimensional) face $(\infty, p, NULL)$ such that *query* and the triangulation lie on either side of *p*.
If the point *query* lies outside the affine hull, the returned *Face_handle* is *NULL*.
The optional *Face_handle* argument, if provided, is used as a hint of where the locate process has to start its search.

Face_handle *t.locate(Point query, Locate_type& lt, int& li, Face_handle h =Face_handle())*

Same as above. Additionally, the parameters *lt* and *li* describe where the query point is located. The variable *lt* is set to the locate type of the query. If *lt==VERTEX* the variable *li* is set to the index of the vertex, and if *lt==EDGE li* is set to the index of the vertex opposite to the edge. Be careful that *li* has no meaning when the query type is *FACE*, *OUTSIDE_CONVEX_HULL*, or *OUTSIDE_AFFINE_HULL* or when the triangulation is 0-dimensional.

Oriented_side *t.oriented_side(Face_handle f, Point p) const*

Returns on which side of the oriented boundary of f lies the point p.
Precondition: f is finite.

Oriented_side *t.side_of_oriented_circle(Face_handle f, Point p)*

Returns on which side of the circumcircle of face f lies the point p. The circle is assumed to be counterclockwise oriented, so its positive side correspond to its bounded side. This predicate is available only if the corresponding predicates on points is provided in the geometric traits class.

Modifiers

The following operations are guaranteed to lead to a valid triangulation when they are applied on a valid triangulation.

void *t.flip(Face_handle f, int i)*

Exchanges the edge incident to f and *f->neighbor(i)* with the other diagonal of the quadrilateral formed by f and *f->neighbor(i)*.
Precondition: The faces f and *f->neighbor(i)* are finite faces and their union form a convex quadrilateral.

Vertex_handle *t.insert(Point p, Face_handle f = Face_handle())*

Inserts point p in the triangulation and returns the corresponding vertex.
If point p coincides with an already existing vertex, this vertex is returned and the triangulation remains unchanged.
If point p is on an edge, the two incident faces are split in two.
If point p is strictly inside a face of the triangulation, the face is split in three.
If point p is strictly outside the convex hull, p is linked to all visible points on the convex hull to form the new triangulation.
At last, if p is outside the affine hull (in case of degenerate 1-dimensional or 0-dimensional triangulations), p is linked all the other vertices to form a triangulation whose dimension is increased by one. The last argument f is an indication to the underlying locate algorithm of where to start.

Vertex_handle *t.insert(Point p, Locate_type lt, Face_handle loc, int li)*

Same as above except that the location of the point p to be inserted is assumed to be given by *(lt,loc,i)* (see the description of the *locate* method above.)

Vertex_handle *t.push_back(Point p)*

Equivalent to *insert(p)*.

template < class InputIterator >
std::ptrdiff_t *t.insert(InputIterator first, InputIterator last)*

Inserts the points in the range $[first, last)$. Returns the number of inserted points.
Precondition: The *value_type* of *InputIterator* is *Point*.

void *t.remove(Vertex_handle v)*

Removes the vertex from the triangulation. The created hole is re-triangulated.
Precondition: Vertex v must be finite.

Vertex_handle *t.move_if_no_collision(Vertex_handle v, Point p)*

if there is not already another vertex placed on p, the triangulation is modified such that the new position of vertex v is p, and v is returned. Otherwise, the triangulation is not modified and the vertex at point p is returned.
Precondition: Vertex v must be finite.

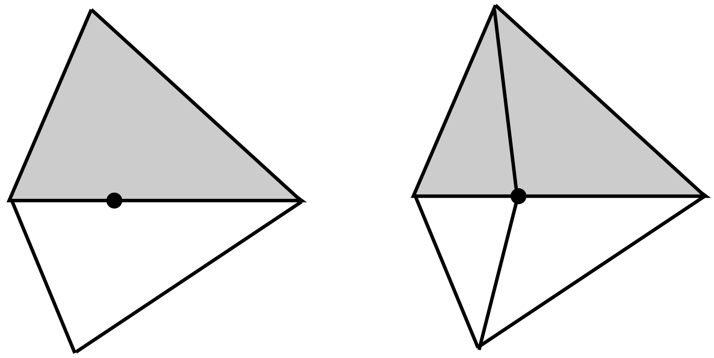

Figure 37.12: Insertion of a point on an edge.

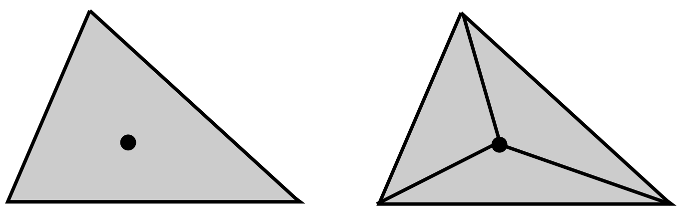

Figure 37.13: Insertion in a face.

Vertex_handle *t.move(Vertex_handle v, Point p)*

same as above if there is no collision. Otherwise, v is deleted and the vertex placed on p is returned.
Precondition: Vertex v must be finite.

advanced

The following member functions offer more specialized versions of the insertion or removal operations to be used when one knows to be in the corresponding case.

Vertex_handle *t.insert_first(Point p)*

Inserts the first finite vertex .

Vertex_handle *t.insert_second(Point p)*

Inserts the second finite vertex .

Vertex_handle *t.insert_in_face(Point p, Face_handle f)*

Inserts vertex v in face f. Face f is modified, two new faces are created.
Precondition: The point in vertex v lies inside face f.

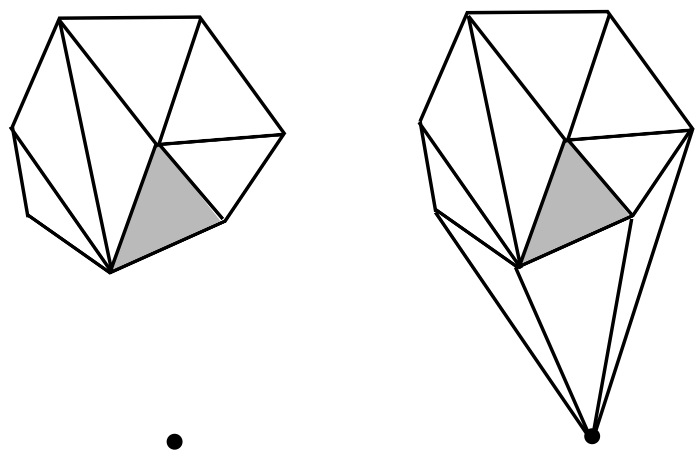

Figure 37.14: Insertion outside the convex hull.

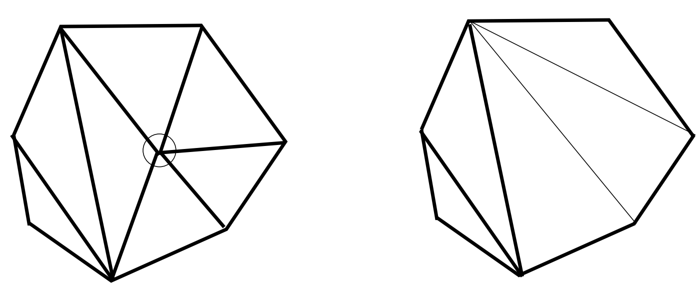

Figure 37.15: Removal

Vertex_handle *t.insert_in_edge(Point p, Face_handle f, int i)*

Inserts vertex v in edge *i* of *f*.
Precondition: The point in vertex *v* lies on the edge opposite to the vertex *i* of face *f*.

Vertex_handle *t.insert_outside_convex_hull(Point p, Face_handle f)*

Inserts a point which is outside the convex hull but in the affine hull.
Precondition: The handle *f* points to a face which is a proof of the location of*p*, see the description of the *locate* method above.

Vertex_handle *t.insert_outside_affine_hull(Point p)*

Inserts a point which is outside the affine hull.

void *t.remove_degree_3(Vertex_handle v)*

Removes a vertex of degree three. Two of the incident faces are destroyed, the third one is modified.
Precondition: Vertex *v* is a finite vertex with degree three.

void *t.remove_second(Vertex_handle v)*

Removes the before last finite vertex.

void *t.remove_first(Vertex_handle v)*

Removes the last finite vertex.

The following functions are mainly intended to be used in conjunction with the *find_conflicts()* member functions of Delaunay and constrained Delaunay triangulations to perform insertions.

template<class EdgeIt>
Vertex_handle *t.star_hole(Point p, EdgeIt edge_begin, EdgeIt edge_end)*

creates a new vertex *v* and use it to star the hole whose boundary is described by the sequence of edges *[edge_begin, edge_end[*. Returns a handle to the new vertex.

template<class EdgeIt, class FaceIt>
Vertex_handle *t.star_hole(Point p,*
EdgeIt edge_begin,
EdgeIt edge_end,
FaceIt face_begin,
FaceIt face_end)

same as above, except that the algorithm first recycles faces in the sequence *[face_begin, face_end[* and create new ones only when the sequence is exhausted.

advanced

Traversal of the Triangulation

A triangulation can be seen as a container of faces and vertices. Therefore the triangulation provides several iterators and circulators that allow to traverse it (completely or partially).

Face, Edge and Vertex Iterators

The following iterators allow respectively to visit finite faces, finite edges and finite vertices of the triangulation. These iterators are non mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the triangulation.

Finite_vertices_iterator *t.finite_vertices_begin() const*

Starts at an arbitrary finite vertex

Finite_vertices_iterator *t.finite_vertices_end() const*

Past-the-end iterator

Finite_edges_iterator *t.finite_edges_begin() const*

Starts at an arbitrary finite edge

Finite_edges_iterator *t.finite_edges_end() const*

Past-the-end iterator

Finite_faces_iterator *t.finite_faces_begin() const*

Starts at an arbitrary finite face

Finite_faces_iterator *t.finite_faces_end() const*

Past-the-end iterator

Point_iterator *t.points_begin() const*

Point_iterator *t.points_end() const* Past-the-end iterator

The following iterators allow respectively to visit all (finite or infinite) faces, edges and vertices of the triangulation. These iterators are non mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the triangulation.

All_vertices_iterator *t.all_vertices_begin() const*

Starts at an arbitrary vertex

All_vertices_iterator *t.all_vertices_end() const*

Past-the-end iterator

All_edges_iterator	*t.all_edges_begin() const*	
		Starts at an arbitrary edge
All_edges_iterator	*t.all_edges_end() const*	Past-the-end iterator
All_faces_iterator	*t.all_faces_begin() const*	Starts at an arbitrary face
All_faces_iterator	*t.all_faces_end() const*	Past-the-end iterator

Line Face Circulator

The triangulation defines a circulator that allows to visit all faces that are intersected by a line. A face f is considered has being intersected by the oriented line l if either:

- f is a finite face whose interior intersects l, or
- f is a finite face with an edge collinear with l and lies to the left of l, or
- f is an infinite face incident to a convex hull edge whose interior is intersected by l, or
- f is an infinite face incident to a convex hull vertex lying on l and the finite edge of f lies to the left of l.

The circulator has a singular value if the line l intersect no finite face of the triangulation. This circulator is non-mutable and bidirectional. Its value type is *Face*.

Line_face_circulator *t.line_walk(Point p, Point q, Face_handle f = Face_handle())*

This function returns a circulator that allows to visit the faces intersected by the line pq. If there is no such face the circulator has a singular value.
The starting point of the circulator is the face f, or the first finite face traversed by l , if f is omitted.
The circulator wraps around the *infinite_vertex* : after the last traversed finite face, it steps through the infinite face adjacent to this face then through the infinite face adjacent to the first traversed finite face then through the first finite traversed face again.
Precondition: The triangulation must have dimension 2.
Precondition: Points p and q must be different points.
Precondition: If *f != NULL*, it must point to a finite face and the point p must be inside or on the boundary of f.

Figure 37.16 illustrates which finite faces are enumerated. Lines l_1 and l_2 have no face to their left. Lines l_3 and l_4 have faces to their left. Note that the finite faces that are only vertex incident to lines l_3 and l_4 are not enumerated.

A line face circulator is invalidated if the face the circulator refers to is changed.

Face, Edge and Vertex Circulators

The triangulation also provides circulators that allows to visit respectively all faces or edges incident to a given vertex or all vertices adjacent to a given vertex. These circulators are non-mutable and bidirectional. The *operator++* moves the circulator counterclockwise around the vertex while the *operator--* moves clockwise.

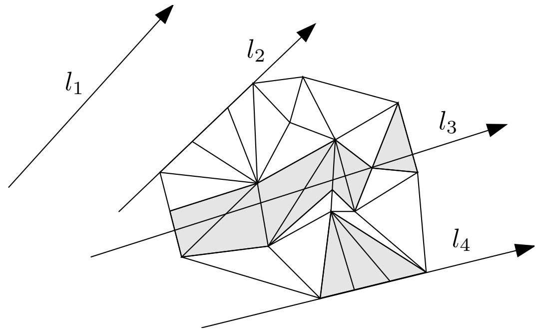

Figure 37.16: The line face circulator.

A face circulator is invalidated by any modification of the face pointed to. An edge or a vertex circulator are invalidated by any modification of one of the two faces incident to the edge pointed to.

Face_circulator *t.incident_faces(Vertex_handle v) const*

Starts at an arbitrary face incident to *v*.

Face_circulator *t.incident_faces(Vertex_handle v, Face_handle f) const*

Starts at face *f*.
Precondition: Face *f* is incident to vertex *v*.

Edge_circulator *t.incident_edges(Vertex_handle v) const*

Starts at an arbitrary edge incident to *v*.

Edge_circulator *t.incident_edges(Vertex_handle v, Face_handle f) const*

Starts at the first edge of *f* incident to *v*, in counterclockwise order around *v*.
Precondition: Face *f* is incident to vertex *v*.

Vertex_circulator *t.incident_vertices(Vertex_handle v) const*

Starts at an arbitrary vertex incident to *v*.

Vertex_circulator *t.incident_vertices(Vertex_handle v, Face_handle f)*

Starts at the first vertex of *f* adjacent to *v* in counterclockwise order around *v*.
Precondition: Face *f* is incident to vertex *v*.

Traversal of the Convex Hull

Applied on the *infinite_vertex* the above functions allow to visit the vertices on the convex hull and the infinite edges and faces. Note that a counterclockwise traversal of the vertices adjacent to the *infinite_vertex* is a clockwise traversal of the convex hull.

Face_circulator *t.incident_faces(t.infinite_vertex())*
Face_circulator *t.incident_faces(t.infinite_vertex(), Face_handle f) const*
Edge_circulator *t.incident_edges(t.infinite_vertex())*

Edge_circulator	*t.incident_edges(t.infinite_vertex(), Face_handle f)*
Vertex_circulator	*t.incident_vertices(t.infinite_vertex() v)*
Vertex_circulator	*t.incident_vertices(t.infinite_vertex(), Face_handle f)*

Traversal between adjacent faces

Vertex_handle *t.mirror_vertex(Face_handle f, int i) const*

returns the vertex of the i^{th} neighbor of f that is opposite to f.
Precondition: $0 \leq i \leq 2$.

int *t.mirror_index(Face_handle f, int i) const*

returns the index of f in its i^{th} neighbor.
Precondition: $0 \leq i \leq 2$.

Edge *t.mirror_edge(Edge e) const*

returns the same edge seen from the other adjacent face.
Precondition: $0 \leq i \leq 2$.

Miscellaneous

int *t.ccw(int i) const* Returns $i+1$ modulo 3.
Precondition: $0 \leq i \leq 2$.

int *t.cw(int i) const* Returns $i+2$ modulo 3.
Precondition: $0 \leq i \leq 2$.

Triangle

t.triangle(Face_handle f) const

Returns the triangle formed by the three vertices of f.
Precondition: The face is finite.

Segment *t.segment(Face_handle f, int i) const*

Returns the line segment formed by the vertices *ccw(i)* and *cw(i)* of face f.
Precondition: $0 \leq i \leq 2$. The vertices *ccw(i)* and *cw(i)* of f are finite.

Segment *t.segment(Edge e) const* Returns the line segment corresponding to edge e.
Precondition: e is a finite edge

Segment *t.segment(Edge_circulator ec) const*

Returns the line segment corresponding to edge **ec*.
Precondition: **ec* is a finite edge.

Segment *t.segment(Edge_iterator ei) const*

Returns the line segment corresponding to edge **ei*.
Precondition: **ei* is a finite edge.

Point *t.circumcenter(Face_handle f) const*

Compute the circumcenter of the face pointed to by f. This function is available only if the corresponding function is provided in the geometric traits.

advanced

Setting

void *t.set_infinite_vertex(Vertex_handle v)*

Checking

The responsibility of keeping a valid triangulation belongs to the users if advanced operations are used. Obviously the advanced user, who implements higher levels operations may have to make a triangulation invalid at some times. The following method is provided to help the debugging.

bool *t.is_valid(bool verbose = false, int level = 0) const*

Checks the combinatorial validity of the triangulation and also the validity of its geometric embedding. This method is mainly a debugging help for the users of advanced features.

advanced

I/O

The I/O operators are defined for *iostream*. The format for the iostream is an internal format.

ostream& *ostream& os << T*

Inserts the triangulation *t* into the stream *os*.
Precondition: The insert operator must be defined for *Point*.

istream& *istream& is >> T* Reads a triangulation from stream *is* and assigns it to *t*.
Precondition: The extract operator must be defined for *Point*.

The information output in the *iostream* is:
- the number of vertices (including the infinite one), the number of faces (including infinite ones), and the dimension.
- for each vertex (except the infinite vertex), the non combinatorial information stored in that vertex (point, etc.).
- for each faces, the indices of its vertices and the non combinatorial information (if any) in this face.
- for each face again the indices of the neighboring faces.
The index of an item (vertex of face) is the rank of this item in the output order. When dimension < 2, the same information is output for faces of maximal dimension instead of faces.

CGAL also provides a stream operator << to draw triangulations for *CGAL::Qt_widget*, the Qt based graphic package. These operators require the include statement :
#include CGAL/IO/Qt_widget_Triangulation_2.h
See the *Qt_widget* class.

Implementation

Locate is implemented by a line walk from a vertex of the face given as optional parameter (or from a finite vertex of *infinite_face()* if no optional parameter is given). It takes time $O(n)$ in the worst case, but only $O(\sqrt{n})$ on average if the vertices are distributed uniformly at random.

Insertion of a point is done by locating a face that contains the point, and then splitting this face. If the point falls outside the convex hull, the triangulation is restored by flips. Apart from the location, insertion takes a time time $O(1)$. This bound is only an amortized bound for points located outside the convex hull.

Removal of a vertex is done by removing all adjacent triangles, and re-triangulating the hole. Removal takes time $O(d^2)$ in the worst case, if d is the degree of the removed vertex, which is $O(1)$ for a random vertex.

The face, edge, and vertex iterators on finite features are derived from their counterparts visiting all (finite and infinite) features which are themselves derived from the corresponding iterators of the triangulation data structure.

CGAL::Triangulation_cw_ccw_2

Class

Definition

The class *Triangulation_cw_ccw_2* offer two functions *int cw(int i)* and *int ccw(int i)* which given the index of a vertex in a face compute the index of the next vertex of the same face in clockwise or counterclockwise order. This works also for neighbor indexes. Thus, for example the neighbor *neighbor(cw(i))* of a face f is the neighbor which is next to *neighbor(i)* turning clockwise around f. The face *neighbor(cw(i))* is also the first face encountered after f when turning clockwise around vertex i of f.

Many of the classes in the triangulation package inherit from *Triangulation_cw_ccw_2*. This is for instance the case for *CGAL::Triangulation_2<Traits,Tds>::Face*. Thus, for example the neighbor *neighbor(cw(i))* of a face f is the neighbor which is next to *neighbor(i)* turning clockwise around f. The face *neighbor(cw(i))* is also the first face encountered after f when turning clockwise around vertex i of f.

#include <CGAL/Triangulation_2.h>

Creation

Triangulation_cw_ccw_2 a; default constructor.

Operations

int *a.ccw(const int i) const*

returns the index of the neighbor or vertex that is next to the neighbor or vertex with index i in counterclockwise order around a face.

int *a.cw(const int i) const*

returns the index of the neighbor or vertex that is next to the neighbor or vertex with index i in counterclockwise order around a face.

CGAL::Triangulation_euclidean_traits_xy_3<K>

The functionality of this class has been generalized to other packages than 2D triangulations. The more general class *Projection_traits_xy_3* can be found in the 2D and 3D Linear Geometric Kernel.

deprecated

Definition

The class *Triangulation_euclidean_traits_xy_3<K>* is a geometric traits class which allows to triangulate a terrain. This traits class is designed to build a two dimensional triangulation embedded in 3D space, i.e. a triangulated surface, such that its on the *xy* plane is a Delaunay triangulation. This is a usual construction for GIS terrains. Instead of really projecting the 3D points and maintaining a mapping between each point and its projection (which costs space and is error prone) the class *Triangulation_euclidean_traits_xy_3<K>* supplies geometric predicates that ignore the *z*-coordinate of the points.

The class is a model of the concept *DelaunayTriangulationTraits_2* except that it does not provide the type and constructors required to build the dual Voronoi diagram. The class is also a model of the concept *ConstrainedTriangulationTraits_2*.

Parameters

The template parameter *K* has to be instantiated by a model of the *Kernel* concept. *Triangulation_euclidean_traits_xy_3<K>* uses types and predicates defined in *K*.

#include <CGAL/Triangulation_euclidean_traits_xy_3.h>

Types

typedef Point_3<K> *Point_2;*
typedef Segment_3<K>
Segment_2;
typedef Triangle_3<K>
Triangle_2;
typedef Line_3<K> *Line_2;*

The following predicates and constructor types are provided

Triangulation_euclidean_traits_xy_3<K>:: Construct_segment_2

A constructor object for *Segment_2*. Provides :
Segment_2 operator()(Point_2 p,Point_2 q),
which constructs a segment from two points.

Triangulation_euclidean_traits_xy_3<K>:: Construct_triangle_2

A constructor object for *Triangle_2*. Provides :
Triangle_2 operator()(Point_2 p,Point_2 q,Point_2 r),
which constructs a triangle from three points.

Triangulation_euclidean_traits_xy_3<K>:: Construct_line_2

A constructor object for *Line_2*. Provides :
Line_2 operator()(Point_2 p,Point_2 q),
which constructs a line from two points.

Triangulation_euclidean_traits_xy_3<K>:: Compute_squared_distance_2

A construction object. Provides the operator :
RT operator()(Line_2 l, Point_2 p); which returns the squared distance between the projection of *p* and the projection of *l*.

Triangulation_euclidean_traits_xy_3<K>:: Intersect_2

A construction object. Provides the operator :
Object_2 operator()(Segment_2 s1, Segment_2 s2); which returns the intersection of the projection of *s1* and the projection of *s2* embedded in *3D*. If the intersection is a segment, the *z*-coordinates of its extremities is *0*. If the intersection is a point *p*, let *p1* and *p2* be the points on *s1* and *s2* respectively, such that their projections are *p*. The point returned is the middle of the segment *p1p2*.
Precondition: The projection of *s1* and the projection of *s2* are non-degenerate *2D* segments.

Triangulation_euclidean_traits_xy_3<K>:: Compare_x_2

Predicate object. Provides the operator :
Comparison_result operator()(Point_2 p, Point_2 q)
which returns *SMALLER, EQUAL* or *LARGER* according to the *x*-ordering of points *p* and *q*.

Triangulation_euclidean_traits_xy_3<K>:: Compare_y_2

Predicate object. Provides the operator :
Comparison_result operator()(Point_2 p, Point_2 q)
which returns (*SMALLER, EQUAL* or *LARGER*) according to the *y*-ordering of points *p* and *q*.

Triangulation_euclidean_traits_xy_3<K>:: Orientation_2

Predicate object. Provides the operator :
Orientation operator()(Point_2 p, Point_2 q, Point_2 r)
which returns *LEFT_TURN*, *RIGHT_TURN* or *COLLINEAR* according to the position of the projection of *r* with respect to the projection of the oriented line *pq*.

Triangulation_euclidean_traits_xy_3<K>:: Side_of_oriented_circle_2

Predicate object. Provides the operator : *Oriented_side operator()(Point_2 p, Point_2 q, Point_2 r, Point_2 s)* which takes four points p,q,r,s as arguments and returns *ON_POSITIVE_SIDE*, *ON_NEGATIVE_SIDE* or, *ON_ORIENTED_BOUNDARY* according to the position of the projection of point*s* with respect to the oriented circle through the projections of p,q and *r*.

Triangulation_euclidean_traits_xy_3<K>:: Compare_distance_2

Predicate object. Provides the operator :
Comparison_result operator()(Point_2 p, Point_2 q, Point_2 r) which returns *SMALLER*, *EQUAL* or *LARGER* according to the distance between the projection of p and the projection of q being smaller, equal or larger than the distance between the projection of p and the projection of r.

Creation

Triangulation_euclidean_traits_xy_3<K> traits;

default constructor.

Triangulation_euclidean_traits_xy_3<K> traits(Triangulation_euclidean_traits_xy_3 tr);

Copy constructor.

Triangulation_euclidean_traits_xy_3 *traits = Triangulation_euclidean_traits_xy_3 tr*

Assignment operator.

CGAL::Triangulation_face_base_2<Traits,Fb>

Class

Definition

The class *Triangulation_face_base_2<Traits,Fb>* is a model for the concept *TriangulationFaceBase_2*. It is the default face base class for basic and Delaunay triangulation.

These default base class can be used directly or can serve as a base to derive other base classes with some additional attribute (a color for example) tuned for specific applications.

Parameters

The first template parameter of *Triangulation_face_base_2<Traits,Fb>* is a geometric traits class. The geometric traits is actually not used by the class.

The second template parameter has to be a model of the concept *TriangulationDSFaceBase_2* and will serve as a base class for *Triangulation_face_base_2<Traits,Fb>* . CGAL provides a default instantiation for this parameter which is *Triangulation_ds_face_base_2<>*.

#include <CGAL/Triangulation_face_base_2.h>

Class

CGAL::Triangulation_face_base_with_info_2<Info,Traits,Fb>

Definition

The class *Triangulation_face_base_with_info_2<Info,Traits,Fb>* is a model of the concept *TriangulationFaceBase_2* to be plugged into the triangulation data structure of a triangulation class. It provides an easy way to add some user defined information in the faces of a triangulation.

#include <CGAL/Triangulation_face_base_with_info_2.h>

Parameters

The first template argument is the information the user would like to add to a face. It has to be *DefaultConstructible* and *Assignable*.

The second template argument is a geometric traits class and is actually not used in *Triangulation_face_base_with_info_2<Info,Traits,Fb>* .

The third parameter is a face base class from which *Triangulation_face_base_with_info_2<Info,Traits,Fb>* derives.

Inherits From

Fb

Is Model for the Concepts

Because *Triangulation_face_base_with_info_2<Info,Traits,Fb>* derives from the class instantiating its third parameter, it will be a model of the same face base concept as its parameter : *TriangulationFaceBase_2*,
ConstrainedTriangulationFaceBase_2 ,
or *RegularTriangulationFaceBase_2*

Types

typedef Info	*Info;*

Access Functions

const Info&	*f.info() const*	Returns a const reference to the object of type *Info* stored in the face.
Info&	*f.info()*	Returns a reference to the object of type *Info* stored in the face.

CGAL::Triangulation_hierarchy_2<Tr>

Class

Definition

The class *Triangulation_hierarchy_2<Tr>* implements a triangulation augmented with a data structure which allows fast point location queries.

The data structure is a hierarchy of triangulations. The triangulation at the lowest level is the original triangulation where operations and point location are to be performed. Then at each succeeding level, the data structure stores a triangulation of a small random sample of the vertices of the triangulation at the preceding level.

Point location is done through a top-down nearest neighbor query. The nearest neighbor query is first performed naively in the top level triangulation. Then, at each following level, the nearest neighbor at that level is found through a linear walk performed from the nearest neighbor found at the preceding level.

Because the number of vertices in each triangulation is only a small fraction of the number of vertices of the preceding triangulation the data structure remains small and achieves fast point location queries on real data. As proved in [Dev98], this structure has an optimal behavior when it is built for Delaunay triangulations. However it can be used as well for other triangulations. The class *Triangulation_hierarchy_2<Tr>* is templated by a parameter which is to be instantiated by anyone of the CGAL triangulation classes.

#include <CGAL/Triangulation_hierarchy_2.h>

Inherits From

Tr

Types

The class *Triangulation_hierarchy_2<Tr>* inherits the types from its base triangulation class *Tr*.

The class *Triangulation_hierarchy_2<Tr>* offers exactly the same functionalities as the triangulation Tr does. Location queries are overloaded to benefit from the data structure. Modifiers (insertion, removal, and displacement) are overloaded to take care of updating the data structure.

Be careful that I/O operations are not overloaded. Writing a *Triangulation_hierarchy_2<Tr>* into a file writes only the lowest level triangulation and drop the hierarchy and reading it from a file results in a triangulation whose efficiency will be that of an ordinary triangulation.

Chapter 38

2D Triangulation Data Structure

Sylvain Pion and Mariette Yvinec

Contents

38.1 Definition

A triangulation data structure is a data structure designed to handle the representation of a two dimensional triangulation. The concept of triangulation data structure was primarily designed to serve as a data structure for CGAL 2D triangulation classes which are triangulations embedded in a plane. However it appears that the concept is more general and can be used for any orientable triangulated surface without boundary, whatever may be the dimensionality of the space the triangulation is embedded in.

38.1.1 A Data Structure Based on Faces and Vertices

The representation of CGAL 2D triangulations is based on faces and vertices, Edges are only implicitly represented trough the adjacency relations between two faces.

The triangulation data structure can be seen as a container for faces and vertices maintaining incidence and adjacency relations among them.

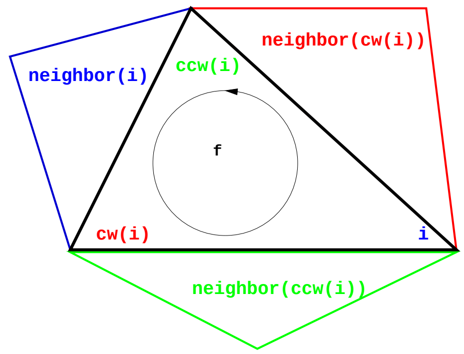

Figure 38.1: Vertices and neighbors.

Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces.

The three vertices of a face are indexed with 0, 1 and 2. The neighbors of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. See Figure 38.1, the functions *ccw(i)* and *cw(i)* shown on this figure compute respectively $i+1$ and $i-1$ modulo 3

Each edge has two implicit representations: the edge of a face f which is opposed to the vertex indexed i, can be represented as well as an edge of the *neighbor(i)* of f.

This kind or representation of simplicial complexes extends in any dimension. More precisely, in dimension d, the data structure will explicitly represents cells (i. e. faces of maximal dimension) and vertices (i. e. faces of dimension 0). All faces of dimension between 1 and $d-1$ will have an implicit representation. The 2D triangulation data structure can represent simplicial complexes of dimension 2, 1 or 0.

38.1.2 The Set of Faces and Vertices

The set of faces maintained by a 2D triangulation data structure is such that each edge is incident to two faces. In other words, the set of maintained faces is topologically equivalent to a two-dimensional triangulated sphere.

This rules extends to lower dimensional triangulation data structure arising in degenerate cases or when the triangulations have less than three vertices. A one dimensional triangulation structure maintains a set of vertices and edges which forms a ring topologically equivalent to a 1-sphere.

A zero dimensional triangulation data structure only includes two adjacent vertices that is topologically equivalent to a 0-sphere.

38.2 The Concept of Triangulation Data Structure

A model of *TriangulationDataStructure_2* can be seen has a container for the faces and vertices of the triangulation. This class is also responsible for the combinatorial integrity of the triangulation. This means that the triangulation data structure maintains proper incidence and adjacency relations among the vertices and faces of a triangulation while combinatorial modifications of the triangulation are performed. The term combinatorial modification refers to operations which do not involve any knowledge about the geometric embedding of the triangulation. For example, the insertion of a new vertex in a given face, or in a given edge, the suppression

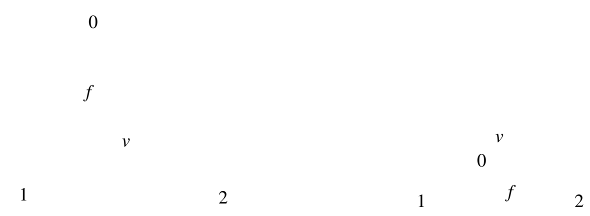

Figure 38.2: Insertion of a new vertex, splitting a face

of a vertex of degree three, the flip of two edge are examples of combinatorial operation performed at the data structure level.

The triangulation data structure is required to provide:

- the types *Vertex* and *Face* for the vertices and faces of the triangulations
- the type *Vertex_handle* and *Face_handle* which are models of the concept *Handle* and through which the vertices and faces are accessed.
- iterators to visit all the vertices, edges and faces of the triangulation,
- circulators to visit all the vertices, edges and faces incident to a given vertex

The triangulation data structure is responsible for the creation and removal of faces and vertices (memory management). It provides function that gives the number of faces, edges and vertices of the triangulation.

The triangulation data structure provides member functions to perform the following combinatorial transformation of the triangulation:

- flip of two adjacent faces,
- addition of a new vertex splitting a given face see Figure 38.2,
- addition of a new vertex splitting a given edge,
- addition of a new vertex raising by one the dimension of a degenerate – lower dimensional triangulation,
- removal of a vertex incident to three faces,
- removal of a vertex lowering the dimension of the triangulation

38.3 The Default Triangulation Data Structure

CGAL provides the class *CGAL::Triangulation_data_structure_2<Vb,Fb>* as a default triangulation data structure.

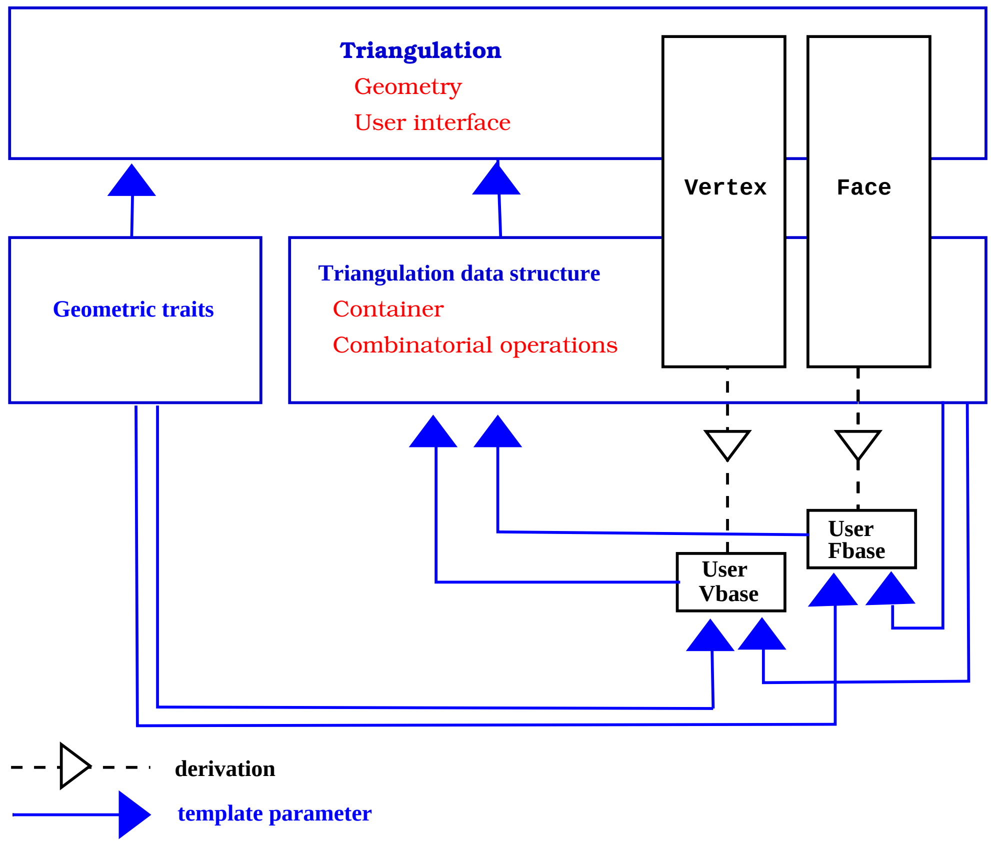

Figure 38.3: The cyclic dependency in triangulations software design.

38.3.1 Flexibility

In order to provide flexibility, the default triangulation data structure is templated by two parameters which stands respectively for a vertex base class and a face base class. The concept *TriangulationDSVertexBase_2* and *TriangulationDSFaceBase_2* describe the requirements for the vertex and face classes of a triangulation data structure.

This design allows the user to plug in the triangulation data structure his own vertex or face classes tuned for his application.

38.3.2 The Cyclic Dependency of Template Parameters

Since adjacency and incidence relation are stored in vertices and faces, the vertex and face classes have to know the types of handles on faces and vertices provided by the triangulation data structure. Therefore, vertex and face classes need to be templated by the triangulation data structure. Because the triangulation data structure is itself templated by the vertex and face classes this induces a cyclic dependency. See figure 38.3.

38.3.3 The Rebind Mechanism

The solution proposed by CGAL to resolve this cyclic dependency is based on a rebind mechanism similar to the mechanism used in the standard allocator class std::allocator. The vertex and face classes plugged in the instantiation of a triangulation data structure are themselves instantiated with a fake data structure. The triangulation data structure will then rebind these classes, plugging itself at the place of the fake data structure, before using them to derive the vertex and face classes. The rebinding is performed through a nested template class *Rebind_TDS* in the vertex and face class, which provide the rebound class as a type called *Other*.

Here is how it works schematically. First, here is the rebinding taking place in the triangulation data structure.

```
template < class Vb, class Fb >
class Triangulation_data_structure
{
  typedef Triangulation_data_structure<Vb,Fb>    Self;

  // Rebind the vertex and face base to the actual TDS (Self).
  typedef typename Vb::template Rebind_TDS<Self>::Other  VertexBase;
  typedef typename Fb::template Rebind_TDS<Self>::Other  FaceBase;

  // ... further internal machinery leads to the final public types:
public:
  typedef ...  Vertex;
  typedef ...  Face;
  typedef ...  Vertex_handle;
  typedef ...  Face_handle;
};
```

Then, here is the vertex class with its nested *Rebind_TDS* template class and its template parameter set by default to an an internal type faking a triangulation data structure.

```
template < class TDS = an internal type faking a triangulation data
structure >
class Vertex_base
{
public:
  template < class TDS2 >
  struct Rebind_TDS {
    typedef Vertex_base<TDS2>    Other;
  };
...
};
```

Imagine an analog *Face_base* class. The triangulation data structure is then instantiate as follows :

```
typedef Triangulation_data_structure< Vertex_base<>, Face_base<> > TDS;
```

38.3.4 Making Use of the Flexibility

There is several possibilities to make use of the flexibility offered by the triangulation data structure.

- First, when the user needs to have, in vertices and faces, additional information which do not depend on types defined by the triangulated data structure, predefined classes *Triangulation_vertex_base_with_info* and *Triangulation_face_base_with_info* can be plugged in. Those classes have a template parameter *Info* to be instantiated by a user defined type. They store a data member of this type and gives access to it.

- Second, the user can derive his own base classes from the default base classes: *Triangulation_ds_vertex_base_2*, and *Triangulation_ds_face_base_2* are the default base classes to be plugged in a triangulation data structure used alone. Triangulation classes requires a data structure in which other base classes have been plugged it. The default base classes for most of the triangulation classes are *Triangulation_vertex_base_2*, and *Triangulation_face_base_2* are the default base classes to be used when the triangulation data structure is plugged in a triangulation class.

  When derivation is used, the rebind mechanism is slightly more involved, because it is necessary to rebind the base class itself. However the user will be able to use in his classes references to types provided by the triangulation data structure. For example,

```
template < class Gt, class Vb = CGAL::Triangulation_vertex_base_2<Gt>
     >
class My_vertex_base
  : public  Vb
{
public :
  template < typename TDS2 >
  struct Rebind_TDS {
    typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
    typedef My_vertex_base<Gt,Vb2>                           Other;
  };

  typedef typename Vb::Triangulation_data_structure    Tds;
  typedef typename Tds::Vertex_handle                  Vertex_handle;
  ......
};
```

- At last the user can write his own base classes. If the triangulation data structure is used alone, the requirements for the base classes are described by the concepts *TriangulationDSVertexBase_2* and *TriangulationDSFaceBase_2*, documented page 2600 and page 2594. If the triangulation data structure is plugged into a triangulation class, the concepts for the vertex and base classes depends on the triangulation class. The most basic concepts, valid for basic and Delaunay triangulations are *TriangulationVertexBase_2* and *TriangulationFaceBase_2*, documented page 2544 and page 2539.

See section 37.11 for examples of using the triangulation data structure flexibility.

2D Triangulation Data Structure Reference Manual

Sylvain Pion and Mariette Yvinec

The triangulation data structure can be seen as a container for the faces and vertices of a triangulation. This class also takes care of all the combinatorial operations performed on the triangulation.

The class *CGAL::Triangulation_data_structure_2<Vb,Fb>* is a model of the concept *TriangulationDataStructure_2*. which includes the sub-concepts *TriangulationDataStructure_2::Face* and *TriangulationDataStructure_2::Vertex*.

To ensure all the **flexibility** of the triangulation classes, described and in Section 37.11 of Chapter 37, the model *CGAL::Triangulation_data_structure_2<Vb,Fb>* has two templates parameters. The class *CGAL::Triangulation_data_structure_2<Vb,Fb>* derives its *Vertex* and *Face* types from the two template parameters *Vb* and *Fb* respectively.
If the triangulation data structure is used alone, these parameters have to be instantiated by models of the concepts *TriangulationDSFaceBase_2* and *TriangulationDSVertexBase_2*. These concepts are described in this chapter together with their default models *CGAL::Triangulation_ds_face_base_2<Tds>* and *CGAL::Triangulation_ds_vertex_base_2<Tds>*.
If the triangulation data structure is plugged into a triangulation class, the parameters have to be instantiated by models of different refining concepts according to the actual type of the triangulation. These refining concepts and their models are described in Chapter 37.12

TriangulationDataStructure_2

Definition

The concept TriangulationDataStructure_2 describes the requirements for the second template parameter of the basic triangulation class *Triangulation_2<Traits,Tds>* and of all other 2D triangulation classes.

The concept can be seen as a container for the faces and vertices of the triangulation. The concept TriangulationDataStructure_2 includes two sub-concepts *TriangulationDataStructure_2::Vertex* and *TriangulationDataStructure_2::Face*, described respectively page 2602 and page 2597.

The TriangulationDataStructure_2 maintains incidence and adjacency relations among vertices and faces.

Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces.

The three vertices of a face are indexed with 0, 1 and 2. The neighbors of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by i is opposite to the vertex with the same index.

Each edge has two implicit representations : the edge of a face f which is opposed to the vertex indexed i, can be represented as well as an edge of the *neighbor(i)* of f. See Figure 37.2

The triangulation data structure is responsible for the combinatorial integrity of the triangulation. This means that the triangulation data structure allows to perform some combinatorial operations on the triangulation and guarantees the maintenance on proper incidence and adjacency relations among the vertices and faces. The term combinatorial operations means that those operations are purely topological and do not depend on the geometric embedding. Insertion of a new vertex in a given face, or in a given edge, suppression of a vertex of degree three, flip of two edges are examples of combinatorial operations.

Types

TriangulationDataStructure_2:: size_type	Size type (unsigned integral type)
TriangulationDataStructure_2:: difference_type	Difference type (signed integral type)

TriangulationDataStructure_2:: Vertex	The vertex type. Requirements for this type are described in concept *TriangulationDataStructure_2::Vertex* page 2602.
TriangulationDataStructure_2:: Face	The face type. Requirements for this type are described in concept *TriangulationDataStructure_2::Face* page 2597.

Vertices and faces are accessed via *Vertex_handle* and *Face_handle*. These types are models of the concept *Handles* which basically supports the two dereference operators * and ->.

TriangulationDataStructure_2:: Vertex_handle	Handle to a vertex
TriangulationDataStructure_2:: Face_handle	Handle to a face.

advanced

TriangulationDataStructure_2:: template <typename Vb2> struct Rebind_vertex

This nested template class allows to get the type of a triangulation data structure that only changes the vertex type. It has to define a type *Other* which is a *rebound* triangulation data structure, that is, the one whose *TriangulationDSVertexBase_2* will be *Vb2*.

TriangulationDataStructure_2:: template <typename Fb2> struct Rebind_face

This nested template class allows to get the type of a triangulation data structure that only changes the face type. It has to define a type *Other* which is a *rebound* triangulation data structure, that is, the one whose *TriangulationDSFaceBase_2* will be *Fb2*.

advanced

typedef std::pair<Face_handle,int> Edge; The edge type. The *Edge(f,i)* is edge common to faces f and *f.neighbor(i)*. It is also the edge joining the vertices *vertex(cw(i))* and *vertex(ccw(i))* of f.

The following iterators allow one to visit all the vertices, edges and faces of a triangulation data structure. They are all bidirectional, non-mutable iterators.

TriangulationDataStructure_2:: Face_iterator
TriangulationDataStructure_2:: Edge_iterator
TriangulationDataStructure_2:: Vertex_iterator

The following circulators allow to visit all the edges or faces incident to a given vertex and all the vertices adjacent to a given vertex. They are all bidirectional and non mutable.

TriangulationDataStructure_2:: Face_circulator
TriangulationDataStructure_2:: Edge_circulator
TriangulationDataStructure_2:: Vertex_circulator

Iterators and circulators are convertible to the corresponding handles, thus they can be passed directly as argument to the functions expecting a handle.

Creation

TriangulationDataStructure_2 tds; default constructor.

TriangulationDataStructure_2 tds(tds1); Copy constructor. All the vertices and faces are duplicated.

TriangulationDataStructure_2& $tds = tds1$

Assignment. All the vertices and faces of *tds1* are duplicated in *tds* . Former faces and vertices of *tds* , if any, are deleted

Vertex_handle *tds.copy_tds(tds1, Vertex_handle v = Vertex_handle())*

tds1 is copied into *tds*. If $v \,!= NULL$, the vertex of *tds* corresponding to *v* is returned, otherwise *Vertex_handle()* is returned.
Precondition: The optional argument *v* is a vertex of *tds1*.

void *tds.swap(& tds1)* Swaps *tds* and *tds1*. Should be preferred to *tds*=*tds1* or *tds*(*tds1*) when *tds1* is deleted after that.

void *tds.clear()* Deletes all faces and all finite vertices.

Access Functions

int *tds.dimension() const* returns the dimension of the triangulation.

size_type
tds.number_of_vertices() const returns the number of vertices in the data structure.

size_type
tds.number_of_faces() const returns the number of two dimensional faces in the data structure.

size_type
tds.number_of_edges() const returns the number of edges in the triangulation data structure.

size_type
tds.number_of_full_dim_faces() const returns the number of full dimensional faces, i.e. faces of dimension equal to the dimension of the triangulation. This is the actual number of faces stored in the triangulation data structure.

advanced

Setting

void *tds.set_dimension(int n)* sets the dimension.

advanced

Queries

bool *tds.is_vertex(Vertex_handle v) const*

returns true if *v* is a vertex of *tds*.

bool *tds.is_edge(Face_handle fh, int i) const*

tests whether *(fh,i)* is an edge of *tds*. Answers *false* when *dimension()* < 1 .

bool *tds.is_edge(Vertex_handle va, Vertex_handle vb) const*

returns true if *va vb* is an edge of *tds*.

bool *tds.is_edge(Vertex_handle va, Vertex_handle vb, Face_handle &fr, int &i) const*

as previous. In addition, if true is returned *fr* and *i* are set such that the pair *(fr,i)* is the description of the ordered edge *va vb*.

bool *tds.is_face(Face_handle fh) const*

tests whether *fh* is a face of *tds*. Answers *false* when *dimension()* < 2 .

bool *tds.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3) const*

true if there is a face having *v1*, *v2* and*v3* as vertices.

bool *tds.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3, Face_handle &fr) const*

as above. In addition, if *true* is returned, fr is a pointer to the face with *v1*, *v2* and *v3* as vertices.

Traversing the triangulation

Face_iterator *tds.faces_begin() const* visits all faces

Face_iterator *tds.faces_end() const*

Vertex_iterator *tds.vertices_begin() const*

visits all vertices

Vertex_iterator *tds.vertices_end() const*

Edge_iterator *tds.edges_begin() const*

visits all edges

Edge_iterator *tds.edges_end() const*

Three circulator classes allow to traverse the edges or faces incident to a vertex or the vertices adjacent to this vertex.. A face circulator is invalidated by any modification of the face it points to. An edge circulator is invalidated by any modification of anyone of the two faces incident to the edge pointed to. A vertex circulator that turns around vertex *v* and that has as value a pointer to vertex *w*, is invalidated by any modification of anyone of the two faces incident to *v* and *w*.

Vertex_circulator *tds.incident_vertices(Vertex_handle v, Face_handle f=NULL) const*

Precondition: If the face *f* is given, it has to be incident to be a face of *tds* incident to *v* and the circulator begins with the vertex *f->vertex(ccw(i))* if *i* is the index of *v* in *f*.

Edge_circulator *tds.incident_edges(Vertex_handle v, Face_handle f=NULL) const*

Precondition: If the face *f* is given, it has to be a face of *tds* incident to *v* and the circulator begins with the edge *(f,cw(i))* of *f* if *i* is the index of *v* in *f*.

Face_circulator *tds.incident_faces(Vertex_handle v, Face_handle f=NULL) const*

Precondition: If the face *f* is given, it has to be a face of *tds* incident to *v* and the circulator begins with the face *f*.

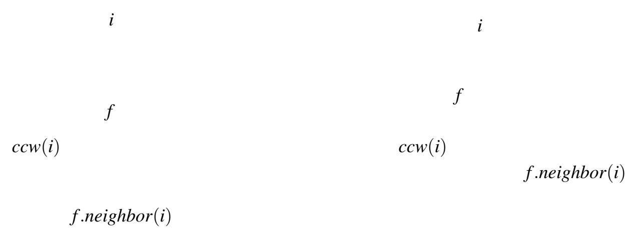

Figure 38.4: Flip.

Vertical_handle *tds.mirror_vertex(Face_handle f, int i) const*

returns vertex of *f->neighbor(i)*.

int *tds.mirror_index(Face_handle f, int i) const*

returns the index of *f* as a neighbor of *f->neighbor(i)*.

Edge *tds.mirror_edge(Edge e) const*

returns the same edge seen from the other adjacent face.

Modifiers

The following modifier member functions guarantee the combinatorial validity of the resulting triangulation.

void *tds.flip(Face_handle f, int i)* exchanges the edge incident to *f* and *f->neighbor(i)* with the other diagonal of the quadrilateral formed by *f* and *f->neighbor(i)*.

Vertex_handle *tds.insert_first()* creates the first vertex and returns a pointer to it.

Vertex_handle *tds.insert_second()* creates the second vertex and returns a pointer to it.

Vertex_handle *tds.insert_in_edge(Face_handle f, int i)* adds a vertex *v* splitting edge *i* of face *f*. Return a pointer to *v*.

Vertex_handle *tds.insert_in_face(Face_handle f)* adds a vertex *v* splitting face *f* in three. Face *f* is modified, two new faces are created. Return a pointer to *v*

Vertex_handle *tds.insert_dim_up(Vertex_handle w, bool orient=true)*

adds a vertex *v*, increasing by one the dimension of the triangulation. Vertex *v* and the existing vertex *w* are linked to all the vertices of the triangulation. The Boolean *orient* decides the final orientation of all faces. A pointer to vertex *v* is returned.

Figure 38.5: Insertion

void *tds.remove_degree_3(Vertex_handle v, Face *f=NULL)*

removes a vertex of degree 3. Two of the incident faces are destroyed, the third one is modified. If parameter f is specified, it has to be a face incident to v and will be the modified face.
Precondition: Vertex v is a finite vertex with degree 3 and, if specified, face f is incident to v.

void *tds.remove_second(Vertex_handle v)* removes the before last vertex.

void *tds.remove_first(Vertex_handle v)* removes the last vertex.

void *tds.remove_dim_down(Vertex_handle v)* removes vertex v incident to all other vertices and decreases by one the dimension of the triangulation.
Precondition: if the dimension is 2, the number of vertices is more than 3, if the dimension is 1, the number of vertices is 2.

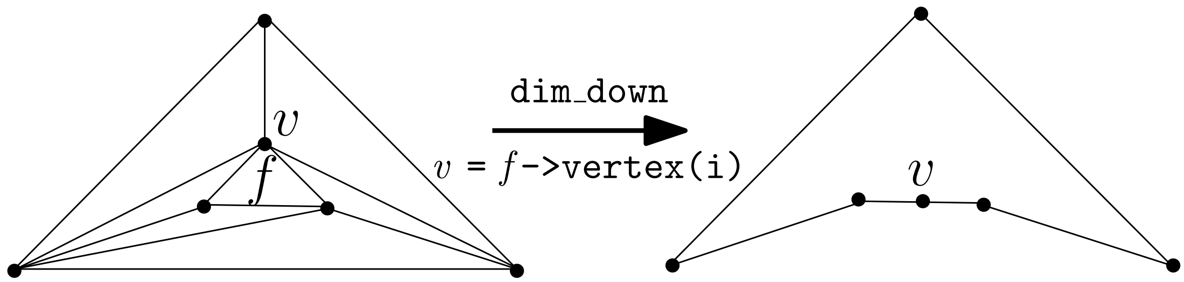

Figure 38.6: From a two-dimensional data structure to a one-dimensional data structure.

The following operation, `dim_down`, is necessary when the displacement of a vertex decreases the dimension of the triangulation.

void *tds.dim_down(Face_handle f, int i)*

The link of a vertex v is formed by the edges disjoint from v that are included in the faces incident to v. When the link of v = *f->vertex(i)* contains all the other vertices of the two-dimensional triangulation data-structure ($\mathbb{S}^2$), *dim_down* crushes the two-dimensional data-structure ($\mathbb{S}^2$) onto the one-dimensional data structure ($\mathbb{S}^1$) formed by the link of v augmented with the vertex v itself; this one is placed on the edge *(f, i)*. (see Fig. 38.6).
Precondition: *dimension()* must be equal to *2*, the degree of *f->vertex(i)* must be equal to the total number of vertices minus 1.

advanced

The following modifiers are required for convenience of the advanced user. They do not guarantee the combinatorial validity of the resulting triangulation.

template< class EdgeIt>
Vertex_handle *tds.star_hole(EdgeIt edge_begin, EdgeIt edge_end)*

creates a new vertex v and use it to star the hole whose boundary is described by the sequence of edges *[edge_begin, edge_end[*. Returns a pointer to the vertex.

template< class EdgeIt, class FaceIt>
Vertex_handle *tds.star_hole(EdgeIt edge_begin, EdgeIt edge_end, FaceIt face_begin, FaceIt face_end)*

same as above, except that, to build the new faces, the algorithm first recycles faces in the sequence *[face_begin, face_end[* and create new ones when the sequence is exhausted.

template< class EdgeIt>
void *tds.star_hole(Vertex_handle v, EdgeIt edge_begin, EdgeIt edge_end)*

uses vertex v to star the hole whose boundary is described by the sequence of edges*[edge_begin, edge_end[*.

template< class EdgeIt, class FaceIt>

void *tds.star_hole(Vertex_handle v,*
EdgeIt edge_begin,
EdgeIt edge_end,
FaceIt face_begin,
FaceIt face_end)

same as above, recycling faces in the sequence *[face_begin, face_end[* .

void *tds.make_hole(Vertex_handle v, List_edges& hole)*

removes the vertex v, and store in *hole* the list of edges on the boundary of the hole.

Vertex_handle *tds.create_vertex()* adds a new vertex.

Face_handle *tds.create_face(Face_handle f1, int i1, Face_handle f2, int i2, Face_handle f3, int i3)*

adds a face which is the neighbor *i1* of *f1*, *i2* of *f2* and *i3* of *f3*.

Face_handle *tds.create_face(Face_handle f1, int i1, Face_handle f2, int i2)*

adds a face which is the neighbor *i1* of *f1*, and the neighbor *i2* of *f2*.

Face_handle *tds.create_face(Face_handle f1, int i1, Vertex_handle v)*

adds a face which is the neighbor *i1* of *f1*, and has *v* as vertex.

Face_handle *tds.create_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)*

adds a face with vertices *v1*, *v2* and *v3*.

Face_handle *tds.create_face(Vertex_handle v1,*
Vertex_handle v2,
Vertex_handle v3,
Face_handle f1,
Face_handle f2,
Face_handle f3)

adds a face with vertices *v1*, *v2* and *v3*, and neighbors *f1*, *f2*, *f3*.

Face_handle *tds.create_face()* adds a face whose vertices and neighbors are set to NULL.

void *tds.delete_face(Face_handle)* deletes a face.

void *tds.delete_vertex(Vertex_handle)*

deletes a vertex.

advanced

Miscellaneous

int *tds.ccw(int i) const* returns $i+1$ modulo 3.
Precondition: $0 \leq i \leq 2$.

int	*tds.cw(int i) const*	returns $i+2$ modulo 3. *Precondition*: $0 \leq i \leq 2$.
bool	*tds.is_valid()*	checks the combinatorial validity of the triangulation: call the *is_valid()* member function for each vertex and each face, checks the number of vertices and the Euler relation between numbers of vertices, faces and edges.
size_type	*tds.degree(Vertex_handle v) const*	Returns the degree of v in the triangulation.

I/O

The information output in the *iostream* is: the dimension, the number of (finite) vertices, the number of (finite) faces. Then comes for each vertex, the non combinatorial information stored in that vertex if any. Then comes for each faces, the indices of its vertices and the non combinatorial information (if any) stored in this face. Then comes for each face again the indices of the neighboring faces. The index of an item (vertex of face) the rank of this item in the output order. When dimension < 2, the same information is output for faces of maximal dimension instead of faces.

void	*tds.file_output(ostream& os, Vertex_handle v = Vertex_handle(), bool skip_first=false)*	writes *tds* into the stream *os*. If v is not a null handle, vertex v is output first or skipped if *skip_first* is true.
Vertex_handle	*tds.file_input(istream& is, bool skip_first=false)*	inputs *tds* from file and returns a pointer to the first input vertex. If *skip_first* is true, it is assumed that the first vertex has been omitted when output.
istream&	*istream& is >> TriangulationDataStructure_3 & tds*	reads a combinatorial triangulation from *is* and assigns it to *tds*
ostream&	*ostream& os << TriangulationDataStructure_3 tds*	writes *tds* into the stream *os*

Concept

TriangulationDSFaceBase_2

Definition

The concept TriangulationDSFaceBase_2 describes the requirements for the base face of a *Triangulation_data_structure_2<Vb,Fb>*.

Note that if the *Triangulation_data_structure_2* is plugged into a triangulation class, the face base class may have additional geometric requirements depending on the triangulation class.

At the base level, (see Sections 37.3 and 38.3), a face stores handles on its three vertices and on the three neighboring faces. The vertices and neighbors are indexed 0,1 and 2. Neighbor i lies opposite to vertex i.

Since the *Triangulation_data_structure_2* is the class which defines the handle types, the face base class has to be somehow parameterized by the triangulation data structure. But since the *Triangulation_data_structure_2* itself is parameterized by the face and vertex base classes, there is a cycle in the definition of these classes. In order to break the cycle, the base classes for faces and vertices which are plugged in to instantiate a *Triangulation_data_structure_2* use a *void* as triangulation data structure parameter. Then, the *Triangulation_data_structure_2* uses a *rebind* mechanism (similar to the one specified in *std::allocator*) in order to plug itself as parameter in the face and vertex base classes. This mechanism requires that the base class provides a templated nested class *Rebind_TDS* that itself provides the subtype *Rebind_TDS<TDS2>::Other* which is the *rebound* version of the base class. This *rebound* base class is the class that the *Triangulation_data_structure_2* actually uses as a base class for the class *Triangulation_data_structure_2::Face*.

Types

The concept TriangulationDSFaceBase_2 has to provide the following types.

TriangulationDSFaceBase_2:: template <typename TDS2> struct Rebind_TDS

This nested template class has to define a type *Other* which is the *rebound* face base, where the *Triangulation_data_structure_2* is actually plugged in. This type *Other* will be the actual base of the class *Triangulation_data_structure_2::Face*.

typedef TriangulationDataStructure_2 *Triangulation_data_structure;*
typedef TriangulationDataStructure_2::Vertex_handle *Vertex_handle;*
typedef TriangulationDataStructure_2::Face_handle *Face_handle;*

Creation

TriangulationDSFaceBase_2 f; default constructor.

TriangulationDSFaceBase_2 f(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2);

Initializes the vertices with *v0, v1, v2* and the neighbors with *Face_handle()*.

TriangulationDSFaceBase_2 f(Vertex_handle v0,
Vertex_handle v1,
Vertex_handle v2,
Face_handle n0,
Face_handle n1,
Face_handle n2)

initializes the vertices with *v0,v1, v2* and the neighbors with *n0, n1, n2*.

Access Functions

int	*f.dimension()*	returns the dimension.
Vertex_handle	*f.vertex(int i) const*	returns the vertex *i* of *f*. *Precondition*: $0 \leq i \leq 2$.
bool	*f.has_vertex(Vertex_handle v)*	returns true if *v* is a vertex of *f*.
bool	*f.has_vertex(Vertex_handle v, int& i) const*	as above, and sets *i* to the index of *v* in *f*.
int	*f.index(Vertex_handle v) const*	returns the index of *v* in *f*.
Face_handle	*f.neighbor(int i) const*	returns the neighbor *i* of *f*. *Precondition*: $0 \leq i \leq 2$.
bool	*f.has_neighbor(Face_handle n)*	returns true if *n* is a neighbor of *f*.
bool	*f.has_neigbor(Face_handle n, int& i) const*	as above, and sets i to the index of *n* in *f*.
int	*f.index(const Face_handle n) const*	returns the index of neighbor *n* in *f*.

Setting

void	*f.set_vertex(int i, Vertex_handle v)*	sets vertex *i* to *v*. *Precondition*: $0 \leq i \leq 2$.
void	*f.set_vertices()*	sets the vertices to *Vertex_handle()*.
void	*f.set_vertices(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2)*	sets the vertices.
void	*f.set_neighbor(int i, Face_handle n)*	sets neighbors *i* to *n*. *Precondition*: $0 \leq i \leq 2$.
void	*f.set_neighbors()*	sets the neighbors to *Face_handle()*.
void	*f.set_neighbors(Face_handle n0, Face_handle n1, Face_handle n2)*	sets the neighbors.

Orientation

void	*f.reorient()*	Changes the orientation of *f* by exchanging *vertex(0)* with *vertex(1)* and *neighbor(0)* with *neighbor(1)*.

void	f*.ccw_permute()*	preforms a counterclockwise permutation of the vertices and neighbors of f.
void	f*.cw_permute()*	preforms a clockwise permutation of the vertices and neighbors of f.

Checking

bool	f*.is_valid(bool verbose = false) const*	performs any required test on a face. If *verbose* is set to *true*, messages are printed to give a precise indication of the kind of invalidity encountered.

Various

*void**	f*.for_compact_container() const*
*void**&	f*.for_compact_container()*

These member functions are required by *Triangulation_data_structure_2* because it uses *Compact_container* to store its faces. See the documentation of *Compact_container* for the exact requirements.

TriangulationDataStructure_2::Face

Concept

Definition

The concept TriangulationDataStructure_2::Face describes the types used to store the faces face class of a *TriangulationDataStructure_2*, see page 2585. A TriangulationDataStructure_2::Face stores three pointers to its three vertices and three pointers to its three neighbors. The vertices are indexed 0,1, and 2 in counterclockwise order. The neighbor indexed i lies opposite to vertex i.

In degenerate cases, when the triangulation data structure stores a simplicial complex of dimension 0 and 1, the type TriangulationDataStructure_2::Face is used to store the faces of maximal dimension of the complex : i.e. a vertex in dimension 0, an edge in dimension 1. Only vertices and neighbors with index 0 are set in the first case, only vertices and neighbors with index 0 or 1 are set in the second case.

Types

The class TriangulationDataStructure_2::Face defines the same types as the triangulation data structure except the iterators and the circulators.

Creation

The methods *create_face* and *delete_face()* have to be used to define new faces and to delete non longer used faces.

Vertex Access Functions

Vertex_handle	*f.vertex(int i) const*	returns the vertex i of f. *Precondition*: $0 \leq i \leq 2$.
int	*f.index(Vertex_handle v) const*	returns the index of vertex v in f. *Precondition*: v is a vertex of f
bool	*f.has_vertex(Vertex_handle v) const*	returns *true* if v is a vertex of f.
bool	*f.has_vertex(Vertex_handle v, int& i) const*	returns *true* if v is a vertex of f, and computes the index i of v in f.

Neighbor Access Functions

The neighbor with index i is the neighbor which is opposite to the vertex with index i.

Face_handle	*f.neighbor(int i) const*	returns the neighbor i of f. *Precondition*: $0 \leq i \leq 2$.
int	*f.index(Face_handle n) const*	returns the index of face n. *Precondition*: n is a neighbor of f.

bool	*f.has_neighbor(Face_handle n) const*	
		returns *true* if n is a neighbor of f.
bool	*f.has_neighbor(Face_handle n, int& i) const*	
		returns *true* if n is a neighbor of f, and compute the index i of n.

advanced

Setting

void	*f.set_vertex(int i, Vertex_handle v)*	sets vertex i to be v. *Precondition*: $0 \leq i \leq 2$.
void	*f.set_neighbor(int i, Face_handle n)*	sets neighbor i to be n. *Precondition*: $0 \leq i \leq 2$.
void	*f.set_vertices()*	sets the vertices pointers to *NULL*.
void	*f.set_vertices(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2)*	
		sets the vertices pointers.
void	*f.set_neighbors()*	sets the neighbors pointers to *NULL*.
void	*f.set_neighbors(Face_handle n0, Face_handle n1, Face_handle n2)*	
		sets the neighbors pointers.

Checking

bool	*f.is_valid() const*	returns *true* if the function *is_valid()* of the base class returns *true* and if, for each index i, $0 \leq i < 3$, face f is a neighbor of its neighboring face *neighbor(i)* and shares with this neighbor the vertices *cw(i)* and *ccw(i)* in correct reverse order.

advanced

Miscellaneous

int	*f.ccw(int i) const*	Returns $i+1$ modulo 3. *Precondition*: $0 \leq i \leq 2$.
int	*f.cw(int i) const*	Returns $i+2$ modulo 3. *Precondition*: $0 \leq i \leq 2$.

I/O

istream&	*istream& is* >> *& f*	Inputs any non combinatorial information possibly stored in the face.
ostream&	*ostream& os* << *f*	Outputs any non combinatorial information possibly stored in the face.

Concept

TriangulationDSVertexBase_2

Definition

The concept TriangulationDSVertexBase_2 describes the requirements for the vertex base class of a *Triangulation_data_structure_2<Vb,Fb>*.

Note that if the *Triangulation_data_structure_2* is plugged into a triangulation class, the vertex base class has additional geometric requirements depending on the triangulation class.

At the base level, provides access to one of its incident face through a *Face_handle*.

Since the *Triangulation_data_structure_2* is the class which defines the handle types, the vertex base class has to be somehow parameterized by the triangulation data structure. But since the *Triangulation_data_structure_2* itself is parameterized by the face and vertex base classes, there is a cycle in the definition of these classes. In order to break the cycle, the base classes for faces and vertices which are plugged in to instantiate a *Triangulation_data_structure_2* use a *void* as triangulation data structure parameter. Then, the *Triangulation_data_structure_2* uses a *rebind* mechanism (similar to the one specified in *std::allocator*) in order to plug itself as parameter in the face and vertex base classes. This mechanism requires that the base class provides a templated nested class *Rebind_TDS* that itself provides the subtype *Rebind_TDS<TDS2>::Other* which is the *rebound* version of the base class. This *rebound* base class is the class that the *Triangulation_data_structure_2* actually uses as a base class for the class of *Triangulation_data_structure_2::Vertex*.

Refines

TriangulationDataStructure_2::Vertex

Types

The concept TriangulationDSVertexBase_2 has to provide the following types.

TriangulationDSVertexBase_2:: template <typename TDS2> struct Rebind_TDS

This nested template class has to define a type *Other* which is the *rebound* vertex base , where the actual *Triangulation_data_structure_2* is plugged in. This type *Other* will be the actual base of the class *Triangulation_data_structure_2::Vertex*.

typedef TriangulationDataStructure_2	*Triangulation_data_structure;*
typedef TriangulationDataStructure_2::Vertex_handle	*Vertex_handle;*
typedef TriangulationDataStructure_2::Face_handle	*Face_handle;*

Creation

TriangulationDSVertexBase_2 v;	default constructor.
TriangulationDSVertexBase_2 v(Face_handle f);	Constructs a vertex pointing to face *f*.

Various

*void**	*v.for_compact_container() const*
void&*	*v.for_compact_container()*

These member functions are required by *Triangulation_data_structure_2* because it uses *Compact_container* to store its faces. See the documentation of *Compact_container* for the exact requirements.

Concept

TriangulationDataStructure_2::Vertex

Definition

The concept TriangulationDataStructure_2::Vertex describes the type used by a *TriangulationDataStructure_2* to store the vertices, see page 2585.

Some of the requirements listed below are of geometric nature and are *optional* when using the triangulation data structure class alone. They became required when the triangulation data structure is plugged into a triangulation.

Types

The class TriangulationDataStructure_2::Vertex defines the same types as the triangulation data structure except the iterators.

TriangulationDataStructure_2::Vertex:: Point *Optional for the triangulation data structure used alone.*

Creation

In order to obtain new vertices or destruct unused vertices, the user must call the *create_vertex()* and *delete_vertex()* methods of the triangulation data structure.

Access Functions

Point	*v.point() const*	returns the geometric information of *v*.
Face_handle	*v.face() const*	returns a face of the triangulation having *v* as vertex.

advanced

Setting

void	*v.set_point(Point p)*	sets the geometric information to *p*.
void	*v.set_face(Face_handle f)*	sets the incident face to *f*.

advanced

Checking

bool *v.is_valid(bool verbose = false) const*

Checks the validity of the vertex. Must check that its incident face has this vertex. The validity of the base vertex is also checked. When *verbose* is set to *true*, messages are printed to give a precise indication on the kind of invalidity encountered.

I/O

istream&	*istream& is >> & v*	Inputs the non-combinatorial information possibly stored in the vertex.
ostream&	*ostream& os << v*	Outputs the non combinatorial operation possibly stored in the vertex.

Class

CGAL::Triangulation_data_structure_2<Vb,Fb>

Definition

The class *Triangulation_data_structure_2<Vb,Fb>* is a model for the *TriangulationDataStructure_2* concept. It can be used to represent an orientable 2D triangulation embedded in a space of any dimension.

The vertices and faces are stored in two nested containers, which are implemented using *CGAL::Compact_container*. The class may offer some flexibility for the choice of container in the future, in the form of additional template parameters.

#include <CGAL/Triangulation_data_structure_2.h>

Is Model for the Concepts

TriangulationDataStructure_2

advanced

In addition to the interface documented in the concept, the class offers the following types and functions.

Types

typedef CGAL::Compact_container<Vertex>

Vertex_range;	Vertex container type.

typedef CGAL::Compact_container<Face>

Face_range;	Face container type.

Operations

Face_range&	*tds.faces() const*	Returns a reference to the container of faces.
Face_range&	*tds.faces()*	Returns a reference to the container of faces.
Vertex_range&	*tds.vertices() const*	Returns a reference to the container of vertices.
Vertex_range&	*tds.vertices()*	Returns a reference to the container of vertices.

advanced

Modifiers

In addition to the modifiers required by the *TriangulationDataStructure_2* concept, the *Triangulation_data_structure_2<Vb,Fb>* class supports also the modifiers below. Note also that the modifiers below guarantee the combinatorial validity of the resulting data structure.

Vertex_handle	*tds.join_vertices(Face_handle f, int i)*	Joins the vertices that are endpoints of the edge *(f,i)*. It returns a vertex handle to common vertex (see Fig. 38.7). *Precondition*: *f* must be different from *Face_handle()* and *i* must be *0*, *1* or *2*.

Vertex_handle	*tds.join_vertices(Edge e)*	Joins the vertices that are endpoints of the edge *e*. It returns a vertex handle to common vertex.
Vertex_handle	*tds.join_vertices(Edge_iterator eit)*	Joins the vertices that are endpoints of the edge **eit*. It returns a vertex handle to common vertex.
Vertex_handle	*tds.join_vertices(Edges_circulator ec)*	Joins the vertices that are endpoints of the edge **ec*. It returns a vertex handle to common vertex.

boost::tuples::tuple<Vertex_handle, Vertex_handle, Face_handle, Face_handle>

tds.split_vertex(Vertex_handle v, Face_handle f1, Face_handle f2)

Splits the vertex *v* into two vertices *v1* and *v2*. The common faces *f* and *g* of *v1* and *v2* are created after (in the counter-clockwise sense) the faces *f1* and *f2*. The 4-tuple *(v1,v2,f,g)* is returned (see Fig. 38.7). *Precondition*: *dimension()* must be equal to *2*, *f1* and *f2* must be different from *Face_handle()* and *v* must be a vertex of both *f1* and *f2*.

Vertex_handle	*tds.insert_degree_2(Face_handle f, int i)*	Inserts a degree two vertex and two faces adjacent to it that have two common edges. The edge defined by the face handle *f* and the integer *i* is duplicated. It returns a handle to the vertex created (see Fig. 38.8).
void	*tds.remove_degree_2(Vertex_handle v)*	Removes a degree 2 vertex and the two faces adjacent to it. The two edges of the star of *v* that are not incident to it are collapsed (see Fig. 38.8). *Precondition*: The degree of *v* must be equal to 2.

Class

CGAL::Triangulation_ds_vertex_base_2<Tds>

Definition

The class *Triangulation_ds_vertex_base_2* can be used as the base vertex for a *Triangulation_data_structure_2*, it is a model of the concept *TriangulationDSVertexBase_2*.

This base class can be used directly or can serve as a base to derive other base classes with some additional attributes (a color for example) tuned for a specific application.

Note that if the *Triangulation_data_structure_2* is used as a parameter of a geometric triangulation, there are additional geometric requirements to be fulfilled by the vertex base class, and *Triangulation_ds_vertex_base_2* cannot be plugged in.

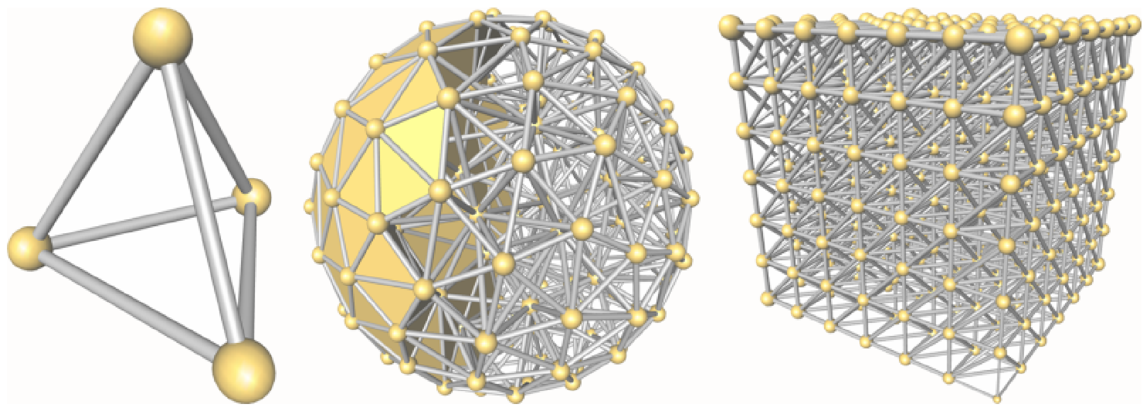
Chapter 39

3D Triangulations

Sylvain Pion and Monique Teillaud

Contents



The basic 3D-triangulation class of CGAL is primarily designed to represent the triangulations of a set of points A in $\mathbb{R}^3$. It is a partition of the convex hull of A into tetrahedra whose vertices are the points of A. Together with the unbounded cell having the convex hull boundary as its frontier, the triangulation forms a partition of $\mathbb{R}^3$. Its cells (3-faces) are such that two cells either do not intersect or share a common facet (2-face), edge (1-face) or vertex (0-face).

39.1 Representation

In order to deal only with tetrahedra, which is convenient for many applications, the unbounded cell can be subdivided into tetrahedra by considering that each convex hull facet is incident to an *infinite cell* having as fourth vertex an auxiliary vertex called the *infinite vertex*. In that way, each facet is incident to exactly two cells and special cases at the boundary of the convex hull are simple to deal with.

The class *Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>* of CGAL implements this point of view and therefore considers the triangulation of the set of points as a set of finite and infinite tetrahedra. Notice that the infinite vertex has no significant coordinates and that no geometric predicate can be applied on it.

A triangulation is a collection of vertices and cells that are linked together through incidence and adjacency relations. Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives access to one of its incident cells.

The four vertices of a cell are indexed with 0, 1, 2 and 3 in positive orientation, the positive orientation being defined by the orientation of the underlying Euclidean space $\mathbb{R}^3$ (see Figure 39.1). The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index.

As in the underlying combinatorial triangulation (see Chapter 40), edges (1-faces) and facets (2-faces) are not explicitly represented: a facet is given by a cell and an index (the facet i of a cell c is the facet of c that is opposite to the vertex with index i) and an edge is given by a cell and two indices (the edge *(i,j)* of a cell c is the edge whose endpoints are the vertices of c with indices i and j). See Figure 40.1.

Degenerate Dimensions The class *Triangulation_3* can also deal with triangulations whose dimension d is less than 3. A triangulation of a set of points in $\mathbb{R}^d$ covers the whole space $\mathbb{R}^d$ and consists of cells having $d+1$ vertices: some of them are infinite, they are obtained by linking the additional infinite vertex to each facet of the convex hull of the points.

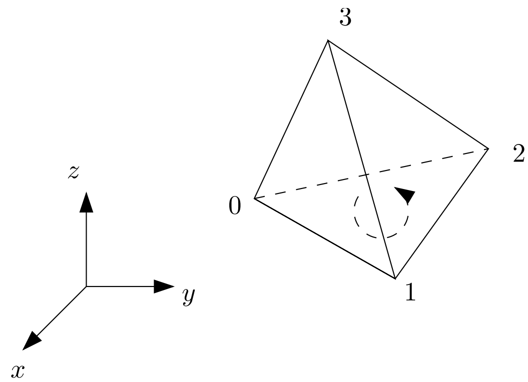


Figure 39.1: Orientation of a cell (3-dimensional case).

- *dimension 2:* when a triangulation only contains coplanar points (which is the case when there are only three points), it consists of triangular faces.
- *dimension 1:* the triangulation contains only collinear points (which is the case when there are only two points), it consists of edges.
- *dimension 0:* the triangulation contains only one finite point.
- *dimension -1:* this is a convention to handle the case when the only vertex of the triangulation is the infinite one.

The same cell class is used in all cases: triangular faces in 2D can be considered as degenerate cells, having only three vertices (resp. neighbors) numbered $(0,1,2)$; edges in 1D have only two vertices (resp. neighbors) numbered 0 and 1.

The implicit representation of facets (resp. edges) still holds for degenerate dimensions (*i.e.* dimensions < 3): in dimension 2, each cell has only one facet of index 3, and 3 edges $(0,1)$, $(1,2)$ and $(2,0)$; in dimension 1, each cell has one edge $(0,1)$.

Validity A triangulation of $\mathbb{R}^3$ is said to be *locally valid* iff

(a)-(b) Its underlying combinatorial graph, the triangulation data structure, is *locally valid* (see Section 40.1 of Chapter 40)
(c) Any cell has its vertices ordered according to positive orientation. See Figure 39.1.

When the triangulation is degenerated into a triangulation of dimension 2, the geometric validity reduces to:

(c-2D) For any two adjacent triangles (u,v,w_1) and (u,v,w_2) with common edge (u,v), w_1 and w_2 lie on opposite sides of (u,v) in the plane.

When all the points are collinear, this condition becomes:

(c-1D) For any two adjacent edges (u,v) and (v,w), u and w lie on opposite sides of the common vertex v on the line.

The *is_valid()* method provided in *Triangulation_3* checks the local validity of a given triangulation. This does not always ensure global validity [MNS+96, DLPT98] but it is sufficient for practical cases.

39.2 Delaunay Triangulation

The class *Delaunay_triangulation_3* represents a three-dimensional Delaunay triangulation.

Delaunay triangulations have the specific *empty sphere property*, that is, the circumscribing sphere of each cell of such a triangulation does not contain any other vertex of the triangulation in its interior. These triangulations are uniquely defined except in degenerate cases where five points are co-spherical. Note however that the CGAL implementation computes a unique triangulation even in these cases.

This implementation is fully dynamic: it supports insertions of points, vertex removals and displacements of points.

39.3 Regular Triangulation

The class *Regular_triangulation_3* implements incremental regular triangulations, also known as weighted Delaunay triangulations.

Let $S^{(w)}$ be a set of weighted points in $\mathbb{R}^3$. Let $p^{(w)} = (p, w_p), p \in \mathbb{R}^3, w_p \in \mathbb{R}$ and $z^{(w)} = (z, w_z), z \in \mathbb{R}^3, w_z \in \mathbb{R}$ be two weighted points. A weighted point $p^{(w)} = (p, w_p)$ can also be seen as a sphere of center p and radius $\sqrt{w_p}$. The *power product* between $p^{(w)}$ and $z^{(w)}$ is defined as

$$\Pi(p^{(w)}, z^{(w)}) = \|p - z\|^2 - w_p - w_z$$

where $\|p - z\|$ is the Euclidean distance between p and z. $p^{(w)}$ and $z^{(w)}$ are said to be *orthogonal* iff $\Pi(p^{(w)}, z^{(w)}) = 0$ (see Figure 39.2).

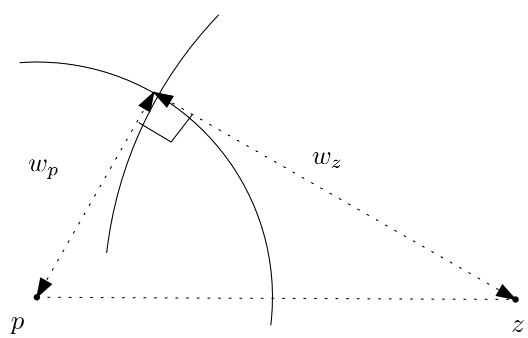

Figure 39.2: Orthogonal weighted points (picture in 2D).

Four weighted points have a unique common orthogonal weighted point called the *power sphere*. The weighted point orthogonal to three weighted points in the plane defined by these three points is called the *power circle*. The *power segment* will denote the weighted point orthogonal to two weighted points on the line defined by these two points.

A sphere $z^{(w)}$ is said to be *regular* if $\forall p^{(w)} \in S^{(w)}, \Pi(p^{(w)}, z^{(w)}) \geq 0$.

A triangulation of $S^{(w)}$ is *regular* if the power spheres of all simplices are regular.

The regular triangulation of $S^{(w)}$ is in fact the projection onto $\mathbb{R}^3$ of the convex hull of the four-dimensional points $(p, \|p - O\|^2 - w_p)$, for $p^{(w)} = (p, w_p) \in S^{(w)}$. Note that all points of $S^{(w)}$ do not necessarily appear as vertices of the regular triangulation. To know more about regular triangulations, see for example [ES96].

When all weights are 0, power spheres are nothing more than circumscribing spheres, and the regular triangulation is exactly the Delaunay triangulation.

The implementation of 3D regular triangulation supports insertions of weighted points, and vertex removals. Displacements are not supported in the current implementation.

39.4 Software Design

The main classes *Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3* are connected to each other by the derivation diagram shown in Figure 39.3. This diagram also shows another class: *Triangulation_utils_3* (page 2743), which provides a set of tools operating on the indices of vertices in cells.

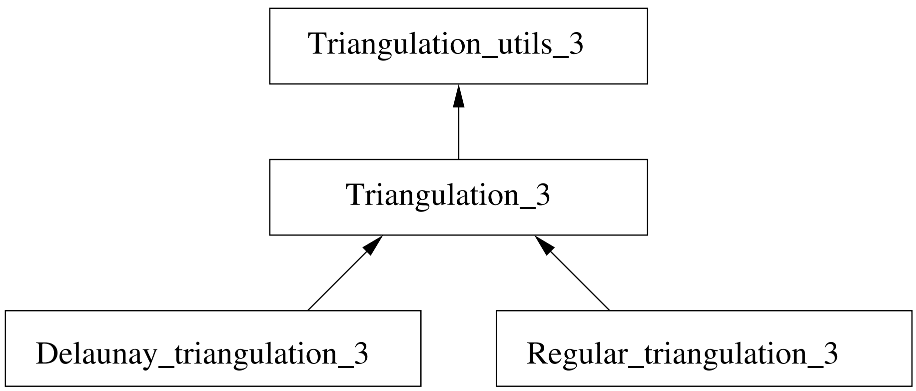

Figure 39.3: Derivation diagram of the 3D triangulation classes.

The three main classes (*Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3*) provide high-level geometric functionality such as location of a point in the triangulation [DPT02], insertion and possibly removal of a point [DT03], and are responsible for the geometric validity. They are built as layers on top of a triangulation data structure, which stores their combinatorial structure. This separation between the geometry and the combinatorics is reflected in the software design by the fact that these three triangulation classes take the following template parameters :

- the **geometric traits** class, which provides the type of points to use as well as the elementary operations on them (predicates and constructions). The concepts for these parameters are described in more details in Section 39.4.1 and in page 2672.
- the **triangulation data structure** class, which stores their combinatorial structure, described in Section 40.2 of Chapter 40.
- the **location policy** tag, which is supported only by the Delaunay triangulation class, described in Section 39.4.3.

39.4.1 The Geometric Traits Parameter

The first template parameter of the triangulation class *Triangulation_3<TriangulationTraits_3, TriangulationDataStructure_3>* is the geometric traits class, described by the concept *TriangulationTraits_3*. It must define the types of the geometric objects (points, segments, triangles and tetrahedra) forming the triangulation together with a few geometric predicates on these objects: orientation in space, orientation in case of coplanar points, order of collinear points.

In addition to the requirements described before, the geometric traits class of *Delaunay_triangulation_3* must define predicates to test for the *empty sphere property*. It is described by the concept *DelaunayTriangulationTraits_3*, which refines *TriangulationTraits_3*.

The kernels provided by CGAL: *Cartesian*, *Homogeneous*, *Simple_cartesian*, *Simple_homogeneous* and *Filtered_kernel* can all be used as models for the geometric traits parameter. They supply the user with all the functionalities described for the concepts *TriangulationTraits_3* (page 2672) and *DelaunayTriangulationTraits_3* (page 2674). In addition, the predefined kernels *Exact_predicates_inexact_constructions_kernel* (page **??**) and *Exact_predicates_exact_constructions_kernel* (page **??**) can also be used, the latter being recommended when the dual construction is used.

In order to be used as the traits class for *Regular_triangulation_3*, a class must provide functions to compute the *power tests* (see Section 39.3). *Regular_triangulation_euclidean_traits_3<K,Weight>* is a traits class designed to be used by the class *Regular_triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3>*. It provides *Weighted_point*, a class for weighted points needed by the regular triangulation, which derives from the three dimensional point class *K::Point_3*. It supplies the user with all the functionalities described for the concept *RegularTriangulationTraits_3* (page 2677). It can be used as a traits class for *Regular_triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3>*.

Note that for regular triangulations, plugging a filtered kernel such as *Exact_predicates_inexact_constructions_kernel* or *Exact_predicates_exact_constructions_kernel* in *Regular_triangulation_euclidean_traits_3<K,Weight>* will provide exact and efficient filtered predicates.

39.4.2 The Triangulation Data Structure Parameter

The second template parameter of the main classes (*Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3*) is a triangulation data structure class. This class can be seen as a container for the cells and vertices maintaining incidence and adjacency relations (see Chapter 40). A model of this triangulation data structure is *Triangulation_data_structure_3* (page 2739), and it is described by the *TriangulationDataStructure_3* concept (page 2715). This model is itself parameterized by a vertex base and a cell base classes, which gives the possibility to customize the vertices and cells used by the triangulation data structure, and hence by the geometric triangulation using it. Depending on the kind of triangulation used, the requirements on the vertex and cell base classes vary, and are expressed by various concepts, following the refinement diagram shown in Figure 39.4.

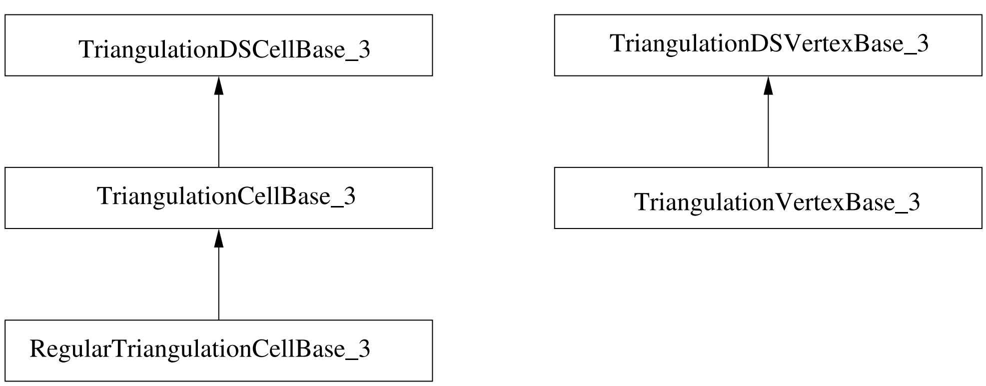

Figure 39.4: Concepts refinement hierarchy for the vertex and cell base classes parameters.

A default value for the triangulation data structure parameter is provided in all the triangulation classes, so it need not be specified by the user unless he wants to use a different triangulation data structure or a different vertex or cell base class.

39.4.3 The Location Policy Parameter

The Delaunay triangulation class supports an optional feature which maintains an additional data structure for fast point location queries. The fast location policy should be used when the user inserts points in a random order or needs to do many unrelated queries. If the user is able to give a good hint to help the point location of its queries (and its newly inserted points), then it should prefer the default policy. In such a case where good hints are provided, the default policy save some memory (few percents), and is faster. Notice that if points are not inserted one by one, but as a range, then a good hint is automatically computed using spatial sort.

Reading Section 39.6 on complexity and performance can help making an informed choice for this parameter.

The point location strategy can be selected with the third template argument of *Delaunay_triangulation_3*, *LocationPolicy*, which enables a fast point location data structure when set to *Fast_location*. By default, it uses *Compact_location*.

Note that you can specify the *LocationPolicy* parameter without specifying the triangulation data structure, in case you are fine with the default there. In this case, the *LocationPolicy* appears as a second parameter after the geometric traits.[1]

The *Fast_location* policy is implemented using a hierarchy of triangulations; it changes the behavior of functions *locate*, *insert*, *move*, and *remove*. As proved in [Dev02], this structure has an optimal behavior when it is built for Delaunay triangulations.

In this setting, if you build a triangulation by iteratively inserting points, you should try to shuffle the points beforehand, as the time complexity is guaranteed only for a randomized order. For example, inserting points in lexicographic order is typically much slower. Note that this shuffling is performed internally by the constructor taking a range of points.

Prior to CGAL 3.6, this functionality was available through the *Triangulation_hierarchy_3* class, which is now deprecated.

39.4.4 Flexibility of the Design

In order to satisfy as many uses as possible, a design has been selected that allows to exchange different parts to meet the users' needs, while still re-using a maximum of the provided functionalities. We have already seen that the main triangulation classes are parameterized by a geometric traits class and a triangulation data structure (TDS), so that each of them can be interchanged with alternate implementations.

The most useful flexibility is the ability given to the user to add his own data in the vertices and cells by providing his own vertex and cell base classes to *Triangulation_data_structure_3*. The Figure 39.5 shows in more detail the flexibility that is provided, and the place where the user can insert his own vertex and/or cell base classes.

The design of the triangulation data structure gives the possibility to store any kind of data, including handles (an entity akin to pointers) directly in the vertex and cell base classes.

To do so, there are three possibilities. The simplest one is to use the class *Triangulation_vertex_base_with_info_3*, and this approach is illustrated in a following subsection 39.5.2. The most complicated one, and probably

[1] The mechanism used behind the scenes to allow this syntactical convenience is called *deduced parameters*.

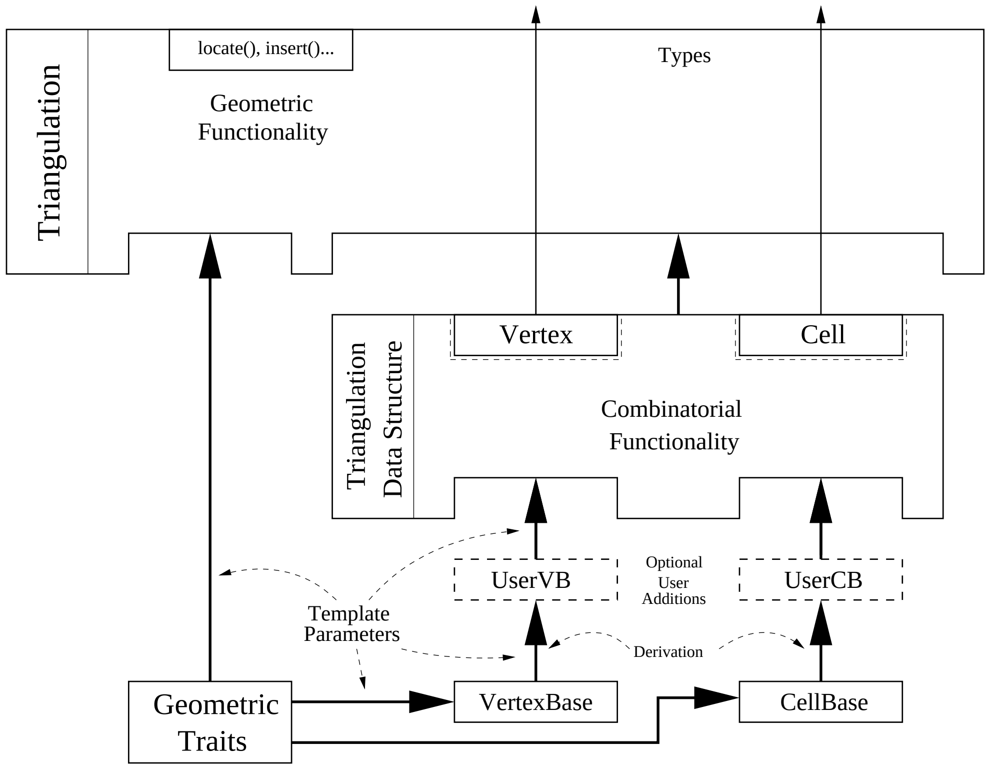

Figure 39.5: Triangulation software design.

useless for almost all cases, is to write a vertex base class from scratch, following the documented requirements. This is mostly useless because most of the time it is enough to derive from the models that CGAL provides, and add the desired features. In this case, when the user needs to access some type that depends on the triangulation data structure (typically handles), then he should write something like:

```
...
template < class GT, class Vb = Triangulation_vertex_base<GT> >
class My_vertex
  : public Vb
{
public:
  typedef typename Vb::Point           Point;
  typedef typename Vb::Cell_handle     Cell_handle;

  template < class TDS2 >
  struct Rebind_TDS {
    typedef typename Vb::template Rebind_TDS<TDS2>::Other  Vb2;
    typedef My_vertex<GT, Vb2>                             Other;
  };

  My_vertex() {}
  My_vertex(const Point&p)                : Vb(p) {}
  My_vertex(const Point&p, Cell_handle c) : Vb(p, c) {}
...
};
... // The rest has not changed
```

The situation is exactly similar for cell base classes. Section 40.2 provides more detailed information.

39.5 Examples

39.5.1 Basic Example

This example shows the incremental construction of a 3D triangulation, the location of a point and how to perform elementary operations on indices in a cell. It uses the default parameter of the *Triangulation_3* class.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_3.h>

#include <iostream>
#include <fstream>
#include <cassert>
#include <list>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_3<K>      Triangulation;

typedef Triangulation::Cell_handle    Cell_handle;
typedef Triangulation::Vertex_handle  Vertex_handle;
typedef Triangulation::Locate_type    Locate_type;
typedef Triangulation::Point          Point;

int main()
{
  // construction from a list of points :
  std::list<Point> L;
  L.push_front(Point(0,0,0));
  L.push_front(Point(1,0,0));
  L.push_front(Point(0,1,0));

  Triangulation T(L.begin(), L.end());

  Triangulation::size_type n = T.number_of_vertices();

  // insertion from a vector :
  std::vector<Point> V(3);
  V[0] = Point(0,0,1);
  V[1] = Point(1,1,1);
  V[2] = Point(2,2,2);

  n = n + T.insert(V.begin(), V.end());

  assert( n == 6 );       // 6 points have been inserted
  assert( T.is_valid() ); // checking validity of T

  Locate_type lt;
  int li, lj;
```

```
  Point p(0,0,0);
  Cell_handle c = T.locate(p, lt, li, lj);
  // p is the vertex of c of index li :
  assert( lt == Triangulation::VERTEX );
  assert( c->vertex(li)->point() == p );

  Vertex_handle v = c->vertex( (li+1)&3 );
  // v is another vertex of c
  Cell_handle nc = c->neighbor(li);
  // nc = neighbor of c opposite to the vertex associated with p
  // nc must have vertex v :
  int nli;
  assert( nc->has_vertex( v, nli ) );
  // nli is the index of v in nc

  std::ofstream oFileT("output",std::ios::out);
  // writing file output;
  oFileT << T;

  Triangulation T1;
  std::ifstream iFileT("output",std::ios::in);
  // reading file output;
  iFileT >> T1;
  assert( T1.is_valid() );
  assert( T1.number_of_vertices() == T.number_of_vertices() );
  assert( T1.number_of_cells() == T.number_of_cells() );

  return 0;
}
```

File: examples/Triangulation_3/simple_triangulation_3.cpp

39.5.2 Changing the Vertex Base

The following two examples show how the user can plug his own vertex base in a triangulation. Changing the cell base is similar.

Adding a Color

When the user doesn't need to add a type in a vertex which depends on the *TriangulationDataStructure_3* (e.g. a *Vertex_handle* or *Cell_handle*), then he can use the *Triangulation_vertex_base_with_info_3* class to add his own information easily in the vertices. The example below shows how to add a *CGAL::Color* this way.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Triangulation_vertex_base_with_info_3.h>
#include <CGAL/IO/Color.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
```

```
typedef CGAL::Triangulation_vertex_base_with_info_3<CGAL::Color, K> Vb;
typedef CGAL::Triangulation_data_structure_3<Vb>                    Tds;
typedef CGAL::Delaunay_triangulation_3<K, Tds>
   Delaunay;

typedef Delaunay::Point   Point;

int main()
{
  Delaunay T;

  T.insert(Point(0,0,0));
  T.insert(Point(1,0,0));
  T.insert(Point(0,1,0));
  T.insert(Point(0,0,1));
  T.insert(Point(2,2,2));
  T.insert(Point(-1,0,1));

  // Set the color of finite vertices of degree 6 to red.
  Delaunay::Finite_vertices_iterator vit;
  for (vit = T.finite_vertices_begin(); vit != T.finite_vertices_end();
   ++vit)
      if (T.degree(vit) == 6)
          vit->info() = CGAL::RED;

  return 0;
}
```

File: examples/Triangulation_3/color.cpp

Adding Handles

When the user needs to add a type in a vertex which depends on the *TriangulationDataStructure_3* (e.g. a *Vertex_handle* or *Cell_handle*), then he has to derive his own vertex base class, as the following example shows.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Triangulation_vertex_base_3.h>

template < class GT, class Vb = CGAL::Triangulation_vertex_base_3<GT> >
class My_vertex_base
  : public Vb
{
public:
  typedef typename Vb::Vertex_handle  Vertex_handle;
  typedef typename Vb::Cell_handle    Cell_handle;
  typedef typename Vb::Point          Point;

  template < class TDS2 >
  struct Rebind_TDS {
    typedef typename Vb::template Rebind_TDS<TDS2>::Other  Vb2;
    typedef My_vertex_base<GT, Vb2>                        Other;
```

```
  };

  My_vertex_base() {}

  My_vertex_base(const Point& p)
    : Vb(p) {}

  My_vertex_base(const Point& p, Cell_handle c)
    : Vb(p, c) {}

  Vertex_handle   vh;
  Cell_handle     ch;
};

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_data_structure_3<My_vertex_base<K> >    Tds;
typedef CGAL::Delaunay_triangulation_3<K, Tds>
   Delaunay;

typedef Delaunay::Vertex_handle    Vertex_handle;
typedef Delaunay::Point            Point;

int main()
{
  Delaunay T;

  Vertex_handle v0 = T.insert(Point(0,0,0));
  Vertex_handle v1 = T.insert(Point(1,0,0));
  Vertex_handle v2 = T.insert(Point(0,1,0));
  Vertex_handle v3 = T.insert(Point(0,0,1));
  Vertex_handle v4 = T.insert(Point(2,2,2));
  Vertex_handle v5 = T.insert(Point(-1,0,1));

  // Now we can link the vertices as we like.
  v0->vh = v1;
  v1->vh = v2;
  v2->vh = v3;
  v3->vh = v4;
  v4->vh = v5;
  v5->vh = v0;

  return 0;
}
```

File: examples/Triangulation_3/adding_handles_3.cpp

39.5.3 Setting Information While Inserting a Range of Points

The most efficient method to insert (weighted) points in a Delaunay (or regular) triangulation is to provide an iterator range over (weighted) points to the insert function. However, an iterator range of (weighted) points does not allow to set different information to each vertex. To solve this problem, in the case the vertex type of the triangulation is a model of the concept *TriangulationVertexBaseWithInfo_3* (such as *Triangulation_vertex_base_with_info_3*), we provide three examples doing the same operation: set an unsigned integer as the information of each vertex. The value of this unsigned integer is the initial order of the corresponding point given in the range.

Using an Iterator Over Pairs

Each point and its information are gathered into a pair. We provide the constructor of the triangulation (which is calling the *insert* function) with a range of such pairs.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Triangulation_vertex_base_with_info_3.h>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel         K;
typedef CGAL::Triangulation_vertex_base_with_info_3<unsigned, K>    Vb;
typedef CGAL::Triangulation_data_structure_3<Vb>                    Tds;
typedef CGAL::Delaunay_triangulation_3<K, Tds>
    Delaunay;
typedef Delaunay::Point
    Point;

int main()
{
  std::vector< std::pair<Point,unsigned> > points;
  points.push_back( std::make_pair(Point(0,0,0),0) );
  points.push_back( std::make_pair(Point(1,0,0),1) );
  points.push_back( std::make_pair(Point(0,1,0),2) );
  points.push_back( std::make_pair(Point(0,0,1),3) );
  points.push_back( std::make_pair(Point(2,2,2),4) );
  points.push_back( std::make_pair(Point(-1,0,1),5) );

  Delaunay T( points.begin(),points.end() );

  CGAL_assertion( T.number_of_vertices() == 6 );

  // check that the info was correctly set.
  Delaunay::Finite_vertices_iterator vit;
  for (vit = T.finite_vertices_begin(); vit != T.finite_vertices_end();
   ++vit)
    if( points[ vit->info() ].first != vit->point() ){
      std::cerr << "Error different info" << std::endl;
      exit(EXIT_FAILURE);
    }
  std::cout << "OK" << std::endl;

  return 0;
}
```

File: examples/Triangulation_3/info_insert_with_pair_iterator.cpp

Using the Boost Zip Iterator

Information and points are in separate containers. We use *boost::zip_iterator* to provide an iterator gathering them.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

Using the Boost Transform Iterator

We define a functor *Auto_count* used together with *boost::transform_iterator* to set the order of each point in the range. Note that this is correct because the iterator is dereferenced only once per point during the insertion.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Triangulation_vertex_base_with_info_3.h>
#include <boost/iterator/transform_iterator.hpp>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel         K;
typedef CGAL::Triangulation_vertex_base_with_info_3<unsigned, K>    Vb;
typedef CGAL::Triangulation_data_structure_3<Vb>                    Tds;
typedef CGAL::Delaunay_triangulation_3<K, Tds>
   Delaunay;
typedef Delaunay::Point
   Point;

//a functor that returns a std::pair<Point,unsigned>.
//the unsigned integer is incremented at each call to
//operator()
struct Auto_count : public std::unary_function<const
   Point&,std::pair<Point,unsigned> >{
  mutable unsigned i;
  Auto_count() : i(0){}
  std::pair<Point,unsigned> operator()(const Point& p) const {
    return std::make_pair(p,i++);
  }
};

int main()
{
  std::vector<Point> points;
  points.push_back(Point(0,0,0));
  points.push_back(Point(1,0,0));
  points.push_back(Point(0,1,0));
  points.push_back(Point(0,0,1));
  points.push_back(Point(2,2,2));
  points.push_back(Point(-1,0,1));

  Delaunay T(
   boost::make_transform_iterator(points.begin(),Auto_count()),
```

```
                boost::make_transform_iterator(points.end(),  Auto_count()
   )  );

  CGAL_assertion( T.number_of_vertices() == 6 );

  // check that the info was correctly set.
  Delaunay::Finite_vertices_iterator vit;
  for (vit = T.finite_vertices_begin(); vit != T.finite_vertices_end();
   ++vit)
    if( points[ vit->info() ] != vit->point() ){
      std::cerr << "Error different info" << std::endl;
      exit(EXIT_FAILURE);
    }
  std::cout << "OK" << std::endl;

  return 0;
}
```

39.5.4 The Simplex Class

The triangulation defines a *Simplex* class that represents a simplex (vertex, edge, facet or cell). This example demonstrates how simplices can be stored in a set.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_3.h>

#include <iostream>
#include <fstream>
#include <list>
#include <set>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_3<K>      Triangulation;

typedef Triangulation::Finite_vertices_iterator Finite_vertices_iterator;
typedef Triangulation::Finite_edges_iterator Finite_edges_iterator;
typedef Triangulation::Finite_facets_iterator Finite_facets_iterator;
typedef Triangulation::Finite_cells_iterator Finite_cells_iterator;
typedef Triangulation::Simplex        Simplex;
typedef Triangulation::Locate_type    Locate_type;
typedef Triangulation::Point          Point;

int main()
{
  // construction from a list of points :
  std::list<Point> L;
  L.push_front(Point(0,0,0));
  L.push_front(Point(1,0,0));
  L.push_front(Point(0,1,0));
```

```
  L.push_front(Point(0,1,1));

  Triangulation T(L.begin(), L.end());

  std::set<Simplex> simplices;

  Finite_vertices_iterator vit = T.finite_vertices_begin();
  simplices.insert(Simplex(vit));

  Finite_cells_iterator cit = T.finite_cells_begin();
  simplices.insert(Simplex(cit));

  Finite_edges_iterator eit = T.finite_edges_begin();
  simplices.insert(Simplex(*eit));

  Finite_facets_iterator fit = T.finite_facets_begin();
  simplices.insert(Simplex(*fit));

  for (std::set<Simplex>::iterator it = simplices.begin();
       it != simplices.end(); it++) {
    std::cout << it->dimension() << std::endl;
  }

  return 0;
}
```

File: examples/Triangulation_3/simplex.cpp

39.5.5 Fast Point Location for Delaunay Triangulations

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Random.h>

#include <vector>
#include <cassert>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Delaunay_triangulation_3<K, CGAL::Fast_location> Delaunay;
typedef Delaunay::Point Point;

int main()
{
  // generating points on a grid.
  std::vector<Point> P;

  for (int z=0 ; z<20 ; z++)
    for (int y=0 ; y<20 ; y++)
      for (int x=0 ; x<20 ; x++)
          P.push_back(Point(x,y,z));
```

```
  // building their Delaunay triangulation.
  Delaunay T(P.begin(), P.end());

  assert( T.number_of_vertices() == 8000 );

  // performing nearest vertex queries to a series of random points,
  // which is a case where the Fast_location policy is beneficial.
  for (int i=0; i<10000; ++i)
    T.nearest_vertex(Point(CGAL::default_random.get_double(0, 20),
                           CGAL::default_random.get_double(0, 20),
                           CGAL::default_random.get_double(0, 20)));

  return 0;
}
```

File: examples/Triangulation_3/fast_location_3.cpp

39.5.6 Finding the Cells in Conflict with a Point in a Delaunay Triangulation

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/point_generators_3.h>

#include <vector>
#include <cassert>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Delaunay_triangulation_3<K>         Delaunay;
typedef Delaunay::Point                           Point;
typedef Delaunay::Cell_handle                     Cell_handle;
typedef Delaunay::Facet                           Facet;

int main()
{
  Delaunay T;
  CGAL::Random_points_in_sphere_3<Point> rnd;

  // First, make sure the triangulation is 3D.
  T.insert(Point(0,0,0));
  T.insert(Point(1,0,0));
  T.insert(Point(0,1,0));
  T.insert(Point(0,0,1));

  assert(T.dimension() == 3);

  // Inserts 100 random points if and only if their insertion
  // in the Delaunay tetrahedralization conflicts with
  // an even number of cells.
  for (int i = 0; i != 100; ++i) {
    Point p = *rnd++;
```

```
    // Locate the point
    Delaunay::Locate_type lt;
    int li, lj;
    Cell_handle c = T.locate(p, lt, li, lj);
    if (lt == Delaunay::VERTEX)
      continue; // Point already exists

    // Get the cells that conflict with p in a vector V,
    // and a facet on the boundary of this hole in f.
    std::vector<Cell_handle> V;
    Facet f;

    T.find_conflicts(p, c,
                     CGAL::Oneset_iterator<Facet>(f), // Get one boundary
     facet
                     std::back_inserter(V));          // Conflict cells
   in V

    if ((V.size() & 1) == 0)  // Even number of conflict cells ?
      T.insert_in_hole(p, V.begin(), V.end(), f.first, f.second);
  }

  std::cout << "Final triangulation has " << T.number_of_vertices()
            << " vertices." << std::endl;

  return 0;
}
```

File: examples/Triangulation_3/find_conflicts_3.cpp

39.5.7 Regular Triangulation

This example shows the building of a regular triangulation. In this triangulation, points have an associated weight, and some points can be hidden and do not result in vertices in the triangulation. Another difference is that a specific traits class has to be used (at least at the moment).

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Regular_triangulation_3.h>
#include <CGAL/Regular_triangulation_euclidean_traits_3.h>
#include <cassert>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Regular_triangulation_euclidean_traits_3<K>  Traits;

typedef Traits::RT                                          Weight;
typedef Traits::Bare_point                                  Point;
typedef Traits::Weighted_point
   Weighted_point;

typedef CGAL::Regular_triangulation_3<Traits>               Rt;
```

```
typedef Rt::Vertex_iterator
    Vertex_iterator;
typedef Rt::Vertex_handle
    Vertex_handle;

int main()
{
  // generate points on a 3D grid
  std::vector<Weighted_point> P;

  int number_of_points = 0;

  for (int z=0 ; z<5 ; z++)
    for (int y=0 ; y<5 ; y++)
      for (int x=0 ; x<5 ; x++) {
          Point p(x, y, z);
          Weight w = (x+y-z*y*x)*2.0; // let's say this is the weight.
          P.push_back(Weighted_point(p, w));
          ++number_of_points;
      }

  Rt T;

  // insert all points in a row (this is faster than one insert() at a
    time).
  T.insert (P.begin(), P.end());

  assert( T.is_valid() );
  assert( T.dimension() == 3 );

  std::cout << "Number of vertices : " << T.number_of_vertices() <<
    std::endl;

  // removal of all vertices
  int count = 0;
  while (T.number_of_vertices() > 0) {
      T.remove (T.finite_vertices_begin());
      ++count;
  }

  assert( count == number_of_points );

  return 0;
}
```

File: examples/Triangulation_3/regular_3.cpp

39.6 Complexity and Performance

In 3D, the worst case complexity of a triangulation is quadratic in the number of points. For Delaunay triangulations, this bound is reached in cases such as points equally distributed on two non-coplanar lines. However, the good news is that, in many cases, the complexity of a Delaunay triangulation is linear or close to linear in the number of points. Several articles [Dwy89, Eri02, AAD07, AB03, ABL03] have proved such good complexity bounds for specific point distributions, such as points distributed on surfaces under some conditions.

39.6.1 Running Time

There are several algorithms provided in this package. We will focus here on the following ones and give practical numbers on their efficiency :

- construction of a triangulation from a range of points,
- location of a point (using the *locate* function),
- removal of a vertex (using the *remove* function).

We will use the following types of triangulations, using *Exact_predicates_inexact_constructions_kernel* as geometric traits (combined with *Regular_triangulation_euclidean_traits_3* in the weighted case) :

- **Delaunay** : *Delaunay_triangulation_3*
- **Delaunay - Fast location** : *Delaunay_triangulation_3* with *Fast_location*
- **Regular** : *Regular_triangulation_3* (default setting : memorize hidden points)
- **Regular - No hidden points** : *Regular_triangulation_3* with hidden points discarded (using *Triangulation_cell_base_3* instead of *Regular_triangulation_cell_base_3*).

Figure 39.6 shows, for all these types of triangulations, the times in seconds taken to build a triangulation from a given number of points, then the average time to perform one point location in triangulations of various sizes, and the average time to perform one vertex removal (which is largely independent on the size of the triangulation).

The data sets used here are points randomly distributed in the unit cube (the coordinates are generated using the `drand48` C function). In the weighted case, the weights are all zero, which means that there are actually no hidden points during execution.

The measurements have been performed using CGAL 3.6, using the GNU C++ compiler version 4.3.2, under Linux (Fedora 10 distribution), with the compilation options `-O3 -DCGAL_NDEBUG`. The computer used was equipped with a 64bit Intel Xeon 3GHz processor and 32GB of RAM (a recent desktop machine as of 2009).

More benchmarks comparing CGAL to other software can be found in [LS05].

39.6.2 Memory Usage

We give here some indication about the memory usage of the triangulations. Those structures being intensively based on pointers, the size almost doubles on 64bit platforms compared to 32bit.

	Delaunay	Delaunay Fast location	Regular	Regular No hidden points
Construction from 10^2 points	0.00054	0.000576	0.000948	0.000955
Construction from 10^3 points	0.00724	0.00748	0.0114	0.0111
Construction from 10^4 points	0.0785	0.0838	0.122	0.117
Construction from 10^5 points	0.827	0.878	1.25	1.19
Construction from 10^6 points	8.5	9.07	12.6	12.2
Construction from 10^7 points	87.4	92.5	129	125
Point location in 10^2 points	9.93e-07	1.06e-06	7.19e-06	6.99e-06
Point location in 10^3 points	2.25e-06	1.93e-06	1.73e-05	1.76e-05
Point location in 10^4 points	4.79e-06	3.09e-06	3.96e-05	3.76e-05
Point location in 10^5 points	2.98e-05	6.12e-06	1.06e-04	1.06e-04
Point location in 10^6 points	1e-04	9.65e-06	2.7e-04	2.67e-04
Point location in 10^7 points	2.59e-04	1.33e-05	6.25e-04	6.25e-04
Vertex removal	1e-04	1.03e-04	1.42e-04	1.38e-04

Figure 39.6: Running times in seconds for algorithms on 3D triangulations.

The size also depends on the size of the point type which is copied in the vertices (hence on the kernel). Obviously, any user data added to vertices and cells also affect the memory used.

More specifically, the memory space used to store a triangulation is first a function of the size of its *Vertex* and *Cell* types times their numbers (and for volumic distribution, one sees about 6.7 times more cells than vertices). However, these are stored in memory using *Compact_container*, which allocates them in lists of blocks of growing size, and this requires some additional overhead for bookkeeping. Moreover, memory is only released to the system when clearing or destroying the triangulation. This can be important for algorithms like simplifications of data sets which will produce fragmented memory usage (doing fresh copies of the data structures are one way out in such cases). The asymptotic memory overhead of *Compact_container* for its internal bookkeeping is otherwise on the order of $O(\sqrt{n})$.

Figure 39.7 shows the number of bytes used per points, as measured empirically using *Memory_sizer* for large triangulations (10^6 random points).

	Delaunay	Delaunay Fast location	Regular	Regular No hidden points
32bit	274	291	336	282
64bit	519	553	635	527

Figure 39.7: Memory usage in bytes per point for large data sets.

39.6.3 Variability Depending on the Data Sets and the Kernel

Besides the complexity of the Delaunay triangulation that varies with the distribution of the points, another critical aspect affects the efficiency : the degeneracy of the data sets. These algorithms are quite sensitive to numerical accuracy and it is important to run them using exact predicates.

Using a kernel with no exact predicates will quickly lead to crashes or infinite loops once they are executed on non-random data sets. More precisely, problems appear with data sets which contain (nearly) degenerate cases for the *orientation* and *side_of_oriented_sphere* predicates, namely when there are (nearly) coplanar or (nearly) cospherical points. This unfortunately happens often in practice with data coming from various kinds of scanners or other automatic acquisition devices.

Using an inexact kernel such as *Simple_cartesian<double>* would lead to optimal performance, which is only about 30% better than *Exact_predicates_inexact_constructions_kernel*. The latter is strongly recommended since it takes care about potential robustness issues. The former can be used for benchmarking purposes mostly, or when you really know that your data sets won't exhibit any robustness issue.

Exact predicates take more time to compute when they hit (nearly) degenerate cases. Depending on the data set, this can have a visible impact on the overall performance of the algorithm or not.

Sometimes you need exact constructions as well, so *Exact_predicates_exact_constructions_kernel* is a must. This is the case for example when you need the *dual* functions to be exact, or when your input is stored in points of such a kernel for other reasons (because it is the output of another algorithm which has this requirement, for example). This will slow down the computations by a factor of 4 to 5 at least, and it can be much more.

Figure 39.8 gives more detailed timings about various kernels one the following data sets : random points in a cube, random points on the surface of an ellipsoid, points scanned on the surface of a Buddha statue, points on a molecular surface, and points scanned on a dryer handle. See Figure 39.9 for pictures of the last 3 objects, which respectively illustrate volumic data, surfacic data, and data with many degenerate cases. This last data set exhibits an infinite loop with an inexact kernel, and of course we are not sure whether what is computed for the other data sets with this inexact kernel is a Delaunay triangulation. General introductory information about these robustness issues can be found in [KMP+08]. More benchmarks around this issue can also be found in [DP03].

	Random	**Ellipsoid**	**Buddha**	**Molecule**	**Dryer Handle**
#points	**100000**	**100000**	**542548**	**525296**	**49787**
Simple_cartesian<double>	0.69	0.627	4.21	3.8	∞-loop
Exact_predicates_inexact_constructions_kernel	0.824	0.749	4.99	4.64	1.68
Exact_predicates_exact_constructions_kernel	4.59	3.85	30.1	26.4	4.57
Simple_cartesian<Gmpq>	492	534	1120	1030	75.2

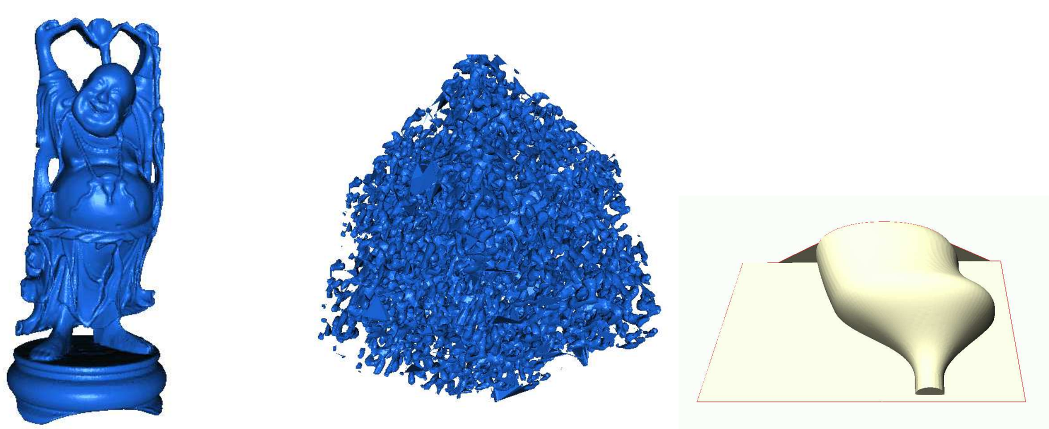

Figure 39.9: Data sets used in the benchmark of Figure 39.8.

39.7 Design and Implementation History

Monique Teillaud started to work on the 3D triangulation packages in 1997, following the design of the 2D triangulation packages. The notions of degenerate dimensions and infinite vertex were formalized [Tei99] and induced changes in the 2D triangulation packages. The packages were first released in CGAL 2.1. They contained basic functionalities on triangulations, Delaunay triangulations, regular triangulations.

A first version of removal of a vertex from a Delaunay triangulation was released in CGAL 2.2. However, this removal became really robust only in CGAL 2.3, after some research that allowed to deal with degenerate cases quite easily [DT03]. Andreas Fabri implemented this revised version of the removal, and a faster removal algorithm for CGAL 3.0.

The latter algorithm was proposed by Mariette Yvinec, who contributed in several ways to the package, first since she was maintaining the close 2D triangulation package and participated in many discussions, she also wrote the traits classes for regular triangulations.

In 2000, Sylvain Pion started working on these packages. He improved the efficiency of triangulations in CGAL 2.3 and 2.4 in several ways [BDP+02]: he implemented the Delaunay hierarchy [Dev02] in 2.3, he improved the memory footprint in 2.4 and 3.0, he also performed work on arithmetic filters [DP03] (see *Filtered_kernel*) to improve the speed of triangulations. He changed the design in CGAL 3.0, allowing users to add handles in their own vertices and cells.

Olivier Devillers, co-author of preliminary versions of the CGAL 2d triangulations, participated in many discussions, in particular about the perturbations, and more concretely in the implementation of the Delaunay hierarchy.

In 2005, Christophe Delage implemented the vertex removal function for regular triangulations, using the symbolic perturbation proposed in [DT06], which allowed to release this functionality in CGAL 3.2.

In 2006, Nico Kruithof wrote the *Triangulation_simplex_3* class that can store simplices of any dimension and improved the internal organization of the code.

As of March 2007, Christophe Delage made the iterator range insert methods and constructors use *spatial_sort* to improve efficiency.

In 2008, Camille Wormser added a few more iterators in the package that were integrated in release 3.4.

In 2009, Sylvain Pion simplified the design of the Delaunay hierarchy so that it became the simple *Fast_location* policy in release 3.6.

In 2010, Pedro de Castro and Olivier Devillers added the point displacement in release 3.7.

In 2011, Pedro de Castro and Olivier Devillers implemented in release 3.8 the structural filtering method, improving the efficiency of point location.

A new demo of this package was introduced in CGAL 3.8, coded by Fei (Sophie) Che, who was co-mentored by Manuel Caroli and Monique Teillaud in the framework of the Google Summer of Code, 2010.

The authors wish to thank Lutz Kettner for inspiring discussions about the design of CGAL. Jean-Daniel Boissonnat is also acknowledged [BDTY00].

3D Triangulations Reference Manual

Sylvain Pion and Monique Teillaud

A three-dimensional triangulation is a three-dimensional simplicial complex, pure connected and without singularities [BY98]. Its cells (3-faces) are such that two cells either do not intersect or share a common facet (2-face), edge (1-face) or vertex (0-face).

The basic 3D-triangulation class of CGAL is primarily designed to represent the triangulations of a set of points A in $\mathbb{R}^3$. It can be viewed as a partition of the convex hull of A into tetrahedra whose vertices are the points of A. Together with the unbounded cell having the convex hull boundary as its frontier, the triangulation forms a partition of $\mathbb{R}^3$.

In order to deal only with tetrahedra, which is convenient for many applications, the unbounded cell can be subdivided into tetrahedra by considering that each convex hull facet is incident to an *infinite cell* having as fourth vertex an auxiliary vertex called the *infinite vertex*. In that way, each facet is incident to exactly two cells and special cases at the boundary of the convex hull are simple to deal with.

A triangulation is a collection of vertices and cells that are linked together through incidence and adjacency relations. Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives access to one of its incident cells.

The four vertices of a cell are indexed with 0, 1, 2 and 3 in positive orientation, the positive orientation being defined by the orientation of the underlying Euclidean space $\mathbb{R}^3$. The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. See Figure 39.1.

Class

CGAL::Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>

Definition

The class *Triangulation_3* represents a 3-dimensional tetrahedralization of points.

#include <CGAL/Triangulation_3.h>

Parameters

The first template argument must be a model of the *TriangulationTraits_3* concept.

The second template argument must be a model of the *TriangulationDataStructure_3* concept. It has the default value *Triangulation_data_structure_3< Triangulation_vertex_base_3<TriangulationTraits_3> ,Triangulation_cell_base_3<TriangulationTraits_3> >*.

Inherits From

Triangulation_utils_3

Types

The class *Triangulation_3* defines the following types:

typedef TriangulationDataStructure_3	*Triangulation_data_structure;*
typedef TriangulationTraits_3	*Geom_traits;*

typedef TriangulationTraits_3::Point_3	*Point;*
typedef TriangulationTraits_3::Segment_3	*Segment;*
typedef TriangulationTraits_3::Triangle_3	*Triangle;*
typedef TriangulationTraits_3::Tetrahedron_3	*Tetrahedron;*

Only vertices (0-faces) and cells (3-faces) are stored. Edges (1-faces) and facets (2-faces) are not explicitly represented and thus there are no corresponding classes (see Section 39.1).

typedef TriangulationDataStructure_3::Vertex	*Vertex;*
typedef TriangulationDataStructure_3::Cell	*Cell;*
typedef TriangulationDataStructure_3::Facet	*Facet;*
typedef TriangulationDataStructure_3::Edge	*Edge;*

The vertices and faces of the triangulations are accessed through *handles*, *iterators* and *circulators*. A handle is a model of the *Handle* concept, and supports the two dereference operators *operator** and *operator->*. A circulator is a model of the concept *Circulator*. Iterators and circulators are bidirectional and non-mutable. The edges and facets of the triangulation can also be visited through iterators and circulators which are bidirectional and non-mutable.

Iterators and circulators are convertible to the corresponding handles, thus the user can pass them directly as arguments to the functions.

typedef TriangulationDataStructure_3::Vertex_handle	*Vertex_handle;*	handle to a vertex
typedef TriangulationDataStructure_3::Cell_handle	*Cell_handle;*	handle to a cell
typedef Triangulation_simplex_3<Self>	*Simplex;*	Reference to a simplex (vertex, edge, facet or cell) of the triangulation
typedef TriangulationDataStructure_3::size_type	*size_type;*	Size type (an unsigned integral type)
typedef TriangulationDataStructure_3::difference_type	*difference_type;*	Difference type (a signed integral type)
typedef TriangulationDataStructure_3::Cell_iterator	*All_cells_iterator;*	iterator over cells
typedef TriangulationDataStructure_3::Facet_iterator	*All_facets_iterator;*	iterator over facets
typedef TriangulationDataStructure_3::Edge_iterator	*All_edges_iterator;*	iterator over edges
typedef TriangulationDataStructure_3::Vertex_iterator	*All_vertices_iterator;*	iterator over vertices

Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Finite_cells_iterator

iterator over finite cells

Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Finite_facets_iterator

iterator over finite facets

Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Finite_edges_iterator

iterator over finite edges

Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Finite_vertices_iterator

iterator over finite vertices

Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Point_iterator

iterator over the points corresponding to the finite vertices of the triangulation.

typedef TriangulationDataStructure_3::Cell_circulator	*Cell_circulator;*	circulator over all cells incident to a given edge
typedef TriangulationDataStructure_3::Facet_circulator	*Facet_circulator;*	circulator over all facets incident to a given edge

The triangulation class also defines the following enum type to specify which case occurs when locating a point in the triangulation.

enum Locate_type { *VERTEX=0,*
EDGE,
FACET,
CELL,
OUTSIDE_CONVEX_HULL,
OUTSIDE_AFFINE_HULL}

Creation

Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3> t(TriangulationTraits_3 traits = TriangulationTraits_3())

Introduces a triangulation *t* having only one vertex which is the infinite vertex.

Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3> t(Triangulation_3 tr);

Copy constructor. All vertices and faces are duplicated.

template < class InputIterator>
Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3> t(InputIterator first, InputIterator last, TriangulationTraits_3 traits = TriangulationTraits_3())

Equivalent to constructing an empty triangulation with the optional traits class argument and calling *insert(first,last)*.

Assignment

Triangulation_3 & *t = Triangulation_3 tr*

The triangulation *tr* is duplicated, and modifying the copy after the duplication does not modify the original. The previous triangulation held by *t* is deleted.

void *t.swap(Triangulation_3 & tr)*

The triangulations *tr* and *t* are swapped. *t.swap(tr)* should be preferred to *t* = *tr* or to *t(tr)* if *tr* is deleted after that. Indeed, there is no copy of cells and vertices, thus this method runs in constant time.

void *t.clear()* Deletes all finite vertices and all cells of *t*.

template < class GT, class Tds1, class Tds2 >

bool *Triangulation_3<GT, Tds1> t1* == *Triangulation_3<GT, Tds2> t2*

Equality operator. Returns true iff there exist a bijection between the vertices of *t1* and those of *t2* and a bijection between the cells of *t1* and those of *t2*, which preserve the geometry of the triangulation, that is, the points of each corresponding pair of vertices are equal, and the tetrahedra corresponding to each pair of cells are equal (up to a permutation of their vertices).

template < class GT, class Tds1, class Tds2 >
bool *Triangulation_3<GT, Tds1> t1* != *Triangulation_3<GT, Tds2> t2*

The opposite of *operator*==.

Access Functions

TriangulationTraits_3	*t.geom_traits() const*	Returns a const reference to the geometric traits object.
TriangulationDataStructure_3	*t.tds() const*	Returns a const reference to the triangulation data structure.

advanced

Non const access

The responsibility of keeping a valid triangulation belongs to the user when using advanced operations allowing a direct manipulation of the *tds*.

TriangulationDataStructure_3&	*t.tds()*	Returns a reference to the triangulation data structure.

This method is mainly a help for users implementing their own triangulation algorithms.

advanced

int	*t.dimension() const*	Returns the dimension of the affine hull.
size_type	*t.number_of_vertices() const*	Returns the number of finite vertices.
size_type	*t.number_of_cells() const*	Returns the number of cells or 0 if *t.dimension()*< 3.
Vertex_handle	*t.infinite_vertex()*	Returns the infinite vertex.
Cell_handle	*t.infinite_cell() const*	Returns a cell incident to the infinite vertex.

Non-constant-time access functions

As previously said, the triangulation is a collection of cells that are either infinite or represent a finite tetrahedra, where an infinite cell is a cell incident to the infinite vertex. Similarly we call an edge (resp. facet) *infinite* if it is incident to the infinite vertex.

size_type	*t.number_of_facets() const*	The number of facets. Returns 0 if *t.dimension()*<2.
size_type	*t.number_of_edges() const*	The number of edges. Returns 0 if *t.dimension()*<1.

size_type *t.number_of_finite_cells() const*

The number of finite cells. Returns 0 if *t.dimension()*<3.

size_type *t.number_of_finite_facets() const*

The number of finite facets. Returns 0 if *t.dimension()*<2.

size_type *t.number_of_finite_edges() const*

The number of finite edges. Returns 0 if *t.dimension()*<1.

Geometric access functions

Tetrahedron *t.tetrahedron(Cell_handle c) const*

Returns the tetrahedron formed by the four vertices of c.
Precondition: *t.dimension()* $=3$ and the cell is finite.

Triangle *t.triangle(Cell_handle c, int i) const*

Returns the triangle formed by the three vertices of facet *(c,i)*. The triangle is oriented so that its normal points to the inside of cell c.
Precondition: *t.dimension()* ≥ 2 and $i \in \{0,1,2,3\}$ in dimension 3, $i=3$ in dimension 2, and the facet is finite.

Triangle *t.triangle(Facet f) const*

Same as the previous method for facet f.
Precondition: *t.dimension()* ≥ 2 and the facet is finite.

Segment *t.segment(Edge e) const*

Returns the line segment formed by the vertices of e.
Precondition: *t.dimension()* ≥ 1 and e is finite.

Segment *t.segment(Cell_handle c, int i, int j) const*

Same as the previous method for edge *(c,i,j)*.
Precondition: As above and $i \neq j$. Moreover $i,j \in \{0,1,2,3\}$ in dimension 3, $i,j \in \{0,1,2\}$ in dimension 2, $i,j \in \{0,1\}$ in dimension 1, and the edge is finite.

Point *t.point(Cell_handle c, int i) const*

Returns the point given by vertex i of cell c.
Precondition: *t.dimension()* ≥ 0 and $i \in \{0,1,2,3\}$ in dimension 3, $i \in \{0,1,2\}$ in dimension 2, $i \in \{0,1\}$ in dimension 1, $i=0$ in dimension 0, and the vertex is finite.

Point *t.point(Vertex_handle v) const*

Same as the previous method for vertex v.
Precondition: *t.dimension()* ≥ 0 and the vertex is finite.

Tests for Finite and Infinite Vertices and Faces

bool *t.is_infinite(Vertex_handle v) const*

true, iff vertex v is the infinite vertex.

bool *t.is_infinite(Cell_handle c) const*

true, iff c is incident to the infinite vertex.
Precondition: *t.dimension()* $= 3$.

bool *t.is_infinite(Cell_handle c, int i) const*

true, iff the facet i of cell c is incident to the infinite vertex.
Precondition: *t.dimension()* ≥ 2 and $i \in \{0,1,2,3\}$ in dimension 3, $i = 3$ in dimension 2.

bool *t.is_infinite(Facet f) const*

true iff facet f is incident to the infinite vertex.
Precondition: *t.dimension()* ≥ 2.

bool *t.is_infinite(Cell_handle c, int i, int j) const*

true, iff the edge *(i,j)* of cell c is incident to the infinite vertex.
Precondition: *t.dimension()* ≥ 1 and $i \neq j$. Moreover $i, j \in \{0,1,2,3\}$ in dimension 3, $i, j \in \{0,1,2\}$ in dimension 2, $i, j \in \{0,1\}$ in dimension 1.

bool *t.is_infinite(Edge e) const*

true iff edge e is incident to the infinite vertex.
Precondition: *t.dimension()* ≥ 1.

Queries

bool *t.is_vertex(Point p, Vertex_handle & v) const*

Tests whether p is a vertex of t by locating p in the triangulation. If p is found, the associated vertex v is given.

bool *t.is_vertex(Vertex_handle v) const*

Tests whether v is a vertex of t.

bool *t.is_edge(Vertex_handle u, Vertex_handle v, Cell_handle & c, int & i, int & j) const*

Tests whether *(u,v)* is an edge of t. If the edge is found, it gives a cell c having this edge and the indices i and j of the vertices u and v in c, in this order.
Precondition: u and v are vertices of t.

bool *t.is_facet(Vertex_handle u,*
Vertex_handle v,
Vertex_handle w,
Cell_handle & c,
int & i,
int & j,

int & k) const

Tests whether *(u,v,w)* is a facet of *t*. If the facet is found, it computes a cell *c* having this facet and the indices *i*, *j* and *k* of the vertices *u*, *v* and *w* in *c*, in this order.
Precondition: *u*, *v* and *w* are vertices of *t*.

bool *t.is_cell(Cell_handle c) const*

Tests whether *c* is a cell of *t*.

bool *t.is_cell(Vertex_handle u,*
Vertex_handle v,
Vertex_handle w,
Vertex_handle x,
Cell_handle & c,
int & i,
int & j,
int & k,
int & l) const

Tests whether *(u,v,w,x)* is a cell of *t*. If the cell *c* is found, the method computes the indices *i*, *j*, *k* and *l* of the vertices *u*, *v*, *w* and *x* in *c*, in this order.
Precondition: *u*, *v*, *w* and *x* are vertices of *t*.

bool *t.is_cell(Vertex_handle u,*
Vertex_handle v,
Vertex_handle w,
Vertex_handle x,
Cell_handle & c) const

Tests whether *(u,v,w,x)* is a cell of *t* and computes this cell *c*.
Precondition: *u*, *v*, *w* and *x* are vertices of *t*.

There is a method *has_vertex* in the cell class. The analogous methods for facets are defined here.

bool *t.has_vertex(Facet f, Vertex_handle v, int & j) const*

If *v* is a vertex of *f*, then *j* is the index of *v* in the cell *f.first*, and the method returns *true*.
Precondition: *t*.dimension()=3

bool *t.has_vertex(Cell_handle c, int i, Vertex_handle v, int & j) const*

Same for facet *(c,i)*. Computes the index *j* of *v* in *c*.

bool *t.has_vertex(Facet f, Vertex_handle v) const*
bool *t.has_vertex(Cell_handle c, int i, Vertex_handle v) const*

Same as the first two methods, but these two methods do not return the index of the vertex.

The following three methods test whether two facets have the same vertices.

bool *t.are_equal(Cell_handle c, int i, Cell_handle n, int j) const*
bool *t.are_equal(Facet f, Facet g) const*

bool *t.are_equal(Facet f, Cell_handle n, int j) const*

For these three methods:
Precondition: t.dimension()=3.

Point location

The class *Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>* provides two functions to locate a given point with respect to a triangulation. It provides also functions to test if a given point is inside a finite face or not. Note that the class *Delaunay_triangulation_3* also provides a *nearest_vertex()* function.

Cell_handle *t.locate(Point query, Cell_handle start = Cell_handle())*

If the point *query* lies inside the convex hull of the points, the cell that contains the query in its interior is returned. If *query* lies on a facet, an edge or on a vertex, one of the cells having *query* on its boundary is returned.
If the point *query* lies outside the convex hull of the points, an infinite cell with vertices $\{p,q,r,\infty\}$ is returned such that the tetrahedron $(p,q,r,query)$ is positively oriented (the rest of the triangulation lies on the other side of facet (p,q,r)).
Note that locate works even in degenerate dimensions: in dimension 2 (resp. 1, 0) the *Cell_handle* returned is the one that represents the facet (resp. edge, vertex) containing the query point.
The optional argument *start* is used as a starting place for the search.

Cell_handle *t.locate(Point query, Vertex_handle hint) const*

Same as above but uses *hint* as the starting place for the search.

Cell_handle *t.locate(Point query, Locate_type & lt, int & li, int & lj, Cell_handle start = Cell_handle())*

If *query* lies inside the affine hull of the points, the *k*-face (finite or infinite) that contains *query* in its interior is returned, by means of the cell returned together with *lt*, which is set to the locate type of the query (*VERTEX, EDGE, FACET, CELL*, or *OUTSIDE_CONVEX_HULL* if the cell is infinite and *query* lies strictly in it) and two indices *li* and *lj* that specify the *k*-face of the cell containing *query*.
If the *k*-face is a cell, *li* and *lj* have no meaning; if it is a facet (resp. vertex), *li* gives the index of the facet (resp. vertex) and *lj* has no meaning; if it is and edge, *li* and *lj* give the indices of its vertices.
If the point *query* lies outside the affine hull of the points, which can happen in case of degenerate dimensions, *lt* is set to *OUTSIDE_AFFINE_HULL*, and the cell returned has no meaning. As a particular case, if there is no finite vertex yet in the triangulation, *lt* is set to *OUTSIDE_AFFINE_HULL* and *locate* returns the default constructed handle.
The optional argument *start* is used as a starting place for the search.

Cell_handle *t.locate(Point query, Locate_type & lt, int & li, int & lj, Vertex_handle hint) const*

Same as above but uses *hint* as the starting place for the search.

Bounded_side　*t.side_of_cell(Point p, Cell_handle c, Locate_type & lt, int & li, int & lj) const*

Returns a value indicating on which side of the oriented boundary of c the point p lies. More precisely, it returns:
- *ON_BOUNDED_SIDE* if p is inside the cell. For an infinite cell this means that p lies strictly in the half space limited by its finite facet and not containing any other point of the triangulation.
- *ON_BOUNDARY* if p on the boundary of the cell. For an infinite cell this means that p lies on the *finite* facet. Then *lt* together with *li* and *lj* give the precise location on the boundary. (See the descriptions of the *locate* methods.)
- *ON_UNBOUNDED_SIDE* if p lies outside the cell. For an infinite cell this means that p does not satisfy either of the two previous conditions.
Precondition: *t.dimension()* $= 3$

Bounded_side　*t.side_of_facet(Point p, Facet f, Locate_type & lt, int & li, int & lj) const*

Returns a value indicating on which side of the oriented boundary of f the point p lies:
- *ON_BOUNDED_SIDE* if p is inside the facet. For an infinite facet this means that p lies strictly in the half plane limited by its finite edge and not containing any other point of the triangulation .
- *ON_BOUNDARY* if p is on the boundary of the facet. For an infinite facet this means that p lies on the finite edge. *lt*, *li* and *lj* give the precise location of p on the boundary of the facet. *li* and *lj* refer to indices in the degenerate cell c representing f.
- *ON_UNBOUNDED_SIDE* if p lies outside the facet. For an infinite facet this means that p does not satisfy either of the two previous conditions.

Precondition: *t.dimension()* $= 2$ and p lies in the plane containing the triangulation. *f.second* $= 3$ (in dimension 2 there is only one facet per cell).

Bounded_side　*t.side_of_facet(Point p, Cell_handle c, Locate_type & lt, int & li, int & lj) const*

Same as the previous method for the facet *(c,3)*.

Bounded_side　*t.side_of_edge(Point p, Edge e, Locate_type & lt, int & li) const*

Returns a value indicating on which side of the oriented boundary of e the point p lies:
- *ON_BOUNDED_SIDE* if p is inside the edge. For an infinite edge this means that p lies in the half line defined by the vertex and not containing any other point of the triangulation.
- *ON_BOUNDARY* if p equals one of the vertices, *li* give the index of the vertex in the cell storing e
- *ON_UNBOUNDED_SIDE* if p lies outside the edge. For an infinite edge this means that p lies on the other half line, which contains the other points of the triangulation.
Precondition: *t.dimension()* $= 1$ and p is collinear with the points of the triangulation. *e.second* $= 0$ and *e.third* $= 1$ (in dimension 1 there is only one edge per cell).

Bounded_side　*t.side_of_edge(Point p, Cell_handle c, Locate_type & lt, int & li) const*

Same as the previous method for edge $(c,0,1)$.

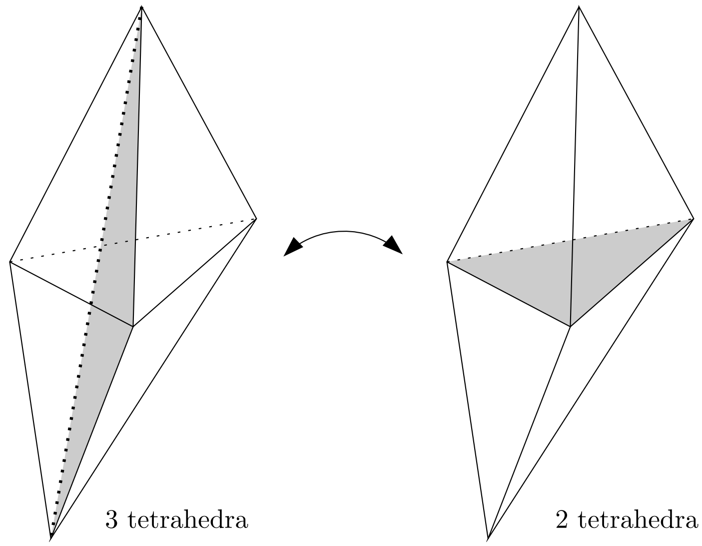

Figure 39.10: Flips.

Flips

Two kinds of flips exist for a three-dimensional triangulation. They are reciprocal. To be flipped, an edge must be incident to three tetrahedra. During the flip, these three tetrahedra disappear and two tetrahedra appear. Figure 39.10(left) shows the edge that is flipped as bold dashed, and one of its three incident facets is shaded. On the right, the facet shared by the two new tetrahedra is shaded.

Flips are possible only under the following conditions:
- the edge or facet to be flipped is not on the boundary of the convex hull of the triangulation
- the five points involved are in convex position.

The following methods guarantee the validity of the resulting 3D triangulation.

Flips for a 2d triangulation are not implemented yet

bool	*t.flip(Edge e)*
bool	*t.flip(Cell_handle c, int i, int j)*

Before flipping, these methods check that edge *e=(c,i,j)* is flippable (which is quite expensive). They return *false* or *true* according to this test.

void	*t.flip_flippable(Edge e)*
void	*t.flip_flippable(Cell_handle c, int i, int j)*

Should be preferred to the previous methods when the edge is known to be flippable.
Precondition: The edge is flippable.

bool	*t.flip(Facet f)*
bool	*t.flip(Cell_handle c, int i)*

Before flipping, these methods check that facet *f=(c,i)* is flippable (which is quite expensive). They return *false* or *true* according to this test.

void *t.flip_flippable(Facet f)*
void *t.flip_flippable(Cell_handle c, int i)*

Should be preferred to the previous methods when the facet is known to be flippable.
Precondition: The facet is flippable.

Insertions

The following operations are guaranteed to lead to a valid triangulation when they are applied on a valid triangulation.

Vertex_handle *t.insert(Point p, Cell_handle start = Cell_handle())*

Inserts point *p* in the triangulation and returns the corresponding vertex.
If point *p* coincides with an already existing vertex, this vertex is returned and the triangulation remains unchanged.
If point *p* lies in the convex hull of the points, it is added naturally: if it lies inside a cell, the cell is split into four cells, if it lies on a facet, the two incident cells are split into three cells, if it lies on an edge, all the cells incident to this edge are split into two cells.
If point *p* is strictly outside the convex hull but in the affine hull, *p* is linked to all visible points on the convex hull to form the new triangulation. See Figure 39.11.
If point *p* is outside the affine hull of the points, *p* is linked to all the points, and the dimension of the triangulation is incremented. All the points now belong to the boundary of the convex hull, so, the infinite vertex is linked to all the points to triangulate the new infinite face. See Figure 39.12. The optional argument *start* is used as a starting place for the search.

Vertex_handle *t.insert(Point p, Vertex_handle hint)*

Same as above but uses *hint* as the starting place for the search.

Vertex_handle *t.insert(Point p, Locate_type lt, Cell_handle loc, int li, int lj)*

Inserts point *p* in the triangulation and returns the corresponding vertex. Similar to the above *insert()* function, but takes as additional parameter the return values of a previous location query. See description of *locate()* above.

template < class InputIterator >
std::ptrdiff_t *t.insert(InputIterator first, InputIterator last)*

Inserts the points in the range $[first, last)$. Returns the number of inserted points. Note that this function is not guaranteed to insert the points following the order of *InputIterator*.
Precondition: The *value_type* of *first* and *last* is *Point*.

The previous methods are sufficient to build a whole triangulation. We also provide some other methods that can be used instead of *insert(p)* when the place where the new point *p* must be inserted is already known. They are also guaranteed to lead to a valid triangulation when they are applied on a valid triangulation.

Vertex_handle *t.insert_in_cell(Point p, Cell_handle c)*

Inserts point p in cell c. Cell c is split into 4 tetrahedra.
Precondition: *t.dimension()* $= 3$ and p lies strictly inside cell c.

Vertex_handle *t.insert_in_facet(Point p, Facet f)*

Inserts point p in facet f. In dimension 3, the 2 neighboring cells are split into 3 tetrahedra; in dimension 2, the facet is split into 3 triangles.
Precondition: *t.dimension()* ≥ 2 and p lies strictly inside face f.

Vertex_handle *t.insert_in_facet(Point p, Cell_handle c, int i)*

As above, insertion in facet *(c,i)*.
Precondition: As above and $i \in \{0,1,2,3\}$ in dimension 3, $i = 3$ in dimension 2.

Vertex_handle *t.insert_in_edge(Point p, Edge e)*

Inserts p in edge e. In dimension 3, all the cells having this edge are split into 2 tetrahedra; in dimension 2, the 2 neighboring facets are split into 2 triangles; in dimension 1, the edge is split into 2 edges.
Precondition: *t.dimension()* ≥ 1 and p lies on edge e.

Vertex_handle *t.insert_in_edge(Point p, Cell_handle c, int i, int j)*

As above, inserts p in edge (i,j) of c.
Precondition: As above and $i \neq j$. Moreover $i, j \in \{0,1,2,3\}$ in dimension 3, $i, j \in \{0,1,2\}$ in dimension 2, $i, j \in \{0,1\}$ in dimension 1.

Vertex_handle *t.insert_outside_convex_hull(Point p, Cell_handle c)*

The cell c must be an infinite cell containing p.
Links p to all points in the triangulation that are visible from p. Updates consequently the infinite faces. See Figure 39.11.
Precondition: *t.dimension()* > 0, c, and the k-face represented by c is infinite and contains t.

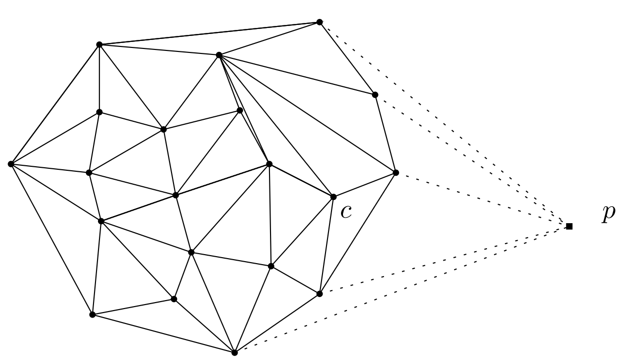

Figure 39.11: *insert_outside_convex_hull* (2-dimensional case).

Vertex_handle   *t.insert_outside_affine_hull(Point p)*

p is linked to all the points, and the infinite vertex is linked to all the points (including p) to triangulate the new infinite face, so that all the points now belong to the boundary of the convex hull. See Figure 39.12.
This method can be used to insert the first point in an empty triangulation.
Precondition: *t.dimension()* < 3 and p lies outside the affine hull of the points.

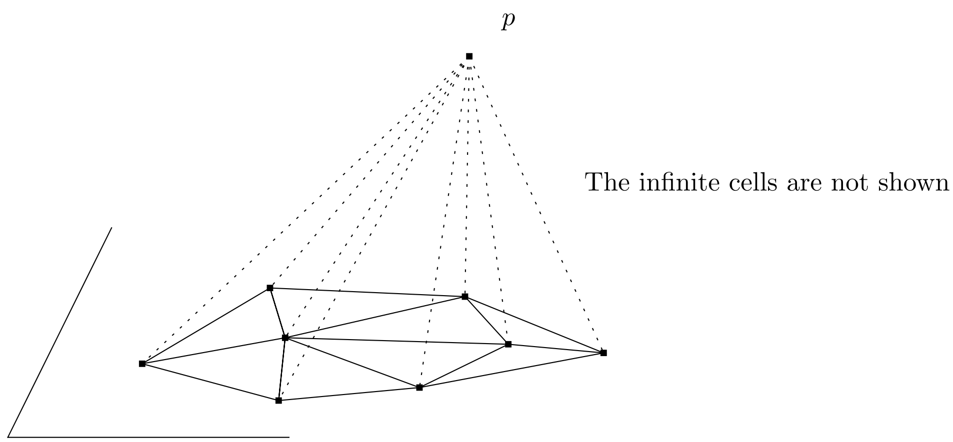

Figure 39.12: *insert_outside_affine_hull* (2-dimensional case).

template <class CellIt>
Vertex_handle   *t.insert_in_hole(Point p, CellIt cell_begin, CellIt cell_end, Cell_handle begin, int i)*

Creates a new vertex by starring a hole. It takes an iterator range [*cell_begin*; *cell_end*[of *Cell_handle*s which specifies a hole: a set of connected cells (resp. facets in dimension 2) which is star-shaped wrt p. (*begin*, i) is a facet (resp. an edge) on the boundary of the hole, that is, *begin* belongs to the set of cells (resp. facets) previously described, and *begin->neighbor(i)* does not. Then this function deletes all the cells (resp. facets) describing the hole, creates a new vertex v, and for each facet (resp. edge) on the boundary of the hole, creates a new cell (resp. facet) with v as vertex. Then *v->set_point(p)* is called and v is returned.
This operation is equivalent to calling *tds().insert_in_hole(cell_begin, cell_end, begin, i); v->set_point(p)*.
Precondition: *t.dimension()* ≥ 2, the set of cells (resp. facets in dimension 2) is connected, its boundary is connected, and p lies inside the hole, which is star-shaped wrt p.

template <class CellIt>
Vertex_handle   *t.insert_in_hole(Point p,*
CellIt cell_begin,
CellIt cell_end,
Cell_handle begin,
int i,
Vertex_handle newv)

Same as above, except that *newv* will be used as the new vertex, which must have been allocated previously with e.g. *create_vertex*.

Traversal of the Triangulation

The triangulation class provides several iterators and circulators that allow one to traverse it (completely or partially).

Cell, Face, Edge and Vertex Iterators

The following iterators allow the user to visit cells, facets, edges and vertices of the triangulation. These iterators are non-mutable, bidirectional and their value types are respectively *Cell*, *Facet*, *Edge* and *Vertex*. They are all invalidated by any change in the triangulation.

Finite_vertices_iterator *t.finite_vertices_begin() const*

Starts at an arbitrary finite vertex. Then ++ and -- will iterate over finite vertices. Returns *finite_vertices_end()* when *t.number_of_vertices()* $= 0$.

Finite_vertices_iterator *t.finite_vertices_end() const*

Past-the-end iterator

Finite_edges_iterator *t.finite_edges_begin() const*

Starts at an arbitrary finite edge. Then ++ and -- will iterate over finite edges. Returns *finite_edges_end()* when *t.dimension()* < 1.

Finite_edges_iterator *t.finite_edges_end() const*

Past-the-end iterator

Finite_facets_iterator *t.finite_facets_begin() const*

Starts at an arbitrary finite facet. Then ++ and -- will iterate over finite facets. Returns *finite_facets_end()* when *t.dimension()* < 2.

Finite_facets_iterator *t.finite_facets_end() const*

Past-the-end iterator

Finite_cells_iterator *t.finite_cells_begin() const*

Starts at an arbitrary finite cell. Then ++ and -- will iterate over finite cells. Returns *finite_cells_end()* when *t.dimension()* < 3.

Finite_cells_iterator *t.finite_cells_end() const* Past-the-end iterator

All_vertices_iterator *t.all_vertices_begin() const*

Starts at an arbitrary vertex. Iterates over all vertices (even the infinite one). Returns *vertices_end()* when *t.number_of_vertices()* $= 0$.

All_vertices_iterator *t.all_vertices_end() const*

Past-the-end iterator

All_edges_iterator	*t.all_edges_begin() const*	
		Starts at an arbitrary edge. Iterates over all edges (even infinite ones). Returns *edges_end()* when *t.dimension()* < 1.
All_edges_iterator	*t.all_edges_end() const*	Past-the-end iterator
All_facets_iterator	*t.all_facets_begin() const*	
		Starts at an arbitrary facet. Iterates over all facets (even infinite ones). Returns *facets_end()* when *t.dimension()* < 2.
All_facets_iterator	*t.all_facets_end() const*	Past-the-end iterator
All_cells_iterator	*t.all_cells_begin() const*	Starts at an arbitrary cell. Iterates over all cells (even infinite ones). Returns *cells_end()* when *t.dimension()* < 3.
All_cells_iterator	*t.all_cells_end() const*	Past-the-end iterator
Point_iterator	*t.points_begin() const*	Iterates over the points of the triangulation.
Point_iterator	*t.points_end() const*	Past-the-end iterator

Cell and Facet Circulators

The following circulators respectively visit all cells or all facets incident to a given edge. They are non-mutable and bidirectional. They are invalidated by any modification of one of the cells traversed.

Cell_circulator *t.incident_cells(Edge e) const*

Starts at an arbitrary cell incident to *e*.
Precondition: *t.dimension()* $= 3$.

Cell_circulator *t.incident_cells(Cell_handle c, int i, int j) const*

As above for edge *(i,j)* of *c*.

Cell_circulator *t.incident_cells(Edge e, Cell_handle start) const*

Starts at cell *start*.
Precondition: *t.dimension()* $= 3$ and *start* is incident to *e*.

Cell_circulator *t.incident_cells(Cell_handle c, int i, int j, Cell_handle start) const*

As above for edge *(i,j)* of *c*.

The following circulators on facets are defined only in dimension 3, though facets are defined also in dimension 2: there are only two facets sharing an edge in dimension 2.

Facet_circulator *t.incident_facets(Edge e) const*

Starts at an arbitrary facet incident to *e*.
Precondition: *t.dimension()* $= 3$

Facet_circulator *t.incident_facets(Cell_handle c, int i, int j) const*

As above for edge *(i,j)* of *c*.

Facet_circulator *t.incident_facets(Edge e, Facet start) const*

Starts at facet *start*.
Precondition: *start* is incident to *e*.

Facet_circulator *t.incident_facets(Edge e, Cell_handle start, int f) const*

Starts at facet of index *f* in *start*.

Facet_circulator *t.incident_facets(Cell_handle c, int i, int j, Facet start) const*

As above for edge *(i,j)* of *c*.

Facet_circulator *t.incident_facets(Cell_handle c, int i, int j, Cell_handle start, int f) const*

As above for edge *(i,j)* of *c* and facet *(start,f)*.

Traversal of the incident cells, facets and edges, and the adjacent vertices of a given vertex

template <class OutputIterator>
OutputIterator *t.incident_cells(Vertex_handle v, OutputIterator cells) const*

Copies the *Cell_handle*s of all cells incident to *v* to the output iterator *cells*. Returns the resulting output iterator.
Precondition: $t.dimension() = 3$, $v \neq Vertex\_handle()$, *t.is_vertex(v)*.

template <class OutputIterator>
OutputIterator *t.finite_incident_cells(Vertex_handle v, OutputIterator cells) const*

Copies the *Cell_handle*s of all finite cells incident to *v* to the output iterator *cells*. Returns the resulting output iterator.
Precondition: $t.dimension() = 3$, $v \neq Vertex\_handle()$, *t.is_vertex(v)*.

template <class OutputIterator>
OutputIterator *t.incident_facets(Vertex_handle v, OutputIterator facets) const*

Copies all *Facet*s incident to *v* to the output iterator *facets*. Returns the resulting output iterator.
Precondition: $t.dimension() > 1$, $v \neq Vertex\_handle()$, *t.is_vertex(v)*.

template <class OutputIterator>
OutputIterator *t.finite_incident_facets(Vertex_handle v, OutputIterator facets) const*

Copies all finite *Facet*s incident to *v* to the output iterator *facets*. Returns the resulting output iterator.
Precondition: $t.dimension() > 1$, $v \neq Vertex\_handle()$, *t.is_vertex(v)*.

template <class OutputIterator>
OutputIterator *t.incident_edges(Vertex_handle v, OutputIterator edges) const*

Copies all *Edge*s incident to *v* to the output iterator *edges*. Returns the resulting output iterator.
Precondition: $t.dimension() > 0$, $v \neq Vertex\_handle()$, *t.is_vertex(v)*.

template <class OutputIterator>
OutputIterator *t.finite_incident_edges(Vertex_handle v, OutputIterator edges) const*

Copies all finite *Edge*s incident to *v* to the output iterator *edges*. Returns the resulting output iterator.
Precondition: *t.dimension()* > 0, $v \neq$ *Vertex_handle()*, *t.is_vertex(v)*.

template <class OutputIterator>
OutputIterator *t.adjacent_vertices(Vertex_handle v, OutputIterator vertices) const*

Copies the *Vertex_handle*s of all vertices adjacent to *v* to the output iterator *vertices*. If *t.dimension()* < 0, then do nothing. Returns the resulting output iterator.
Precondition: $v \neq$ *Vertex_handle()*, *t.is_vertex(v)*.

template <class OutputIterator>
OutputIterator *t.finite_adjacent_vertices(Vertex_handle v, OutputIterator vertices) const*

Copies the *Vertex_handle*s of all finite vertices adjacent to *v* to the output iterator *vertices*. If *t.dimension()* < 0, then do nothing. Returns the resulting output iterator.
Precondition: $v \neq$ *Vertex_handle()*, *t.is_vertex(v)*.

size_type *t.degree(Vertex_handle v) const*

Returns the degree of a vertex, that is, the number of incident vertices. The infinite vertex is counted.
Precondition: $v \neq$ *Vertex_handle()*, *t.is_vertex(v)*.

Traversal between adjacent cells

int *t.mirror_index(Cell_handle c, int i) const*

Returns the index of *c* in its i^{th} neighbor.
Precondition: $i \in \{0,1,2,3\}$.

Vertex_handle *t.mirror_vertex(Cell_handle c, int i) const*

Returns the vertex of the i^{th} neighbor of *c* that is opposite to *c*.
Precondition: $i \in \{0,1,2,3\}$.

Facet *t.mirror_facet(Facet f) const* Returns the same facet seen from the other adjacent cell.

debugging support

Checking

The responsibility of keeping a valid triangulation belongs to the user when using advanced operations allowing a direct manipulation of cells and vertices. We provide the user with the following methods to help debugging.

bool *t.is_valid(bool verbose = false) const*

Checks the combinatorial validity of the triangulation. Checks also the validity of its geometric embedding (see Section 39.1).
When *verbose* is set to true, messages describing the first invalidity encountered are printed.

bool *t.is_valid(Cell_handle c, bool verbose = false) const*

Checks the combinatorial validity of the cell by calling the *is_valid* method of the *TriangulationDataStructure_3* cell class. Also checks the geometric validity of *c*, if *c* is finite. (See Section 2610.)
When *verbose* is set to *true*, messages are printed to give a precise indication of the kind of invalidity encountered.

debugging support

I/O

CGAL provides an interface to Geomview for a 3D-triangulation, see Chapter 80 on *Geomview_stream*. *#include <CGAL/IO/Triangulation_geomview_ostream_3.h>*

istream&	*istream& is >> Triangulation_3 &t*	Reads the underlying combinatorial triangulation from *is* by calling the corresponding input operator of the triangulation data structure class (note that the infinite vertex is numbered 0), and the non-combinatorial information by calling the corresponding input operators of the vertex and the cell classes (such as point coordinates), which are provided by overloading the stream operators of the vertex and cell types. Assigns the resulting triangulation to *t*.
ostream&	*ostream& os << Triangulation_3 t*	Writes the triangulation *t* into *os*.

The information in the *iostream* is: the dimension, the number of finite vertices, the non-combinatorial information about vertices (point, etc; note that the infinite vertex is numbered 0), the number of cells, the indices of the vertices of each cell, plus the non-combinatorial information about each cell, then the indices of the neighbors of each cell, where the index corresponds to the preceding list of cells. When dimension < 3, the same information is stored for faces of maximal dimension instead of cells.

Class

CGAL::Delaunay_triangulation_3<DelaunayTriangulationTraits_3,TriangulationDataStructure_3,LocationPolicy>

Definition

The class *Delaunay_triangulation_3* represents a three-dimensional Delaunay triangulation.

#include <CGAL/Delaunay_triangulation_3.h>

Parameters

The first template argument must be a model of the *DelaunayTriangulationTraits_3* concept.

The second template argument must be a model of the *TriangulationDataStructure_3* concept. It has the default value *Triangulation_data_structure_3<Triangulation_vertex_base_3<DelaunayTriangulationTraits_3>, Triangulation_cell_base_3<DelaunayTriangulationTraits_3> >*.

The third template argument is a tag which must be a *Location_policy<Tag>* : either *Fast_location* or *Compact_location*. *Fast_location* offers faster ($O(\log n)$ time) point location, which can be beneficial when performing point locations or random point insertions (with no good location hint) in large data sets. It is currently implemented using an additional triangulation hierarchy data structure [Dev02]. The default is *Compact_location*, which saves memory (3-5%) by avoiding the need for this separate data structure, and point location is then performed roughly in $O(n^{1/3})$ time. Note that this argument can also come in second position, which can be useful when the default value for the *TriangulationDataStructure_3* parameter is satisfactory (this is using so-called deduced parameters). Note that this argument replaces the functionality provided before CGAL 3.6 by *Triangulation_hierarchy_3*. An example of use can be found in the user manual 39.5.5.

Inherits From

Triangulation_3<DelaunayTriangulationTraits_3,Delaunay_triangulation_3<DelaunayTriangulationTraits_3,TriangulationDataStructure_3,LocationPolicy>::Triangulation_data_structure >

Types

typedef LocationPolicy *Location_policy;*

In addition to those inherited, the following types are defined, for use by the construction of the Voronoi diagram:

typedef DelaunayTriangulationTraits_3::Line_3 *Line;*
typedef DelaunayTriangulationTraits_3::Ray_3 *Ray;*
typedef DelaunayTriangulationTraits_3::Plane_3 *Plane;*
typedef DelaunayTriangulationTraits_3::Object_3 *Object;*

Creation

Delaunay_triangulation_3<DelaunayTriangulationTraits_3,TriangulationDataStructure_3,LocationPolicy> dt(DelaunayTriangulationTraits_3 traits = DelaunayTriangulationTraits_3())

Creates an empty Delaunay triangulation, possibly specifying a traits class *traits*.

Delaunay_triangulation_3<DelaunayTriangulationTraits_3,TriangulationDataStructure_3,LocationPolicy>
dt(Delaunay_triangulation_3 dt1)

Copy constructor.

template < class InputIterator >
Delaunay_triangulation_3<DelaunayTriangulationTraits_3,TriangulationDataStructure_3,LocationPolicy>
dt(InputIterator first,

In-

putIterator last,

DelaunayTriangulati

3 traits = DelaunayTriangulationTraits_3())

Equivalent to constructing an empty triangulation with the optional traits class argument and calling *insert(first,last)*.

Operations

Insertion

The following methods overload the corresponding methods of triangulations to ensure the empty sphere property of Delaunay triangulations.

In the degenerate case when there are co-spherical points, the Delaunay triangulation is known not to be uniquely defined. In this case, CGAL chooses a particular Delaunay triangulation using a symbolic perturbation scheme [DT03].

Vertex_handle *dt.insert(Point p, Cell_handle start = Cell_handle())*

Inserts point *p* in the triangulation and returns the corresponding vertex. Similar to the insertion in a triangulation, but ensures in addition the empty sphere property of all the created faces. The optional argument *start* is used as a starting place for the search.

Vertex_handle *dt.insert(Point p, Vertex_handle hint)*

Same as above but uses *hint* as a starting place for the search.

Vertex_handle *dt.insert(Point p, Locate_type lt, Cell_handle loc, int li, int lj)*

Inserts point *p* in the triangulation and returns the corresponding vertex. Similar to the above *insert()* function, but takes as additional parameter the return values of a previous location query. See description of *Triangulation_3::locate()*.

The following method allows one to insert several points. It returns the number of inserted points.

template < class PointInputIterator >

std::ptrdiff_t *dt.insert(PointInputIterator first, PointInputIterator last)*

Inserts the points in the iterator range $[first, last)$. Returns the number of inserted points. Note that this function is not guaranteed to insert the points following the order of *PointInputIterator*, as *spatial_sort* is used to improve efficiency.
Precondition: The *value_type* of *first* and *last* is *Point*.

template < class PointWithInfoInputIterator >
std::ptrdiff_t *dt.insert(PointWithInfoInputIterator first, PointWithInfoInputIterator last)*

Inserts the points in the iterator range $[first, last)$. Returns the number of inserted points. Note that this function is not guaranteed to insert the points following the order of *PointWithInfoInputIterator*, as *spatial_sort* is used to improve efficiency. Given a pair *(p,i)*, the vertex *v* storing *p* also stores *i*, that is *v.point() == p* and *v.info() == i*. If several pairs have the same point, only one vertex is created, and one of the objects of type *Vertex::Info* will be stored in the vertex.
Precondition: *Vertex* must be model of the concept *TriangulationVertexBaseWithInfo_3*. The *value_type* of *first* and *last* is *std::pair<Point,Vertex::Info>*.

Displacement

Vertex_handle *dt.move_if_no_collision(Vertex_handle v, Point p)*

if there is not already another vertex placed on *p*, the triangulation is modified such that the new position of vertex *v* is *p*, and *v* is returned. Otherwise, the triangulation is not modified and the vertex at point *p* is returned.
Precondition: Vertex *v* must be finite.

Vertex_handle *dt.move(Vertex_handle v, Point p)*

same as above if there is no collision. Otherwise, *v* is deleted and the vertex placed on *p* is returned.
Precondition: Vertex *v* must be finite.

Removal

When a vertex *v* is removed from a triangulation, all the cells incident to *v* must be removed, and the polyhedral region consisting of all the tetrahedra that are incident to *v* must be re-triangulated. So, the problem reduces to triangulating a polyhedral region, while preserving its boundary, or to compute a *constrained* triangulation. This is known to be sometimes impossible: the Schönhardt polyhedron cannot be triangulated [She98a].

However, when dealing with Delaunay triangulations, the case of such polyhedra that cannot be re-triangulated cannot happen, so CGAL proposes a vertex removal.

void *dt.remove(Vertex_handle v)*

Removes the vertex *v* from the triangulation.
Precondition: *v* is a finite vertex of the triangulation.

template < typename InputIterator >
int *dt.remove(InputIterator first, InputIterator beyond)*

Removes the vertices specified by the iterator range [*first, beyond*) of value type *Vertex_handle*. *remove()* is called over each element of the range. The number of vertices removed is returned.
Precondition: (i) all vertices of the range are finite vertices of the triangulation; and (ii) no vertices are repeated in the range.

template < typename InputIterator >
int *dt.remove_cluster(InputIterator first, InputIterator beyond)*

This function has exactly the same result and the same preconditions as *remove(first, beyond)*. The difference is in the implementation and efficiency. This version does not re-triangulate the hole after each point removal but only after removing all vertices. This is more efficient if (and only if) the removed points are organized in a small number of connected components of the Delaunay triangulation.

If, due to some point removals, the size of the Delaunay triangulation decreases drastically, it might be interesting to defragment the *CGAL::Compact_container* (used by the *Triangulation_data_structure_3*).

Queries

Bounded_side *dt.side_of_sphere(Cell_handle c, Point p) const*

Returns a value indicating on which side of the circumscribed sphere of c the point p lies. More precisely, it returns:
- *ON_BOUNDED_SIDE* if p is inside the sphere. For an infinite cell this means that p lies strictly either in the half space limited by its finite facet and not containing any other point of the triangulation, or in the interior of the disk circumscribing the *finite* facet.
- *ON_BOUNDARY* if p on the boundary of the sphere. For an infinite cell this means that p lies on the circle circumscribing the *finite* facet.
- *ON_UNBOUNDED_SIDE* if p lies outside the sphere. For an infinite cell this means that p does not satisfy either of the two previous conditions.
Precondition: $dt.dimension() = 3$.

Bounded_side *dt.side_of_circle(Facet f, Point p) const*

Returns a value indicating on which side of the circumscribed circle of f the point p lies. More precisely, it returns:
- in dimension 3:
– For a finite facet, *ON_BOUNDARY* if p lies on the circle, *ON_UNBOUNDED_SIDE* when it lies in the exterior of the disk, *ON_BOUNDED_SIDE* when it lies in its interior.
– For an infinite facet, it considers the plane defined by the finite facet of the same cell, and does the same as in dimension 2 in this plane.
- in dimension 2:
– For a finite facet, *ON_BOUNDARY* if p lies on the circle, *ON_UNBOUNDED_SIDE* when it lies in the exterior of the disk, *ON_BOUNDED_SIDE* when it lies in its interior.
– For an infinite facet, *ON_BOUNDARY* if the point lies on the finite edge of f (endpoints included), *ON_BOUNDED_SIDE* for a point in the open half plane defined by f and not containing any other point of the triangulation, *ON_UNBOUNDED_SIDE* elsewhere.
Precondition: *dt.dimension()* ≥ 2 and in dimension 3, p is coplanar with f.

Bounded_side *dt.side_of_circle(Cell_handle c, int i, Point p)*

Same as the previous method for facet i of cell c.

Vertex_handle *dt.nearest_vertex(Point p, Cell_handle c = Cell_handle())*

Returns any nearest vertex to the point p, or the default constructed handle if the triangulation is empty. The optional argument c is a hint specifying where to start the search.
Precondition: c is a cell of *dt*.

Vertex_handle *dt.nearest_vertex_in_cell(Point p, Cell_handle c)*

Returns the vertex of the cell c that is nearest to p.

A point p is said to be in conflict with a cell c in dimension 3 (resp. a facet f in dimension 2) iff *dt.side_of_sphere(c, p)* (resp. *dt.side_of_circle(f, p)*) returns *ON_BOUNDED_SIDE*. The set of cells (resp. facets in dimension 2) which are in conflict with p is connected, and it forms a hole.

template <class OutputIteratorBoundaryFacets, class OutputIteratorCells>
std::pair<OutputIteratorBoundaryFacets, OutputIteratorCells>

dt.find_conflicts(Point p,
Cell_handle c,
OutputIteratorBoundaryFacets bfit,

OutputIteratorCells cit)

Computes the conflict hole induced by *p*. The starting cell (resp. facet) *c* must be in conflict. Then this function returns respectively in the output iterators:
– *cit*: the cells (resp. facets) in conflict.
– *bfit*: the facets (resp. edges) on the boundary, that is, the facets (resp. edges) *(t, i)* where the cell (resp. facet) *t* is in conflict, but *t->neighbor(i)* is not.
This function can be used in conjunction with *insert_in_hole()* in order to decide the insertion of a point after seeing which elements of the triangulation are affected. Returns the pair composed of the resulting output iterators.
Precondition: *dt.dimension()* ≥ 2, and *c* is in conflict with *p*.

template <class OutputIteratorBoundaryFacets, class OutputIteratorCells, class OutputIteratorInternalFacets>

Triple<OutputIteratorBoundaryFacets, OutputIteratorCells, OutputIteratorInternalFacets>

dt.find_conflicts(Point p,
Cell_handle c,
OutputIteratorBoundaryFacets bfit,
OutputIteratorCells cit,
OutputIteratorInternalFacets ifit)

Same as the other *find_conflicts()* function, except that it also computes the internal facets, i.e. the facets common to two cells which are in conflict with *p*. Then this function returns respectively in the output iterators:
– *cit*: the cells (resp. facets) in conflict.
– *bfit*: the facets (resp. edges) on the boundary, that is, the facets (resp. edges) *(t, i)* where the cell (resp. facet) *t* is in conflict, but *t->neighbor(i)* is not.
– *ifit*: the facets (resp. edges) inside the hole, that is, delimiting two cells (resp facets) in conflict.
Returns the *Triple* composed of the resulting output iterators.
Precondition: *dt.dimension()* ≥ 2, and *c* is in conflict with *p*.

deprecated

template <class OutputIterator>
OutputIterator *dt.vertices_in_conflict(Point p, Cell_handle c, OutputIterator res)*

This function is renamed *vertices_on_conflict_zone_boundary* since CGAL-3.8.

deprecated

template <class OutputIterator>
OutputIterator *dt.vertices_on_conflict_zone_boundary(Point p, Cell_handle c, OutputIterator res)*

Similar to *find_conflicts()*, but reports the vertices which are on the boundary of the conflict hole of *p*, in the output iterator *res*. Returns the resulting output iterator.
Precondition: *dt.dimension()* ≥ 2, and *c* is in conflict with *p*.

A face (cell, facet or edge) is said to be a Gabriel face iff its smallest circumscribing sphere do not enclose any vertex of the triangulation. Any Gabriel face belongs to the Delaunay triangulation, but the reciprocal is not true. The following member functions test the Gabriel property of Delaunay faces.
bool *dt.is_Gabriel(Cell_handle c, int i)*

bool	*dt.is_Gabriel(Cell_handle c, int i, int j)*
bool	*dt.is_Gabriel(Facet f)*
bool	*dt.is_Gabriel(Edge e)*

Voronoi diagram

CGAL offers several functionalities to display the Voronoi diagram of a set of points in 3D.

Note that the user should use a kernel with exact constructions in order to guarantee the computation of the Voronoi diagram (as opposed to computing the triangulation only, which requires only exact predicates).

Point *dt.dual(Cell_handle c) const*

Returns the circumcenter of the four vertices of c.
Precondition: *dt.dimension()*$=3$ and c is not infinite.

Object *dt.dual(Facet f) const*

Returns the dual of facet f, which is
in dimension 3: either a segment, if the two cells incident to f are finite, or a ray, if one of them is infinite;
in dimension 2: a point.
Precondition: *dt.dimension()* ≥ 2 and f is not infinite.

Object *dt.dual(Cell_handle c, int i) const*

same as the previous method for facet *(c,i)*.

Line *dt.dual_support(Cell_handle c, int i) const*

returns the line supporting the dual of the facet.
Precondition: *dt.dimension()* ≥ 2 and f is not infinite.

template <class Stream>
Stream& *dt.draw_dual(Stream & os)*

Sends the set of duals to all the facets of *dt* into *os*.

debugging support

Checking

bool *dt.is_valid(bool verbose = false) const*

Checks the combinatorial validity of the triangulation and the validity of its geometric embedding (see Section 39.1). Also checks that all the circumscribing spheres (resp. circles in dimension 2) of cells (resp. facets in dimension 2) are empty.
When *verbose* is set to true, messages describing the first invalidity encountered are printed.

bool *dt.is_valid(Cell_handle c, bool verbose = false) const*

Checks the combinatorial and geometric validity of the cell (see Section 39.1). Also checks that the circumscribing sphere (resp. circle in dimension 2) of cells (resp. facet in dimension 2) is empty.
When *verbose* is set to true, messages are printed to give a precise indication of the kind of invalidity encountered.

These methods are mainly a debugging help for the users of advanced features.

CGAL::Regular_triangulation_3

CGAL::Triangulation_hierarchy_3<Tr>

deprecated

Note : this class is deprecated since CGAL 3.6. Its functionality has been replaced by the use of the *Fast_location* tag as the *LocationPolicy* template parameter in *Delaunay_triangulation_3*.

Definition

The class *Triangulation_hierarchy_3* implements a triangulation augmented with a data structure which allows fast point location queries. As proved in [Dev02], this structure has an optimal behavior when it is built for Delaunay triangulations. It can however be used for other triangulations.

#include <CGAL/Triangulation_hierarchy_3.h>

Parameters

It is templated by a parameter which must be instantiated by one of the CGAL triangulation classes. *In the current implementation, only Delaunay_triangulation_3 is supported for Tr.*

Tr::Vertex has to be a model of the concept *TriangulationHierarchyVertexBase_3*.
Tr::Geom_traits has to be a model of the concept *DelaunayTriangulationTraits_3*.

Inherits From

Tr

Triangulation_hierarchy_3<Tr> offers exactly the same functionalities as *Tr*. Most of them (point location, insertion, removal...) are overloaded to improve their efficiency by using the hierarchic structure.

Note that, since the algorithms that are provided are randomized, the running time of constructing a triangulation with a hierarchy may be improved when shuffling the data points.

However, the I/O operations are not overloaded. So, writing a hierarchy into a file will lose the hierarchic structure and reading it from the file will result in an ordinary triangulation whose efficiency will be the same as *Tr*.

Implementation

The data structure is a hierarchy of triangulations. The triangulation at the lowest level is the original triangulation where operations and point location are to be performed. Then at each succeeding level, the data structure stores a triangulation of a small random sample of the vertices of the triangulation at the preceding level. Point location is done through a top-down nearest neighbor query. The nearest neighbor query is first performed naively in the top level triangulation. Then, at each following level, the nearest neighbor at that level is found through a linear walk performed from the nearest neighbor found at the preceding level. Because the number of vertices in each triangulation is only a small fraction of the number of vertices of the preceding triangulation the data structure remains small and achieves fast point location queries on real data.

CGAL::Triangulation_hierarchy_vertex_base_3
CGAL::Delaunay_triangulation_3

deprecated

CGAL::Regular_triangulation_3<RegularTriangulationTraits_3,TriangulationDataStructure_3>

Definition

Let $S^{(w)}$ be a set of weighted points in $\mathbb{R}^3$. Let $p^{(w)} = (p, w_p), p \in \mathbb{R}^3, w_p \in \mathbb{R}$ and $z^{(w)} = (z, w_z), z \in \mathbb{R}^3, w_z \in \mathbb{R}$ be two weighted points. A weighted point $p^{(w)} = (p, w_p)$ can also be seen as a sphere of center p and radius $\sqrt{w_p}$. The *power product* (or *power distance*) between $p^{(w)}$ and $z^{(w)}$ is defined as

$$\Pi(p^{(w)}, z^{(w)}) = \|p - z\|^2 - w_p - w_z$$

where $\|p - z\|$ is the Euclidean distance between p and z. $p^{(w)}$ and $z^{(w)}$ are said to be *orthogonal* if $\Pi(p^{(w)} - z^{(w)}) = 0$ (see Figure 39.2).

Four weighted points have a unique common orthogonal weighted point called the *power sphere*. A sphere $z^{(w)}$ is said to be *regular* if $\forall p^{(w)} \in S^{(w)}, \Pi(p^{(w)} - z^{(w)}) \geq 0$.

A triangulation of $S^{(w)}$ is *regular* if the power spheres of all simplices are regular.

#include <CGAL/Regular_triangulation_3.h>

Parameters

The first template argument must be a model of the *RegularTriangulationTraits_3* concept.

The second template argument must be a model of the *TriangulationDataStructure_3* concept. It has the default value *Triangulation_data_structure_3<Triangulation_vertex_base_3<RegularTriangulationTraits_3>, Regular_triangulation_cell_base_3<RegularTriangulationTraits_3> >*.

Inherits From

Triangulation_3<RegularTriangulationTraits_3,TriangulationDataStructure_3>

Types

typedef RegularTriangulationTraits_3::Bare_point	*Bare_point;*	The type for points p of weighted points $p^{(w)} = (p, w_p)$
typedef RegularTriangulationTraits_3::Weighted_point_3	*Weighted_point;*	

Creation

Regular_triangulation_3<RegularTriangulationTraits_3,TriangulationDataStructure_3> rt(RegularTriangulationTraits_3 traits = RegularTriangulationTraits_3())

Creates an empty regular triangulation, possibly specifying a traits class *traits*.

Regular_triangulation_3<RegularTriangulationTraits_3,TriangulationDataStructure_3> rt(Regular_triangulation_3 rt1)

Copy constructor.

template < class InputIterator >
Regular_triangulation_3<RegularTriangulationTraits_3,TriangulationDataStructure_3> rt(InputIterator first, InputIterator last, RegularTriangulationTraits_3 traits = RegularTriangulationTraits_3())

Equivalent to constructing an empty triangulation with the optional traits class argument and calling *insert(first,last)*.

Operations

Insertion

The following methods, which already exist in *Triangulation_3*, are overloaded to ensure the property that all power spheres are regular.

Vertex_handle *rt.insert(Weighted_point p, Cell_handle start = Cell_handle())*

Inserts weighted point p in the triangulation. The optional argument *start* is used as a starting place for the search.
If this insertion creates a vertex, this vertex is returned.
If p coincides with an existing vertex and has a greater weight, then the existing weighted point becomes hidden (see *RegularTriangulationCellBase_3*) and p replaces it as vertex of the triangulation.
If p coincides with an already existing vertex (both point and weights being equal), then this vertex is returned and the triangulation remains unchanged.
Otherwise if p does not appear as a vertex of the triangulation, then it is stored as a hidden point and this method returns the default constructed handle.

Vertex_handle *rt.insert(Weighted_point p, Vertex_handle hint)*

Same as above but uses *hint* as a starting place for the search.

Vertex_handle *rt.insert(Weighted_point p, Locate_type lt, Cell_handle loc, int li, int lj)*

Inserts weighted point p in the triangulation and returns the corresponding vertex. Similar to the above *insert()* function, but takes as additional parameter the return values of a previous location query. See description of *Triangulation_3::locate()*.

The following method allows one to insert several points.

template < class InputIterator >

std::ptrdiff_t *rt.insert(InputIterator first, InputIterator last)*

Inserts the weighted points in the range [*first*, *last*). It returns the difference of the number of vertices between after and before the insertions (it may be negative due to hidden points). Note that this function is not guaranteed to insert the points following the order of *InputIterator*, as *spatial_sort* is used to improve efficiency.
Precondition: The *value_type* of *first* and *last* is *Weighted_point*.

template < class WeightedPointWithInfoInputIterator >
std::ptrdiff_t *rt.insert(WeightedPointWithInfoInputIterator first, WeightedPointWithInfoInputIterator last)*

Inserts the weighted points in the iterator range [*first*, *last*). It returns the difference of the number of vertices between after and before the insertions (it may be negative due to hidden points). Note that this function is not guaranteed to insert the weighted points following the order of *WeightedPointWithInfoInputIterator*, as *spatial_sort* is used to improve efficiency. Given a pair *(p,i)*, the vertex *v* storing *p* also stores *i*, that is *v.point() == p* and *v.info() == i*. If several pairs have the same point, only one vertex is created, one of the objects of type *Vertex::Info* will be stored in the vertex.
Precondition: *Vertex* must be model of the concept *TriangulationVertexBaseWithInfo_3*. The *value_type* of *first* and *last* is *std::pair<Weighted_point,Vertex::Info>*.

The following methods, which already exist in *Triangulation_3*, are overloaded to ensure that hidden points are well created and maintained.

template <class CellIt>
Vertex_handle *rt.insert_in_hole(Weighted_point p, CellIt cell_begin, CellIt cell_end, Cell_handle begin, int i)*

Creates a new vertex by starring a hole. It takes an iterator range [*cell_begin*; *cell_end*[of *Cell_handle*s which specifies a hole: a set of connected cells (resp. facets in dimension 2) which is star-shaped wrt *p*. (*begin*, *i*) is a facet (resp. an edge) on the boundary of the hole, that is, *begin* belongs to the set of cells (resp. facets) previously described, and *begin->neighbor(i)* does not. Then this function deletes all the cells (resp. facets) describing the hole, creates a new vertex *v*, and for each facet (resp. edge) on the boundary of the hole, creates a new cell (resp. facet) with *v* as vertex. Then *v->set_point(p)* is called and *v* is returned.
If the hole contains interior vertices, each of them is hidden by the insertion of *p* and is stored in the new cell which contains it.
Precondition: *rt.dimension()* ≥ 2, the set of cells (resp. facets in dimension 2) is connected, not empty, its boundary is connected, and *p* lies inside the hole, which is star-shaped wrt *p*.

template <class CellIt>
Vertex_handle *rt.insert_in_hole(Weighted_point p,*

CellIt cell_begin,
CellIt cell_end,
Cell_handle begin,
int i,
Vertex_handle newv)

Same as above, except that *newv* will be used as the new vertex, which must have been allocated previously with e.g. *create_vertex*.

Removal

void *rt.remove(Vertex_handle v)*

Removes the vertex *v* from the triangulation.

Queries

Let us remark that

$$\Pi(p^{(w)} - z^{(w)}) > 0$$

is equivalent to

p lies outside the sphere with center z and radius $\sqrt{w_p^2 + w_z^2}$.

This remark helps provide an intuition about the following predicates.

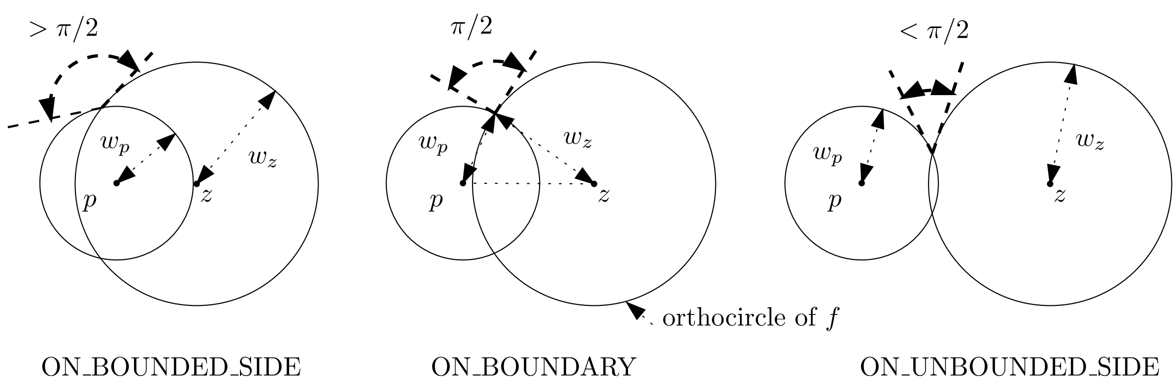

Figure 39.13: side_of_power_circle.

Bounded_side *rt.side_of_power_sphere(Cell_handle c, Weighted_point p) const*

Returns the position of the weighted point p with respect to the power sphere of c. More precisely, it returns:
- *ON_BOUNDED_SIDE* if $\Pi(p^{(w)} - z(c)^{(w)}) < 0$ where $z(c)^{(w)}$ is the power sphere of c. For an infinite cell this means either that p lies strictly in the half space limited by its finite facet and not containing any other point of the triangulation, or that the angle between p and the power circle of the *finite* facet of c is greater than $\pi/2$.
- *ON_BOUNDARY* if p is orthogonal to the power sphere of c i.e. $\Pi(p^{(w)} - z(c)^{(w)}) = 0$. For an infinite cell this means that p is orthogonal to the power circle of its *finite* facet.
- *ON_UNBOUNDED_SIDE* if $\Pi(p^{(w)} - z(c)^{(w)}) > 0$ i.e. the angle between the weighted point p and the power sphere of c is less than $\pi/2$ or if these two spheres do not intersect. For an infinite cell this means that p does not satisfy either of the two previous conditions.
Precondition: *rt.dimension()* $= 3$.

Bounded_side *rt.side_of_power_circle(Facet f, Weighted_point p) const*

Returns the position of the point p with respect to the power circle of f. More precisely, it returns:
— in dimension 3:
– For a finite facet,
ON_BOUNDARY if p is orthogonal to the power circle in the plane of the facet,
ON_UNBOUNDED_SIDE when their angle is less than $\pi/2$,
ON_BOUNDED_SIDE when it is greater than $\pi/2$ (see Figure 39.13).
– For an infinite facet, it considers the plane defined by the finite facet of the cell *f.first*, and does the same as in dimension 2 in this plane.
— in dimension 2:
– For a finite facet,
ON_BOUNDARY if p is orthogonal to the circle,
ON_UNBOUNDED_SIDE when the angle between p and the power circle of f is less than $\pi/2$, *ON_BOUNDED_SIDE* when it is greater than $\pi/2$.
– For an infinite facet,
ON_BOUNDED_SIDE for a point in the open half plane defined by f and not containing any other point of the triangulation,
ON_UNBOUNDED_SIDE in the other open half plane.
If the point p is collinear with the finite edge e of f, it returns:
ON_BOUNDED_SIDE if $\Pi(p^{(w)} - z(e)^{(w)}) < 0$, where $z(e)^{(w)}$ is the power segment of e in the line supporting e,
ON_BOUNDARY if $\Pi(p^{(w)} - z(e)^{(w)}) = 0$,
ON_UNBOUNDED_SIDE if $\Pi(p^{(w)} - z(e)^{(w)}) > 0$.
Precondition: *rt.dimension()* ≥ 2.

Bounded_side *rt.side_of_power_circle(Cell_handle c, int i, Weighted_point p) const*

Same as the previous method for facet i of cell c.

Bounded_side *rt.side_of_power_segment(Cell_handle c, Weighted_point p) const*

In dimension 1, returns
ON_BOUNDED_SIDE if $\Pi(p^{(w)} - z(c)^{(w)}) < 0$, where $z(c)^{(w)}$ is the power segment of the edge represented by c,
ON_BOUNDARY if $\Pi(p^{(w)} - z(c)^{(w)}) = 0$,
ON_UNBOUNDED_SIDE if $\Pi(p^{(w)} - z(c)^{(w)}) > 0$.
Precondition: *rt.dimension()* $= 1$.

Vertex_handle *rt.nearest_power_vertex(Weighted_point p, Cell_handle c = Cell_handle())*

Returns the vertex of the triangulation which is nearest to p with respect to the power distance. This means that the power of the query point p with respect to the weighted point in the returned vertex is smaller than the power of p with respect to the weighted point in any other vertex. Ties are broken arbitrarily. The default constructed handle is returned if the triangulation is empty. The optional argument c is a hint specifying where to start the search.
Precondition: c is a cell of *rt*.

Vertex_handle *rt.nearest_power_vertex_in_cell(Weighted_point p, Cell_handle c)*

Returns the vertex of the cell c that is nearest to p with respect to the power distance.

A weighted point p is said to be in conflict with a cell c in dimension 3 (resp. with a facet f in dimension 2) if it has a negative power distance to the power sphere of c (resp. to the power circle of f). The set of cells (resp. facets in dimension 2) which are in conflict with p is connected.

template <class OutputIteratorBoundaryFacets, class OutputIteratorCells, class OutputIteratorInternalFacets>

Triple<OutputIteratorBoundaryFacets, OutputIteratorCells, OutputIteratorInternalFacets>

rt.find_conflicts(const Weighted_point p,
Cell_handle c,
OutputIteratorBoundaryFacets bfit,
OutputIteratorCells cit,
OutputIteratorInternalFacets ifit)

Compute the conflicts with p. The starting cell (resp. facet) c must be in conflict with p. Then this function returns respectively in the output iterators:
– *cit*: the cells (resp. facets) in conflict with p.
– *bfit*: the facets (resp. edges) on the boundary of the conflict zone, that is, the facets (resp. edges) *(t, i)* where the cell (resp. facet) t is in conflict, but *t->neighbor(i)* is not.
– *ifit*: the facets (resp. edges) inside the conflict zone, that facets incident to two cells (resp facets) in conflict.
Returns the *Triple* composed of the resulting output iterators.
Precondition: *rt.dimension()* ≥ 2, and c is in conflict with p.

deprecated

template <class OutputIterator>

OutputIterator *rt.vertices_in_conflict(Weighted_point p, Cell_handle c, OutputIterator res)*

This function is renamed *vertices_on_conflict_zone_boundary* since CGAL-3.8.

deprecated

template <class OutputIterator>
OutputIterator *rt.vertices_on_conflict_zone_boundary(Weighted_point p, Cell_handle c, OutputIterator res)*

Similar to *find_conflicts()*, but reports the vertices which are on the boundary of the conflict zone of *p*, in the output iterator *res*. Returns the resulting output iterator.
Precondition: *rt.dimension()* ≥ 2, and *c* is a cell containing *p*.

template <class OutputIterator>
OutputIterator *rt.vertices_inside_conflict_zone(Weighted_point p, Cell_handle c, OutputIterator res)*

Similar to *find_conflicts()*, but reports the vertices which are in the interior of the conflict zone of *p*, in the output iterator *res*. The vertices that are on the boundary of the conflict zone are not reported. Returns the resulting output iterator.
Precondition: *rt.dimension()* ≥ 2, and *c* is a cell containing *p*.

In the weighted setting, a face (cell, facet, edge or vertex) is said to be a Gabriel face iff the smallest sphere orthogonal to the weighted points associated to its vertices, has a positive power product with the weighted point of any other vertex of the triangulation. Any weighted Gabriel face belongs to the regular triangulation, but the reciprocal is not true. The following member functions test the Gabriel property of the faces of the regular triangulation.

bool *rt.is_Gabriel(Cell_handle c, int i)*

bool *rt.is_Gabriel(Cell_handle c, int i, int j)*
bool *rt.is_Gabriel(Facet f)*
bool *rt.is_Gabriel(Edge e)*
bool *rt.is_Gabriel(Vertex_handle v)*

Power diagram

CGAL offers several functionalities to display the Power diagram of a set of points in 3D.

Note that the user should use a kernel with exact constructions in order to guarantee the computation of the Voronoi diagram (as opposed to computing the triangulation only, which requires only exact predicates).

Weighted_point

rt.dual(Cell_handle c) const

Returns the weighted circumcenter of the four vertices of c.
Precondition: *rt.dimension()*$= 3$ and *c* is not infinite.

Object *rt.dual(Facet f) const*

Returns the dual of facet f, which is
in dimension 3: either a segment, if the two cells incident to f are finite, or a ray, if one of them is infinite;
in dimension 2: a point.
Precondition: *rt.dimension()* ≥ 2 and f is not infinite.

Object *rt.dual(Cell_handle c, int i) const*

same as the previous method for facet *(c,i)*.

template <class Stream>
Stream& *rt.draw_dual(Stream & os)*

Sends the set of duals to all the facets of *rt* into *os*.

debugging support

Checking

bool *rt.is_valid(bool verbose = false) const*

Checks the combinatorial validity of the triangulation and the validity of its geometric embedding (see Section 39.1). Also checks that all the power spheres (resp. power circles in dimension 2, power segments in dimension 1) of cells (resp. facets in dimension 2, edges in dimension 1) are regular. When *verbose* is set to true, messages describing the first invalidity encountered are printed.
This method is mainly a debugging help for the users of advanced features.

debugging support

Concept

TriangulationTraits_3

Definition

The concept TriangulationTraits_3 is the first template parameter of the class *Triangulation_3*. It defines the geometric objects (points, segments, triangles and tetrahedra) forming the triangulation together with a few geometric predicates and constructions on these objects : lexicographical comparison, orientation in case of coplanar points and orientation in space.

Types

TriangulationTraits_3:: Point_3	The point type. It must be *DefaultConstructible*, *CopyConstructible* and *Assignable*.
TriangulationTraits_3:: Segment_3	The segment type.
TriangulationTraits_3:: Tetrahedron_3	The tetrahedron type.
TriangulationTraits_3:: Triangle_3	The triangle type.

TriangulationTraits_3:: Construct_segment_3

A constructor object that must provide the function operator
Segment_3 operator()(Point_3 p, Point_3 q),
which constructs a segment from two points.

TriangulationTraits_3:: Construct_triangle_3

A constructor object that must provide the function operator
Triangle_3 operator()(Point_3 p, Point_3 q, Point_3 r),
which constructs a triangle from three points.

TriangulationTraits_3:: Construct_tetrahedron_3

A constructor object that must provide the function operator
Tetrahedron_3 operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s),
which constructs a tetrahedron from four points.

TriangulationTraits_3:: Compare_xyz_3

A predicate object that must provide the function operator
Comparison_result operator()(Point p, Point q),
which returns *EQUAL* if the two points are equal. Otherwise it must return a consistent order for any two points chosen in a same line.

TriangulationTraits_3:: Coplanar_orientation_3

A predicate object that must provide the function operator
Orientation operator()(Point p, Point q, Point r),
which returns *COLLINEAR* if the points are collinear. Otherwise it must return a consistent orientation for any three points chosen in a same plane.

TriangulationTraits_3:: Orientation_3

A predicate object that must provide the function operator
Orientation operator()(Point p, Point q, Point r, Point s),
which returns POSITIVE, if s lies on the positive side of the oriented plane h defined by p, q, and r, returns NEGATIVE if s lies on the negative side of h, and returns COPLANAR if s lies on h.

Creation

TriangulationTraits_3 traits;	Default constructor.
TriangulationTraits_3 traits(Triangulation_traits_3 tr);	Copy constructor.

Operations

The following functions give access to the predicate and construction objects:

Construct_tetrahedron_3	*traits.construct_tetrahedron_3_object()*
Construct_triangle_3	*traits.construct_triangle_3_object()*
Construct_segment_3	*traits.construct_segment_3_object()*
Compare_xyz_3	*traits.compare_xyz_3_object()*
Coplanar_orientation_3	*traits.coplanar_orientation_3_object()*
Orientation_3	*traits.orientation_3_object()*

Has Models

CGAL::Exact_predicates_inexact_constructions_kernel (recommended)
CGAL::Exact_predicates_exact_constructions_kernel
CGAL::Filtered_kernel
CGAL::Cartesian
CGAL::Simple_cartesian
CGAL::Homogeneous
CGAL::Simple_homogeneous

Concept

DelaunayTriangulationTraits_3

Definition

The concept DelaunayTriangulationTraits_3 is the first template parameter of the class *Delaunay_triangulation_3*. It defines the geometric objects (points, segments...) forming the triangulation together with a few geometric predicates and constructions on these objects.

Refines

TriangulationTraits_3

In addition to the requirements described for the traits class of *Triangulation_3*, the geometric traits class of a Delaunay triangulation must fulfill the following requirements:

Types

DelaunayTriangulationTraits_3:: Line_3	The line type.
DelaunayTriangulationTraits_3:: Object_3	The object type.
DelaunayTriangulationTraits_3:: Ray_3	The ray type.

DelaunayTriangulationTraits_3:: Coplanar_side_of_bounded_circle_3

A predicate object that must provide the function operator
Bounded_side operator()(Point p, Point q, Point r, Point s),
which determines the bounded side of the circle defined by p, q, and r on which s lies.
Precondition: p, q, r, and s are coplanar and p, q, and r are not collinear.

DelaunayTriangulationTraits_3:: Side_of_oriented_sphere_3

A predicate object that must provide the function operator
Oriented_side operator()(Point p, Point q, Point r, Point s, Point t),
which determines on which side of the oriented sphere circumscribing p, q, r, s the point t lies.

DelaunayTriangulationTraits_3:: Compare_distance_3

A predicate object that must provide the function operator
Comparison_result operator()(Point p, Point q, Point r),
which compares the distance between p and q to the distance between p and r. It is only needed when using the *Fast_location* policy or the *nearest_vertex* function.

In addition, only when the dual operations are used, the traits class must provide the following constructor objects:

DelaunayTriangulationTraits_3:: Construct_circumcenter_3

A constructor object that must provide the function operator
Point_3 operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s),
which constructs the circumcenter of four points.
Precondition: p, q, r and s must be non coplanar.
It must also provide the function operator
Point_3 operator()(Point_3 p, Point_3 q, Point_3 r),
which constructs the circumcenter of three points.
Precondition: p, q and r must be non collinear.

DelaunayTriangulationTraits_3:: Construct_object_3

A constructor object that must provide the function operators
Object_3 operator()(Point_3 p),
Object_3 operator()(Segment_3 s) and
Object_3 operator()(Ray_3 r)
that construct an object respectively from a point, a segment and a ray.

DelaunayTriangulationTraits_3:: Construct_equidistant_line_3

A constructor object that must provide the function operator
Line_3 operator()(Point_3 p1, Point_3 p2, Point_3 p3),
which constructs the line which is at the same distance from the three points.
Precondition: *p1*, *p2* and *p3* must be non collinear.

DelaunayTriangulationTraits_3:: Construct_ray_3

A constructor object that must provide the function operator
Ray_3 operator()(Point_3 p, Line_3 l),
which constructs the ray starting at p with direction given by l.

Operations

The following functions give access to the predicate and construction objects:

Coplanar_side_of_bounded_circle_3	*traits.coplanar_side_of_bounded_circle_3_object()*
Side_of_oriented_sphere_3	*traits.side_of_oriented_sphere_3_object()*

When using the *Fast_location* policy or the *nearest_vertex* function, the traits must provide:

Compare_distance_3	*traits.compare_distance_3_object()*

The following functions must be provided only if the methods of *Delaunay_triangulation_3* returning elements of the Voronoi diagram are instantiated:

Construct_circumcenter_3	*traits.construct_circumcenter_3_object()*
Construct_object_3	*traits.construct_object_3_object()*
Construct_perpendicular_line_3	*traits.construct_perpendicular_line_object()*
Construct_plane_3	*traits.construct_plane_3_object()*
Construct_ray_3	*traits.construct_ray_3_object()*

Has Models

CGAL::Exact_predicates_inexact_constructions_kernel (recommended)
CGAL::Exact_predicates_exact_constructions_kernel (recommended for Voronoi)
CGAL::Filtered_kernel
CGAL::Cartesian
CGAL::Simple_cartesian
CGAL::Homogeneous
CGAL::Simple_homogeneous

RegularTriangulationTraits_3

Concept

Definition

The concept RegularTriangulationTraits_3 is the first template parameter of the class *Regular_triangulation_3*. It defines the geometric objects (points, segments...) forming the triangulation together with a few geometric predicates and constructions on these objects.

Refines

TriangulationTraits_3

In addition to the requirements described for the traits class of *Triangulation_3*, the geometric traits class of *Regular_triangulation_3* must fulfill the following requirements.

Types

RegularTriangulationTraits_3:: Line_3	The line type.
RegularTriangulationTraits_3:: Object_3	The object type.
RegularTriangulationTraits_3:: Plane_3	The plane type.
RegularTriangulationTraits_3:: Ray_3	The ray type.

We use here the same notation as in Section 39.3. To simplify notation, p will often denote in the sequel either the point $p \in \mathbb{R}^3$ or the weighted point $p^{(w)} = (p, w_p)$.

RegularTriangulationTraits_3:: Weighted_point_3	The weighted point type.
RegularTriangulationTraits_3:: Bare_point	The (un-weighted) point type.

RegularTriangulationTraits_3:: Power_test_3

A predicate object which must provide the following function operators:

Oriented_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s, Weighted_point_3 t),
which performs the following:
Let $z(p,q,r,s)^{(w)}$ be the power sphere of the weighted points (p,q,r,s). Returns
ON_ORIENTED_BOUNDARY if t is orthogonal to $z(p,q,r,s)^{(w)}$,
ON_NEGATIVE_SIDE if t lies outside the oriented sphere of center $z(p,q,r,s)$ and radius $\sqrt{w^2_{z(p,q,r,s)} + w^2_t}$ (which is equivalent to $\Pi(t^{(w)}, z(p,q,r,s)^{(w)} > 0)$),
ON_POSITIVE_SIDE if t lies inside this oriented sphere.
Precondition: *p, q, r, s* are not coplanar. Note that with this definition, if all the points have a weight equal to 0, then *power_test_3(p,q,r,s,t) = side_of_oriented_sphere(p,q,r,s,t)*.

Oriented_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 t),
which has an definition analogous to the previous method, for coplanar points, with the power circle $z(p,q,r)^{(w)}$.
Precondition: *p, q, r* are not collinear and *p, q, r, t* are coplanar. If all the points have a weight equal to 0, then *power_test_3(p,q,r,t) = side_of_oriented_circle(p,q,r,t)*.

Oriented_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 t),
which is the same for collinear points, where $z(p,q)^{(w)}$ is the power segment of p and q.
Precondition: p and q have different Bare_points, and *p, q, t* are collinear. If all points have a weight equal to 0, then *power_test_3(p,q,t)* gives the same answer as the kernel predicate *s(p,q).has_on(t)* would give, where *s(p,q)* denotes the segment with endpoints p and q.

Oriented_side operator()(Weighted_point_3 p, Weighted_point_3 q),
which is the same for equal points, that is when p and q have equal coordinates, then it returns the comparison of the weights (*ON_POSITIVE_SIDE* when q is heavier than p).
Precondition: p and q have equal Bare_points.

The following predicate is required if a call to *nearest_power_vertex* or *nearest_power_vertex_in_cell* is issued:

RegularTriangulationTraits_3:: Compare_power_distance_3

A predicate object that must provide the function operator
Comparison_result operator()(Point_3 p, Weighted_point_3 q, Weighted_point_3 r),
which compares the power distance between p and q to the power distance between p and r.

In addition, only when the dual operations are used, the traits class must provide the following constructor objects:

RegularTriangulationTraits_3:: Construct_weighted_circumcenter_3

A constructor type. The operator() constructs the bare point which is the center of the smallest orthogonal sphere to the input weighted points.
Bare_point operator() (Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s);

RegularTriangulationTraits_3:: Construct_object_3

A constructor object that must provide the function operators
Object_3 operator()(Point_3 p),
Object_3 operator()(Segment_3 s) and
Object_3 operator()(Ray_3 r)
that construct an object respectively from a point, a segment and a ray.

RegularTriangulationTraits_3:: Construct_perpendicular_line_3

A constructor object that must provide the function operator
Line_3 operator()(Plane_3 pl, Point_3 p),
which constructs the line perpendicular to *pl* passing through *p*.

RegularTriangulationTraits_3:: Construct_plane_3

A constructor object that must provide the function operator
Plane_3 operator()(Point_3 p, Point_3 q, Point_3 r),
which constructs the plane passing through *p*, *q* and *r*.
Precondition: *p*, *q* and *r* are non collinear.

RegularTriangulationTraits_3:: Construct_ray_3

A constructor object that must provide the function operator
Ray_3 operator()(Point_3 p, Line_3 l),
which constructs the ray starting at *p* with direction given by *l*.

Operations

The following function gives access to the predicate object:

Power_test_3 *traits.power_test_3_object()*

The following functions must be provided only if the member functions of *Regular_triangulation_3* returning elements of the dual diagram are called:

Construct_weighted_circumcenter_3

traits.construct_weighted_circumcenter_3_object()
Construct_object_3 *traits.construct_object_3_object()*
Construct_perpendicular_line_3

traits.construct_perpendicular_line_object()
Construct_plane_3 *traits.construct_plane_3_object()*
Construct_ray_3 *traits.construct_ray_3_object()*

Has Models

CGAL::Regular_triangulation_euclidean_traits_3

CGAL::Regular_triangulation_euclidean_traits_3<K,Weight>

Definition

The class *Regular_triangulation_euclidean_traits_3<K,Weight>* is designed as a default traits class for the class *Regular_triangulation_3<RegularTriangulationTraits_3,TriangulationDataStructure_3>*. It provides *Weighted_point_3*, a class for weighted points, which derives from the three dimensional point class *K::Point_3*.

The first argument *K* must be a model of the *Kernel* concept.

The second argument *Weight* of the class *Regular_triangulation_euclidean_traits_3<K,Weight>* is in fact optional: if is it not provided, *K::RT* will be used.

The class is a model of the concept *RegularTriangulationTraits_3* but it also contains predicates and constructors on weighted points that are not required in the concept *RegularTriangulationTraits_3*.

Note that filtered predicates are automatically used if the boolean *Has_filtered_predicates* in the kernel provided as template parameter of that class is set to *true*.

#include <CGAL/Regular_triangulation_euclidean_traits_3.h>

Is Model for the Concepts

RegularTriangulationTraits_3

Inherits From

K

Types

typedef K::Point_3	*Bare_point;*	The type for point p of a weighted point $p^{(w)} = (p, w_p)$.
typedef Weighted_point <Bare_point, Weight>	*Weighted_point_3;*	The type for weighted points.

Types for predicate functors

Regular_triangulation_euclidean_traits_3<K,Weight>:: Power_test_3

A predicate type for power test. Belongs to the *RegularTriangulationTraits_3* concept.

Regular_triangulation_euclidean_traits_3<K,Weight>:: Compare_power_distance_3

A predicate type to compare power distance. Belongs to the *RegularTriangulationTraits_3* concept.

Regular_triangulation_euclidean_traits_3<K,Weight>:: Compare_weighted_squared_radius_3

A predicate type. The operator() takes weighted point(s) as arguments, together with one weight. It compares the weight of the smallest sphere orthogonal to the weighted points with the input weight.
Comparison_result operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s, FT w) ;
Comparison_result operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, FT w) ;
Comparison_result operator()(Weighted_point_3 p, Weighted_point_3 q, FT w) ;
Comparison_result operator()(Weighted_point_3 p, FT w) ;

Regular_triangulation_euclidean_traits_3<K,Weight>:: In_smallest_orthogonal_sphere_3

A predicate type. The operator() takes weighted points as arguments and returns the sign of the power distance of the last one with respect to the smallest sphere orthogonal to the others.
Sign operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s, Weighted_point_3 t) ;
Sign operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s) ;
Sign operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r) ;
Sign operator()(Weighted_point_3 p, Weighted_point_3 q) ;

Regular_triangulation_euclidean_traits_3<K,Weight>:: Side_of_bounded_orthogonal_sphere_3

A predicate type. The operator() is similar to the operator() of *In_smallest_orthogonal_sphere_3* except that the returned type is not a *Sign* but belongs to the enum *Bounded_side* (A *NEGATIVE*, *ZERO* and *POSITIVE*) corresponding respectively to *ON_BOUNDED_SIDE*, *ON_BOUNDARY* and *ON_UNBOUNDED_SIDE*)).
Bounded_side operator() (Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s, Weighted_point_3 t) ;
Bounded_side operator() (Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s) ;
Bounded_side operator() (Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r) ;

Regular_triangulation_euclidean_traits_3<K,Weight>:: Does_simplex_intersect_dual_support_3

A predicate type. The operator() takes weighted points as arguments, considers the subspace of points with equal power distance with respect to its arguments and the intersection of this subspace with the affine hull of the bare points associated to the arguments. The operator() returns *ON_BOUNDED_SIDE*, *ON_BOUNDARY* or *ON_UNBOUNDED_SIDE* according to the position of this intersection with respect to the simplex formed by the bare points. This predicate is useful for flow computations.
Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s) ;
Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r) ;
Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q) ;

Types for constructor functors

Regular_triangulation_euclidean_traits_3<K,Weight>:: Construct_weighted_circumcenter_3

A constructor type. The operator() constructs the bare point which is the center of the smallest orthogonal sphere to the input weighted points.
Bare_point operator() (Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s);
Bare_point operator() (Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r);
Bare_point operator() (Weighted_point_3 p, Weighted_point_3 q);

Regular_triangulation_euclidean_traits_3<K,Weight>:: Compute_power_product_3

A functor type. The operator() computes the power distance between its arguments.
FT operator() (Weighted_point_3 p, Weighted_point_3 q) ;

Regular_triangulation_euclidean_traits_3<K,Weight>:: Compute_squared_radius_smallest_orthogonal_sphere_3

A functor type. The operator() computes the squared radius of the smallest sphere orthogonal to the argument(s).
FT operator() (Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s);
FT operator() (Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r);
FT operator() (Weighted_point_3 p, Weighted_point_3 q);
FT operator() (Weighted_point_3 p);

Regular_triangulation_euclidean_traits_3<K,Weight>:: Compute_critical_squared_radius_3

A functor type. The operator() takes weighted points as arguments and computes the squared radius of the sphere centered in the last point and orthogonal to the other weighted points. The last argument is a weighted point but its weight does not matter. This construction is ad hoc for pumping slivers. For robustness issue, a predicate to compare critical squared radii for a given last point should be needed.
FT operator() (Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s, Weighted_point_3 t);

Operations

The following functions give access to the predicate and constructor functors.

Power_test_3	*traits.power_test_3_object()*

Compute_critical_squared_radius_3	*traits.compute_critical_squared_radius_3_object()*

Concept

TriangulationCellBase_3

Definition

The cell base required by the basic triangulation does not need to store any geometric information, so only the requirements of the triangulation data structure apply.

However, for the Delaunay triangulation, the ability to store the circumcenter is provided (for optimization reasons), hence an additional requirement only in this case, and only when the dual functions are called.

Refines

TriangulationDSCellBase_3

DelaunayTriangulationTraits_3::Point_3

c.circumcenter(DelaunayTriangulationTraits_3 gt = DelaunayTriangulationTraits_3())

Returns the circumcenter.

TriangulationVertexBase_3

Concept

Definition

The vertex base used by the geometric triangulation must store a point. So we list here the additional requirements compared to a vertex base usable for the triangulation data structure.

Refines

TriangulationDSVertexBase_3

Types

TriangulationVertexBase_3:: Point	Must be the same as the point type *TriangulationTraits_3::Point_3* defined by the geometric traits class of the triangulation.

Creation

TriangulationVertexBase_3 v(Point p);	Constructs a vertex whose geometric embedding is point p.
TriangulationVertexBase_3 v(Point p, Cell_handle c);	Constructs a vertex embedding the point p and pointing to cell c.

Access Functions

Point	*v.point() const*	Returns the point.

Setting

void	*v.set_point(Point p)*	Sets the point.

I/O

istream&	*istream& is >> & v*	Inputs the non-combinatorial information given by the vertex: the point and other possible information.
ostream&	*ostream& os << v*	Outputs the non-combinatorial information given by the vertex: the point and other possible information.

A type model of this concept can be used as vertex base by a triangulation and provides an additional information storage.

Refines

TriangulationVertexBase_3

Types

TriangulationVertexBaseWithInfo_3:: Info	A type which is *DefaultConstructible* and *Assignable*.

Access Functions

Info	*v.info() const*	Returns a const reference to the object of type *Info* stored in the vertex.
Info&	*v.info()*	Returns a reference to the object of type *Info* stored in the vertex.

Has Models

CGAL::Triangulation_vertex_base_with_info_3

CGAL::Triangulation_simplex_3<Triangulation_3>

Definition

The class *Triangulation_simplex_3<Triangulation_3>* stores a simplex of any dimension defined by the *Triangulation_3* class. It also defines the operator less such that simplices can be stored in a *map* or a *set* of simplices. The simplex is invalidated by any change in the triangulation.

#include <CGAL/Triangulation_simplex_3.h>

Parameters

It is parameterized by the triangulation it derives the simplices from.

Types

typedef Triangulation_simplex_3<Triangulation_3>	*Simplex;*	The simplex class itself.
typedef Triangulation_3::Vertex_handle	*Vertex_handle;*	
typedef Triangulation_3::Edge	*Edge;*	
typedef Triangulation_3::Facet	*Facet;*	
typedef Triangulation_3::Cell_handle	*Cell_handle;*	
typedef Triangulation_3::Cell_circulator	*Cell_circulator;*	
typedef Triangulation_3::Facet_circulator	*Facet_circulator;*	
typedef Triangulation_3::Edge_iterator	*Edge_iterator;*	
typedef Triangulation_3::Facet_iterator	*Facet_iterator;*	
typedef Triangulation_3::Finite_vertices_iterator	*Finite_vertices_iterator;*	
typedef Triangulation_3::Finite_edges_iterator	*Finite_edges_iterator;*	
typedef Triangulation_3::Finite_facets_iterator	*Finite_facets_iterator;*	
typedef Triangulation_3::Finite_cells_iterator	*Finite_cells_iterator;*	

Creation

Triangulation_simplex_3<Triangulation_3>	*simplex*;	Initializes the simplex to an invalid simplex.
Triangulation_simplex_3<Triangulation_3>	*simplex(Vertex_handle vh);*	
Triangulation_simplex_3<Triangulation_3>	*simplex(Edge e);*	
Triangulation_simplex_3<Triangulation_3>	*simplex(Facet f);*	
Triangulation_simplex_3<Triangulation_3>	*simplex(Cell_handle ch);*	
Triangulation_simplex_3<Triangulation_3>	*simplex(Cell_circulator ccir);*	
Triangulation_simplex_3<Triangulation_3>	*simplex(Facet_circulator fcir);*	

Triangulation_simplex_3<Triangulation_3> simplex(Edge_iterator eit);
Triangulation_simplex_3<Triangulation_3> simplex(Facet_iterator fit);

Operations

int	*simplex.dimension() const*	
		returns the dimension of the simplex.
Vertex_handle	*Vertex_handle (simplex)*	Returns the *Vertex_handle* stored in the simplex. *Precondition*: dimension() == 0
Edge	*Edge (simplex)*	Returns the *Edge* stored in the simplex. *Precondition*: dimension() == 1
Facet	*Facet (simplex)*	Returns the *Facet* stored in the simplex. *Precondition*: dimension() == 2
Cell_handle	*Cell_handle (simplex)*	Returns the *Cell_handle* stored in the simplex. *Precondition*: dimension() == 3
Cell_handle	*simplex.incident_cell() const*	
		Returns a cell incident to the simplex.
bool	*simplex == s1*	Test whether two simplices are equal.
bool	*simplex < s1*	Defines a ordering on the simplices. This ordering depends on the memory layout and is independent of the geometry. Therefore, the ordering is not intrinsic

RegularTriangulationCellBase_3

Concept

Definition

The regular triangulation of a set of weighted points does not necessarily have one vertex for each of the input points. Some of the input weighted points have no cell in the dual power diagrams and therefore do not correspond to a vertex of the regular triangulation. Those weighted points are said to be *hidden* points. A point which is hidden at a given time may appear later as a vertex of the regular triangulation upon removal on some other weighted point. Therefore, hidden points have to be stored somewhere. The regular triangulation stores those hidden points in its cells.

A hidden point can appear as vertex of the triangulation only when the three dimensional cell where its point component is located (the cell which hides it) is removed. Therefore we decided to store in each cell of a regular triangulation the list of hidden points that are located in the face. Thus points hidden by a face are easily reinserted in the triangulation when the face is removed.

The base cell of a regular triangulation has to be a model of the concept RegularTriangulationCellBase_3, which refines the concept *TriangulationCellBase_3* by adding in the cell a container to store hidden points.

Refines

TriangulationCellBase_3

Types

RegularTriangulationCellBase_3:: Point	Must be the same as the point type *TriangulationTraits_3::Point_3* defined by the geometric traits class of the triangulation.

Types

RegularTriangulationCellBase_3:: Point_iterator

Iterator of value type Point

Access Functions

Point_iterator *rcb.hidden_points_begin()*

Returns an iterator pointing to the first hidden point.

Point_iterator *rcb.hidden_points_end()*

Returns a past-the-end iterator.

Setting

void *rcb.hide_point(Point p)*

Adds *p* to the set of hidden points of the cell.

CGAL::Triangulation_cell_base_3<TriangulationTraits_3, TriangulationDSCellBase_3>

Definition

The class *Triangulation_cell_base_3* is a model of the concept *TriangulationCellBase_3*, the base cell of a 3D-triangulation.

This class can be used directly or can serve as a base to derive other classes with some additional attributes (a color for example) tuned for a specific application.

#include <CGAL/Triangulation_cell_base_3.h>

Parameters

The first template argument is the geometric traits class *TriangulationTraits_3*. It is actually not used by this class.

The second template argument is a combinatorial cell base class from which *Triangulation_cell_base_3* derives. It has the default value *Triangulation_ds_cell_base_3<>*.

Note that this model does not store the circumcenter, but computes it every time the circumcenter function is called. See *CGAL::Triangulation_cell_base_with_circumcenter_3* for a way to cache the circumcenter computation.

Chapter 40

3D Triangulation Data Structure

Sylvain Pion and Monique Teillaud

Contents

A geometric triangulation has two aspects: the combinatorial structure, which gives the incidence and adjacency relations between faces, and the geometric information related to the position of vertices.

CGAL provides 3D geometric triangulations in which these two aspects are clearly separated. As described in Chapter 39, a geometric triangulation of a set of points in $\mathbb{R}^d$, $d \leq 3$ is a partition of the whole space $\mathbb{R}^d$ into cells having $d+1$ vertices. Some of them are infinite, they are obtained by linking an additional vertex at infinity to each facet of the convex hull of the points (see Section 39.1). The underlying combinatorial graph of such a triangulation without boundary of $\mathbb{R}^d$ can be seen as a triangulation of the topological sphere S^d in $\mathbb{R}^{d+1}$.

This chapter deals with 3D-triangulation data structures, meant to maintain the combinatorial information for 3D-geometric triangulations. The reader interested in geometric triangulations of $\mathbb{R}^3$ is advised to read Chapter 39.

40.1 Representation

In CGAL, a 3D triangulation data structure is a container of cells (3-faces) and vertices (0-faces).

Following the standard vocabulary of simplicial complexes, an i-face f_i and a j-face f_j $(0 \leq j < i \leq 3)$ are said to be *incident* in the triangulation if f_j is a (sub)face of f_i, and two i-faces $(0 \leq i \leq 3)$ are said to be *adjacent* if they share a commun incident (sub)face.

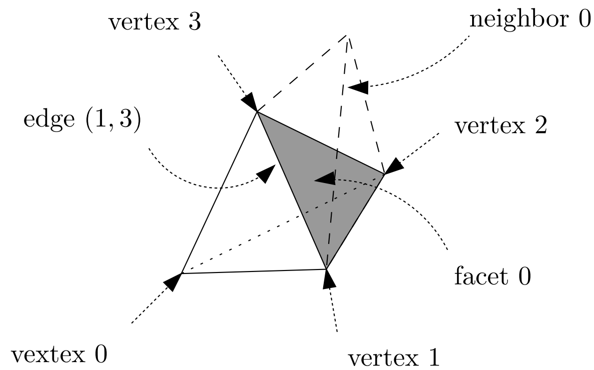

Figure 40.1: Representation.

Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives direct access to one of its incident cells, which is sufficient to retrieve all the incident cells when needed.

The four vertices of a cell are indexed with 0, 1, 2 and 3. The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index (see Figure 40.1).

Edges (1-faces) and facets (2-faces) are not explicitly represented: a facet is given by a cell and an index (the facet i of a cell c is the facet of c that is opposite to the vertex of index i) and an edge is given by a cell and two indices (the edge *(i,j)* of a cell c is the edge whose endpoints are the vertices of indices i and j of c).

Degenerate Dimensions As CGAL explicitly deals with all degenerate cases, a 3D-triangulation data structure in CGAL can handle the cases when the dimension of the triangulation is lower than 3.

Thus, a 3D-triangulation data structure can store a triangulation of a topological sphere S^d of $\mathbb{R}^{d+1}$, for any $d \in \{-1, 0, 1, 2, 3\}$.

Let us give, for each dimension, the example corresponding to the triangulation data structure having a minimal number of vertices, i.e. a simplex. These examples are illustrated by presenting their usual geometric embedding.

- *dimension 3.* The triangulation data structure consists of the boundary of a 4-dimensional simplex, which has 5 vertices. A geometric embedding consists in choosing one of these vertices to be infinite, thus four of the five 3-cells become infinite: the geometric triangulation has one finite tetrahedron remaining, each of its facets being incident to an infinite cell. See Figure 40.2.
- *dimension 2.* We have 4 vertices forming one 3-dimensional simplex, i.e. the boundary of a tetrahedron. The geometric embedding in the plane results from choosing one of these vertices to be infinite, then the geometric triangulation has one finite triangle whose edges are incident to the infinite triangles. See Figure 40.3.
- *dimension 1.* A 2-dimensional simplex (a triangle) has 3 vertices. The geometric embedding is an edge whose vertices are linked to an infinite point. See Figure 40.4.

The last three cases are defined uniquely:

- *dimension 0.* A 0-dimensional triangulation is combinatorially equivalent to the boundary of a 1-dimensional simplex (an edge), which consists of 2 vertices. One of them becomes infinite in the geometric embedding, and there is only one finite vertex remaining. The two vertices are adjacent.

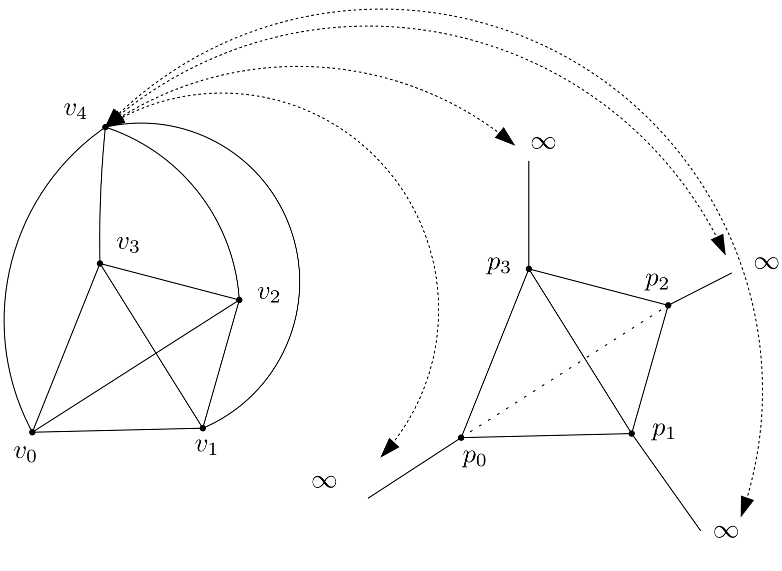

Figure 40.2: 4D simplex and a 3D geometric embedding.

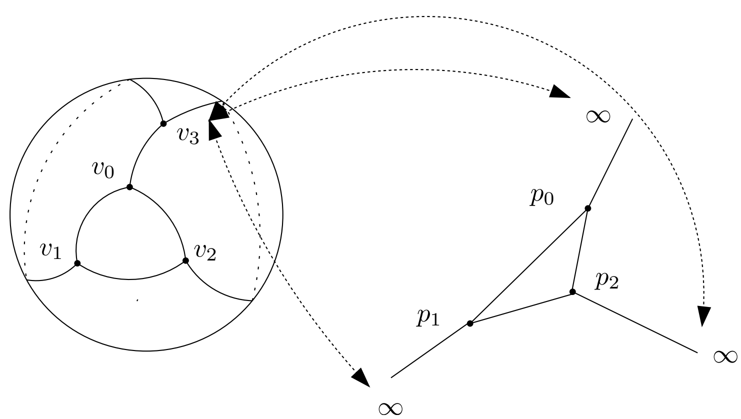

Figure 40.3: 3D simplex and a 2D geometric embedding.

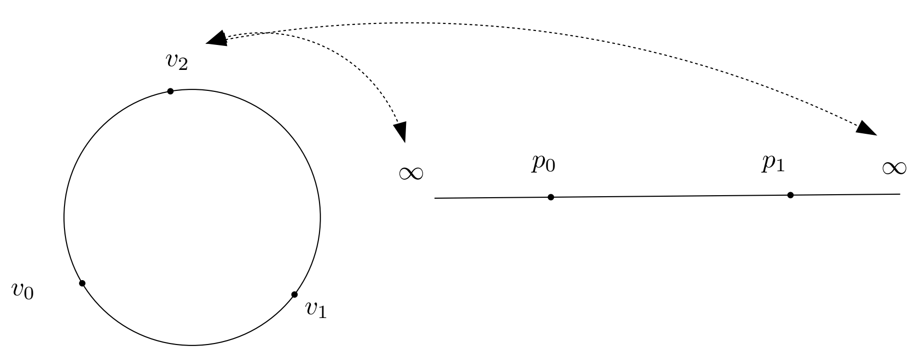

Figure 40.4: 2D simplex and a 1D geometric embedding.

- *dimension -1.* This dimension is a convention to represent a 0-dimensional simplex, that is a sole vertex, which will be geometrically embedded as an "empty" triangulation, having only one infinite vertex.
- *dimension -2.* This is also a convention. The triangulation data structure has no vertex. There is no associated geometric triangulation.

Note that the notion of infinite vertex has no meaning for the triangulation data structure. The infinite vertex of the geometric embedding is a vertex that cannot be distinguished from the other vertices in the combinatorial triangulation.

The same cell class is used in all cases: triangular faces in 2D can be considered as degenerate cells, having only three vertices (resp. neighbors) numbered $(0,1,2)$; edges in 1D have only two vertices (resp. neighbors) numbered 0 and 1.

The implicit representation of facets (resp. edges) still holds for degenerate (< 3) dimensions : in dimension 2, each cell has only one facet of index 3, and 3 edges $(0,1)$, $(1,2)$ and $(2,0)$; in dimension 1, each cell has one edge $(0,1)$.

Validity A 3D combinatorial triangulation is said to be *locally valid* iff the following is true:

(a) When a cell c has a neighbor pointer to another cell c', then reciprocally this cell c' has a neighbor pointer to c, and c and c' have three vertices in common. These cells are called adjacent.

(b) The cells have a coherent orientation: if two cells c_1 and c_2 are adjacent and share a facet with vertices u,v,w, then the vertices of c_1 are numbered $(v_0^1 = u, v_1^1 = v, v_2^1 = w, v_3^1)$, and the vertices of c_2 are numbered $(v_0^2 = v, v_1^2 = u, v_2^2 = w, v_3^2)$, up to positive permutations of $(0,1,2,3)$. In other words, if we embed the triangulation in $\mathbb{R}^3$, then the fourth vertices v_3^1 and v_3^2 of c_1 and c_2 see the common facet in opposite orientations. See Figure 40.5.

The set σ_4 of permutations of $(0,1,2,3)$ has cardinality 24, and the set of positive permutations A_4 has cardinality 12. Thus, for a given orientation, there are up to 12 different orderings of the four vertices of a cell. Note that cyclic permutations are negative and so do not preserve the orientation of a cell.

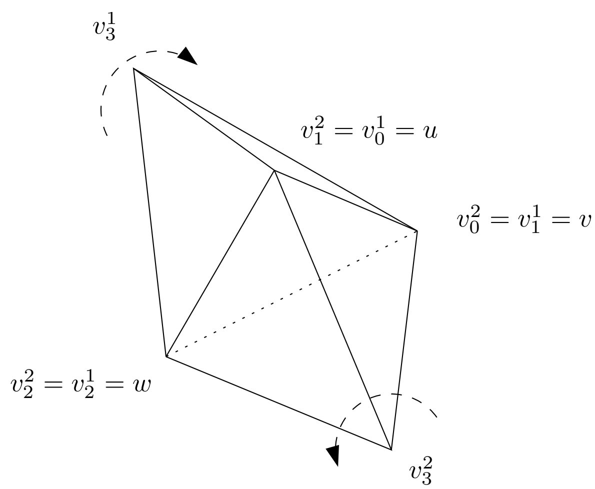

Figure 40.5: Coherent orientations of two cells (3-dimensional case).

The *is_valid()* method provided by *Triangulation_data_structure_3* checks the local validity of a given triangulation data structure.

40.2 Software Design

The 3D-triangulation data structure class of CGAL, *Triangulation_data_structure_3*, is designed to be used as a combinatorial layer upon which a geometric layer can be built [Ket98]. This geometric layer is typically one of the 3D-triangulation classes of CGAL: *Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3*. This relation is described in more details in Chapter 39, where the Section 39.4 explains other important parts of the design related to the geometry.

We focus here on the design of the triangulation data structure (TDS) itself, which the Figure 40.6 illustrates.

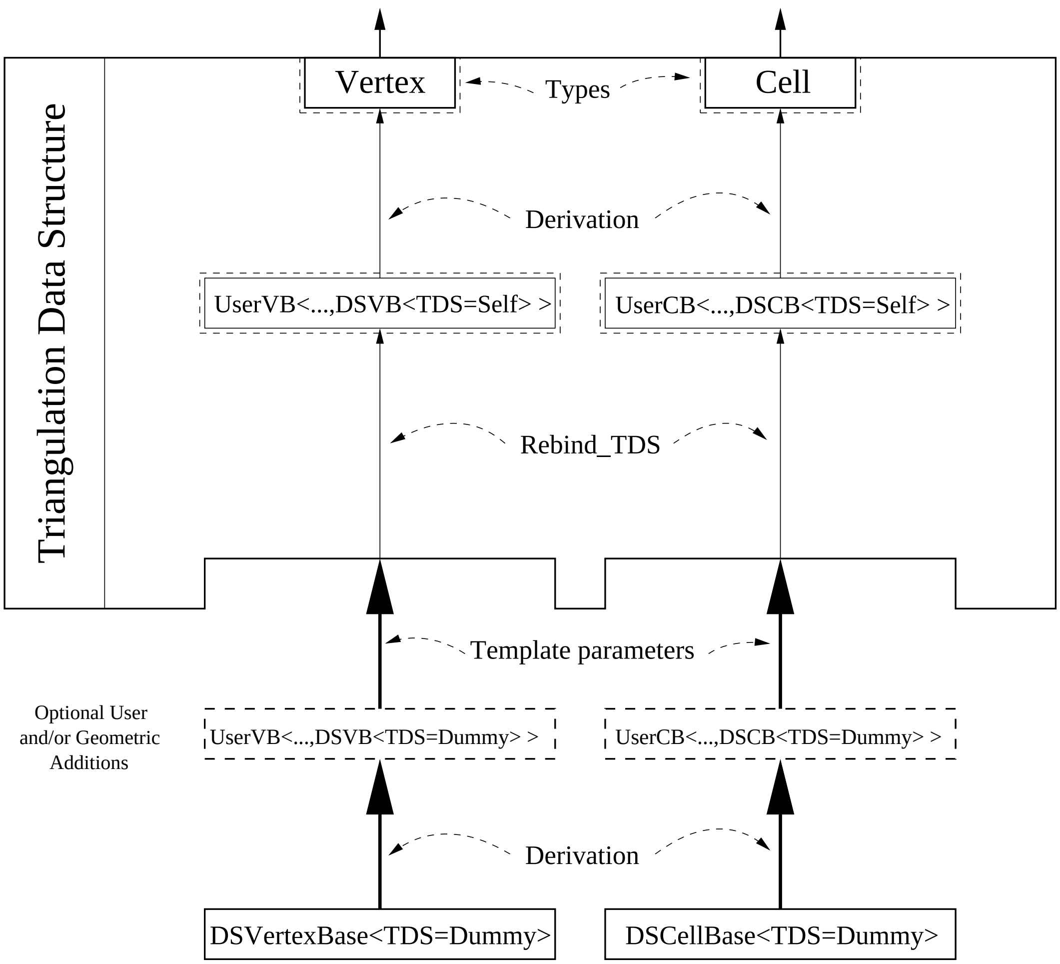

Figure 40.6: Triangulation Data Structure software design.

40.2.1 Flexibility of the Design

In order for the user to be able to add his own data in the vertices and cells, the design of the TDS is split into two layers:

- In the bottom layer, the (vertex and cell) base classes store elementary incidence and adjacency (and possibly geometric or other) information. These classes are parameterized by the TDS which provides the handle types. (They can also be parameterized by a geometric traits class or anything else.) A vertex stores a *Cell_handle*, and a cell stores four *Vertex_handle*s and four *Cell_handle*s.

- The middle layer is the TDS, which is purely combinatorial. It provides operations such as insertion of a new vertex in a given cell, on a 1 or 2-face. It also allows one, if the dimension of the triangulation is smaller than 3, to insert a vertex so that the dimension of the triangulation is increased by one. The TDS is responsible for the combinatorial integrity of the eventual geometric triangulation built on top of it (the upper layer, see Chapter 39).

The user has several ways to add his own data in the vertex and cell base classes used by the TDS. He can either:

- use the classes *Triangulation_vertex_base_with_info_3* and *Triangulation_cell_base_with_info_3*, which allow to add one data member of a user provided type, and give access to it.
- derive his own classes from the default base classes *Triangulation_ds_vertex_base*, and *Triangulation_ds_cell_base* (or the geometric versions typically used by the geometric layer, *Triangulation_vertex_base*, and *Triangulation_cell_base*).
- write his own base classes following the requirements given by the concepts *TriangulationCellBase_3* and *TriangulationVertexBase_3* (described in page 2684 and page 2685).

40.2.2 Cyclic Dependency

Since adjacency relations are stored in the vertices and cells, it means that the vertex and cell base classes have to be able to store handles (an entity akin to pointers) to their neighbors in the TDS. This in turns means that the vertex and cell base classes have to know the types of these handles, which are provided by the TDS. So in a sense, the base classes are parameterized by the TDS, and the TDS is parameterized by the vertex and cell base classes ! This is a cycle which cannot be resolved easily.

The solution that we have chosen is similar to the mechanism used by the standard class *std::allocator*: the vertex and cell base classes are initially given a fake or dummy TDS template parameter, whose unique purpose is to provide the types that can be used by the vertex and cell base classes (such as handles). Then, inside the TDS itself, these base classes are *rebound* to the real TDS type, that is we obtain the same vertex and cell base classes, but parameterized with the real TDS instead of the dummy one. Rebinding is performed by a nested template class of the vertex and cell base classes (see code below), which provides a type which is the rebound vertex or cell base class[1].

Here is how it works, schematically:

```
template < class Vb, class Cb >
class TDS
{
  typedef TDS<Vb, Cb>    Self;

  // Rebind the vertex and cell base to the actual TDS (Self).
  typedef typename Vb::template Rebind_TDS<Self>::Other  VertexBase;
  typedef typename Cb::template Rebind_TDS<Self>::Other  CellBase;

  // ... further internal machinery leads to the final public types:
public:
  typedef ...  Vertex;
  typedef ...  Cell;
```

[1]It is logically equivalent to a mechanism that does not exist yet in the C++ language: *template typedef* or *template aliasing*

```
  typedef ...  Vertex_handle;
  typedef ...  Cell_handle;
};

template < class TDS = ... >  // The default is some internal type faking
     a TDS
class Triangulation_ds_vertex_base_3
{
public:
  template < class TDS2 >
  struct Rebind_TDS {
    typedef Triangulation_ds_vertex_base_3<TDS2>    Other;
  };
...
};
```

When derivation is used for the vertex or cell base classes, which is the case at the geometric level with *Triangulation_vertex_base_3*, then it gets slightly more involved because its base class has to be rebound as well:

```
template < class GT, class Vb = Triangulation_ds_vertex_base_3<> >
class Triangulation_vertex_base_3 : public Vb
{
public:
  template < class TDS2 >
  struct Rebind_TDS {
    typedef typename Vb::template Rebind_TDS<TDS2>::Other  Vb2;
    typedef Triangulation_vertex_base_3<GT, Vb2>           Other;
  };
...
};
```

40.3 Examples

40.3.1 Incremental Construction

The following example shows how to construct a 3D triangulation data structure by inserting vertices.

```
#include <CGAL/Triangulation_data_structure_3.h>
#include <iostream>
#include <fstream>
#include <cassert>
#include <vector>

typedef CGAL::Triangulation_data_structure_3<>      Tds;

typedef Tds::size_type                              size_type;
typedef Tds::Cell_handle                            Cell_handle;
typedef Tds::Vertex_handle                          Vertex_handle;

int main()
```

```
{
  Tds T;

  assert( T.number_of_vertices() == 0 );
  assert( T.dimension() == -2 );
  assert( T.is_valid() );

  std::vector<Vertex_handle> PV(7);

  PV[0] = T.insert_increase_dimension();
  assert( T.number_of_vertices() == 1 );
  assert( T.dimension() == -1 );
  assert( T.is_valid() );

  // each of the following insertions of vertices increases the dimension
  for ( int i=1; i<5; i++ ) {
    PV[i] = T.insert_increase_dimension(PV[0]);
    assert( T.number_of_vertices() == (size_type) i+1 );
    assert( T.dimension() == i-1 );
    assert( T.is_valid() );
  }
  assert( T.number_of_cells() == 5 );

  // we now have a simplex in dimension 4

  // cell incident to PV[0]
  Cell_handle c = PV[0]->cell();
  int ind;
  bool check = c->has_vertex( PV[0], ind );
  assert( check );
  // PV[0] is the vertex of index ind in c

  // insertion of a new vertex in the facet opposite to PV[0]
  PV[5] = T.insert_in_facet(c, ind);

  assert( T.number_of_vertices() == 6 );
  assert( T.dimension() == 3 );
  assert( T.is_valid() );

  // insertion of a new vertex in c
  PV[6] = T.insert_in_cell(c);

  assert( T.number_of_vertices() == 7 );
  assert( T.dimension() == 3 );
  assert( T.is_valid() );

  std::ofstream oFileT("output_tds",std::ios::out);
  // writing file output_tds;
  oFileT << T;

  return 0;
}
```

File: examples/Triangulation_3/tds.cpp

40.3.2 Cross-Linking Between a 2D and a 3D Data Structures

This example program illustrates how to setup a 2D and a 3D triangulation data structures whose vertices respectively store vertex handles of the other one.

```
#include <CGAL/Triangulation_data_structure_2.h>
#include <CGAL/Triangulation_data_structure_3.h>
#include <cassert>

// declare the 2D vertex base type, parametrized by some 3D TDS.
template < typename T3, typename Vb =
    CGAL::Triangulation_ds_vertex_base_2<> >
class My_vertex_2;

// declare the 3D vertex base type, parametrized by some 2D TDS.
template < typename T2, typename Vb =
    CGAL::Triangulation_ds_vertex_base_3<> >
class My_vertex_3;

// Then, we have to break the dependency cycle.

// we need to refer to a dummy 3D TDS.
typedef
    CGAL::Triangulation_ds_vertex_base_3<>::Triangulation_data_structure
        Dummy_tds_3;
// the 2D TDS, initially plugging a dummy 3D TDS in the vertex type
// (to break the dependency cycle).
typedef CGAL::Triangulation_data_structure_2<My_vertex_2<Dummy_tds_3> >
    TDS_2;
// the 3D TDS, here we can plug the 2D TDS directly.
typedef CGAL::Triangulation_data_structure_3<My_vertex_3<TDS_2> >
    TDS_3;

template < typename T3, typename Vb >
class My_vertex_2
  : public Vb
{
public:
  typedef typename Vb::Face_handle    Face_handle;

  template <typename TDS2>
  struct Rebind_TDS {
    typedef typename Vb::template Rebind_TDS<TDS2>::Other  Vb2;
    // we also have to break the cycle here by hardcoding TDS_3 instead
   of T3.
    typedef My_vertex_2<TDS_3, Vb2>                           Other;
  };

  My_vertex_2() {}
```

```
  My_vertex_2(Face_handle f) : Vb(f) {}

  // we store a vertex handle of the 3D TDS.
  typename T3::Vertex_handle v3;
};

template < typename T2, typename Vb >
class My_vertex_3
  : public Vb
{
public:
  typedef typename Vb::Cell_handle    Cell_handle;

  template <typename TDS2>
  struct Rebind_TDS {
    typedef typename Vb::template Rebind_TDS<TDS2>::Other  Vb2;
    typedef My_vertex_3<T2, Vb2>                           Other;
  };

  My_vertex_3() {}

  My_vertex_3(Cell_handle c) : Vb(c) {}

  // we store a vertex handle of the 2D TDS.
  typename T2::Vertex_handle v2;
};

int main() {
  TDS_2 t2;
  TDS_3 t3;

  TDS_2::Vertex_handle v2 = t2.insert_dim_up();
  TDS_3::Vertex_handle v3 = t3.insert_increase_dimension();

  v2->v3 = v3;
  v3->v2 = v2;

  assert(t2.is_valid());
  assert(t3.is_valid());
  return 0;
}
```

40.4 Design and Implementation History

Monique Teillaud introduced the triangulation of the topological sphere S^d in $\mathbb{R}^{d+1}$ to manage the underlying graph of geometric triangulations and handle degenerate dimensions [Tei99].

Sylvain Pion improved the software in several ways, in particular regarding the memory management.

3D Triangulation Data Structure Reference Manual

Sylvain Pion and Monique Teillaud

The triangulation data structure is able to represent a triangulation of a topological sphere S^d of $\mathbb{R}^{d+1}$, for $d \in \{-1,0,1,2,3\}$. (See 40.1.)

The vertex class of a 3D-triangulation data structure must define a number of types and operations. The requirements that are of geometric nature are required only when the triangulation data structure is used as a layer for the geometric triangulation classes. (See Section 40.2.)

The cell class of a triangulation data structure stores four handles to its four vertices and four handles to its four neighbors. The vertices are indexed 0, 1, 2, and 3 in a consistent order. The neighbor indexed i lies opposite to vertex i.

In degenerate dimensions, cells are used to store faces of maximal dimension: in dimension 2, each cell represents only one facet of index 3, and 3 edges $(0,1)$, $(1,2)$ and $(2,0)$; in dimension 1, each cell represents one edge $(0,1)$. (See Section 40.1.)

TriangulationDataStructure_3

Concept

Definition

3D-triangulation data structures are meant to maintain the combinatorial information for 3D-geometric triangulations.

In CGAL, a triangulation data structure is a container of cells (3-faces) and vertices (0-faces). Following the standard vocabulary of simplicial complexes, an i-face f_i and a j-face f_j $(0 \leq j < i \leq 3)$ are said to be *incident* in the triangulation if f_j is a (sub)face of f_i, and two i-faces $(0 \leq i \leq 3)$ are said to be *adjacent* if they share a common incident (sub)face.

Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives direct access to one of its incident cells, which is sufficient to retrieve all the incident cells when needed.

The four vertices of a cell are indexed with 0, 1, 2 and 3. The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index (see Figure 40.1).

Edges (1-faces) and facets (2-faces) are not explicitly represented: a facet is given by a cell and an index (the facet i of a cell c is the facet of c that is opposite to the vertex of index i) and an edge is given by a cell and two indices (the edge *(i,j)* of a cell c is the edge whose endpoints are the vertices of indices i and j of c).

As CGAL explicitly deals with all degenerate cases, a 3D-triangulation data structure in CGAL can handle the cases when the dimension of the triangulation is lower than 3 (see Section 40.1).

Thus, a 3D-triangulation data structure can store a triangulation of a topological sphere S^d of $\mathbb{R}^{d+1}$, for any $d \in \{-1,0,1,2,3\}$.

The second template parameter of the basic triangulation class (see Chapter 39 , page 2636) *Triangulation_3* is a triangulation data structure class. (See Chapter 40.)

To ensure all the **flexibility** of the class *Triangulation_3*, a model of a triangulation data structure must be templated by the base vertex and the base cell classes (see 40.1): *TriangulationDataStructure_3< TriangulationVertexBase_3,TriangulationCellBase_3>*. The optional functionalities related to geometry are compulsory for this use as a template parameter of *Triangulation_3*.

A class that satisfies the requirements for a triangulation data structure class must provide the following types and operations.

Types

TriangulationDataStructure_3:: Vertex	Vertex type
TriangulationDataStructure_3:: Cell	Cell type
TriangulationDataStructure_3:: size_type	Size type (unsigned integral type)
TriangulationDataStructure_3:: difference_type	Difference type (signed integral type)

Vertices and cells are usually manipulated via *handles*, which support the two dereference operators *operator** and *operator->*.

TriangulationDataStructure_3:: Vertex_handle
TriangulationDataStructure_3:: Cell_handle

Requirements for *Vertex* and *Cell* are described in *TriangulationDataStructure_3::Vertex* and *TriangulationDataStructure_3::Cell* (page 2732 and page 2730).

advanced

TriangulationDataStructure_3:: template <typename Vb2> struct Rebind_vertex

This nested template class allows to get the type of a triangulation data structure that only changes the vertex type. It has to define a type *Other* which is a *rebound* triangulation data structure, that is, the one whose *TriangulationDSVertexBase_3* will be *Vb2*.

TriangulationDataStructure_3:: template <typename Cb2> struct Rebind_cell

This nested template class allows to get the type of a triangulation data structure that only changes the cell type. It has to define a type *Other* which is a *rebound* triangulation data structure, that is, the one whose *TriangulationDSCellBase_3* will be *Cb2*.

advanced

typedef Triple<Cell_handle, int, int>	*Edge;*	*(c,i,j)* is the edge of cell *c* whose vertices indices are *i* and *j*. (See Section 40.1.)
typedef std::pair<Cell_handle, int>	*Facet;*	*(c,i)* is the facet of *c* opposite to the vertex of index *i*. (See Section 40.1.)

The following iterators allow one to visit all the vertices, edges, facets and cells of the triangulation data structure. They are all bidirectional, non-mutable iterators.

TriangulationDataStructure_3:: Cell_iterator
TriangulationDataStructure_3:: Facet_iterator
TriangulationDataStructure_3:: Edge_iterator
TriangulationDataStructure_3:: Vertex_iterator

The following circulators allow us to visit all the cells and facets incident to a given edge. They are bidirectional and non-mutable.

TriangulationDataStructure_3:: Facet_circulator
TriangulationDataStructure_3:: Cell_circulator

Iterators and circulators are convertible to the corresponding handles, thus the user can pass them directly as arguments to the functions.

Creation

TriangulationDataStructure_3 tds; Default constructor.

TriangulationDataStructure_3	*tds(tds1);*	Copy constructor. All vertices and cells are duplicated.
TriangulationDataStructure_3&	*tds = tds1*	Assignment operator. All vertices and cells are duplicated, and the former data structure of *tds* is deleted.

Vertex_handle *tds.copy_tds(tds1, Vertex_handle v = Vertex_handle())*

tds1 is copied into *tds*. If *v != Vertex_handle()*, the vertex of *tds* corresponding to *v* is returned, otherwise *Vertex_handle()* is returned.
Precondition: The optional argument *v* is a vertex of *tds1*.

void	*tds.swap(& tds1)*	Swaps *tds* and *tds1*. There is no copy of cells and vertices, thus this method runs in constant time. This method should be preferred to *tds*=*tds1* or *tds*(*tds1*) when *tds1* is deleted after that.
void	*tds.clear()*	Deletes all cells and vertices. *tds* is reset as a triangulation data structure constructed by the default constructor.

Operations

Access Functions

int	*tds.dimension() const*	The dimension of the triangulated topological sphere.
size_type	*tds.number_of_vertices() const*	The number of vertices. Note that the triangulation data structure has one more vertex than an associated geometric triangulation, if there is one, since the infinite vertex is a standard vertex and is thus also counted.
size_type	*tds.number_of_cells() const*	The number of cells. Returns 0 if *tds.dimension()*<3.

Non constant-time access functions

size_type	*tds.number_of_facets() const*	The number of facets. Returns 0 if *tds.dimension()*<2.
size_type	*tds.number_of_edges() const*	The number of edges. Returns 0 if *tds.dimension()*<1.

advanced

Setting

void	*tds.set_dimension(int n)*	Sets the dimension to *n*.

advanced

Queries

bool *tds.is_vertex(Vertex_handle v) const*

Tests whether *v* is a vertex of *tds*.

bool *tds.is_edge(Cell_handle c, int i, int j) const*

Tests whether *(c,i,j)* is an edge of *tds*. Answers *false* when *dimension()* < 1 .
Precondition: $i, j \in \{0,1,2,3\}$

bool *tds.is_edge(Vertex_handle u, Vertex_handle v, Cell_handle & c, int & i, int & j) const*

Tests whether *(u,v)* is an edge of *tds*. If the edge is found, it computes a cell *c* having this edge and the indices *i* and *j* of the vertices *u* and *v*, in this order.

bool *tds.is_edge(Vertex_handle u, Vertex_handle v) const*

Tests whether *(u,v)* is an edge of *tds*.

bool *tds.is_facet(Cell_handle c, int i) const*

Tests whether *(c,i)* is a facet of *tds*. Answers *false* when *dimension()* < 2 .
Precondition: $i \in \{0,1,2,3\}$

bool *tds.is_facet(Vertex_handle u, Vertex_handle v, Vertex_handle w, Cell_handle & c, int & i, int & j, int & k) const*

Tests whether *(u,v,w)* is a facet of *tds*. If the facet is found, it computes a cell *c* having this facet and the indices *i*, *j* and *k* of the vertices *u*, *v* and *w*, in this order.

bool *tds.is_cell(Cell_handle c) const* Tests whether *c* is a cell of *tds*. Answers *false* when *dimension()* < 3 .

bool *tds.is_cell(Vertex_handle u, Vertex_handle v, Vertex_handle w, Vertex_handle t, Cell_handle & c, int & i, int & j, int & k, int & l) const*

Tests whether *(u,v,w,t)* is a cell of *tds*. If the cell *c* is found, it computes the indices *i*, *j*, *k* and *l* of the vertices *u*, *v*, *w* and *t* in *c*, in this order.

There is a method *has_vertex* in the cell class. The analogous methods for facets are defined here.

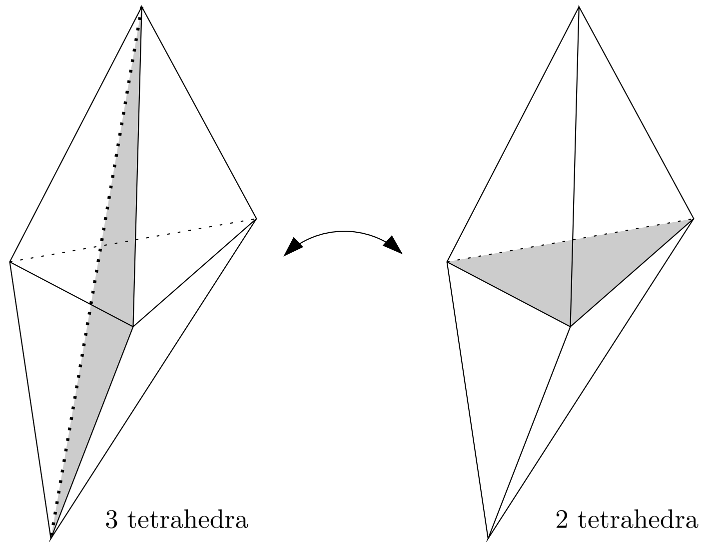

Figure 40.7: Flips.

bool *tds.has_vertex(Facet f, Vertex_handle v, int & j) const*

If v is a vertex of f, then j is the index of v in the cell *f.first*, and the method returns *true*.
Precondition: *tds*.dimension()=3

bool *tds.has_vertex(Cell_handle c, int i, Vertex_handle v, int & j) const*

Same for facet *(c,i)*. Computes the index j of v in c.

bool *tds.has_vertex(Facet f, Vertex_handle v) const*
bool *tds.has_vertex(Cell_handle c, int i, Vertex_handle v) const*

Same as the first two methods, but these two methods do not return the index of the vertex.

The following three methods test whether two facets have the same vertices.

bool *tds.are_equal(Facet f, Facet g) const*
bool *tds.are_equal(Cell_handle c, int i, Cell_handle n, int j) const*
bool *tds.are_equal(Facet f, Cell_handle n, int j) const*

For these three methods:
Precondition: *tds*.dimension()=3.

Flips

Two kinds of flips exist for a three-dimensional triangulation. They are reciprocal. To be flipped, an edge must be incident to three tetrahedra. During the flip, these three tetrahedra disappear and two tetrahedra appear. Figure 40.7(left) shows the edge that is flipped as bold dashed, and one of its three incident facets is shaded. On the right, the facet shared by the two new tetrahedra is shaded.

The following methods guarantee the validity of the resulting 3D combinatorial triangulation. Moreover the flip operations do not invalidate the vertex handles, and only invalidate the cell handles of the affected cells.

Flips for a 2d triangulation are not implemented yet

bool *tds.flip(Edge e)*
bool *tds.flip(Cell_handle c, int i, int j)*

Before flipping, these methods check that edge *e=(c,i,j)* is flippable (which is quite expensive). They return *false* or *true* according to this test.

void *tds.flip_flippable(Edge e)*
void *tds.flip_flippable(Cell_handle c, int i, int j)*

Should be preferred to the previous methods when the edge is known to be flippable.
Precondition: The edge is flippable.

bool *tds.flip(Facet f)*
bool *tds.flip(Cell_handle c, int i)*

Before flipping, these methods check that facet *f=(c,i)* is flippable (which is quite expensive). They return *false* or *true* according to this test.

void *tds.flip_flippable(Facet f)*
void *tds.flip_flippable(Cell_handle c, int i)*

Should be preferred to the previous methods when the facet is known to be flippable.
Precondition: The facet is flippable.

Insertions

The following modifier member functions guarantee the combinatorial validity of the resulting triangulation.

Vertex_handle *tds.insert_in_cell(Cell_handle c)*

Creates a new vertex, inserts it in cell c and returns its handle. The cell c is split into four new cells, each of these cells being formed by the new vertex and a facet of c.
Precondition: *tds.dimension()* $= 3$ and c is a cell of *tds*.

Vertex_handle *tds.insert_in_facet(Facet f)*

Creates a new vertex, inserts it in facet f and returns its handle. In dimension 3, the two incident cells are split into 3 new cells; in dimension 2, the facet is split into 3 facets.
Precondition: *tds.dimension()* ≥ 2 and f is a facet of *tds*.

Vertex_handle *tds.insert_in_facet(Cell_handle c, int i)*

Creates a new vertex, inserts it in facet i of c and returns its handle.
Precondition: *tds.dimension()* ≥ 2, $i \in \{0,1,2,3\}$ in dimension 3, $i = 3$ in dimension 2 and *(c,i)* is a facet of *tds*.

Vertex_handle *tds.insert_in_edge(Edge e)*

Creates a new vertex, inserts it in edge *e* and returns its handle. In dimension 3, all the incident cells are split into 2 new cells; in dimension 2, the 2 incident facets are split into 2 new facets; in dimension 1, the edge is split into 2 new edges.
Precondition: *tds.dimension()* ≥ 1 and *e* is an edge of *tds*.

Vertex_handle *tds.insert_in_edge(Cell_handle c, int i, int j)*

Creates a new vertex, inserts it in edge (i, j) of c and returns its handle.
Precondition: *tds.dimension()* ≥ 1. $i \neq j$, $i, j \in \{0,1,2,3\}$ in dimension 3, $i, j \in \{0,1,2\}$ in dimension 2, $i, j \in \{0,1\}$ in dimension 1 and *(c,i,j)* is an edge of *tds*.

Vertex_handle *tds.insert_increase_dimension(Vertex_handle star = Vertex_handle())*

Transforms a triangulation of the sphere S^d of $\mathbb{R}^{d+1}$ into the triangulation of the sphere S^{d+1} of $\mathbb{R}^{d+2}$ by adding a new vertex v: v is linked to all the vertices to triangulate one of the two half-spheres of dimension $(d+1)$. Vertex *star* is used to triangulate the second half-sphere (when there is an associated geometric triangulation, *star* is in fact the vertex associated with its infinite vertex). See Figure 40.8.
The numbering of the cells is such that, if f was a face of maximal dimension in the initial triangulation, then *(f,v)* (in this order) is the corresponding face in the new triangulation. This method can be used to insert the first two vertices in an empty triangulation.
A handle to v is returned.
Precondition: *tds.dimension()* $= d < 3$. When *tds.number_of_vertices()* > 0, $star \neq$ *Vertex_handle()* and *star* is a vertex of *tds*.

template <class CellIt>
Vertex_handle *tds.insert_in_hole(CellIt cell_begin, CellIt cell_end, Cell_handle begin, int i)*

Creates a new vertex by starring a hole. It takes an iterator range [*cell_begin*; *cell_end*[of *Cell_handles* which specifies a set of connected cells (resp. facets in dimension 2) describing a hole. (*begin*, *i*) is a facet (resp. an edge) on the boundary of the hole, that is, *begin* belongs to the set of cells (resp. facets) previously described, and *begin->neighbor(i)* does not. Then this function deletes all the cells (resp. facets) describing the hole, creates a new vertex v, and for each facet (resp. edge) on the boundary of the hole, creates a new cell (resp. facet) with v as vertex. v is returned.
Precondition: *tds.dimension()* ≥ 2, the set of cells (resp. facets) is connected, and its boundary is connected.

template <class CellIt>

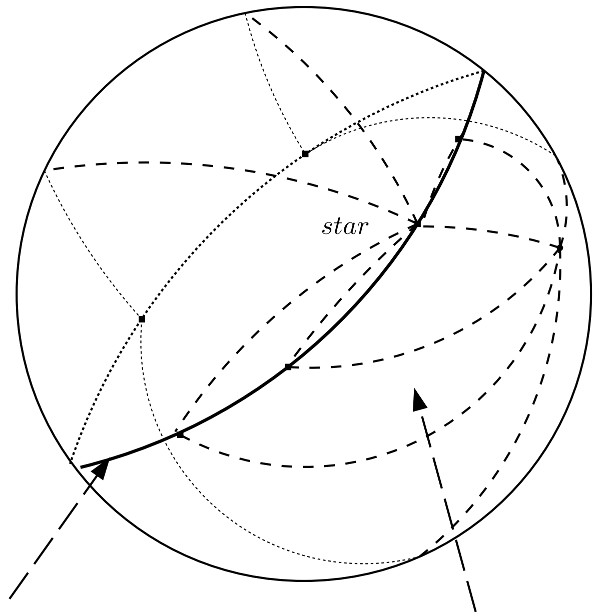

Figure 40.8: *insert_increase_dimension* (1-dimensional case).

Vertex_handle *tds.insert_in_hole(CellIt cell_begin,*
CellIt cell_end,
Cell_handle begin,
int i,
Vertex_handle newv)

Same as above, except that *newv* will be used as the new vertex, which must have been allocated previously with e.g. *create_vertex*.

Removal

void *tds.remove_decrease_dimension(Vertex_handle v, Vertex_handle w = v)*

This operation is the reciprocal of *insert_increase_dimension()*. It transforms a triangulation of the sphere S^d of $\mathbb{R}^{d+1}$ into the triangulation of the sphere S^{d-1} of $\mathbb{R}^d$ by removing the vertex v. Delete the cells incident to w, keep the others.
Precondition: *tds.dimension()* $= d \geq -1$. *tds.degree(v)* = *degree(w)* = *tds.number_of_vertices()* -1.

Cell_handle *tds.remove_from_maximal_dimension_simplex(Vertex_handle v)*

Removes *v*. The incident simplices of maximal dimension incident to *v* are replaced by a single simplex of the same dimension. This operation is exactly the reciprocal to *tds.insert_in_cell(v)* in dimension 3, *tds.insert_in_facet(v)* in dimension 2, and *tds.insert_in_edge(v)* in dimension 1.
Precondition: *tds.degree(v) = tds.dimension()+1*.

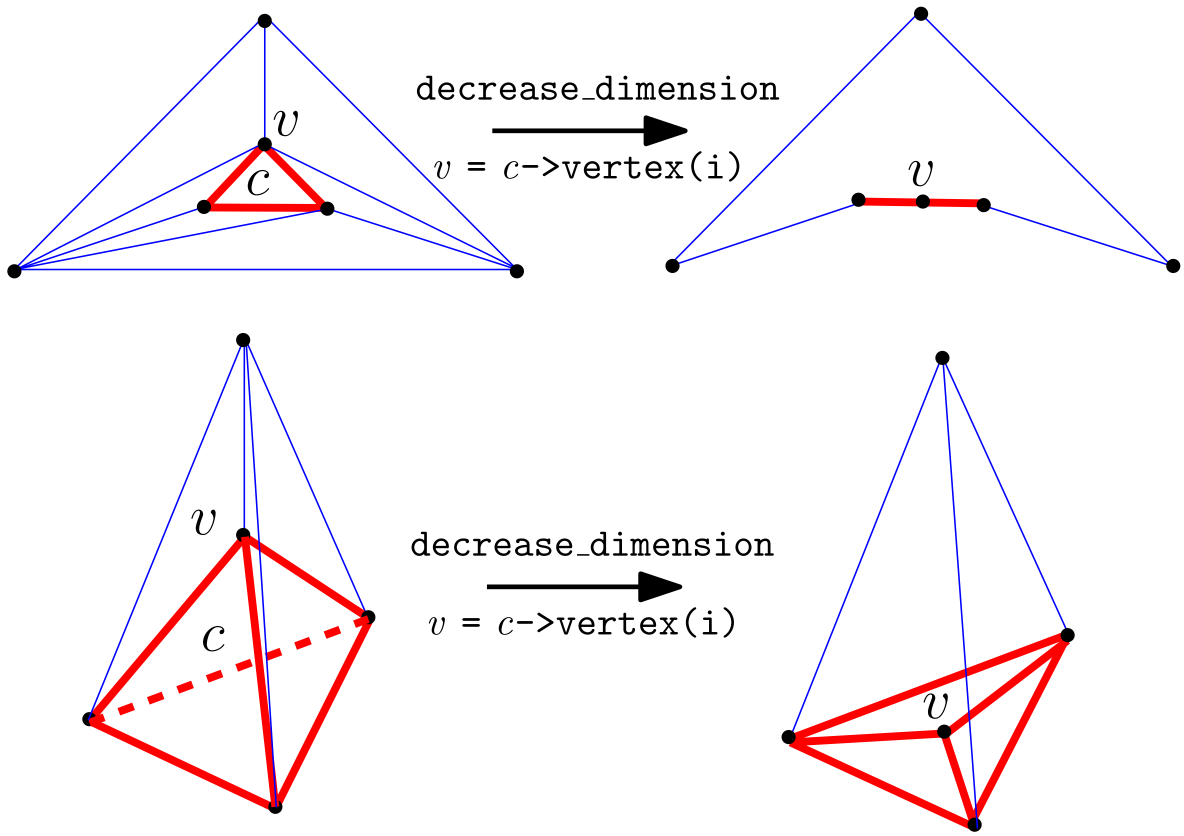

Figure 40.9: From an S^d data structure to an S^{d-1} data structure (top: $d == 2$, bottom: $d == 3$).

Dimension Manipulation

The following operation, `decrease_dimension`, is necessary when the displacement of a vertex decreases the dimension of the triangulation.

void *tds.decrease_dimension(Cell_handle c, int i)*

The link of a vertex v is formed by the facets disjoint from v that are included in the cells incident to v. When the link of v = *c->vertex(i)* contains all the other vertices, *decrease_dimension* crushes the triangulation of the sphere S^d of $\mathbb{R}^{d+1}$ onto the triangulation of the sphere S^{d-1} of $\mathbb{R}^d$ formed by the link of v augmented with the vertex v itself, for d==2,3; this one is placed on the facet *(c, i)* (see Fig. 40.9).
Precondition: The dimension must be 2 or 3. The degree of v must be equal to the total number of vertices of the triangulation data structure minus 1.

advanced

Other modifiers

The following modifiers can affect the validity of the triangulation data structure.

void	*tds.reorient()*	Changes the orientation of all cells of the triangulation data structure. *Precondition*: *tds.dimension()* ≥ 1.

Vertex_handle *tds.create_vertex(Vertex v = Vertex())*

Adds a copy of the vertex *v* to the triangulation data structure.

Vertex_handle *tds.create_vertex(Vertex_handle v)*

Creates a vertex which is a copy of the one pointed to by *v* and adds it to the triangulation data structure.

Cell_handle *tds.create_cell(Cell c = Cell())*

Adds a copy of the cell *c* to the triangulation data structure.

Cell_handle *tds.create_cell(Cell_handle c)*

Creates a cell which is a copy of the one pointed to by *c* and adds it to the triangulation data structure.

Cell_handle *tds.create_cell(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)*

Creates a cell and adds it into the triangulation data structure. Initializes the vertices of the cell, its neighbor handles being initialized with the default constructed handle.

Cell_handle *tds.create_cell(Vertex_handle v0,*
Vertex_handle v1,
Vertex_handle v2,
Vertex_handle v3,
Cell_handle n0,
Cell_handle n1,
Cell_handle n2,
Cell_handle n3)

Creates a cell, initializes its vertices and neighbors, and adds it into the triangulation data structure.

void *tds.delete_vertex(Vertex_handle v)*

Removes the vertex from the triangulation data structure.
Precondition: The vertex is a vertex of *tds*.

void *tds.delete_cell(Cell_handle c)*

Removes the cell from the triangulation data structure.
Precondition: The cell is a cell of *tds*.

template <class VertexIt>
void *tds.delete_vertices(VertexIt first, VertexIt last)*

Calls *delete_vertex* over an iterator range of value type *Vertex_handle*.

template <class CellIt>
void *tds.delete_cells(CellIt first, CellIt last)*

Calls *delete_cell* over an iterator range of value type *Cell_handle*.

advanced

Traversing the triangulation

Cell_iterator *tds.cells_begin() const*

Returns *cells_end()* when *tds.dimension()* < 3.

Cell_iterator *tds.cells_end() const*
Cell_iterator *tds.raw_cells_begin() const*

Low-level access to the cells, does not return *cells_end()* when *tds.dimension()* < 3.

Cell_iterator *tds.raw_cells_end() const*
Facet_iterator *tds.facets_begin() const*

Returns *facets_end()* when *tds.dimension()* < 2.

Facet_iterator *tds.facets_end() const*
Edge_iterator *tds.edges_begin() const*

Returns *edges_end()* when *tds.dimension()* < 1.

Edge_iterator *tds.edges_end() const*
Vertex_iterator *tds.vertices_begin() const*
Vertex_iterator *tds.vertices_end() const*

Cell and facet circulators

Cell_circulator *tds.incident_cells(Edge e) const* Starts at an arbitrary cell incident to *e*.
Precondition: *tds.dimension()* $= 3$

Cell_circulator *tds.incident_cells(Cell_handle c, int i, int j) const*

As above for edge *(i,j)* of *c*.

Cell_circulator *tds.incident_cells(Edge e, Cell_handle start) const*

Starts at cell *start*.
Precondition: *tds.dimension()* $= 3$ and *start* is incident to *e*.

Cell_circulator *tds.incident_cells(Cell_handle c, int i, int j, Cell_handle start) const*

As above for edge *(i,j)* of *c*.

The following circulators on facets are defined only in dimension 3, though facets are defined also in dimension 2: there are only two facets sharing an edge in dimension 2.

Facet_circulator *tds.incident_facets(Edge e) const*

Starts at an arbitrary facet incident to *e*.
Precondition: *tds.dimension()* $= 3$

Facet_circulator *tds.incident_facets(Cell_handle c, int i, int j) const*

As above for edge *(i,j)* of *c*.

Facet_circulator *tds.incident_facets(Edge e, Facet start) const*

Starts at facet *start*.
Precondition: *start* is incident to *e*.

Facet_circulator *tds.incident_facets(Edge e, Cell_handle start, int f) const*

Starts at facet of index *f* in *start*.

Facet_circulator *tds.incident_facets(Cell_handle c, int i, int j, Facet start) const*

As above for edge *(i,j)* of *c*.

Facet_circulator *tds.incident_facets(Cell_handle c, int i, int j, Cell_handle start, int f) const*

As above for edge *(i,j)* of *c* and facet *(start,f)*.

Traversal of the incident cells, facets and edges, and the adjacent vertices of a given vertex

template <class OutputIterator>
OutputIterator *tds.incident_cells(Vertex_handle v, OutputIterator cells) const*

Copies the *Cell_handle*s of all cells incident to *v* to the output iterator *cells*. Returns the resulting output iterator.
Precondition: *tds.dimension()* $= 3$, $v \neq$ *Vertex_handle()*, *tds.is_vertex(v)*.

template <class OutputIterator>
OutputIterator *tds.incident_facets(Vertex_handle v, OutputIterator facets) const*

Copies the *Facet*s incident to *v* to the output iterator *facets*. Returns the resulting output iterator.
Precondition: *tds.dimension()* > 1, $v \neq$ *Vertex_handle()*, *tds.is_vertex(v)*.

template <class OutputIterator>
OutputIterator *tds.incident_edges(Vertex_handle v, OutputIterator edges) const*

Copies all *Edge*s incident to *v* to the output iterator *edges*. Returns the resulting output iterator.
Precondition: *tds.dimension()* > 0, $v \neq$ *Vertex_handle()*, *tds.is_vertex(v)*.

template <class OutputIterator>

OutputIterator *tds.adjacent_vertices(Vertex_handle v, OutputIterator vertices) const*

Copies the *Vertex_handle*s of all vertices adjacent to v to the output iterator *vertices*. If *tds.dimension()* < 0, then do nothing. Returns the resulting output iterator.
Precondition: $v \neq$ *Vertex_handle()*, *tds.is_vertex(v)*.

size_type *tds.degree(Vertex_handle v) const*

Returns the degree of a vertex, that is, the number of incident vertices.
Precondition: $v \neq$ *Vertex_handle()*, *tds.is_vertex(v)*.

Traversal between adjacent cells

int *tds.mirror_index(Cell_handle c, int i) const*

Returns the index of c in its i^{th} neighbor.
Precondition: $i \in \{0,1,2,3\}$.

Vertex_handle *tds.mirror_vertex(Cell_handle c, int i) const*

Returns the vertex of the i^{th} neighbor of c that is opposite to c.
Precondition: $i \in \{0,1,2,3\}$.

Facet *tds.mirror_facet(Facet f) const* Returns the same facet seen from the other adjacent cell.

debugging support

Checking

bool *tds.is_valid(bool verbose = false) const*

Checks the combinatorial validity of the triangulation by checking the local validity of all its cells and vertices (see functions below). (See Section 40.1.) Moreover, the Euler relation is tested.
When *verbose* is set to *true*, messages are printed to give a precise indication on the kind of invalidity encountered.

bool *tds.is_valid(Vertex_handle v, bool verbose = false) const*

Checks the local validity of the adjacency relations of the triangulation. It also calls the *is_valid* member function of the vertex. When *verbose* is set to *true*, messages are printed to give a precise indication on the kind of invalidity encountered.

bool *tds.is_valid(Cell_handle c, bool verbose = false) const*

Checks the local validity of the adjacency relations of the triangulation. It also calls the *is_valid* member function of the cell. When *verbose* is set to *true*, messages are printed to give a precise indication on the kind of invalidity encountered.

debugging support

I/O

istream& *istream& is >> & tds* Reads a combinatorial triangulation from *is* and assigns it to *tds*

ostream& *ostream& os << tds* Writes *tds* into the stream *os*

The information stored in the *iostream* is: the dimension, the number of vertices, the number of cells, the indices of the vertices of each cell, then the indices of the neighbors of each cell, where the index corresponds to the preceding list of cells. When dimension < 3, the same information is stored for faces of maximal dimension instead of cells.

See Also

TriangulationDataStructure_3::Vertex
TriangulationDataStructure_3::Cell

Concept

TriangulationDataStructure_3::Cell

Definition

The concept Cell stores four *Vertex_handle*s to its four vertices and four *Cell_handle*s to its four neighbors. The vertices are indexed 0, 1, 2, and 3 in consistent order. The neighbor indexed i lies opposite to vertex i.

In degenerate dimensions, cells are used to store faces of maximal dimension: in dimension 2, each cell represents only one facet of index 3, and 3 edges $(0,1)$, $(1,2)$ and $(2,0)$; in dimension 1, each cell represents one edge $(0,1)$. (See also Section 40.1.)

Types

The class Cell defines the following types.

typedef TriangulationDataStructure_3	*Triangulation_data_structure;*
typedef TriangulationDataStructure_3::Vertex_handle	*Vertex_handle;*
typedef TriangulationDataStructure_3::Cell_handle	*Cell_handle;*

Creation

In order to obtain new cells or destruct unused cells, the user must call the *create_cell()* and *delete_cell()* methods of the triangulation data structure.

Operations

Access Functions

Vertex_handle	*c.vertex(int i) const*	Returns the vertex i of c. *Precondition*: $i \in \{0,1,2,3\}$.
int	*c.index(Vertex_handle v) const*	Returns the index of vertex v in c. *Precondition*: v is a vertex of c.
bool	*c.has_vertex(Vertex_handle v) const*	Returns *true* if v is a vertex of c.
bool	*c.has_vertex(Vertex_handle v, int & i) const*	Returns *true* if v is a vertex of c, and computes its index i in c.
Cell_handle	*c.neighbor(int i) const*	Returns the neighbor i of c. *Precondition*: $i \in \{0,1,2,3\}$.
int	*c.index(Cell_handle n) const*	Returns the index corresponding to neighboring cell n. *Precondition*: n is a neighbor of c.
bool	*c.has_neighbor(Cell_handle n) const*	Returns *true* if n is a neighbor of c.

bool	*c.has_neighbor(Cell_handle n, int & i) const*	
		Returns *true* if *n* is a neighbor of *c*, and computes its index *i* in *c*.

Setting

void	*c.set_vertex(int i, Vertex_handle v)*	Sets vertex *i* to *v*. *Precondition*: $i \in \{0,1,2,3\}$.
void	*c.set_vertices(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)*	
		Sets the vertex pointers.
void	*c.set_neighbor(int i, Cell_handle n)*	Sets neighbor *i* to *n*. *Precondition*: $i \in \{0,1,2,3\}$.
void	*c.set_neighbors(Cell_handle n0, Cell_handle n1, Cell_handle n2, Cell_handle n3)*	
		Sets the neighbors pointers.

debugging support

Checking

bool	*c.is_valid(bool verbose = false, int level = 0) const*	
	User defined local validity checking function.	

debugging support

TriangulationDataStructure_3::Vertex.

Concept

TriangulationDataStructure_3::Vertex

Definition

The concept Vertex represents the vertex class of a 3D-triangulation data structure. It must define the types and operations listed in this section. Some of these requirements are of geometric nature, they are *optional* when using the triangulation data structure class alone. They become compulsory when the triangulation data structure is used as a layer for the geometric triangulation class. (See Section 40.2.)

Types

Vertex:: Point	*Optional for the triangulation data structure alone.*

The class Vertex defines types that are the same as some of the types defined by the triangulation data structure class *TriangulationDataStructure_3*.

typedef TriangulationDataStructure_3	*Triangulation_data_structure;*
typedef TriangulationDataStructure_3::Vertex_handle	*Vertex_handle;*
typedef TriangulationDataStructure_3::Cell_handle	*Cell_handle;*

Creation

In order to obtain new vertices or destruct unused vertices, the user must call the *create_vertex()* and *delete_vertex()* methods of the triangulation data structure.

Operations

Access Functions

Cell_handle	*v.cell() const*	Returns a cell of the triangulation having *v* as vertex.
Point	*v.point() const*	Returns the point stored in the vertex. *Optional for the triangulation data structure alone.*

Setting

void	*v.set_cell(Cell_handle c)*	Sets the incident cell to *c*.
void	*v.set_point(Point p)*	Sets the point to *p*. *Optional for the triangulation data structure alone.*

debugging support

Checking

bool *v.is_valid(bool verbose = false) const*

Checks the validity of the vertex. Must check that its incident cell has this vertex. The validity of the base vertex is also checked.
When *verbose* is set to *true*, messages are printed to give a precise indication on the kind of invalidity encountered.

debugging support

TriangulationDataStructure_3::Cell.

TriangulationDSCellBase_3

Definition

At the base level (see Sections 39.4 and 40.2), a cell stores handles to its four vertices and to its four neighbor cells. The vertices and neighbors are indexed 0, 1, 2 and 3. Neighbor *i* lies opposite to vertex *i*.

Since the Triangulation data structure is the class which defines the handle types, the cell base class has to be somehow parameterized by the Triangulation data structure. But since it is itself parameterized by the cell and vertex base classes, there is a cycle in the definition of these classes. In order to break the cycle, the base classes for vertex and cell which are given as arguments for the Triangulation data structure use *void* as Triangulation data structure parameter, and the Triangulation data structure then uses a *rebind*-like mechanism (similar to the one specified in *std::allocator*) in order to put itself as parameter to the vertex and cell classes. The *rebound* base classes so obtained are the classes which are used as base classes for the final vertex and cell classes. More information can be found in Section 40.2.

Types

The concept TriangulationDSCellBase_3 has to provide the following types.

TriangulationDSCellBase_3:: template <typename TDS2> struct Rebind_TDS

This nested template class has to define a type *Other* which is the *rebound* cell, that is, the one whose *Triangulation_data_structure* will be the actually used one. The *Other* type will be the real base class of *Triangulation_data_structure_3::Cell*.

typedef TriangulationDataStructure_3	*Triangulation_data_structure;*
typedef TriangulationDataStructure_3::Vertex_handle	*Vertex_handle;*
typedef TriangulationDataStructure_3::Cell_handle	*Cell_handle;*
typedef TriangulationDataStructure_3::Cell_data	*TDS_data;*

Creation

TriangulationDSCellBase_3 c;

Default constructor

TriangulationDSCellBase_3 c(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3);

Initializes the vertices with *v0, v1, v2, v3*. Neighbors are initialized to the default constructed handle.

TriangulationDSCellBase_3 c(Vertex_handle v0,
Vertex_handle v1,
Vertex_handle v2,
Vertex_handle v3,
Cell_handle n0,
Cell_handle n1,
Cell_handle n2,

Cell_handle n3)

Initializes the vertices with *v0, v1, v2, v3* and the neighbors with *n0, n1, n2, n3*.

Access Functions

Vertex_handle	*c.vertex(int i) const*	Returns the vertex i of c. *Precondition*: $i \in \{0,1,2,3\}$.
int	*c.index(Vertex_handle v) const*	Returns the index of v. *Precondition*: v is a vertex of c
bool	*c.has_vertex(Vertex_handle v)*	True iff v is a vertex of c.
bool	*c.has_vertex(Vertex_handle v, int & i) const*	Returns *true* if v is a vertex of c, and computes its index i in c.
Cell_handle	*c.neighbor(int i) const*	Returns the neighbor i of c. *Precondition*: $i \in \{0,1,2,3\}$.
int	*c.index(Cell_handle n) const*	Returns the index of cell n in c. *Precondition*: n is a neighbor of c.
bool	*c.has_neighbor(Cell_handle n)*	Returns *true* if n is a neighbor of c.
bool	*c.has_neighbor(Cell_handle n, int & i) const*	Returns *true* if n is a neighbor of c, and computes its index i in c.

Setting

void	*c.set_vertex(int i, Vertex_handle v)*	Sets vertex i to v. *Precondition*: $i \in \{0,1,2,3\}$.
void	*c.set_vertices()*	Sets the vertices to the default constructed handle.
void	*c.set_vertices(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)*	Sets the vertices.
void	*c.set_neighbor(int i, Cell_handle n)*	Sets neighbor i to n. *Precondition*: $i \in \{0,1,2,3\}$.
void	*c.set_neighbors()*	Sets the neighbors to the default constructed handle.
void	*c.set_neighbors(Cell_handle n0, Cell_handle n1, Cell_handle n2, Cell_handle n3)*	Sets the neighbors.

debugging support

Checking

bool *c.is_valid(bool verbose = false, int level = 0) const*

Performs any desired geometric test on a cell. When *verbose* is set to *true*, messages are printed to give a precise indication of the kind of invalidity encountered. *level* increases the level of testing.

debugging support

advanced

Various

*void** *c.for_compact_container() const*
void&* *c.for_compact_container()*

These member functions are required by *Triangulation_data_structure_3* because it uses *Compact_container* to store its cells. See the documentation of *Compact_container* for the exact requirements.

TDS_data& *c.tds_data()*
TDS_data *c.tds_data() const*

These functions are used internally by the triangulation data structure. The user is not encouraged to use them directly as they may change in the future.

advanced

TriangulationDSVertexBase_3

Definition

At the bottom level of 3D-triangulations (see Sections 39.4 and 40.2), a vertex provides access to one of its incident cells through a handle.

Note that when you use the triangulation data structure as parameter of a geometric triangulation, the vertex base class has additional geometric requirements : it has to match the *TriangulationVertexBase_3* concept.

Since the Triangulation data structure is the class which defines the handle types, the vertex base class has to be somehow parameterized by the Triangulation data structure. But since it is itself parameterized by the cell and vertex base classes, there is a cycle in the definition of these classes. In order to break the cycle, the base classes for vertex and cell which are given as arguments for the Triangulation data structure use *void* as Triangulation data structure parameter, and the Triangulation data structure then uses a *rebind*-like mechanism (similar to the one specified in *std::allocator*) in order to put itself as parameter to the vertex and cell classes. The *rebound* base classes so obtained are the classes which are used as base classes for the final vertex and cell classes. More information can be found in Section 40.2.

Types

The class TriangulationDSVertexBase_3 has to define the following types.

TriangulationDSVertexBase_3:: template <typename TDS2> struct Rebind_TDS

This nested template class has to define a type *Other* which is the *rebound* vertex, that is, the one whose *Triangulation_data_structure* will be the actually used one. The *Other* type will be the real base class of *Triangulation_data_structure_3::Vertex*.

typedef TriangulationDataStructure_3	*Triangulation_data_structure;*
typedef TriangulationDataStructure_3::Vertex_handle	*Vertex_handle;*
typedef TriangulationDataStructure_3::Cell_handle	*Cell_handle;*

Creation

TriangulationDSVertexBase_3 v;	Default constructor.
TriangulationDSVertexBase_3 v(Cell_handle c);	Constructs a vertex pointing to cell *c*.

Operations

Access Functions

Cell_handle	*v.cell() const*	Returns the pointer to an incident cell

Setting

void	*v.set_cell(Cell_handle c)*	Sets the incident cell.

debugging support

Checking

bool *v.is_valid(bool verbose=false, int level=0) const*

Performs any desired test on a vertex. Checks that the pointer to an incident cell is not the default constructed handle.

debugging support

Various

*void** *v.for_compact_container() const*
void&* *v.for_compact_container()*

These member functions are required by *Triangulation_data_structure_3* because it uses *Compact_container* to store its cells. See the documentation of *Compact_container* for the exact requirements.

I/O

istream&	*istream& is >> & v*	Inputs the non-combinatorial information given by the vertex.
ostream&	*ostream& os << v*	Outputs the non-combinatorial information given by the vertex.

CGAL::Triangulation_data_structure_3<TriangulationDSVertexBase_3,TriangulationDSCellBase_3>

Class

Definition

The class *Triangulation_data_structure_3* stores a 3D-triangulation data structure and provides the optional geometric functionalities to be used as a parameter for a 3D-geometric triangulation (see Chapter 39).

The vertices and cells are stored in two nested containers, which are implemented using *CGAL::Compact_container*. The class may offer some flexibility for the choice of container in the future, in the form of additional template parameters.

#include <CGAL/Triangulation_data_structure_3.h>

Parameters

It is parameterized by base classes for vertices and cells which have to match the requirements for the concepts *TriangulationDSCellBase_3* and *TriangulationDSVertexBase_3* respectively (see page 2734 and page 2737).

They have the default values *Triangulation_ds_vertex_base_3<>* and *Triangulation_ds_cell_base_3<>* respectively.

TriangulationDataStructure_3

Inherits From

CGAL::Triangulation_utils_3

The class *Triangulation_utils_3* defines basic computations on indices of vertices and neighbors of cells.

advanced

In addition to the interface documented in the concept, the class offers the following types and functions.

Types

typedef CGAL::Compact_container<Vertex>

Vertex_range; Vertex container type.

typedef CGAL::Compact_container<Cell>

Cell_range; Cell container type.

Operations

Cell_range&	*tds.cells() const*	Returns a reference to the container of cells.
Cell_range&	*tds.cells()*	Returns a reference to the container of cells.
Vertex_range&	*tds.vertices() const*	Returns a reference to the container of vertices.
Vertex_range&	*tds.vertices()*	Returns a reference to the container of vertices.

CGAL::Triangulation_utils_3

Definition

The class *Triangulation_utils_3* defines operations on the indices of vertices and neighbors within a cell.

#include <CGAL/Triangulation_utils_3.h>

Operations

unsigned int *next_around_edge(unsigned int i, unsigned int j) const*

In dimension 3, index of the neighbor *n* that is next to the current cell, when turning positively around an oriented edge whose endpoints are indexed *i* and *j*. According to the usual numbering of vertices and neighbors in a given cell, it is also the index of the vertex opposite to this neighbor *n*. (see Figure 40.10).
Precondition: *(i < 4)* `&&` *(j < 4)* `&&` *(i != j)*.

unsigned int *ccw(unsigned int i) const*

Has a meaning only in dimension 2.
Computes the index of the vertex that is next to the vertex numbered *i* in counterclockwise direction. (see Figure 40.10).
Precondition: *i<3*.

unsigned int *cw(unsigned int i) const*

Same for clockwise.

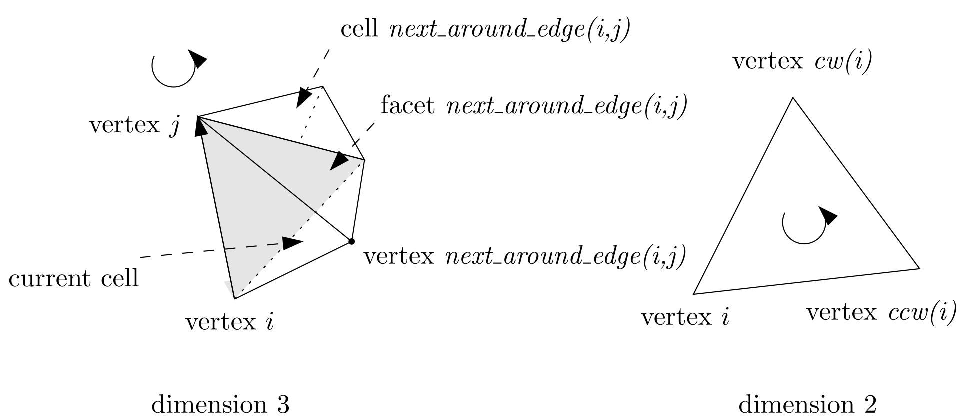

Figure 40.10: Operations on indices.

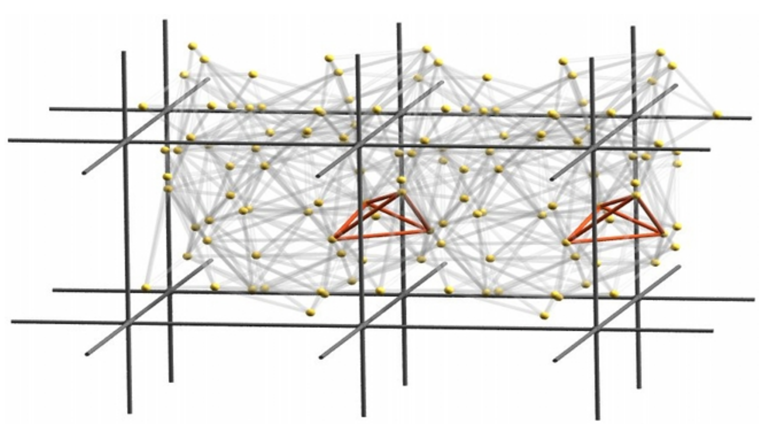
Chapter 41

3D Periodic Triangulations

Manuel Caroli and Monique Teillaud

Contents



The periodic 3D-triangulation class of CGAL is designed to represent the triangulations of a set of points in the three-dimensional flat torus. The triangulation forms a partition of the space it is computed in. It is a simplicial complex, i.e. it contains all incident j-simplices ($j < k$) of any k-simplex and two k-simplices either do not intersect or share a common j-face, $j < k$. The occurring simplices of dimension up to three are called *vertex*, *edge*, *facet*, and *cell*, respectively.

41.1 The Flat Torus

The 3D Periodic Triangulation package computes triangulations in the space $\mathbb{T}_c^3$, which is defined as follows: Let $c \in \mathbb{R} \setminus \{0\}$ and G be the group $(c \cdot \mathbb{Z}^3, +)$, where $c \cdot \mathbb{Z}$ denotes the set containing all integer multiples of c. The flat torus is the quotient space: $\mathbb{T}_c^3 := \mathbb{R}^3/G$. The parameter c defines the period.

The elements of $\mathbb{T}_c^3$ are the equivalence classes of sets of points in $\mathbb{R}^3$. We call these points *representatives* of an element of $\mathbb{T}_c^3$. The implementation works not directly on elements of $\mathbb{T}_c^3$ but on some representatives in $\mathbb{R}^3$. So there need to be distinguished representatives to work on. Given α, β, and γ, the cube $[\alpha, \alpha + c) \times [\beta, \beta + c) \times [\gamma, \gamma + c)$ contains exactly one representative of each element in $\mathbb{T}_c^3$. We call it *original domain*. From now on, when we talk about *points*, we generally mean representatives of elements of $\mathbb{T}_c^3$ that lie inside the original domain. Note that any input point is required to be an element of the half-open cube representing the original domain as defined above.

There are simplices containing points inside the original domain but also points outside it. The points outside the original domain are periodic copies of points inside the original domain. So, to specify a simplex we need points together with some additional information that determines the respective periodic copy of each point. The set of representatives of an element of $\mathbb{T}_c^3$ is a cubic point grid. We address each representative by a three-dimensional integer vector (o_x, o_y, o_z), called *offset*. It represents the number of periods a representative in the original domain must be translated in x-, y-, and z-direction. The vector $(0,0,0)$ corresponds to the representative in the original domain. To specify a k-simplex we need $k+1$ point-offset pairs (cf. Fig. 41.1).

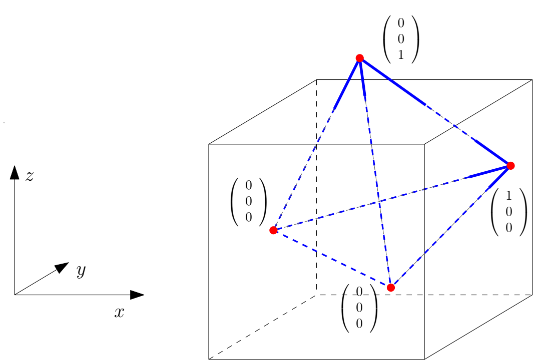


Figure 41.1: Offsets in a cell.

41.2 Representation

A triangulation is a collection of vertices and cells that are linked together through incidence and adjacency relations. Each cell gives access to its four incident vertices, their corresponding offsets, and to its four adjacent cells. Each vertex gives access to one of its incident cells.

The four vertices of a cell are indexed with 0, 1, 2 and 3 in positive orientation. The orientation of a simplex in

$\mathbb{T}_c^3$ is defined as the orientation of the corresponding simplex in $\mathbb{R}^3$ given by representatives determined by the respective offsets (see Figure 41.2).

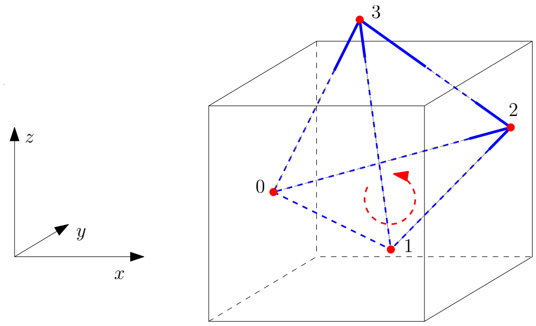

Figure 41.2: Orientation of a cell.

As in the underlying combinatorial triangulation (see Chapter 40), the neighbors of a cell are indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. Also edges (1-faces) and facets (2-faces) are not explicitly represented: a facet is given by a cell and an index (the facet i of a cell c is the facet of c that is opposite to the vertex with index i) and an edge is given by a cell and two indices (the edge *(i,j)* of a cell c is the edge whose endpoints are the vertices of c with indices i and j). See Figure 40.1.

Some point sets do not admit a triangulation in $\mathbb{T}_c^3$. In this case we use 27 periodic copies of the point set arranged in a cube of edge length $3c$. Any point set constructed in this way has a triangulation in $\mathbb{R}^3/G'$ with $G' = ((3c \cdot \mathbb{Z})^3, +)$ [CT09]. So we compute the triangulation in this space, which is a *27-sheeted covering space* of $\mathbb{T}_c^3$ (see Figure 41.3).

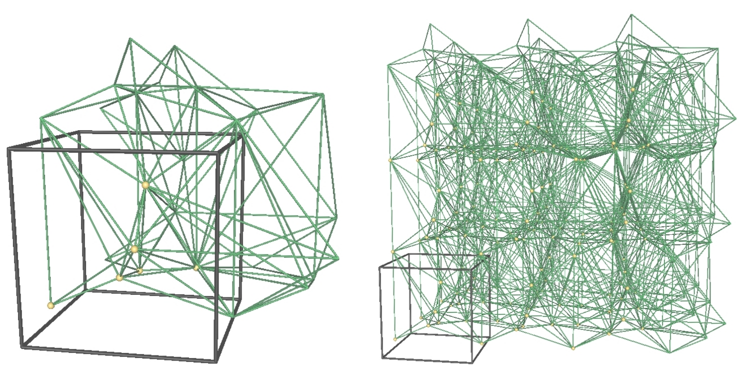

Figure 41.3: The same periodic triangulation in the 1-sheeted covering space and the 27-sheeted covering space.

The machinery that manages the copies is largely hidden from the user. However there are some effects that cannot be ignored. For example if the point set does not permit a triangulation in $\mathbb{T}_c^3$ then the combinatorial iterators (*Cell_iterator*, *Facet_iterator*, *Edge_iterator*, and *Vertex_iterator*) return all simplices that are internally stored, which correspond to 27 periodic copies of each geometric primitive (Tetrahedron, Triangle, Segment, and Point). This is necessary to ensure consistency in the adjacency relations. In case it is desired to have only one periodic copy of each primitive, we provide *geometric* iterators. They return geometric primitives of the triangulation without relations between them. Another effect is that when the algorithm switches from the 27-sheeted covering space to the 1-sheeted covering space, the *Vertex_handle*s and *Cell_handle*s referencing deleted items become invalid.

In the data structure each vertex stores the input point it corresponds to. If we are computing in the 27-sheeted covering space, each vertex stores the representative *inside* the original domain it corresponds to. So, the 27 vertices corresponding to the same element of $\mathbb{T}_c^3$ all store the same representative in $\mathbb{R}^3$, and not different periodic copies.

Validity A periodic triangulation is said to be *locally valid* iff

(a)-(b) Its underlying combinatorial graph, the triangulation data structure, is *locally valid* (see Section 40.1 of Chapter 40)
(c) Any cell has its vertices ordered according to positive orientation. See Figure 41.2.

41.3 Delaunay Triangulation

The class *Periodic_3_Delaunay_triangulation_3* implements Delaunay triangulations of point sets in $\mathbb{T}_c^3$.

Delaunay triangulations have the *empty sphere property*, that is, the circumscribing sphere of each cell does not contain any other vertex of the triangulation in its interior. These triangulations are uniquely defined except in degenerate cases where five points are co-spherical. Note however that the CGAL implementation computes a unique triangulation even in these cases [DT03].

This implementation is fully dynamic: it supports both insertions of points and vertex removal.

41.4 Triangulation Hierarchy

The class *Periodic_3_triangulation_hierarchy_3* is the adaptation of the hierarchical structure described in chapter 39 to the periodic case.

41.5 Software Design

We have chosen the prefix "Periodic_3" to emphasize that the triangulation is periodic in all three directions of space. There are also "cylindrical" periodicities where the triangulation is periodic only in one or two directions of space.

The two main classes *Periodic_3_Delaunay_triangulation_3* and *Periodic_3_triangulation_3* provide high-level geometric functionality and are responsible for the geometric validity. *Periodic_3_Delaunay_triangulation_3* contains all the functionality that is special to Delaunay triangulations, such as point insertion and vertex removal, the side-of-sphere test, finding the conflicting region of a given point, dual functions etc. *Periodic_3_triangulation_3* contains all the functionality that is common to triangulations in general, such as location of a point in the triangulation [DPT02], access functions, geometric queries like the orientation test etc.

They are built as layers on top of a triangulation data structure, which stores their combinatorial structure. This separation between the geometry and the combinatorics is reflected in the software design by the fact that the triangulation classes take two template parameters:

- the **geometric traits** class, which provides the type of points to use as well as the elementary operations on them (predicates and constructions). Furthermore it contains the offset type. The concept for this parameter is described in more detail in Section 41.5.1 and as the concept *Periodic_3DelaunayTriangulationTraits_3* in the reference manual on page 2783.

- the **triangulation data structure** class, which stores the combinatorial structure, described in Section 41.5.2 and in more detail in Chapter 40. The triangulation data structure needs models of the concepts *Periodic_3TriangulationDSCellBase_3* and *Periodic_3TriangulationDSVertexBase_3* as template parameters.

41.5.1 The Geometric Traits Parameter

The first template parameter of the Delaunay triangulation class *Periodic_3_Delaunay_triangulation_3< Periodic_3DelaunayTriangulationTraits_3, TriangulationDataStructure_3>* is the geometric traits class, described by the concept *Periodic_3DelaunayTriangulationTraits_3*. It is different to the DelaunayTriangulationTraits_3 (see chapter 39.4.1) in that it implements all objects, predicates and constructions with using offsets.

The class *Periodic_3_triangulation_traits_3<Traits,Periodic_3Offset_3>* provides the required functionality. It expects two template parameters: A model of the concept *DelaunayTriangulationTraits_3* and a model of the concept *Periodic_3Offset_3*.

The kernels *Cartesian*, *Homogeneous*, *Simple_cartesian*, *Simple_homogeneous* and *Filtered_kernel* can all be used as models for *Traits*. *Periodic_3_triangulation_traits_3* provides exact predicates and exact constructions if *Traits* does. It provides exact predicates but not exact constructions if *Filtered_kernel<CK>* with *CK* an inexact kernel is used as its first template parameter. Using *Exact_predicates_inexact_constructions_kernel* (page **??**) as *Traits* provides fast and exact predicates and not exact constructions, using *Exact_predicates_exact_constructions_kernel* (page **??**) provides fast and exact predicates and exact constructions. The latter is recommended if the dual constructions and constructions of points, segments, triangles, and tetrahedra are used.

The second parameter *Periodic_3Offset_3* defaults to *Periodic_3_offset_3*.

41.5.2 The Triangulation Data Structure Parameter

The second template parameter of the main classes *Periodic_3_triangulation_3* and *Periodic_3_Delaunay_triangulation_3* is a triangulation data structure class. This class can be seen as a container for the cells and vertices maintaining incidence and adjacency relations (see Chapter 40). A model of this triangulation data structure is *Triangulation_data_structure_3*, and it is described by the *TriangulationDataStructure_3* concept. This model is itself parameterized by a vertex base class and a cell base class, which gives the possibility to customize the vertices and cells used by the triangulation data structure, and hence by the geometric triangulation using it. To represent periodic triangulations the cell base and vertex base classes need to meet the concepts *Periodic_3TriangulationDSCellBase_3* and *Periodic_3TriangulationDSVertexBase_3*.

A default value for the triangulation data structure parameter is provided in all the triangulation classes, so it does not need to be specified by the user unless he wants to use a different triangulation data structure or a different vertex or cell base class.

41.5.3 Flexibility of the Design

Periodic_3_triangulation_3 uses the *TriangulationDataStructure_3* in essentially the same way as *Triangulation_3*. That is why the flexibility described in 39.4 is applicable in exactly the same way. Also the classes *Triangulation_vertex_base_with_info_3* and *Triangulation_cell_base_with_info_3* can be reused directly, see also Example 41.6.2.

41.6 Examples

41.6.1 Basic Example

This example shows the incremental construction of a 3D Delaunay triangulation, the location of a point and how to perform elementary operations on indices in a cell. It uses the default parameter of the *Periodic_3_Delaunay_triangulation_3* class for the triangulation data structure.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Periodic_3_triangulation_traits_3.h>
#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>

#include <iostream>
#include <fstream>
#include <cassert>
#include <list>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Periodic_3_triangulation_traits_3<K> GT;

typedef CGAL::Periodic_3_Delaunay_triangulation_3<GT> PDT;

typedef PDT::Cell_handle       Cell_handle;
typedef PDT::Vertex_handle     Vertex_handle;
typedef PDT::Locate_type       Locate_type;
typedef PDT::Point             Point;
typedef PDT::Iso_cuboid        Iso_cuboid;

int main()
{
  Iso_cuboid domain(-1,-1,-1,2,2,2);  // The cube for the periodic domain

  // construction from a list of points :
  std::list<Point> L;
  L.push_front(Point(0,0,0));
  L.push_front(Point(1,0,0));
  L.push_front(Point(0,1,0));

  PDT T(L.begin(), L.end(), domain); // Put the domain with the
    constructor

  PDT::size_type n = T.number_of_vertices();

  // insertion from a vector :
  std::vector<Point> V(3);
  V[0] = Point(0,0,1);
  V[1] = Point(1,1,1);
  V[2] = Point(-1,-1,-1);

  n = n + T.insert(V.begin(), V.end());

  assert( n == 6 );       // 6 points have been inserted
```

```
  assert( T.is_valid() ); // checking validity of T

  Locate_type lt;
  int li, lj;
  Point p(0,0,0);
  Cell_handle c = T.locate(p, lt, li, lj);
  // p is the vertex of c of index li :
  assert( lt == PDT::VERTEX );
  assert( c->vertex(li)->point() == p );

  Vertex_handle v = c->vertex( (li+1)&3 );
  // v is another vertex of c
  Cell_handle nc = c->neighbor(li);
  // nc = neighbor of c opposite to the vertex associated with p
  // nc must have vertex v :
  int nli;
  assert( nc->has_vertex( v, nli ) );
  // nli is the index of v in nc

  std::ofstream oFileT("output.tri",std::ios::out);
  // writing file output;
  oFileT << T;

  PDT T1;
  std::ifstream iFileT("output.tri",std::ios::in);
  // reading file output;
  iFileT >> T1;
  assert( T1.is_valid() );
  assert( T1.number_of_vertices() == T.number_of_vertices() );
  assert( T1.number_of_cells() == T.number_of_cells() );

  return 0;
}
```

File: examples/Periodic_3_triangulation_3/simple_example.cpp

41.6.2 Changing the Vertex Base

The following two examples show how the user can plug his own vertex base in a triangulation. Changing the cell base is similar.

Adding a Color

If the user does not need to add a type in a vertex that depends on the *TriangulationDataStructure_3* (e.g. a *Vertex_handle* or *Cell_handle*), then he can use the *Triangulation_vertex_base_with_info_3* class to add his own information easily in the vertices. The example below shows how to add a *CGAL::Color* this way.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Periodic_3_triangulation_filtered_traits_3.h>
#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>
```

```
#include <CGAL/Triangulation_vertex_base_with_info_3.h>
#include <CGAL/IO/Color.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Periodic_3_triangulation_filtered_traits_3<K> GT;

typedef CGAL::Periodic_3_triangulation_ds_vertex_base_3<> VbDS;
typedef CGAL::Triangulation_vertex_base_3<GT,VbDS> Vb;

typedef CGAL::Periodic_3_triangulation_ds_cell_base_3<> CbDS;
typedef CGAL::Triangulation_cell_base_3<GT,CbDS> Cb;

typedef CGAL::Triangulation_vertex_base_with_info_3<CGAL::Color, GT, Vb>
   VbInfo;
typedef CGAL::Triangulation_data_structure_3<VbInfo, Cb>    TDS;
typedef CGAL::Periodic_3_Delaunay_triangulation_3<GT, TDS>  PDT;

typedef PDT::Point   Point;

int main()
{
  PDT T;

  T.insert(Point(0,0,0));
  T.insert(Point(.1,0,0));
  T.insert(Point(0,.1,0));
  T.insert(Point(0,0,.1));
  T.insert(Point(.2,.2,.2));
  T.insert(Point(.9,0,.1));

  // Set the color of finite vertices of degree 6 to red.
  PDT::Vertex_iterator vit;
  for (vit = T.vertices_begin(); vit != T.vertices_end(); ++vit)
    if (T.degree(vit) == 6)
      vit->info() = CGAL::RED;

  return 0;
}
```

File: examples/Periodic_3_triangulation_3/colored_vertices.cpp

Adding Handles

If the user needs to add a type in a vertex that depends on the *TriangulationDataStructure_3* (e.g. a *Vertex_handle* or *Cell_handle*), then he has to derive his own vertex base class, as the following example shows.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Periodic_3_triangulation_filtered_traits_3.h>
#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>
#include <CGAL/Periodic_3_triangulation_ds_vertex_base_3.h>
#include <CGAL/Triangulation_vertex_base_3.h>
```

```
template < class GT, class VbDS,
           class Vb = CGAL::Triangulation_vertex_base_3<GT,VbDS> >
class My_vertex_base
  : public Vb
{
public:
  typedef typename Vb::Vertex_handle  Vertex_handle;
  typedef typename Vb::Cell_handle    Cell_handle;
  typedef typename Vb::Point          Point;

  template < class TDS2 >
  struct Rebind_TDS {
    typedef typename Vb::template Rebind_TDS<TDS2>::Other  Vb2;
    typedef My_vertex_base<GT, Vb2>                        Other;
  };

  My_vertex_base() {}

  My_vertex_base(const Point& p)
    : Vb(p) {}

  My_vertex_base(const Point& p, Cell_handle c)
    : Vb(p, c) {}

  Vertex_handle   vh;
  Cell_handle     ch;
};

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Periodic_3_triangulation_filtered_traits_3<K> GT;

typedef CGAL::Periodic_3_triangulation_ds_vertex_base_3<> VbDS;
typedef CGAL::Periodic_3_triangulation_ds_cell_base_3<> CbDS;
typedef CGAL::Triangulation_cell_base_3<GT,CbDS> Cb;

typedef CGAL::Triangulation_data_structure_3<My_vertex_base<GT,VbDS>, Cb>
    TDS;
typedef CGAL::Periodic_3_Delaunay_triangulation_3<GT,TDS> PDT;

typedef PDT::Vertex_handle    Vertex_handle;
typedef PDT::Point            Point;

int main()
{
  PDT T;

  Vertex_handle v0 = T.insert(Point(0,0,0));
  Vertex_handle v1 = T.insert(Point(.1,0,0));
  Vertex_handle v2 = T.insert(Point(0,.1,0));
  Vertex_handle v3 = T.insert(Point(0,0,.1));
  Vertex_handle v4 = T.insert(Point(.2,.2,.2));
  Vertex_handle v5 = T.insert(Point(.9,0,.1));
```

```
  // Now we can link the vertices as we like.
  v0->vh = v1;
  v1->vh = v2;
  v2->vh = v3;
  v3->vh = v4;
  v4->vh = v5;
  v5->vh = v0;

  return 0;
}
```

File: examples/Periodic_3_triangulation_3/periodic_adding_handles.cpp

41.6.3 The 27-sheeted Covering Space

The user can check at any time whether a triangulation would be a simplicial complex in $\mathbb{T}_c^3$ and force a conversion if so. However this should be done very carefully in order to be sure that the internal structure always remains a simplicial complex and thus a triangulation.

In this example we construct a triangulation that can be converted to the 1-sheeted covering space. However, we can insert new points such that the point set does not have a Delaunay triangulation in the 1-sheeted covering space anymore, so the triangulation is not *extensible*.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Periodic_3_triangulation_traits_3.h>
#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>

#include <iostream>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Periodic_3_triangulation_traits_3<K> GT;

typedef CGAL::Periodic_3_Delaunay_triangulation_3<GT> PDT;

typedef PDT::Point                    Point;
typedef PDT::Covering_sheets          Covering_sheets;

int main()
{
  PDT T;

  // Input point grid (27 points)
  for (double x=0. ; x < .9 ; x += 0.33) {
    for (double y=0. ; y < .9 ; y += 0.33) {
      for (double z=0. ; z < .9 ; z += 0.33) {
        T.insert(Point(x,y,z));
  } } }

  Covering_sheets cs = T.number_of_sheets();
  std::cout<<"Current covering: "<<cs[0]<<' '<<cs[1]<<'
   '<<cs[2]<<std::endl;
```

```
  if ( T.is_triangulation_in_1_sheet() ) {
            // = true
    bool is_extensible = T.is_extensible_triangulation_in_1_sheet_h1()
      || T.is_extensible_triangulation_in_1_sheet_h2();
            // = false
    T.convert_to_1_sheeted_covering();
    cs = T.number_of_sheets();
    std::cout<<"Current covering: "<<cs[0]<<' '<<cs[1]<<'
   '<<cs[2]<<std::endl;
    if ( is_extensible )
            // = false
      std::cout<<"It is safe to change the triangulation
   here."<<std::endl;
    else
      std::cout<<"It is NOT safe to change the triangulation
   here!"<<std::endl;

    T.convert_to_27_sheeted_covering();
    cs = T.number_of_sheets();
    std::cout<<"Current covering: "<<cs[0]<<' '<<cs[1]<<'
   '<<cs[2]<<std::endl;
  }

  std::cout<<"It is (again) safe to modify the
   triangulation."<<std::endl;

  return 0;
}
```

File: examples/Periodic_3_triangulation_3/covering.cpp

41.6.4 Large Point Set

For large point sets there are two optimizations available. Firstly, there is spatial sorting that sorts the input points according to a Hilbert curve, see chapter 65.3 on page **??**. The second one inserts 36 appropriately chosen dummy points to avoid the use of a 27-sheeted covering space in the beginning. The 36 dummy points are deleted in the end. If the point set turns out to not have a Delaunay triangulation in the 1-sheeted covering space, the triangulation is converted to the 27-sheeted covering space during the removal of the 36 dummy points. This might take even longer than computing the triangulation without using this optimization. In general, uniformly distributed random point sets of more than 1000 points have a Delaunay triangulation in the 1-sheeted covering space.

It is recommended to run this example only when compiled in release mode because of the relatively large number of points.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Periodic_3_triangulation_traits_3.h>
#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>

#include <CGAL/Random.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Timer.h>
```

```
#include <iostream>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Periodic_3_triangulation_traits_3<K> GT;

typedef CGAL::Periodic_3_Delaunay_triangulation_3<GT> PDT;

typedef PDT::Point          Point;

int main()
{
  CGAL::Timer t;
  typedef CGAL::Creator_uniform_3<double, Point> Creator;
  CGAL::Random random(7);
  CGAL::Random_points_in_cube_3<Point, Creator> in_cube(.5, random);

  int n = 10000;
  std::vector<Point> pts;

  PDT PT1, PT2, PT3;

  // Generating n random points
  for (int i=0 ; i < n ; i++) {
    Point p = *in_cube;
    in_cube++;
    pts.push_back(Point(p.x()+.5,p.y()+.5,p.z()+.5));
  }

  // Standard insertion
  t.start();
  for (int i=0 ; i < n ; i++) {
    PT1.insert(pts[i]);
  }
  t.stop();
  std::cout<<"  Time: "<<t.time()<<" sec. (Standard
   insertion)"<<std::endl;
  t.reset();

  // Iterator range insertion using spatial sorting but no dummy points
  t.start();
  PT2.insert(pts.begin(), pts.end()); // third parameter defaults to
   false
  t.stop();
  std::cout<<"  Time: "<<t.time()<<" sec. (with spatial
   sorting)"<<std::endl;
  t.reset();

  // Iterator range insertion using spatial sorting and dummy point
   heuristic
  t.start();
  PT3.insert(pts.begin(), pts.end(), true);
  t.stop();
```

```
  std::cout<<"  Time: "<<t.time()<<" sec. (Dummy point
   heuristic)"<<std::endl;

  return 0;
}
```

File: examples/Periodic_3_triangulation_3/large_point_set.cpp

41.6.5 Geometric Access

There might be applications that need the geometric primitives of a triangulation as an input but do not require a simplicial complex. For these cases we provide the geometric iterators that return only the geometric primitives fulfilling some properties. In the following example we use the *Periodic_triangle_iterator* with the option *UNIQUE_COVER_DOMAIN*. This means that only those triangles are returned that have a non-empty intersection with the original domain of the 1-sheeted covering space, see Figure 41.4 (Page 2772). The *Periodic_triangle* is actually a three-dimensional array of point-offset pairs. We check for all three entries of the periodic triangle whether the offset is (0,0,0) using the method *is_null*. If so, we convert the periodic triangle to a *PK::Triangle_3*, which requires *exact constructions* to be exact.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Periodic_3_triangulation_traits_3.h>
#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Periodic_3_triangulation_traits_3<K>          PK;
typedef CGAL::Periodic_3_Delaunay_triangulation_3<PK>       P3DT3;

typedef PK::Point_3        Point;
typedef PK::Triangle_3     Triangle;

typedef P3DT3::Periodic_triangle            Periodic_triangle;
typedef P3DT3::Periodic_triangle_iterator  Periodic_triangle_iterator;
typedef P3DT3::Iterator_type                Iterator_type;

int main() {
  P3DT3 T;

  T.insert(Point(0,0,0));
  T.insert(Point(0,0,0.5));
  T.insert(Point(0,0.5,0.5));
  T.insert(Point(0.5,0,0.5));

  Periodic_triangle pt;
  Triangle t_bd;

  // Extracting the triangles that have a non-empty intersection with
  // the original domain of the 1-sheeted covering space
  for (Periodic_triangle_iterator ptit =
   T.periodic_triangles_begin(P3DT3::UNIQUE_COVER_DOMAIN);
       ptit != T.periodic_triangles_end(P3DT3::UNIQUE_COVER_DOMAIN);
   ++ptit) {
    pt = *ptit;
```

```
    if (! (pt[0].second.is_null() && pt[1].second.is_null() &&
   pt[2].second.is_null()) ) {
      // Convert the current Periodic_triangle to a Triangle if it is
      // not strictly contained inside the original domain.
      // Note that this requires EXACT constructions to be exact!
      t_bd = T.construct_triangle(pt);
    }
  }
}
```

41.6.6 Periodic Alpha Shapes

It is possible to use *Periodic_3_Delaunay_triangulation_3* as underlying triangulation for computing alpha shapes (cf. Chapter 43). For an example see Section 43.5.6.

41.7 Design and Implementation History

In 2006, Nico Kruithof started to work with Monique Teillaud on the 3D Periodic Triangulations package.

In 2007, Manuel Caroli continued work on the algorithms [CT09] and on the package with Monique Teillaud.

The package follows the design of the 3D Triangulations package (see Chapter 39).

3D Periodic Triangulations Reference Manual

Manuel Caroli and Monique Teillaud

The main classes of the 3D Periodic Triangulation package are *Periodic_3_triangulation_3* and *Periodic_3_Delaunay_triangulation_3*. They contain functionality to access triangulations and to run queries on them. *Periodic_3_Delaunay_triangulation_3* can construct and modify Delaunay triangulations. It takes the geometric traits as well as the triangulation data structure as template parameters.

The geometric traits class must be a model of the concept *Periodic_3DelaunayTriangulationTraits_3*. It contains all predicates and constructions that are needed by the functions in the triangulation classes.

The package uses *Triangulation_data_structure_3* to represent the triangulation. The cells and vertices need to be models of the concepts *Periodic_3TriangulationDSCellBase_3* and *Periodic_3TriangulationDSVertexBase_3*, respectively. A triangulation is stored as a collection of vertices and cells that are linked together through incidence and adjacency relations. Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives access to one of its incident cells.

The four vertices of a cell are indexed with 0, 1, 2 and 3 in positive orientation, the positive orientation being defined by the orientation of the underlying space $\mathbb{T}_c^3$. The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. See Figure 41.2.

In order to be able to specify the tetrahedra that contain vertices both inside and outside the original domain we store an additional offset information in each vertex of a cell. These offsets are models of the concept *Periodic_3Offset_3*.

CGAL::Periodic_3_triangulation_3<PT,TDS>

Definition

The class *Periodic_triangulation_3* represents a 3-dimensional triangulation of a point set in $\mathbb{T}_c^3$.

#include <CGAL/Periodic_3_triangulation_3.h>

Parameters

The first template argument *PT* must be a model of the *Periodic_3DelaunayTriangulationTraits_3* concept.

The second template argument *TDS* must be a model of the *TriangulationDataStructure_3* concept with some additional functionality in cells and vertices. Its default value is *Triangulation_data_structure_3< Triangulation_vertex_base_3<PT,Periodic_3_triangulation_ds_vertex_base_3<>>,Triangulation_cell_base_3< PT,Periodic_3_triangulation_ds_cell_base_3<>>>*.

Types

The class *Triangulation_3* defines the following types:

typedef PT	*Geometric_traits;*	
typedef TDS	*Triangulation_data_structure;*	
typedef Geometric_traits::Periodic_3_offset_3	*Offset;*	
typedef Geometric_traits::Iso_cuboid_3	*Iso_cuboid;*	A type representing an axis-aligned cuboid. It must be a model of *PT::Iso_cuboid_3*. Used to represent the original domain.
typedef array<int,3>	*Covering_sheets;*	Integer triple to store the number of sheets in each direction of space.
typedef Geometric_traits::Point_3	*Point;*	
typedef Geometric_traits::Segment_3	*Segment;*	
typedef Geometric_traits::Triangle_3	*Triangle;*	
typedef Geometric_traits::Tetrahedron_3	*Tetrahedron;*	
typedef std::pair< Point, Offset >	*Periodic_point;*	Represents a point-offset pair. The point in the pair lies in the original domain.
typedef array< Periodic_point, 2>	*Periodic_segment;*	
typedef array< Periodic_point, 3>	*Periodic_triangle;*	
typedef array< Periodic_point, 4>	*Periodic_tetrahedron;*	

Only vertices (0-faces) and cells (3-faces) are stored. Edges (1-faces) and facets (2-faces) are not explicitly represented and thus there are no corresponding classes (see Section 41.2).

typedef Triangulation_data_structure::Vertex	*Vertex;*
typedef Triangulation_data_structure::Cell	*Cell;*
typedef Triangulation_data_structure::Edge	*Edge;*

typedef Triangulation_data_structure::Facet *Facet;*

The vertices and faces of the triangulations are accessed through *handles*, *iterators* and *circulators*. A handle is a type which supports the two dereference operators *operator** and *operator->*. The Handle concept is documented in the support library. Iterators and circulators are bidirectional and non-mutable. The edges and facets of the triangulation can also be visited through iterators and circulators which are bidirectional and non-mutable.

Iterators and circulators are convertible to the corresponding handles, thus the user can pass them directly as arguments to the functions.

typedef Triangulation_data_structure::Vertex_handle	*Vertex_handle;*	handle to a vertex
typedef Triangulation_data_structure::Cell_handle	*Cell_handle;*	handle to a cell
typedef Triangulation_data_structure::size_type	*size_type;*	Size type (an unsigned integral type)
typedef Triangulation_data_structure::difference_type	*difference_type;*	Difference type (a signed integral type)
typedef Triangulation_data_structure::Cell_iterator	*Cell_iterator;*	iterator over cells
typedef Triangulation_data_structure::Facet_iterator	*Facet_iterator;*	iterator over facets
typedef Triangulation_data_structure::Edge_iterator	*Edge_iterator;*	iterator over edges
typedef Triangulation_data_structure::Vertex_iterator	*Vertex_iterator;*	iterator over vertices
Periodic_3_triangulation_3<PT,TDS>:: Unique_vertex_iterator		iterator over the vertices whose corresponding points lie in the original domain, i.e. for each set of periodic copies the *Unique_vertex_iterator* iterates over exactly one representative.
typedef Triangulation_data_structure::Cell_circulator	*Cell_circulator;*	circulator over all cells incident to a given edge
typedef Triangulation_data_structure::Facet_circulator	*Facet_circulator;*	circulator over all facets incident to a given edge

Geometric iterators:

Periodic_3_triangulation_3<PT,TDS>:: Periodic_tetrahedron_iterator	iterator over the tetrahedra corresponding to cells of the triangulation.
Periodic_3_triangulation_3<PT,TDS>:: Periodic_triangle_iterator	iterator over the triangles corresponding to facets of the triangulation.
Periodic_3_triangulation_3<PT,TDS>:: Periodic_segment_iterator	iterator over the segments corresponding to edges of the triangulation.
Periodic_3_triangulation_3<PT,TDS>:: Periodic_point_iterator	iterator over the points corresponding to vertices of the triangulation.

Enums:

The triangulation class also defines the following enum types:

To specify which case occurs when locating a point in the triangulation.
enum Locate_type { *VERTEX=0, EDGE, FACET, CELL, EMPTY*}*;*

To specify the behavior of geometric iterators.
enum Iterator_type { *STORED=0, UNIQUE, STORED_COVER_DOMAIN, UNIQUE_COVER_DOMAIN*}*;*

Creation

Periodic_3_triangulation_3<PT,TDS> t(Iso_cuboid domain = Iso_cuboid(0,0,0,1,1,1), Geometric_traits traits = Geometric_traits())

Introduces an empty triangulation *t* with *domain* as original domain.
Precondition: *domain* is a cube.

Periodic_3_triangulation_3<PT,TDS> t(Periodic_3_triangulation_3 tr);

Copy constructor. All vertices and faces are duplicated.

Assignment

Periodic_3_triangulation_3 & *t = Periodic_3_triangulation_3 tr*

The triangulation *tr* is duplicated, and modifying the copy after the duplication does not modify the original. The previous triangulation held by *t* is deleted.

void *t.swap(Periodic_3_triangulation_3 & tr)*

The triangulations *tr* and *t* are swapped. *t.swap(tr)* should be preferred to *t = tr* or to *t(tr)* if *tr* is deleted after that. Indeed, there is no copy of cells and vertices, thus this method runs in constant time.

void *t.clear()* Deletes all vertices and all cells of *t*.

template < class PT, class TDS1, class TDS2 >
bool *operator==(Periodic_3_triangulation_3<PT, TDS1> t1, Periodic_3_triangulation_3<PT, TDS2> t2)*

Equality operator. Returns true iff there exist a bijection between the vertices of *t1* and those of *t2* and a bijection between the cells of *t1* and those of *t2*, which preserve the geometry of the triangulation, that is, the points of each corresponding pair of vertices are equal, and the tetrahedra corresponding to each pair of cells are equal (up to a permutation of their vertices).

template < class PT, class TDS1, class TDS2 >

bool *operator!=(Periodic_3_triangulation_3<PT, TDS1> t1, Periodic_3_triangulation_3<PT, TDS2> t2)*

The opposite of *operator==*.

Access Functions

Geometric_traits	*t.geom_traits() const*	Returns a const reference to the geometric traits object.
Triangulation_data_structure	*t.tds() const*	Returns a const reference to the triangulation data structure.
Iso_cuboid	*t.domain() const*	Returns the original domain.

advanced

Covering_sheets *t.number_of_sheets() const*

Returns the number of sheets of the covering space the triangulation is currently computed in.

Non const access

void *t.set_domain(const Iso_cuboid dom)*

Changes the domain. Note that this function calls *clear()*, i.e., it erases the existing triangulation.

The responsibility of keeping a valid triangulation belongs to the user when using advanced operations allowing a direct manipulation of the *tds*. This method is mainly a help for users implementing their own triangulation algorithms.

Triangulation_data_structure& *t.tds()* Returns a reference to the triangulation data structure.

Non-constant-time queries and conversions

bool *t.is_extensible_triangulation_in_1_sheet_h1() const*

The current triangulation remains a triangulation in the 1-sheeted covering space even after adding points if this method returns *true*. This test relies on a heuristic, i.e. if it answers *false* nothing is known. This test runs in constant-time when not computing in the 1-sheeted covering space. (This test uses the length of the longest edge in the triangulation as a criterion [CT09].)

bool *t.is_extensible_triangulation_in_1_sheet_h2() const*

The same as *is_extensible_triangulation_in_1_sheet_h1()* but with a more precise heuristic, i.e. it might answer *true* in cases in which *is_extensible_triangulation_in_1_sheet_h1()* would not. However, it is much less time efficient when not computing in the 1-sheeted covering space. (This test uses the diameter of the largest empty ball in the input point set as a criterion [CT09].)

bool *t.is_triangulation_in_1_sheet() const* Returns *true* if the current triangulation would still be a triangulation in the 1-sheeted covering space, returns *false* otherwise.

It is not recommended to interfere with the built-in covering management. Especially a premature conversion to the 1-sheeted covering space might lead to problems when modifying the triangulation later.

void *t.convert_to_1_sheeted_covering() const* Converts the current triangulation into the same periodic triangulation in the 1-sheeted covering space.

void *t.convert_to_27_sheeted_covering() const* Converts the current triangulation into the same periodic triangulation in the 27-sheeted covering space.

advanced

size_type *t.number_of_vertices() const* Returns the number of vertices. Counts all vertices that are representatives of the same point in $\mathbb{T}_c^3$ as one vertex.

size_type *t.number_of_cells() const* Returns the number of cells. Counts all cells that are representatives of the same tetrahedron in $\mathbb{T}_c^3$ as one cell.

advanced

size_type *t.number_of_stored_vertices() const*

Returns the number of vertices in the data structure. This is the same as the number of sheets times *number_of_vertices()*.

size_type *t.number_of_stored_cells() const*

Returns the number of cells in the data structure. This is the same as the number of sheets times *number_of_cells()*.

advanced

Non-constant-time access functions

size_type *t.number_of_edges() const* Returns the number of edges. Counts all edges that are representatives of the same segment in $\mathbb{T}_c^3$ as one edge.

size_type *t.number_of_facets() const* Returns the number of facets. Counts all facets that are representatives of the same triangle in $\mathbb{T}_c^3$ as one facet.

advanced

size_type *t.number_of_stored_edges() const*

Returns the number of edges in the data structure. This is the same as the number of sheets times *number_of_edges()*.

size_type *t.number_of_stored_facets() const*

Returns the number of facets in the data structure. This is the same as the number of sheets times *number_of_facets()*.

advanced

Geometric access functions

Periodic_point *t.periodic_point(const Vertex_handle v) const*

Returns the periodic point given by vertex *v*. If *t* is represented in the 1-sheeted covering space, the offset is always zero. Otherwise *v* can correspond to a periodic copy outside *domain* of an input point.

Periodic_point *t.periodic_point(const Cell_handle c, int i) const*

If *t* is represented in the 1-sheeted covering space, this function returns the periodic point given by the *i*-th vertex of cell *c*, that is the point in the original domain and the offset of the vertex in *c*. If *t* is represented in the 27-sheeted covering space, this offset is possibly added to another offset determining the periodic copy.
Precondition: $i \in \{0,1,2,3\}$

Periodic_segment *t.periodic_segment(const Cell_handle c, int i, int j) const*

Returns the periodic segment formed by the two point-offset pairs corresponding to the two vertices of edge *(c,i,j)*.
Precondition: $i, j \in \{0,1,2,3\}$, $i \neq j$

Periodic_segment *t.periodic_segment(Edge e) const*

Same as the previous method for edge *e*.

Periodic_triangle *t.periodic_triangle(const Cell_handle c, int i) const*

Returns the periodic triangle formed by the three point-offset pairs corresponding to the three vertices of facet *(c,i)*. The triangle is oriented so that its normal points to the inside of cell *c*.
Precondition: $i \in \{0,1,2,3\}$

Periodic_triangle *t.periodic_triangle(Facet f) const*

Same as the previous method for facet *f*.

Periodic_tetrahedron *t.periodic_tetrahedron(const Cell_handle c) const*

Returns the periodic tetrahedron formed by the four point-offset pairs corresponding to the four vertices of *c*.

Note that a traits class providing exact constructions should be used in order to guarantee the following operations to be exact (as opposed to computing the triangulation only, which requires only exact predicates).

Point *t.point(Periodic_point p) const*

Converts the *Periodic_point s* (point-offset pair) to the corresponding *Point* in $\mathbb{R}^3$.

Segment *t.segment(Periodic_segment s) const*

Converts the *Periodic_segment s* to a *Segment*.

Triangle *t.triangle(Periodic_triangle t) const*

Converts the *Periodic_triangle t* to a *Triangle*.

Tetrahedron *t.tetrahedron(Periodic_tetrahedron t) const*

Converts the *Periodic_tetrahedron t* to a *Tetrahedron*.

Queries

bool *t.is_vertex(Point p, Vertex_handle & v) const*

Tests whether *p* is a vertex of *t* by locating *p* in the triangulation. If *p* is found, the associated vertex *v* is given.

bool *t.is_vertex(Vertex_handle v) const*

Tests whether *v* is a vertex of *t*.

bool *t.is_edge(Vertex_handle u, Vertex_handle v, Cell_handle & c, int & i, int & j) const*

Tests whether *(u,v)* is an edge of *t*. If the edge is found, it gives a cell *c* having this edge and the indices *i* and *j* of the vertices *u* and *v* in *c*, in this order.
Precondition: *u* and *v* are vertices of *t*.

bool *t.is_edge(Vertex_handle u,*
Offset offu,
Vertex_handle v,
Offset offv,
Cell_handle & c,
int & i,
int & j) const

Tests whether *((u,offu),(v,offu))* is an edge of *t*. If the edge is found, it gives a cell *c* having this edge and the indices *i* and *j* of the vertices *u* and *v* in *c*, in this order.
Precondition: *u* and *v* are vertices of *t*.

bool *t.is_facet(Vertex_handle u,*
Vertex_handle v,
Vertex_handle w,
Cell_handle & c,
int & i,
int & j,
int & k) const

Tests whether *(u,v,w)* is a facet of *t*. If the facet is found, it computes a cell *c* having this facet and the indices *i*, *j* and *k* of the vertices *u*, *v* and *w* in *c*, in this order.
Precondition: *u*, *v* and *w* are vertices of *t*.

bool *t.is_facet(Vertex_handle u,*
Offset offu,
Vertex_handle v,
Offset offv,
Vertex_handle w,
Offset offw,
Cell_handle & c,
int & i,
int & j,
int & k) const

Tests whether *((u,offu),(v,offv),(w,offw))* is a facet of *t*. If the facet is found, it computes a cell *c* having this facet and the indices *i*, *j* and *k* of the vertices *u*, *v* and *w* in *c*, in this order.
Precondition: *u*, *v* and *w* are vertices of *t*.

bool *t.is_cell(Cell_handle c) const*

Tests whether *c* is a cell of *t*.

bool *t.is_cell(Vertex_handle u,*
Vertex_handle v,
Vertex_handle w,
Vertex_handle x,
Cell_handle & c,
int & i,
int & j,
int & k,
int & l) const

Tests whether *(u,v,w,x)* is a cell of *t*. If the cell *c* is found, the method computes the indices *i*, *j*, *k* and *l* of the vertices *u*, *v*, *w* and *x* in *c*, in this order.
Precondition: *u*, *v*, *w* and *x* are vertices of *t*.

bool *t.is_cell(Vertex_handle u, Vertex_handle v, Vertex_handle w, Vertex_handle x, Cell_handle & c) const*

Tests whether *(u,v,w,x)* is a cell of *t* and computes this cell *c*.
Precondition: *u*, *v*, *w* and *x* are vertices of *t*.

bool *t.is_cell(Vertex_handle u,*
Offset offu,
Vertex_handle v,
Offset offv,
Vertex_handle w,
Offset offw,
Vertex_handle x,
Offset offx,
Cell_handle & c,
int & i,
int & j,
int & k,

int & l) const

Tests whether *((u,offu),(v,offv),(w,offv),(x,offx))* is a cell of *t*. If the cell *c* is found, the method computes the indices *i*, *j*, *k* and *l* of the vertices *u*, *v*, *w* and *x* in *c*, in this order.
Precondition: *u*, *v*, *w* and *x* are vertices of *t*.

bool *t.is_cell(Vertex_handle u,*
Offset offu,
Vertex_handle v,
Offset offv,
Vertex_handle w,
Offset offw,
Vertex_handle x,
Offset offx,
Cell_handle & c) const

Tests whether *((u,offu),(v,offv),(w,offv),(x,offx))* is a cell of *t* and computes this cell *c*.
Precondition: *u*, *v*, *w* and *x* are vertices of *t*.

There is a method *has_vertex* in the cell class. The analogous methods for facets are defined here.

bool *t.has_vertex(Facet f, Vertex_handle v, int & j) const*

If *v* is a vertex of *f*, then *j* is the index of *v* in the cell *f.first*, and the method returns *true*.

bool *t.has_vertex(Cell_handle c, int i, Vertex_handle v, int & j) const*

Same for facet *(c,i)*. Computes the index *j* of *v* in *c*.

bool *t.has_vertex(Facet f, Vertex_handle v) const*
bool *t.has_vertex(Cell_handle c, int i, Vertex_handle v) const*

Same as the first two methods, but these two methods do not return the index of the vertex.

The following three methods test whether two facets have the same vertices.

bool *t.are_equal(Cell_handle c, int i, Cell_handle n, int j) const*
bool *t.are_equal(Facet f, Facet g) const*
bool *t.are_equal(Facet f, Cell_handle n, int j) const*

Point location

The class *Periodic_3_triangulation_3<PT,TDS>* provides three functions to locate a given point with respect to a triangulation. It provides also functions to test if a given point is inside a face or not. Note that the class *Periodic_3_Delaunay_triangulation_3* also provides a *nearest_vertex()* function.

Cell_handle *t.locate(Point query, Cell_handle start = Cell_handle())*

Returns the cell that contains the query in its interior. If *query* lies on a facet, an edge or on a vertex, one of the cells having *query* on its boundary is returned.
The optional argument *start* is used as a starting place for the search.
Precondition: *query* lies in the original domain *domain*.

Cell_handle *t.locate(Point query, Locate_type & lt, int & li, int & lj, Cell_handle start = Cell_handle())*

The k-face that contains *query* in its interior is returned, by means of the cell returned together with *lt*, which is set to the locate type of the query (*VERTEX, EDGE, FACET, CELL*) and two indices *li* and *lj* that specify the k-face of the cell containing *query*.
If the k-face is a cell, *li* and *lj* have no meaning; if it is a facet (resp. vertex), *li* gives the index of the facet (resp. vertex) and *lj* has no meaning; if it is an edge, *li* and *lj* give the indices of its vertices.
If there is no vertex in the triangulation yet, *lt* is set to *EMPTY* and *locate* returns the default constructed handle.
The optional argument *start* is used as a starting place for the search.
Precondition: *query* lies in the original domain *domain*.

Bounded_side *t.side_of_cell(Point p, Cell_handle c, Locate_type & lt, int & li, int & lj) const*

Returns a value indicating on which side of the oriented boundary of c the point p lies. More precisely, it returns:
- *ON_BOUNDED_SIDE* if p is inside the cell.
- *ON_BOUNDARY* if p on the boundary of the cell. Then *lt* together with *li* and *lj* give the precise location on the boundary. (See the descriptions of the *locate* methods.)
- *ON_UNBOUNDED_SIDE* if p lies outside the cell.
Precondition: *query* lies in the original domain *domain*.

Traversal of the Triangulation

The periodic triangulation class provides several iterators and circulators that allow one to traverse it.

Cell, Face, Edge and Vertex Iterators

The following iterators allow the user to visit cells, facets, edges and vertices of the stored triangulation, i.e. in case of computing in a multiply sheeted covering space all stored periodic copies of each item are returned. These iterators are non-mutable, bidirectional and their value types are respectively *Cell*, *Facet*, *Edge* and *Vertex*. They are all invalidated by any change in the triangulation.

Vertex_iterator	*t.vertices_begin() const*	Starts at an arbitrary vertex. Iterates over all vertices. Returns *vertices_end()* if *t.number_of_vertices()* $= 0$.
Vertex_iterator	*t.vertices_end() const*	Past-the-end iterator
Edge_iterator	*t.edges_begin() const*	Starts at an arbitrary edge. Iterates over all edges. Returns *edges_end()* if *t.number_of_vertices()* $= 0$.
Edge_iterator	*t.edges_end() const*	Past-the-end iterator
Facet_iterator	*t.facets_begin() const*	Starts at an arbitrary facet. Iterates over all facets. Returns *facets_end()* if *t.number_of_vertices()* $= 0$.
Facet_iterator	*t.facets_end() const*	Past-the-end iterator
Cell_iterator	*t.cells_begin() const*	Starts at an arbitrary cell. Iterates over all cells. Returns *cells_end()* if *t.number_of_vertices()* $= 0$.

Cell_iterator	*t.cells_end() const*	Past-the-end iterator
Unique_vertex_iterator	*t.unique_vertices_begin() const*	Starts at an arbitrary vertex. Iterates over all vertices whose corresponding points lie in the original domain, i.e. for each set of periodic copies the *Unique_vertex_iterator* iterates over exactly one representative. Returns *unique_vertices_end()* if *t.number_of_vertices()* $= 0$.
Unique_vertex_iterator	*t.unique_vertices_end() const*	Past-the-end iterator

Geometric iterators

The following iterators allow the user to obtain geometric primitives corresponding to cells, facets, edges, and vertices of the triangulation. These iterators are non-mutable, bidirectional and their value types are respectively *Periodic_point*, *Periodic_segment*, *Periodic_triangle*, and *Periodic_tetrahedron*. They are all invalidated by any change in the triangulation. If the periodic triangulation is not computed in the 1-sheeted covering space, these iterators can be used to retain only the geometric primitives in the original domain. This can be controlled using the enum *Iterator_type*, see page 2796.

Periodic_point_iterator	*t.periodic_points_begin(Iterator_type it = STORED) const*	Iterates over the points of the triangulation. Its behavior is defined by the *Iterator_type it* as described on page 2796.
Periodic_point_iterator	*t.periodic_points_end(Iterator_type it = STORED) const*	Past-the-end iterator. Note that to match another *Periodic_point_iterator* both must have the same *Iterator_type it*.
Periodic_segment_iterator	*t.periodic_segments_begin(Iterator_type it = STORED) const*	Iterates over the segments of the triangulation. Its behavior is defined by the *Iterator_type it* as described on page 2796.
Periodic_segment_iterator	*t.periodic_segments_end(Iterator_type it = STORED) const*	Past-the-end iterator. Note that to match another *Periodic_segment_iterator* both must have the same *Iterator_type it*.
Periodic_triangle_iterator	*t.periodic_triangles_begin(Iterator_type it = STORED) const*	Iterates over the triangles of the triangulation. Its behavior is defined by the *Iterator_type it* as described on page 2796.
Periodic_triangle_iterator	*t.periodic_triangles_end(Iterator_type it = STORED) const*	Past-the-end iterator. Note that to match another *Periodic_triangle_iterator* both must have the same *Iterator_type it*.

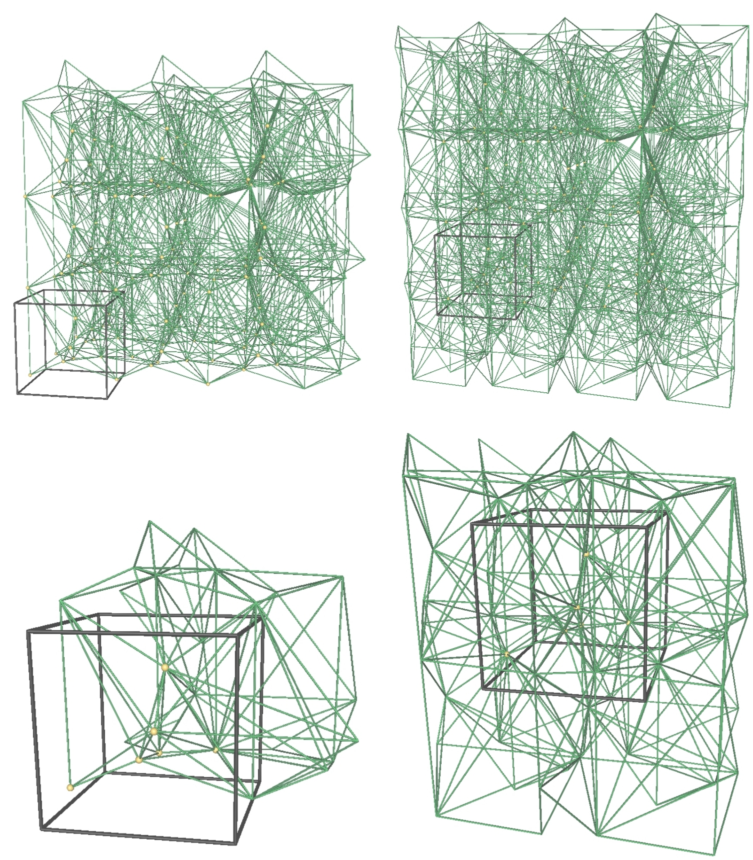

Figure 41.4: The four different modes of the geometric iterators: STORED, STORED_COVER_DOMAIN, UNIQUE, UNIQUE_COVER_DOMAIN. Note that in case of computing in the 1-sheeted covering space, STORED and UNIQUE give the same result.

Periodic_tetrahedron_iterator *t.periodic_tetrahedra_begin(Iterator_type it = STORED) const*

Iterates over the tetrahedra of the triangulation. Its behavior is defined by the *Iterator_type it* as described on page 2796.

Periodic_tetrahedron_iterator *t.periodic_tetrahedra_end(Iterator_type it = STORED) const*

Past-the-end iterator. Note that to match another *Periodic_tetrahedron_iterator* both must have the same *Iterator_type it*.

Cell and Facet Circulators

The following circulators respectively visit all cells or all facets incident to a given edge. They are non-mutable and bidirectional. They are invalidated by any modification of one of the cells traversed.

Cell_circulator *t.incident_cells(Edge e) const* Starts at an arbitrary cell incident to *e*.

Cell_circulator *t.incident_cells(Cell_handle c, int i, int j) const*

As above for edge *(i,j)* of *c*.

Cell_circulator *t.incident_cells(Edge e, Cell_handle start) const*

Starts at cell *start*.
Precondition: *start* is incident to *e*.

Cell_circulator *t.incident_cells(Cell_handle c, int i, int j, Cell_handle start) const*

As above for edge *(i,j)* of *c*.

Facet_circulator *t.incident_facets(Edge e) const* Starts at an arbitrary facet incident to *e*.

Facet_circulator *t.incident_facets(Cell_handle c, int i, int j) const*

As above for edge *(i,j)* of *c*.

Facet_circulator *t.incident_facets(Edge e, Facet start) const*

Starts at facet *start*.
Precondition: *start* is incident to *e*.

Facet_circulator *t.incident_facets(Edge e, Cell_handle start, int f) const*

Starts at facet of index *f* in *start*.

Facet_circulator *t.incident_facets(Cell_handle c, int i, int j, Facet start) const*

As above for edge *(i,j)* of *c*.

Facet_circulator *t.incident_facets(Cell_handle c, int i, int j, Cell_handle start, int f) const*

As above for edge *(i,j)* of *c* and facet *(start,f)*.

Traversal of the incident cells and facets, and the adjacent vertices of a given vertex

template <class OutputIterator>

OutputIterator *t.incident_cells(Vertex_handle v, OutputIterator cells) const*

Copies the *Cell_handle*s of all cells incident to *v* to the output iterator *cells*. Returns the resulting output iterator.
Precondition: $v \neq$ *Vertex_handle()*, *t.is_vertex(v)*.

template <class OutputIterator>
OutputIterator *t.incident_facets(Vertex_handle v, OutputIterator facets) const*

Copies the *Facet*s incident to *v* to the output iterator *facets*. Returns the resulting output iterator.
Precondition: $v \neq$ *Vertex_handle()*, *t.is_vertex(v)*.

template <class OutputIterator>
OutputIterator *t.incident_edges(Vertex_handle v, OutputIterator edges) const*

Copies the *Edge*s incident to *v* to the output iterator *edges*. Returns the resulting output iterator.
Precondition: $v \neq$ *Vertex_handle()*, *t.is_vertex(v)*.

template <class OutputIterator>
OutputIterator *t.adjacent_vertices(Vertex_handle v, OutputIterator vertices) const*

Copies the *Vertex_handle*s of all vertices adjacent to *v* to the output iterator *vertices*. Returns the resulting output iterator.
Precondition: $v \neq$ *Vertex_handle()*, *t.is_vertex(v)*.

size_type *t.degree(Vertex_handle v) const*

Returns the degree of a vertex, that is, the number of adjacent vertices.
Precondition: $v \neq$ *Vertex_handle()*, *t.is_vertex(v)*.

Traversal between adjacent cells

int *t.mirror_index(Cell_handle c, int i) const*

Returns the index of *c* in its i^{th} neighbor.
Precondition: $i \in \{0,1,2,3\}$.

Vertex_handle *t.mirror_vertex(Cell_handle c, int i) const*

Returns the vertex of the i^{th} neighbor of *c* that is opposite to *c*.
Precondition: $i \in \{0,1,2,3\}$.

Facet *t.mirror_facet(Facet f) const* Returns the same facet viewed from the other adjacent cell.

advanced

Checking

The responsibility of keeping a valid triangulation belongs to the user when using advanced operations allowing a direct manipulation of cells and vertices. We provide the user with the following methods to help debugging.

bool *t.is_valid(bool verbose = false) const*

Checks the combinatorial validity of the triangulation. Checks also the validity of its geometric embedding (see Section 41.2).
When *verbose* is set to true, messages describing the first invalidity encountered are printed.

bool *t.is_valid(Cell_handle c, bool verbose = false) const*

Checks the combinatorial validity of the cell by calling the *is_valid* method of the *Triangulation_data_structure* cell class. Also checks the geometric validity of *c*, if *c* is finite. (See Section 41.2.)
When *verbose* is set to *true*, messages are printed to give a precise indication of the kind of invalidity encountered.

advanced

I/O

istream&	*istream& is >> Periodic_3_triangulation_3 &t*	Reads a triangulation from *is* and stores it in *t*. *Precondition*: *is* has the below described format.
ostream&	*ostream& os << Periodic_3_triangulation_3 t*	Writes the triangulation *t* into *os*.

The information in the *iostream* is:

- the original domain
- the number of sheets of the covering space as in *number_of_sheets()*
- the number of vertices
- the non-combinatorial information of vertices (point resp. point-offset pairs, etc.)
- the number of cells
- the indices of the vertices of each cell
- the indices of the neighbors of each cell, where the index corresponds to the preceding list of cells
- the offsets corresponding to the vertices of the cells
- the non-combinatorial information of each cell

Periodic_3_Delaunay_triangulation_3

CGAL::Periodic_3_Delaunay_triangulation_3<PT,TDS>

Definition

The class *Periodic_3_Delaunay_triangulation_3* represents a Delaunay triangulation in three-dimensional periodic space.

#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>

Parameters

The first template argument *PT* must be a model of the *Periodic_3DelaunayTriangulationTraits_3* concept.

The second template argument *TDS* must be a model of the *TriangulationDataStructure_3* concept with some additional functionality in cells and vertices. Its default value is *Triangulation_data_structure_3< Triangulation_vertex_base_3<PT,Periodic_3_triangulation_ds_vertex_base_3<>>,Triangulation_cell_base_3< PT,Periodic_3_triangulation_ds_cell_base_3<>>>*.

Inherits From

Periodic_3_triangulation_3<Periodic_3DelaunayTriangulationTraits_3,TriangulationDataStructure_3>

Creation

Periodic_3_Delaunay_triangulation_3<PT,TDS> dt(Iso_cuboid domain = Iso_cuboid(0,0,0,1,1,1),
Geom_traits traits = Geom_traits())

Creates an empty periodic Delaunay triangulation *dt*, with *domain* as original domain and possibly specifying a traits class *traits*.
Precondition: *domain* is a cube.

Periodic_3_Delaunay_triangulation_3<PT,TDS> dt(Periodic_3_Delaunay_triangulation_3 dt1);

Copy constructor.

template < class InputIterator >
Periodic_3_Delaunay_triangulation_3<PT,TDS> dt(InputIterator first,
InputIterator last,
Iso_cuboid domain = Iso_cuboid(0,0,0,1,1,1),
Geom_traits traits = Geom_traits())

Equivalent to constructing an empty triangulation with the optional domain and traits class arguments and calling *insert(first,last)*.
Precondition: The *value_type* of *first* and *last* are *Point*s lying inside *domain* and *domain* is a cube.

Operations

Insertion

The following methods insert points in the triangulation ensuring the empty sphere property of Delaunay triangulations. The inserted points need to lie in the original domain (see Section 41.1 of the user manual).

In the degenerate case when there are co-spherical points, the Delaunay triangulation is known not to be uniquely defined. In this case, CGAL chooses a particular Delaunay triangulation using a symbolic perturbation scheme [DT03].

Note that insertion of a new point can cause a switch from computing in the 27-sheeted covering space to computing in the 1-sheeted covering space, which invalidates some *Vertex_handle*s and *Cell_handle*s.

Vertex_handle *dt.insert(Point p, Cell_handle start = Cell_handle())*

Inserts point *p* in the triangulation and returns the corresponding vertex. The optional argument *start* is used as a starting place for the point location.
Precondition: *p* lies in the original domain *domain*.

Vertex_handle *dt.insert(Point p, Locate_type lt, Cell_handle loc, int li, int lj)*

Inserts point *p* in the triangulation and returns the corresponding vertex. Similar to the above *insert()* function, but takes as additional parameter the return values of a previous location query. See description of *Periodic_3_triangulation_3::locate()*.
Precondition: *p* lies in the original domain *domain*.

The following method allows one to insert several points. It returns the number of inserted points.

template < class InputIterator >
std::ptrdiff_t *dt.insert(InputIterator first, InputIterator last, bool is_large_point_set = false)*

Inserts the points in the iterator range $[first, last)$. Returns the number of inserted points. This function uses spatial sorting (cf. chapter 65.3) and therefore is not guaranteed to insert the points following the order of *InputIterator*. If the third argument *is_large_point_set* is set to *true* a heuristic for optimizing the insertion of large point sets is applied.
Precondition: The *value_type* of *first* and *last* are *Point*s lying inside *domain*.

Point moving

Vertex_handle *dt.move_point(Vertex_handle v, Point p)*

Moves the point stored in *v* to *p*, while preserving the Delaunay property. This performs an action semantically equivalent to *remove(v)* followed by *insert(p)*, but is supposedly faster when the point has not moved much. Returns the handle to the new vertex.
Precondition: *p* lies in the original domain *domain*.

Removal

When a vertex *v* is removed from a triangulation, all the cells incident to *v* must be removed, and the polyhedral region consisting of all the tetrahedra that are incident to *v* must be re-triangulated. So, the problem reduces to triangulating a polyhedral region, while preserving its boundary, or to compute a *constrained* triangulation. This is known to be sometimes impossible: the Schönhardt polyhedron cannot be triangulated [She98a].

However, when dealing with Delaunay triangulations, the case of such polyhedra that cannot be re-triangulated cannot happen, so CGAL proposes a vertex removal.

void *dt.remove(Vertex_handle v)*

Removes the vertex *v* from the triangulation. When computing in the 27-sheeted covering space it removes all 27 copies of *v*.

template < class InputIterator >
std::ptrdiff_t *dt.remove(InputIterator first, InputIterator beyond)*

Removes the vertices specified by the iterator range (*first, beyond*) of value type *Vertex_handle*. *remove()* is called for each element of the range. The number of vertices removed is returned; this number does not account for periodic copies of removed vertices.
Precondition: The iterator must not iterate over several periodic copies of the same vertex, use e.g. the *Unique_vertex_iterator*.

Queries

Bounded_side *dt.side_of_sphere(Cell_handle c, Point p, Offset off = Offset(0,0,0))*

Returns a value indicating on which side of the circumscribed sphere of *c* the point-offset pair (*p*,*off*) lies. More precisely, it returns:
- *ON_BOUNDED_SIDE* if (*p*,*off*) is inside the sphere.
- *ON_BOUNDARY* if (*p*,*off*) on the boundary of the sphere.
- *ON_UNBOUNDED_SIDE* if (*p*,*off*) lies outside the sphere.
Precondition: *p* lies in the original domain *domain*.

Vertex_handle *dt.nearest_vertex(Point p, Cell_handle c = Cell_handle())*

Returns any nearest vertex to the point *p*, or the default constructed handle if the triangulation is empty. The optional argument *c* is a hint specifying where to start the search. It always returns a vertex corresponding to a point inside *domain* even if computing in a multiply sheeted covering space.
Precondition: *c* is a cell of *dt* and *p* lies in the original domain *domain*.

Vertex_handle *dt.nearest_vertex_in_cell(Cell_handle c, Point p, Offset off = Offset(0,0,0))*

Returns the vertex of the cell *c* that is nearest to the point-offset pair (*p*,*off*).
Precondition: *p* lies in the original domain *domain*.

A point-offset pair (*p*,*off*) is said to be in conflict with a cell *c* iff *dt.side_of_sphere(c, p, off)* returns *ON_BOUNDED_SIDE*. The set of cells that are in conflict with (*p*,*off*) is star-shaped.

template <class OutputIteratorBoundaryFacets, class OutputIteratorCells, class OutputIteratorInternalFacets>

Triple<OutputIteratorBoundaryFacets, OutputIteratorCells, OutputIteratorInternalFacets>

dt.find_conflicts(Point p,
Cell_handle c,
OutputIteratorBoundaryFacets bfit,
OutputIteratorCells cit,
OutputIteratorInternalFacets ifit)

Computes the conflict hole induced by *p*. The starting cell *c* must be in conflict. Then this function returns respectively in the output iterators:
– *cit*: the cells in conflict.
– *bfit*: the facets on the boundary, that is, the facets *(t, i)* where the cell *t* is in conflict, but *t->neighbor(i)* is not.
– *ifit*: the facets inside the hole, that is, delimiting two cells in conflict.
Returns the pair composed of the resulting output iterators.
Precondition: *c* is in conflict with *p* and *p* lies in the original domain *domain*.

template <class OutputIterator>
OutputIterator

dt.vertices_in_conflict(Point p, Cell_handle c, OutputIterator res)

Similar to *find_conflicts()*, but reports the vertices which are on the boundary of the conflict hole of *p*, in the output iterator *res*. Returns the resulting output iterator.
Precondition: *c* is in conflict with *p* and *p* lies in the original domain *domain*.

A face (cell, facet or edge) is said to be a Gabriel face iff its smallest circumscribing sphere do not enclose any vertex of the triangulation. Any Gabriel face belongs to the Delaunay triangulation, but the reciprocal is not true. The following member functions test the Gabriel property of Delaunay faces.

bool	*dt.is_Gabriel(Cell_handle c, int i)*
bool	*dt.is_Gabriel(Cell_handle c, int i, int j)*
bool	*dt.is_Gabriel(Facet f)*
bool	*dt.is_Gabriel(Edge e)*

Voronoi diagram

CGAL offers several functions to display the Voronoi diagram of a set of points in 3D.

Note that a traits class providing exact constructions should be used in order to guarantee the computation of the Voronoi diagram (as opposed to computing the triangulation only, which requires only exact predicates).

Point	*dt.dual(Cell_handle c) const*	Returns the representative of the circumcenter of the four vertices of c that lies in the original domain *domain*.
Periodic_segment	*dt.dual(Facet f) const*	Returns the dual of facet *f*, which is a periodic segment.
Periodic_segment	*dt.dual(Cell_handle c, int i) const*	

same as the previous method for facet *(c,i)*.
Precondition: $i \in \{0,1,2,3\}$

template <class OutputIterator>
OutputIterator *dt.dual(Edge e, OutputIterator pts) const*

Returns in the output iterator the points of the dual polygon of edge *e* in the same order as the *Facet_circulator* returns facets incident to the edge *e*. The points form the dual polygon in $\mathbb{R}^3$, so they do not necessarily all lie inside the original domain.

template <class OutputIterator>
OutputIterator *dt.dual(Cell_handle c, int i, int j, OutputIterator pts) const*

same as the previous method for edge *(c,i,j)*.
Precondition: $i, j \in \{0,1,2,3\}, i \neq j$

template <class OutputIterator>
OutputIterator *dt.dual(Vertex_handle v, OutputIterator pts) const*

Returns in the output iterator the points of the dual polyhedron of vertex *v* in no particular order. The points form the dual polyhedron in $\mathbb{R}^3$, so they do not necessarily lie all inside the original domain.

template <class Stream>
Stream& *dt.draw_dual(Stream & os)* Sends the set of duals to all the facets of *dt* into *os*.

Geom_traits::FT *dt.dual_volume(Vertex_handle v) const*

Returns the volume of the Voronoi cell dual to *v*.

Point *dt.dual_centroid(Vertex_handle v) const*

Returns the centroid of the Voronoi cell dual to *v*.

advanced

Checking

bool *dt.is_valid(bool verbose = false) const*

Checks the combinatorial validity of the triangulation and the validity of its geometric embedding (see Section 41.2). Also checks that all the circumscribing spheres of cells are empty.
When *verbose* is set to true, messages describing the first invalidity encountered are printed.

bool *dt.is_valid(Cell_handle c, bool verbose = false) const*

Checks the combinatorial and geometric validity of the cell (see Section 41.2). Also checks that the circumscribing sphere of cells is empty.
When *verbose* is set to true, messages are printed to give a precise indication of the kind of invalidity encountered.

These methods are mainly a debugging help for the users of advanced features.

Periodic_3_triangulation_3

Class

CGAL::Periodic_3_triangulation_hierarchy_3<PTr>

Definition

The class *Periodic_3_triangulation_hierarchy_3* implements a triangulation augmented with a data structure which allows fast point location queries.

#include <CGAL/Periodic_3_triangulation_hierarchy_3.h>

Parameters

It is templated by a parameter which must be instantiated by one of the CGAL periodic triangulation classes. *In the current implementation, only Periodic_3_Delaunay_triangulation_3 is supported for PTr.*

PTr::Vertex has to be a model of the concept *Periodic_3TriangulationHierarchyVertexBase_3*.
PTr::Geom_traits has to be a model of the concept *Periodic_3DelaunayTriangulationTraits_3*.

Inherits From

PTr

Periodic_3_triangulation_hierarchy_3<PTr> offers exactly the same functionalities as *PTr*. Most of them (point location, insertion, removal. . .) are overloaded to improve their efficiency by using the hierarchic structure.

Note that, since the algorithms that are provided are randomized, the running time of constructing a triangulation with a hierarchy may be improved when shuffling the data points.

However, the I/O operations are not overloaded. So, writing a hierarchy into a file will lose the hierarchic structure and reading it from the file will result in an ordinary triangulation whose efficiency will be the same as *PTr*.

Implementation

The data structure is a hierarchy of triangulations. The triangulation at the lowest level is the original triangulation where operations and point location are to be performed. Then at each succeeding level, the data structure stores a triangulation of a small random sample of the vertices of the triangulation at the preceding level. Point location is done through a top-down nearest neighbor query. The nearest neighbor query is first performed naively in the top level triangulation. Then, at each following level, the nearest neighbor at that level is found through a linear walk performed from the nearest neighbor found at the preceding level. Because the number of vertices in each triangulation is only a small fraction of the number of vertices of the preceding triangulation the data structure remains small and achieves fast point location queries on real data.

Periodic_3DelaunayTriangulationTraits_3

Concept

Definition

The concept Periodic_3DelaunayTriangulationTraits_3 is the first template parameter of the classes *Periodic_3_Delaunay_triangulation_3* and *Periodic_3_triangulation_3*. It refines the concept *DelaunayTriangulationTraits_3* from the CGAL 3D Triangulation (Page **??**) package. It redefines the geometric objects, predicates and constructions to work with point-offset pairs. In most cases the offsets will be (0,0,0) and the predicates from *DelaunayTriangulationTraits_3* can be used directly. For efficiency reasons we maintain for each functor the version without offsets.

Refines

DelaunayTriangulationTraits_3

In addition to the requirements described for the traits class *DelaunayTriangulationTraits_3*, the geometric traits class of a Periodic Delaunay triangulation must fulfill the following requirements:

Types

Periodic_3DelaunayTriangulationTraits_3:: Point_3	The point type. It must be a model of *Kernel::Point_3*.
Periodic_3DelaunayTriangulationTraits_3:: Vector_3	The vector type. It must be a model of *Kernel::Vector_3*.
Periodic_3DelaunayTriangulationTraits_3:: Periodic_3_offset_3	The offset type. It must be a model of the concept *Periodic_3Offset_3*.
Periodic_3DelaunayTriangulationTraits_3:: Iso_cuboid_3	A type representing an axis-aligned cuboid. It must be a model of *Kernel::Iso_cuboid_3*.

The following three types represent geometric primitives in $\mathbb{R}^3$. They are required to provide functions converting primitives from $\mathbb{T}_c^3$ to $\mathbb{R}^3$, i.e. constructing representatives in $\mathbb{R}^3$.

Periodic_3DelaunayTriangulationTraits_3:: Segment_3	A segment type. It must be a model of *Kernel::Segment_3*.
Periodic_3DelaunayTriangulationTraits_3:: Triangle_3	A triangle type. It must be a model of *Kernel::Triangle_3*.
Periodic_3DelaunayTriangulationTraits_3:: Tetrahedron_3	A tetrahedron type. It must be a model of *Kernel::Tetrahedron_3*.

Periodic_3DelaunayTriangulationTraits_3:: Compare_xyz_3

A predicate object that must provide the function operators
Comparison_result operator()(Point_3 p, Point_3 q),
which returns *EQUAL* if the two points are equal and
Comparison_result operator()(Point_3 p, Point_3 q, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q),
which returns *EQUAL* if the two point-offset pairs are equal. Otherwise it must return a consistent order for any two points chosen in a same line.
Precondition: *p*, *q* lie inside the domain.

Periodic_3DelaunayTriangulationTraits_3:: Orientation_3

A predicate object that must provide the function operators
Orientation operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s),
which returns *POSITIVE*, if *s* lies on the positive side of the oriented plane *h* defined by *p*, *q*, and *r*, returns *NEGATIVE* if *s* lies on the negative side of *h*, and returns *COPLANAR* if *s* lies on *h* and
Orientation operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r, Periodic_3_offset_3 o_s),
which returns *POSITIVE*, if the point-offset pair *(s,o_s)* lies on the positive side of the oriented plane *h* defined by *(p,o_p)*, *(q,o_q)*, and *(r,o_r)*, returns *NEGATIVE* if *(s,o_s)* lies on the negative side of *h*, and returns *COPLANAR* if *(s,o_s)* lies on *h*.
Precondition: *p*, *q*, *r*, *s* lie inside the domain.

Periodic_3DelaunayTriangulationTraits_3:: Side_of_oriented_sphere_3

A predicate object that must provide the function operators
Oriented_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Point_3 t),
which determines on which side of the oriented sphere circumscribing *p, q, r, s* the point *t* lies and
Oriented_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Point_3 t, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r, Periodic_3_offset_3 o_s, Periodic_3_offset_3 o_t),
which determines on which side of the oriented sphere circumscribing *(p,o_p), (q,o_q), (r,o_r), (s,o_s)* the point-offset pair *(t,o_t)* lies.
Precondition: *p*, *q*, *r*, *s*, *t* lie inside the domain.

Periodic_3DelaunayTriangulationTraits_3:: Compare_distance_3

A predicate object that must provide the function operators
Comparison_result operator()(Point_3 p, Point_3 q, Point_3 r),
which compares the distance between *p* and *q* to the distance between *p* and *r* and
Comparison_result operator()(Point_3 p, Point_3 q, Point_3 r, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r),
which compares the distance between *(p,o_p)* and *(q,o_q)* to the distance between *(p,o_p)* and *(r,o_r)*.
Precondition: *p*, *q*, *r* lie inside the domain.

In addition, only when vertex removal is used, the traits class must provide the following predicate objects:
Periodic_3DelaunayTriangulationTraits_3:: Coplanar_orientation_3

A predicate object that must provide the function operators
Orientation operator()(Point_3 p, Point_3 q, Point_3 r),
which returns *COLLINEAR*, if the points are collinear; otherwise it must return a consistent orientation for any three points chosen in a same plane and
Orientation operator()(Point_3 p, Point_3 q, Point_3 r Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r),
which returns *COLLINEAR*, if the point-offset pairs are collinear; otherwise it must return a consistent orientation for any three point-offset pairs chosen in a same plane.
Precondition: *p*, *q*, *r* lie inside the domain.

Periodic_3DelaunayTriangulationTraits_3:: Coplanar_side_of_bounded_circle_3

A predicate object that must provide the function operators
Bounded_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s),
which determines the bounded side of the circle defined by *p, q*, and *r* on which the point *s* lies and
Bounded_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r, Periodic_3_offset_3 o_s),
which determines the bounded side of the circle defined by *(p,o_p), (q,o_q)*, and *(r,o_r)* on which the point-offset pair *(s,o_s)* lies.
Precondition: *p,q,r*, and *s* are coplanar and *p,q*, and *r* are not collinear, *(p,o_p),(q,o_q),(r,o_r)*, and *(s,o_s)* are coplanar and *(p,o_p),(q,o_q)*, and *(r,o_r)* are not collinear, respectively, and *p*, *q*, *r*, *s*, *t* lie inside the domain.

In addition, only when *is_Gabriel* is used, the traits class must provide the following predicate object: *Periodic_3DelaunayTriangulationTraits_3:: Side_of_bounded_sphere_3*

A predicate object that must provide the function operators
Bounded_side operator()(Point_3 p, Point_3 q, Point_3 t),
which returns the position of the point *t* relative to the sphere that has *pq* as its diameter,
Bounded_side operator()(Point_3 p, Point_3 q, Point_3 t, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_t),
which returns the position of the point-offset pair *(t,o_t)* relative to the sphere that has *(p,o_p)(q,o_q)* as its diameter,
Bounded_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 t),
which returns the position of the point *t* relative to the sphere passing through *p, q*, and *r* and whose center is in the plane defined by these three points,
Bounded_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 t, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r, Periodic_3_offset_3 o_q),
which returns the position of the point-offset pair *(t,o_t)* relative to the sphere passing through *(p,o_p), (q,o_q)*, and *(r,o_r)* and whose center is in the plane defined by these three point-offset pairs,
Bounded_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Point_3 t),
which returns the relative position of point *t* to the sphere defined by *p, q, r*, and *s*; the order of the points *p, q, r*, and *s* does not matter, and
Bounded_side operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Point_3 t, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r, Periodic_3_offset_3 o_s, Periodic_3_offset_3 o_q),
which returns the relative position of the point-offset pair *(t,o_t)* to the sphere defined by *(p,o_p), (q,o_q), (r,o_r)*, and *(s,o_s)*; the order of the point-offset pairs *(p,o_p), (q,o_q), (r,o_r)*, and *(s,o_s)* does not matter.
Precondition: *p, q, r*, and *s* are not coplanar, *(p,o_p), (q,o_q), (r,o_r)*, and *(s,o_s)* are not coplanar, *p*, *q*, *r*, *s*, *t* lie inside the domain.

Note that the traits must provide exact constructions in order to guarantee exactness of the following construction functors.

Periodic_3DelaunayTriangulationTraits_3:: Construct_point_3

A constructor object that must provide the function operator
Point_3 operator()(Point_3 p, Periodic_3_offset_3 o_p),
which constructs a point from a point-offset pair.
Precondition: *p* lies inside the domain.

Periodic_3DelaunayTriangulationTraits_3:: Construct_segment_3

A constructor object that must provide the function operators
Segment_3 operator()(Point_3 p, Point_3 q),
which constructs a segment from two points and
Segment_3 operator()(Point_3 p, Point_3 q, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q),
which constructs a segment from two point-offset pairs.
Precondition: *p*, *q* lie inside the domain.

Periodic_3DelaunayTriangulationTraits_3:: Construct_triangle_3

A constructor object that must provide the function operators
Triangle_3 operator()(Point_3 p, Point_3 q, Point_3 r),
which constructs a triangle from three points and
Triangle_3 operator()(Point_3 p, Point_3 q, Point_3 r, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r),
which constructs a triangle from three point-offset pairs.
Precondition: *p*, *q*, *r* lie inside the domain.

Periodic_3DelaunayTriangulationTraits_3:: Construct_tetrahedron_3

A constructor object that must provide the function operators
Tetrahedron_3 operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s),
which constructs a tetrahedron from four points and
Tetrahedron_3 operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r, Periodic_3_offset_3 o_s),
which constructs a tetrahedron from four point-offset pairs.
Precondition: *p*, *q*, *r*, *s* lie inside the domain.

In addition, only when the dual operations are used, the traits class must provide the following constructor object:

Periodic_3DelaunayTriangulationTraits_3:: Construct_circumcenter_3

A constructor object that must provide the function operators
Point_3 operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s),
which constructs the circumcenter of four points and
Point_3 operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s, Periodic_3_offset_3 o_p, Periodic_3_offset_3 o_q, Periodic_3_offset_3 o_r, Periodic_3_offset_3 o_s),
which constructs the circumcenter of four point-offset pairs.
Precondition: *p*, *q*, *r* and *s* as well as *(p,o_p)*, *(q,o_q)*, *(r,o_r)* and *(s,o_s)* must be non coplanar. *p*, *q*, *r*, *s* lie inside the domain.

The optional types must be provided in any case, however they can be replaced by dummy types if the respective functions are not used.

Creation

Periodic_3DelaunayTriangulationTraits_3 traits; Default constructor.

Periodic_3DelaunayTriangulationTraits_3 traits(Periodic_triangulation_traits_3 tr);

Copy constructor.

Access Functions

void *traits.set_domain(Iso_cuboid_3 domain)*

Set the size of the fundamental domain. This is necessary to evaluate predicates correctly.
Precondition: *domain* represents a cube.

Operations

The following functions give access to the predicate and construction objects:

Compare_xyz_3	*traits.compare_xyz_3_object()*
Orientation_3	*traits.orientation_3_object()*

Side_of_oriented_sphere_3	*traits.side_of_oriented_sphere_3_object()*
Compare_distance_3	*traits.compare_distance_3_object()*

The following functions must be provided if vertex removal is used; otherwise dummy functions can be provided.

Coplanar_orientation_3	*traits.coplanar_3_orientation_3_object()*
Coplanar_side_of_bounded_circle_3	*traits.coplanar_side_of_bounded_circle_3_object()*

The following function must be provided only if the *is_Gabriel* methods of *Periodic_3_Delaunay_triangulation_3* are used; otherwise a dummy function can be provided.

Side_of_bounded_sphere_3	*traits.side_of_bounded_sphere_3_object()*

Construct_segment_3	*traits.construct_segment_3_object()*
Construct_triangle_3	*traits.construct_triangle_3_object()*
Construct_tetrahedron_3	*traits.construct_tetrahedron_3_object()*

The following function must be provided only if the methods of *Periodic_3_Delaunay_triangulation_3* returning elements of the Voronoi diagram are used; otherwise a dummy function can be provided:

Construct_circumcenter_3	*traits.construct_circumcenter_3_object()*

CGAL::Periodic_3_triangulation_traits_3<Traits,Periodic_3Offset_3>

Definition

The class *Periodic_3_triangulation_traits_3<Traits,Periodic_3Offset_3>* is designed as a default traits class for the class *Periodic_3_triangulation_3<Periodic_3TriangulationTraits_3,TriangulationDataStructure_3>*.

The argument *Traits* must be a model of the *DelaunayTriangulationTraits_3* concept. The argument *Periodic_3Offset_3* must be a model of the concept *Periodic_3Offset_3* and defaults to *Periodic_3_offset_3*.

Note that this template class is specialized for *CGAL::Filtered_kernel*, so that it automatically provides filtered predicates. This holds implicitly for *CGAL::Exact_predicates_inexact_constructions_kernel*, as it is an instantiation of *CGAL::Filtered_kernel*.

#include <CGAL/Periodic_3_triangulation_traits_3.h>

Is Model for the Concepts

Periodic_3DelaunayTriangulationTraits_3

Inherits From

Traits

Concept

Periodic_3TriangulationDSCellBase_3

Definition

At the base level (see Sections 41.5 and 40.2), a cell stores handles to its four vertices and to its four neighbor cells. The vertices and neighbors are indexed 0, 1, 2 and 3. Neighbor i lies opposite to vertex i.

Refines

TriangulationDSCellBase_3

For periodic triangulation the cell base class needs to additionally store an offset for each vertex. Only the last three bits of each integer are required to be stored. The remaining part does not contain any information.

Access Functions

int *c.offset(int i) const*

Returns the offset of vertex i.
Precondition: $i \in \{0, 1, 2, 3\}$.

Setting

void *c.set_offsets(int off0, int off1, int off2, int off3)*

Sets the vertex offsets according to *off0* to *off3*.

Concept

Periodic_3TriangulationDSVertexBase_3

Definition

At the base level of 3D-triangulations (see Sections 41.5 and 40.2), a vertex provides access to one of its incident cells through a handle.

For optimization purposes we need to extend the concept *TriangulationDSVertexBase_3* as follows.

Refines

TriangulationDSVertexBase_3

Periodic_3TriangulationDSVertexBase_3 needs to store an offset and some index inside the vertex.

Types

Periodic_3TriangulationDSVertexBase_3:: Periodic_3_offset_3	A model of the concept *Periodic_3Offset_3*

Access Functions

Periodic_3_offset_3	*v.offset() const*	Returns the offset stored in the vertex.
bool	*v.get_offset_flag() const*	Returns *true* if the offset has been set, *false* otherwise.
void	*v.set_offset(Periodic_3_offset_3 o)*	Sets the offset and sets the offset flag to *true*.
void	*v.clear_offset()*	Sets the offset flag to *false* and clears the offset.

Periodic_3Offset_3

Definition

The concept Periodic_3Offset_3 describes a three-dimensional integer vector with some specialized access functions and operations.

Creation

Periodic_3Offset_3 o;	Default constructor.
Periodic_3Offset_3 o(int x, int y, int z);	Constructs the offset (x,y,z).

Operations

Periodic_3Offset_3	$o + o'$	Return the vector sum of *o* and *o'*.
Periodic_3Offset_3	$o - o'$	Return the vector difference of *o* and *o'*.
Periodic_3Offset_3	$-o$	Return the negative vector of *o*.
void	$o += o'$	Add *o'* to *o* using vector addition.
void	$o -= o'$	Subtract *o'* from *o* using vector subtraction.
bool	$o == o'$	Return *true* if *o'* and *o* represent the same vector.
bool	$o \mathrel{!=} o'$	Return *true* if *o'* and *o* do not represent the same vector.
bool	$o < o'$	Compare *o* and *o'* lexicographically.

Access Functions

int	*o*[*int i*]	Return the *i*-th entry of *o*.
int	*o.x() const*	Return the *x*-entry of *o*.
int	*o.y() const*	Return the *y*-entry of *o*.
int	*o.z()*	Return the *z*-entry of *o*.
bool	*o.is_null() const*	Returns *true* if *o* is equal to (0,0,0).

I/O

istream&	*istream & is >> Periodic_3_offset_3 & off*	
		Inputs an offset from *is*.
ostream&	*ostream & os << Periodic_3_offset_3 & off*	
		Outputs an offset from *os*.

Enum

CGAL::Periodic_3_triangulation_3::Iterator_type

Definition

The enum *Iterator_type* is defined by *Periodic_3_triangulation_3* to specify the behavior of geometric iterators.

enum Iterator_type { *STORED=0, UNIQUE, STORED_COVER_DOMAIN, UNIQUE_COVER_DOMAIN*}*;*

The elements of the enum have the following meaning:

- STORED: Return all geometric primitives as they are stored internally in *Triangulation_data_structure_3*.
- UNIQUE: Return only one representative of each geometric primitive even if the triangulation is computed in a multiply sheeted covering space. Choose the representative whose maximum offset is minimal but non-negative in each direction of space.
- STORED_COVER_DOMAIN: Same as STORED but return additionally all primitives whose intersection with the original domain of the current covering space is non-empty.
- UNIQUE_COVER_DOMAIN: Same as UNIQUE but return additionally all primitives whose intersection with the original domain is non-empty.

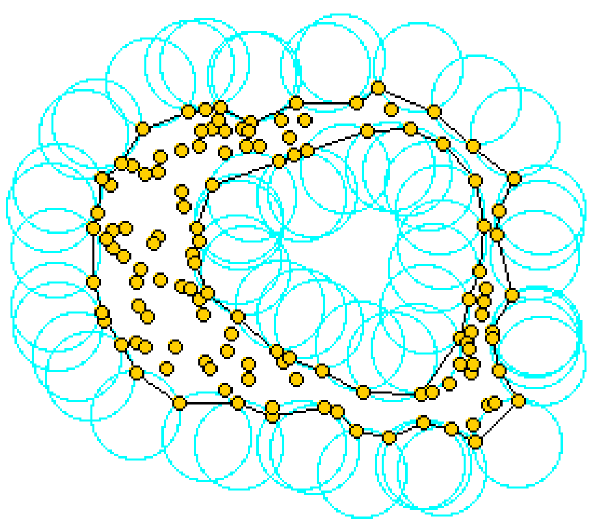
Chapter 42

2D Alpha Shapes

Tran Kai Frank Da

Contents



Assume we are given a set S of points in 2D or 3D and we'd like to have something like "the shape formed by these points." This is quite a vague notion and there are probably many possible interpretations, the α-shape being one of them. Alpha shapes can be used for shape reconstruction from a dense unorganized set of data points. Indeed, an α-shape is demarcated by a frontier, which is a linear approximation of the original shape [BB97].

As mentioned in Edelsbrunner's and Mücke's paper [EM94], one can intuitively think of an α-shape as the following. Imagine a huge mass of ice-cream making up the space $\mathbb{R}^3$ and containing the points as "hard" chocolate pieces. Using one of these sphere-formed ice-cream spoons we carve out all parts of the ice-cream block we can reach without bumping into chocolate pieces, thereby even carving out holes in the inside (e.g. parts not reachable by simply moving the spoon from the outside). We will eventually end up with a (not necessarily convex) object bounded by caps, arcs and points. If we now straighten all "round" faces to triangles and line segments, we have an intuitive description of what is called the α-shape of S. Here's an example for this process in 2D (where our ice-cream spoon is simply a circle):

And what is α in the game? α is the squared radius of the carving spoon. A very small value will allow us to eat up all of the ice-cream except the chocolate points themselves. Thus we already see that the α-shape degenerates to the point-set S for $\alpha \rightarrow 0$. On the other hand, a huge value of α will prevent us even from moving the spoon between two points since it's way too large. So we will never spoon up ice-cream lying in the inside of the convex hull of S, and hence the α-shape for $\alpha \rightarrow \infty$ is the convex hull of S.[1]

42.1 Definitions

We distinguish two versions of alpha shapes. *Basic alpha shapes* are based on the Delaunay triangulation. *Weighted alpha shapes* are based on its generalization, the regular triangulation, replacing the euclidean distance by the power to weighted points.

There is a close connection between alpha shapes and the underlying triangulations. More precisely, the α-complex of S is a subcomplex of this triangulation of S, containing the α-exposed k-simplices, $0 \leq k \leq d$. A simplex is α-exposed, if there is an open disk (resp. ball) of radius $\sqrt{\alpha}$ through the vertices of the simplex that does not contain any other point of S, for the metric used in the computation of the underlying triangulation. The corresponding α-shape is defined as the underlying interior space of the α-complex (see [EM94]).

In general, an α-complex is a non-connected and non-pure polytope, it means, that one k-simplex, $0 \leq k \leq d-1$ is not necessary adjacent to a $(k+1)$-simplex.

The α-shapes of S form a discrete family, even though they are defined for all real numbers α with $0 \leq \alpha \leq \infty$. Thus, we can represent the entire family of α-shapes of S by the underlying triangulation of S. In this representation each k-simplex of the underlying triangulation is associated with an interval that specifies for which values of α the k-simplex belongs to the α-shape. Relying on this fact, the family of α-shapes can be computed efficiently and relatively easily. Furthermore, we can select an appropriate α-shape from a finite number of different α-shapes and corresponding α-values.

42.2 Functionality

The class *CGAL::Alpha_shape_2<Dt>* represents the family of α-shapes of points in a plane for *all* positive α. It maintains the underlying triangulation *Dt* which represents connectivity and order among squared radius of its faces. Each k-dimensional face of the *Dt* is associated with an interval that specifies for which values of

[1] ice cream, ice cream!!! The wording of this introductory paragraphs is borrowed from Kaspar Fischer's " Introduction to Alpha Shapes" which can be found at http://people.inf.ethz.ch/fischerk/pubs/as.pdf. The picture has been taken from Walter Luh's homepage at http://www.stanford.edu/w̃luh/cs448b/alphashapes.html.

α the face belongs to the α-shape. There are links between the intervals and the *k*-dimensional faces of the triangulation.

The class *CGAL::Alpha_shape_2<Dt>* provides functions to set and get the current α-value, as well as an iterator that enumerates the α-values where the α-shape changes.

It provides iterators to enumerate the vertices and edges that are in the α-shape, and functions that allow to classify vertices, edges and faces with respect to the α-shape. They can be in the interior of a face that belongs or does not belong to the α-shape. They can be singular/regular, that is be on the boundary of the α-shape, but not incident/incident to a triangle of the α-complex.

Finally, it provides a function to determine the α-value such that the α-shape satisfies the following two properties, or at least the second one if there is no such α that both are satisfied:

(i) The number of components equals a number of your choice and
(ii) all data points are either on the boundary or in the interior of the regularized version of the α-shape (no singular edges).

The current implementation is static, that is after its construction points cannot be inserted or removed.

42.3 Concepts and Models

We currently do not specify concepts for the underlying triangulation type. Models that work for a basic alpha-shape are the classes *CGAL::Delaunay_triangulation_2* and *CGAL::Triangulation_hierarchy_2* templated with a Delaunay triangulation. A model that works for a weighted alpha-shape is the class *CGAL::Regular_triangulation_2*.

The triangulation needs a geometric traits class as argument. The requirements of this class are described in the concept *CGAL::AlphaShapeTraits_2* for which the CGAL kernels and *CGAL::Weighted_alpha_shape_euclidean_traits_2* are models.

There are no requirements on the triangulation data structure. However it must be parameterized with vertex and face classes, which are model of the concepts *AlphaShapeVertex_2* and *AlphaShapeFace_2*, by default the classes *CGAL::Alpha_shape_vertex_base_2<Gt>* and *CGAL::Alpha_shape_face_base_2<Gt>*.

42.4 Examples

42.4.1 Example for Basic Alpha-Shapes

The basic alpha shape needs a Delaunay triangulation as underlying triangulation *Dt*. The Delaunay triangulation class is parameterized with a geometric and a triangulation data structure traits.

For the geometric traits class we can use a CGAL kernel.

For the triangulation data structure traits, we have to choose the vertex and face classes needed for alpha shapes, namely *CGAL::Alpha_shape_vertex_base_2<Gt, Dv>* and *CGAL::Alpha_shape_face_base_2<Gt,Df>*. As default vertex and face type they use *CGAL::Triangulation_vertex_base_2<Gt>* and *CGAL::Triangulation_face_base_2<Gt>* respectively.

The following code snippet shows how to obtain a basic alpha shape type.

```
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Alpha_shape_vertex_base_2<K> Av;

typedef CGAL::Triangulation_face_base_2<K> Tf;
typedef CGAL::Alpha_shape_face_base_2<K,Tf> Af;

typedef CGAL::Triangulation_default_data_structure_2<K,Av,Af> Tds;
typedef CGAL::Delaunay_triangulation_2<K,Tds> Dt;
typedef CGAL::Alpha_shape_2<Dt> Alpha_shape_2;
```

42.4.2 Example for Basic Alpha-Shapes with Many Points

When the input data set is huge, say more than 10.000 points, it pays off to use a triangulation hierarchy. It has the same API as the Delaunay triangulation and differs only in the types of the vertices and faces. Therefore, the only part that changes are the typedefs in the beginning.

```
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Alpha_shape_vertex_base_2<K> Avb;
typedef CGAL::Triangulation_hierarchy_vertex_base_2<Avb> Av

typedef CGAL::Triangulation_face_base_2<K> Tf;
typedef CGAL::Alpha_shape_face_base_2<K,Tf> Af;

typedef CGAL::Triangulation_default_data_structure_2<K,Av,Af> Tds;
typedef CGAL::Delaunay_triangulation_2<K,Tds> Dt;
typedef CGAL::Triangulation_hierarchy_2<Dt> Ht;
typedef CGAL::Alpha_shape_2<Ht> Alpha_shape_2;
```

42.4.3 Example for Weighted Alpha-Shapes

A weighted alpha shape, needs a regular triangulation as underlying triangulation *Dt*, and it needs a particular face class, namely *CGAL::Regular_triangulation_face_base_2<Gt>*. Note that there is no special weighted alpha shape class.

```
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Weighted_alpha_shape_euclidean_traits_2<K> Gt;

typedef CGAL::Alpha_shape_vertex_base_2<Gt> Av;

typedef CGAL::Regular_triangulation_face_base_2<Gt> Rf;
typedef CGAL::Alpha_shape_face_base_2<Gt,Rf>  Af;

typedef CGAL::Triangulation_default_data_structure_2<Gt,Av,Af> Tds;
typedef CGAL::Regular_triangulation_2<Gt,Tds> Rt;
typedef CGAL::Alpha_shape_2<Rt> Alpha_shape_2;
```

2D Alpha Shapes Reference Manual

Tran Kai Frank Da

This chapter presents a framework for alpha shapes. The description is based on the articles [EM94, Ede92]. Alpha shapes are the generalization of the convex hull of a point set. Let S be a finite set of points in $\mathbb{R}^d$, $d = 2,3$ and α a parameter with $0 \leq \alpha \leq \infty$. For $\alpha = \infty$, the α-shape is the convex hull of S. As α decreases, the α-shape shrinks and develops cavities, as soon as a sphere of radius $\sqrt{\alpha}$ can be put inside. Finally, for $\alpha = 0$, the α-shape is the set S itself.

We distinguish two versions of alpha shapes, one is based on the Delaunay triangulation and the other on its generalization, the regular triangulation, replacing the natural distance by the power to weighted points. The metric used determines an underlying triangulation of the alpha shape and thus, the version computed. The *basic alpha shape* (cf. 42.4.1) is associated with the Delaunay triangulation (cf. 37.5). The *weighted alpha shape* (cf. 42.4.3) is associated with the regular triangulation (cf. 37.6).

There is a close connection between alpha shapes and the underlying triangulations. More precisely, the α-complex of S is a subcomplex of this triangulation of S, containing the α-exposed k-simplices, $0 \leq k \leq d$. A simplex is α-exposed, if there is an open disk (resp. ball) of radius $\sqrt{\alpha}$ through the vertices of the simplex that does not contain any other point of S, for the metric used in the computation of the underlying triangulation. The corresponding α-shape is defined as the underlying interior space of the α-complex.

In general, an α-complex is a non-connected and non-pure polytope, it means, that one k-simplex, $0 \leq k \leq d-1$ is not necessary adjacent to a $(k+1)$-simplex.

The α-shapes of S form a discrete family, even though they are defined for all real numbers α with $0 \leq \alpha \leq \infty$. Thus, we can represent the entire family of α-shapes of S by the underlying triangulation of S. In this representation each k-simplex of the underlying triangulation is associated with an interval that specifies for which values of α the k-simplex belongs to the α-shape. Relying on this result, the family of α-shapes can be computed efficiently and relatively easily. Furthermore, we can select an appropriate α-shape from a finite number of different α-shapes and corresponding α-values.

CGAL::Alpha_shape_2<Dt,ExactAlphaComparisonTag>

Class

Definition

The class *Alpha_shape_2<Dt,ExactAlphaComparisonTag>* represents the family of α-shapes of points in a plane for *all* positive α. It maintains the underlying triangulation *Dt* which represents connectivity and order among its faces. Each k-dimensional face of the *Dt* is associated with an interval that specifies for which values of α the face belongs to the α-shape. There are links between the intervals and the k-dimensional faces of the triangulation.

Note that this class is at the same time used for *basic* and for *weighted* Alpha Shapes.

#include <CGAL/Alpha_shape_2.h>

Parameters

The template parameter *Dt* has to be either *Delaunay_triangulation_2* or *Regular_triangulation_2*. Note that *DT::Geom_traits*, *DT::Vertex* and *DT::Face* must model the concepts *AlphaShapeTraits_2*, *AlphaShapeVertex_2* and *AlphaShapeFace_2* respectively.

The template parameter *ExactAlphaComparisonTag* is a tag that, when set to *CGAL::Tag_true*, triggers exact comparisons between alpha values. This is useful when the underlying triangulation is instantiated with an exact predicates inexact constructions kernel. By default the *ExactAlphaComparisonTag* is set to *CGAL::Tag_false* as it induces a small overhead. Note that since such a strategy does not make sense if used together with a traits class with exact constructions, the tag *ExactAlphaComparisonTag* is not taken into account if *Dt::Geom_traits::FT* is not a floating point number type.

Inherits From

Dt

This class is the underlying triangulation class.

The modifying functions *insert* and *remove* will overwrite the inherited functions. At the moment, only the static version is implemented.

Types

Alpha_shape_2<Dt,ExactAlphaComparisonTag>:: Gt

the alpha shape traits type.

it has to derive from a triangulation traits class. For example *Dt::Point* is a Point class.

typedef Gt::FT

FT; the number type for computation.

Alpha_shape_2<Dt,ExactAlphaComparisonTag>:: size_type

The size type.

Alpha_shape_2<Dt,ExactAlphaComparisonTag>:: Alpha_iterator

A bidirectional and non-mutable iterator that allow to traverse the increasing sequence of different α-values.
Precondition: Its *value_type* is *FT*

Alpha_shape_2<Dt,ExactAlphaComparisonTag>:: Alpha_shape_vertices_iterator

A bidirectional and non-mutable iterator that allow to traverse the vertices which belongs to the α-shape for the current α.
Precondition: Its *value_type* is *Dt::Vertex_handle*

Alpha_shape_2<Dt,ExactAlphaComparisonTag>:: Alpha_shape_edges_iterator

A bidirectional and non-mutable iterator that allow to traverse the edges which belongs to the α-shape for the current α.
Precondition: Its *value_type* is *Dt::Edge*.

enum Classification_type { *EXTERIOR, SINGULAR, REGULAR, INTERIOR*};

Distinguishes the different cases for classifying a k-dimensional face of the underlying triangulation of the α-shape.
EXTERIOR if the face does not belong to the α-complex.
SINGULAR if the face belongs to the boundary of the α-shape, but is not incident to any 2-dimensional face of the α-complex
REGULAR if the face belongs to the boundary of the α-shape and is incident to a 2-dimensional face of the α-complex
INTERIOR if the face belongs to the α-complex, but does not belong to the boundary of the α-shape.

enum Mode { *GENERAL, REGULARIZED*};

In general, an alpha shape can be disconnected and contain many singular edges or vertices. Its regularized version is formed by the set of regular edges and their vertices.

Creation

Alpha_shape_2<Dt,ExactAlphaComparisonTag> A(FT alpha = 0, Mode m = GENERAL);

Introduces an empty α-shape *A* for a positive α-value *alpha*.
Precondition: $alpha \geq 0$.

Alpha_shape_2<Dt,ExactAlphaComparisonTag> A(Dt& dt, FT alpha = 0, Mode m = GENERAL);

Builds an alpha shape of mode *m* from the triangulation *dt* for a positive α-value *alpha*. Be careful that this operation destroys the triangulation.
Precondition: *alpha* $\geq$ 0.

template < class InputIterator >
Alpha_shape_2<Dt,ExactAlphaComparisonTag> A(InputIterator first, InputIterator last, FT alpha = 0, Mode m = GENERAL)

Initializes the family of alpha-shapes with the points in the range [*first*, *last*) and introduces an α-shape *A* for a positive α-value *alpha*.
Precondition: The *value_type* of *first* and *last* is *Point*.
alpha $\geq$ 0.

Operations

template < class InputIterator >
std::ptrdiff_t A.make_alpha_shape(InputIterator first, InputIterator last)

Initialize the family of alpha-shapes with the points in the range [*first*, *last*). Returns the number of inserted points.
If the function is applied to an non-empty family of alpha-shape, it is cleared before initialization.
Precondition: The *value_type* of *first* and *last* is *Point*.

void *A.clear()* Clears the structure.

FT *A.set_alpha(FT alpha)*

Sets the α-value to *alpha*. Returns the previous α-value.
Precondition: *alpha* $\geq$ 0.

FT *A.get_alpha(void) const*

Returns the current α-value.

FT *A.get_nth_alpha(size_type n) const*

Returns the *n*-th alpha-value, sorted in an increasing order.
Precondition: *n* < number of alphas.

size_type *A.number_of_alphas() const*

Returns the number of different alpha-values.

Mode *A.set_mode(Mode m = GENERAL)*

Sets A to its general or regularized version. Returns the previous mode.

Mode *A.get_mode(void) const*

Returns whether A is general or regularized.

Alpha_shape_vertices_iterator

A.alpha_shape_vertices_begin()

Starts at an arbitrary finite vertex which belongs to the α-shape for the current α.

Alpha_shape_vertices_iterator

A.alpha_shape_vertices_end()

Past-the-end iterator.

Alpha_shape_edges_iterator

A.alpha_shape_edges_begin()

Starts at an arbitrary finite edge which belongs to the α-shape for the current α. In regularized mode, edges are represented as a pair (f,i), where f is an interior face of the α-shape.

Alpha_shape_edges_iterator

A.alpha_shape_edges_end()

Past-the-end iterator.

Predicates

Classification_type

A.classify(Point p, FT alpha = get_alpha())

Locates a point p in the underlying triangulation and Classifies the associated k-face with respect to A.

Classification_type

A.classify(Face_handle f, FT alpha = get_alpha())

Classifies the face f of the underlying triangulation with respect to A.

Classification_type

A.classify(Edge e, FT alpha = get_alpha())

Classifies the edge *e* of the underlying triangulation with respect to *A*.

Classification_type

A.classify(Face_handle f, int i, FT alpha = get_alpha())

Classifies the edge of the face *f* opposite to the vertex with index *i* of the underlying triangulation with respect to *A*.

Classification_type

A.classify(Vertex_handle v, FT alpha = get_alpha())

Classifies the vertex *v* of the underlying triangulation with respect to *A*.

Traversal of the α-Values

Alpha_iterator

A.alpha_begin() const

Returns an iterator that allows to traverse the sorted sequence of α-values of the family of alpha shapes.

Alpha_iterator

A.alpha_end() const

Returns the corresponding past-the-end iterator.

Alpha_iterator

A.alpha_find(FT alpha) const

Returns an iterator pointing to an element with α-value *alpha*, or the corresponding past-the-end iterator if such an element is not found.

Alpha_iterator

A.alpha_lower_bound(FT alpha) const

Returns an iterator pointing to the first element with α-value not less than *alpha*.

Alpha_iterator

A.alpha_upper_bound(FT alpha) const

Returns an iterator pointing to the first element with α-value greater than *alpha*.

Operations

size_type *A.number_of_solid_components(FT alpha = get_alpha())*

Returns the number of solid components of *A*, that is, the number of components of its regularized version.

Alpha_iterator

A.find_optimal_alpha(size_type nb_components) const

Returns an iterator pointing to the first element with α-value such that *A* satisfies the following two properties:
nb_components equals the number of solid components and
all data points are either on the boundary or in the interior of the regularized version of *A*.
If no such value is found, the iterator points to the first element with α-value such that *A* satisfies the second property.

I/O

The I/O operators are defined for *iostream*. The format for the iostream is an internal format.

#include <CGAL/IO/io.h>

ostream& *ostream& os << Alpha_shape_2<Dt> A*

Inserts the alpha shape *A* for the current α-value into the stream *os*.
Precondition: The insert operator must be defined for *Point*.

Implementation

The set of intervals associated with the *k*-dimensional faces of the underlying triangulation are stored in *multimaps*.

The cross links between the intervals and the *k*-dimensional faces of the triangulation are realized using methods in the *k*-dimensional faces themselves.

A.alpha_find uses linear search, while *A.alpha_lower_bound* and *A.alpha_upper_bound* use binary search. *A.number_of_solid_components* performs a graph traversal and takes time linear in the number of faces of the underlying triangulation. *A.find_optimal_alpha* uses binary search and takes time $O(n \log n)$, where n is the number of points.

Concept

AlphaShapeTraits_2

Definition

A model of the concept AlphaShapeTraits_2 must provide the following predicate and operations in addition to the requirements for the underlying triangulation traits class. It means, the metric has to be Euclidean for Delaunay triangulation or the power metric for regular triangulation.

Refines

TriangulationTraits_2

Has Models

The kernels supplied by CGAL are models of AlphaShapeTraits_2.

Projection_traits_xy_3<K> . . . . page **??**

Types

AlphaShapeTraits_2:: FT

A type to hold a coordinate type class. The type must provide a copy constructor, assignment, comparison operators, negation, multiplication, division and allow the declaration and initialization with a small integer constant (cf. requirements for number types).
Precondition: An obvious choice would be coordinate type of the point class.

Creation

Only a default constructor is required. Note that further constructors can be provided.

AlphaShapeTraits_2 t;

A default constructor.

Constructions by function objects

Compute_squared_radius_2

t.compute_squared_radius_2_object()

Returns an object, which has to be able to compute the squared radius of the circle of the points *p0, p1, p2* or the squared radius of smallest circle of the points *p0, p1*, as *FT* associated with *the metric used by Dt*.

Predicate by function object

Side_of_bounded_circle_2

t.side_of_bounded_circle_2_object()

Returns an object, which has to be able to compute the relative position of point *test* to the smallest circle of the points *p0, p1*, using *the same metric as Dt*.

Class

CGAL::Weighted_alpha_shape_euclidean_traits_2<K>

Definition

The class *Weighted_alpha_shape_euclidean_traits_2<K>* is the default model for the concept *AlphaShapeTraits_2* for the regular version of Alpha Shapes. *K* must be a kernel.

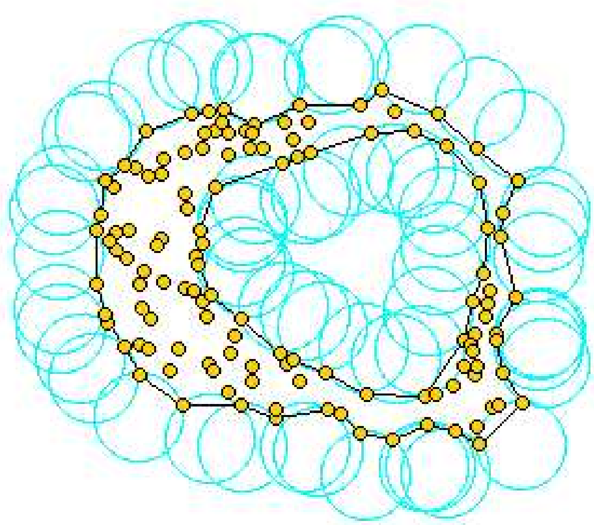
3D Alpha Shapes

Tran Kai Frank Da, Sébastien Loriot, and Mariette Yvinec

Contents



Assume we are given a set S of points in 2D or 3D and we'd like to have something like "the shape formed by these points." This is quite a vague notion and there are probably many possible interpretations, the alpha shape being one of them. Alpha shapes can be used for shape reconstruction from a dense unorganized set of data points. Indeed, an alpha shape is demarcated by a frontier, which is a linear approximation of the original shape [BB97].

As mentioned in Edelsbrunner's and Mücke's paper [EM94], one can intuitively think of an alpha shape as the following. Imagine a huge mass of ice-cream making up the space $\mathbb{R}^3$ and containing the points as "hard" chocolate pieces. Using one of those sphere-formed ice-cream spoons we carve out all parts of the ice-cream block we can reach without bumping into chocolate pieces, thereby even carving out holes in the inside (e.g. parts not reachable by simply moving the spoon from the outside). We will eventually end up with a (not necessarily convex) object bounded by caps, arcs and points. If we now straighten all "round" faces to triangles and line segments, we have an intuitive description of what is called the alpha shape of S. Here's an example for this process in 2D (where our ice-cream spoon is simply a circle):

Alpha shapes depend on a parameter α from which they are named. What is α in the ice-cream game? α is the squared radius of the carving spoon. A very small value will allow us to eat up all of the ice-cream except the chocolate points themselves. Thus we already see that the alpha shape degenerates to the point-set S for $\alpha \to 0$. On the other hand, a huge value of α will prevent us even from moving the spoon between two points since it's way too large. So we will never spoon up ice-cream lying in the inside of the convex hull of S, and hence the alpha shape for $\alpha \to \infty$ is the convex hull of S.[1]

43.1 Definitions

More precisely, the definition of alpha shapes is based on an underlying triangulation that may be a Delaunay triangulation in case of basic alpha shapes or a regular triangulation (cf. 39.3) in case of weighted alpha shapes.

Let us consider the basic case with a Delaunay triangulation. We first define the alpha complex of the set of points S. The alpha complex is a subcomplex of the Delaunay triangulation. For a given value of α, the alpha complex includes all the simplices in the Delaunay triangulation which have an empty circumscribing sphere with squared radius equal or smaller than α. Here "empty" means that the open sphere do not include any points of S. The alpha shape is then simply the domain covered by the simplices of the alpha complex (see [EM94]).

In general, an alpha complex is a disconnected and non-pure complex: This means in particular that the alpha complex may have singular faces. For $0 \leq k \leq d-1$, a k-simplex of the alpha complex is said to be singular if it is not a facet of a $(k+1)$-simplex of the complex. CGAL provides two versions of alpha shapes. In the general mode, the alpha shapes correspond strictly to the above definition. The regularized mode provides a regularized version of the alpha shapes. It corresponds to the domain covered by a regularized version of the alpha complex where singular faces are removed (See Figure 43.1 for an example).

The alpha shapes of a set of points S form a discrete family, even though they are defined for all real numbers α. The entire family of alpha shapes can be represented through the underlying triangulation of S. In this representation each k-simplex of the underlying triangulation is associated with an interval that specifies for which values of α the k-simplex belongs to the alpha complex. Relying on this fact, the family of alpha shapes can be computed efficiently and relatively easily. Furthermore, we can select the optimal value of α to get an alpha shape including all data points and having less than a given number of connected components. Also, the alpha-values allows to define a filtration on the faces of the triangulation of a set of points. In this filtration, the faces of the triangulation are output in increasing order of the alpha value for which they appear in the alpha complex. In case of equal alpha value lower dimensional faces are output first.

[1] ice cream, ice cream!!! The wording of this introductory paragraphs is borrowed from Kaspar Fischer's " Introduction to Alpha Shapes" which can be found at http://people.inf.ethz.ch/fischerk/pubs/as.pdf. The picture has been taken from Walter Luh's homepage at http://www.stanford.edu/w̃luh/cs448b/alphashapes.html.

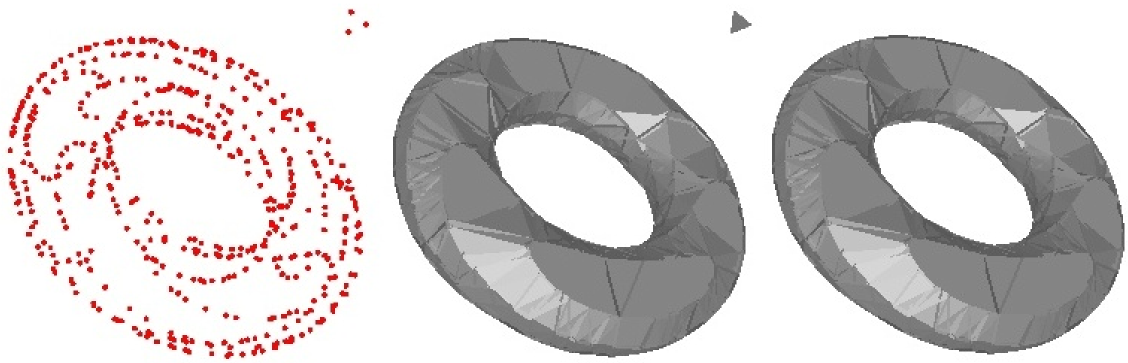


Figure 43.1: Comparison of general and regularized alpha-shape. **Left:** Some points are taken on the surface of a torus, three points being taken relatively far from the surface of the torus; **Middle:** The general alpha-shape (for a large enough alpha value) contains the singular triangle facet of the three isolated points; **Right:** The regularized version (for the same value of alpha) does not contains any singular facet.

The definition is analog in the case of weighted alpha shapes. The input set is now a set of weighted points (which can be regarded as spheres) and the underlying triangulation is the regular triangulation of this set. Two spheres, or two weighted points , with centers C_1, C_2 and radii r_1, r_2 are said to be orthogonal iff $C_1C_2^2 = r_1^2 + r_2^2$ and suborthogonal iff $C_1C_2^2 < r_1^2 + r_2^2$. For a given value of α the weighted alpha complex is formed with the simplices of the regular triangulation triangulation such that there is a sphere orthogonal to the weighted points associated with the vertices of the simplex and suborthogonal to all the other input weighted points. Once again the alpha shape is then defined as the domain covered by a the alpha complex and comes in general and regularized versions.

43.2 Functionality

43.2.1 Family of alpha shapes

The class *CGAL::Alpha_shape_3<Dt,ExactAlphaComparisonTag>* represents the whole family of alpha shapes for a given set of points. The class includes the underlying triangulation *Dt* of the set, and associates to each *k*-face of this triangulation an interval specifying for which values of α the face belongs to the alpha complex.

The class provides functions to set and get the current α-value, as well as an iterator that enumerates the α values where the alpha shape changes.

Also the class has a filtration member function that, given an output iterator with *CGAL::object* as value type, outputs the faces of the triangulation according to the order of apparition in the alpha complex when alpha increases.

Finally, it provides a function to determine the smallest value α such that the alpha shape satisfies the following two properties
(ii) all data points are either on the boundary or in the interior of the regularized version of the alpha shape (no singular faces).
(i) The number of components is equal or less than a given number .

The current implementation is static, that is after its construction points cannot be inserted or removed.

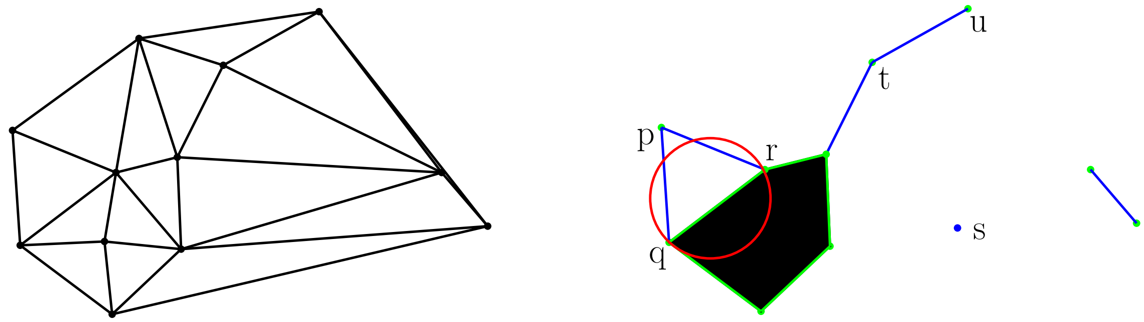

Figure 43.2: Classification of simplices, a 2D example. **Left:** The 2D Delaunay triangulation of a set of points; **Right:** Classification of simplices for a given alpha (the squared radius of the red circle). *INTERIOR*, *REGULAR* and *SINGULAR* simplices are depicted in black, green and blue respectively. *EXTERIOR* simplices are not depicted. The vertex s and the edge tu are *SINGULAR* since all higher dimension simplices they are incident to are *EXTERIOR*. The facet pqr is *EXTERIOR* because the squared radius of its circumscribed circle is larger than alpha.

43.2.2 Alpha shape for a fixed alpha

Given a value of alpha, the class *CGAL::Fixed_alpha_shape_3<Dt>* represents one alpha shape for a given set of points. The class includes the underlying triangulation *Dt* of the set, and associates to each *k*-face of this triangulation a classification type.

The current implementation of this class is dynamic, that is after its construction points can be inserted or removed.

43.2.3 Classification and iterators

Both classes provide member functions to classify for a (given) value of $alpha$ the different faces of the triangulation as *EXTERIOR*, *SINGULAR*, *REGULAR* or *INTERIOR* with respect to the alpha shape. A *k*-face on the boundary of the alpha complex is said to be: *REGULAR* if it is a subface of the alpha-complex which is a subface of a $(k+1)$-face of the alpha complex, and *SINGULAR* otherwise. A *k*-face of the alpha complex which is not on the boundary of the alpha complex is said to be *INTERIOR*. See Figure 43.2 for a 2D illustration.

The classes provide also output iterators to get for a given $alpha$ value the vertices, edges, facets and cells of the different types (*EXTERIOR*, *SINGULAR*, *REGULAR* or *INTERIOR*).

43.3 Concepts and Models

We currently do not specify concepts for the underlying triangulation type. Models that work for a familly alpha-shapes are the instantiations of the classes *CGAL::Delaunay_triangulation_3* and *CGAL::Periodic_3_Delaunay_triangulation_3* (see example 43.5.6). A model that works for a fixed alpha-shape are the instantiations of the class *CGAL::Delaunay_triangulation_3*. A model that works for a weighted alpha-shape is the class *CGAL::Regular_triangulation_3*. The triangulation needs a geometric traits class and a triangulation data structure as template parameters.

For the class *CGAL::Alpha_shape_3<Dt,ExactAlphaComparisonTag>*, the requirements of the traits class are described in the concepts *CGAL::AlphaShapeTraits_3* in the non-weighted case and

CGAL::WeightedAlphaShapeTraits_3 in the weighted case. The CGAL kernels are models in the non-weighted case, and the class *CGAL::Regular_triangulation_euclidean_traits_3* is a model in the weighted case. The triangulation data structure of the triangulation has to be a model of the concept *CGAL::TriangulationDataStructure_3*, and it must be parameterized with vertex and cell classes, which are model of the concepts *AlphaShapeVertex_3* and *AlphaShapeCell_3*. The package provides by default the classes *CGAL::Alpha_shape_vertex_base_3<Gt>* and *CGAL::Alpha_shape_cell_base_3<Gt>*. When using *CGAL::Periodic_3_Delaunay_triangulation_3* as underlying triangulation the vertex and cell classes need to be models to both *AlphaShapeVertex_3* and *Periodic_3TriangulationDSVertexBase_3* as well as *AlphaShapeCell_3* and *Periodic_3TriangulationDSCellBase_3* (see example 43.5.6).

For the class *CGAL::Fixed_alpha_shape_3<Dt>*, the requirements of the traits class are described in the concepts *CGAL::FixedAlphaShapeTraits_3* in the non-weighted case and *CGAL::FixedWeightedAlphaShapeTraits_3* in the weighted case. The CGAL kernels are models in the non-weighted case, and the class *CGAL::Regular_triangulation_euclidean_traits_3* is a model in the weighted case. The triangulation data structure of the triangulation has to be a model of the concept *CGAL::TriangulationDataStructure_3*, and it must be parameterized with vertex and cell classes, which are model of the concepts *FixedAlphaShapeVertex_3* and *FixedAlphaShapeCell_3*. The package provides models *CGAL::Fixed_alpha_shape_vertex_base_3<Gt>* and *CGAL::Fixed_alpha_shape_cell_base_3<Gt>*, respectively.

43.4 *Alpha_shape_3* or *Fixed_alpha_shape_3*

The class *CGAL::Alpha_shape_3<Dt,ExactAlphaComparisonTag>* represents the whole family of alpha shapes for a given set of points while the class *CGAL::Fixed_alpha_shape_3<Dt>* represents only one alpha shape (for a fixed alpha). When using the same kernel, *CGAL::Fixed_alpha_shape_3<Dt>* being a lighter version, it is naturally much more efficient when the alpha-shape is needed for a single given value of alpha. In addition note that the class *CGAL::Alpha_shape_3<Dt,ExactAlphaComparisonTag>* requires constructions (squared radius of simplices) while the class *CGAL::Fixed_alpha_shape_3<Dt>* uses only predicates. This implies that a certified construction of one (several) alpha-shape, using the *CGAL::Alpha_shape_3<Dt,ExactAlphaComparisonTag>* requires a kernel with exact predicates and exact constructions (or setting *ExactAlphaComparisonTag* to *CGAL::Tag_true*) while using a kernel with exact predicates is sufficient for the class *CGAL::Fixed_alpha_shape_3<Dt>*. This makes the class *CGAL::Fixed_alpha_shape_3<Dt>* even more efficient in this setting. In addition, note that the *Fixed* version is the only of the two that supports incremental insertion and removal of points.

We give the time spent while computing the alpha shape of a protein (considered as a set of weighted points) featuring 4251 atoms (using *gcc 4.3* under Linux with *-O3* and *-DNDEBUG* flags, on a 2.27GHz Intel(R) Xeon(R) E5520 CPU): Using *CGAL::Exact_predicates_inexact_constructions_kernel*, building the regular triangulation requires 0.09s, then the class *CGAL::Fixed_alpha_shape_3<Dt>* required 0.05s while the class *CGAL::Alpha_shape_3<Dt,ExactAlphaComparisonTag>* requires 0.35s if *ExactAlphaComparisonTag* is *CGAL::Tag_false* (and 0.70s with *CGAL::Tag_true*). Using *CGAL::Exact_predicates_exact_constructions_kernel*, building the regular triangulation requires 0.19s and then the class *CGAL::Alpha_shape_3<Dt,ExactAlphaComparisonTag>* requires 0.90s.

43.5 Examples

43.5.1 Example for Basic Alpha-Shapes

This example builds a basic alpha shape using a Delaunay triangulation as underlying triangulation.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Alpha_shape_3.h>

#include <fstream>
#include <list>
#include <cassert>

typedef CGAL::Exact_predicates_inexact_constructions_kernel Gt;

typedef CGAL::Alpha_shape_vertex_base_3<Gt>          Vb;
typedef CGAL::Alpha_shape_cell_base_3<Gt>            Fb;
typedef CGAL::Triangulation_data_structure_3<Vb,Fb>  Tds;
typedef CGAL::Delaunay_triangulation_3<Gt,Tds>       Triangulation_3;
typedef CGAL::Alpha_shape_3<Triangulation_3>         Alpha_shape_3;

typedef Gt::Point_3                                  Point;
typedef Alpha_shape_3::Alpha_iterator               Alpha_iterator;

int main()
{
  std::list<Point> lp;

  //read input
  std::ifstream is("./data/bunny_1000");
  int n;
  is >> n;
  std::cout << "Reading " << n << " points " << std::endl;
  Point p;
  for( ; n>0 ; n--)    {
    is >> p;
    lp.push_back(p);
  }

  // compute alpha shape
  Alpha_shape_3 as(lp.begin(),lp.end());
  std::cout << "Alpha shape computed in REGULARIZED mode by default"
            << std::endl;

  // find optimal alpha value
  Alpha_iterator opt = as.find_optimal_alpha(1);
  std::cout << "Optimal alpha value to get one connected component is "
            <<  *opt    << std::endl;
  as.set_alpha(*opt);
  assert(as.number_of_solid_components() == 1);
  return 0;
}
```

File: examples/Alpha_shapes_3/ex_alpha_shapes_3.cpp

43.5.2 Building Basic Alpha Shapes for Many Points

When many points are input in the alpha shape, say more than 10 000, it may pay off to use a Delaunay triangulation with *Fast_location* policy as underlying triangulation in order to speed up point location queries (cf. 39.4.3).

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Alpha_shape_3.h>

#include <fstream>
#include <list>
#include <cassert>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Alpha_shape_vertex_base_3<K>               Vb;
typedef CGAL::Alpha_shape_cell_base_3<K>                 Fb;
typedef CGAL::Triangulation_data_structure_3<Vb,Fb>      Tds;
typedef CGAL::Delaunay_triangulation_3<K,Tds,CGAL::Fast_location>
   Delaunay;
typedef CGAL::Alpha_shape_3<Delaunay>                    Alpha_shape_3;

typedef K::Point_3                                  Point;
typedef Alpha_shape_3::Alpha_iterator               Alpha_iterator;
typedef Alpha_shape_3::NT                           NT;

int main()
{
  Delaunay dt;
  std::ifstream is("./data/bunny_1000");
  int n;
  is >> n;
  Point p;
  std::cout << n << " points read" << std::endl;
  for( ; n>0 ; n--) {
    is >> p;
    dt.insert(p);
  }
  std::cout << "Delaunay computed." << std::endl;

  // compute alpha shape
  Alpha_shape_3 as(dt);
  std::cout << "Alpha shape computed in REGULARIZED mode by defaut."
            << std::endl;

   // find optimal alpha values
  Alpha_shape_3::NT alpha_solid = as.find_alpha_solid();
  Alpha_iterator opt = as.find_optimal_alpha(1);
  std::cout << "Smallest alpha value to get a solid through data points
   is "
            << alpha_solid << std::endl;
  std::cout << "Optimal alpha value to get one connected component is "
            <<  *opt    << std::endl;
```

```
  as.set_alpha(*opt);
  assert(as.number_of_solid_components() == 1);
  return 0;
}
```

File: examples/Alpha_shapes_3/ex_alpha_shapes_with_fast_location_3.cpp

43.5.3 Example for Weighted Alpha-Shapes

The following examples build a weighted alpha shape requiring a regular triangulation as underlying triangulation. The alpha shape is built in *GENERAL* mode.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Regular_triangulation_euclidean_traits_3.h>
#include <CGAL/Regular_triangulation_3.h>
#include <CGAL/Alpha_shape_3.h>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Regular_triangulation_euclidean_traits_3<K> Gt;

typedef CGAL::Alpha_shape_vertex_base_3<Gt>         Vb;
typedef CGAL::Alpha_shape_cell_base_3<Gt>           Fb;
typedef CGAL::Triangulation_data_structure_3<Vb,Fb> Tds;
typedef CGAL::Regular_triangulation_3<Gt,Tds>       Triangulation_3;
typedef CGAL::Alpha_shape_3<Triangulation_3>        Alpha_shape_3;

typedef Alpha_shape_3::Cell_handle          Cell_handle;
typedef Alpha_shape_3::Vertex_handle        Vertex_handle;
typedef Alpha_shape_3::Facet                Facet;
typedef Alpha_shape_3::Edge                 Edge;
typedef Gt::Weighted_point                  Weighted_point;
typedef Gt::Bare_point                      Bare_point;

int main()
{
  std::list<Weighted_point> lwp;

  //input : a small molecule
  lwp.push_back(Weighted_point(Bare_point( 1, -1, -1), 4));
  lwp.push_back(Weighted_point(Bare_point(-1,  1, -1), 4));
  lwp.push_back(Weighted_point(Bare_point(-1, -1,  1), 4));
  lwp.push_back(Weighted_point(Bare_point( 1,  1,  1), 4));

43.5.5 Building an Alpha Shapes with Exact Comparisons of Alpha Values

On some platforms, the alpha shapes of the set of points of this example cannot be computed when using a traits with inexact constructions. To be able to compute them with a traits with inexact constructions, the tag *ExactAlphaComparisonTag* is set to *CGAL::Tag_true*.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Alpha_shape_3.h>

#include <fstream>
#include <list>
#include <cassert>

typedef CGAL::Exact_predicates_inexact_constructions_kernel
        Gt;
typedef CGAL::Tag_true
        Alpha_cmp_tag;
//We use CGAL::Default to skip the complete declaration of base classes
```

```
typedef CGAL::Alpha_shape_vertex_base_3<Gt,CGAL::Default,Alpha_cmp_tag>
        Vb;
typedef CGAL::Alpha_shape_cell_base_3<Gt,CGAL::Default,Alpha_cmp_tag>
        Fb;
typedef CGAL::Triangulation_data_structure_3<Vb,Fb>
        Tds;
typedef CGAL::Delaunay_triangulation_3<Gt,Tds>
        Triangulation_3;
//Alpha shape with ExactAlphaComparisonTag set to true (note that the tag
    is also
//set to true for Vb and Fb)
typedef CGAL::Alpha_shape_3<Triangulation_3,Alpha_cmp_tag>
        Alpha_shape_3;
typedef Gt::Point_3
        Point;

int main()
{
  //Set of points for which the alpha shapes cannot be computed with
  //a floating point alpha value (on certain platforms)
  std::list<Point> lp;
  lp.push_back(Point(49.2559,29.1767,6.7723));
  lp.push_back(Point(49.3696,31.4775,5.33777));
  lp.push_back(Point(49.4264,32.6279,4.6205));
  lp.push_back(Point(49.3127,30.3271,6.05503));

   // compute alpha shape
  Alpha_shape_3 as(lp.begin(),lp.end(),0,Alpha_shape_3::GENERAL);

  return 0;
}
```

File: examples/Alpha_shapes_3/ex_alpha_shapes_exact_alpha.cpp

43.5.6 Example for periodic Alpha Shapes

The following example shows how to use the periodic Delaunay triangulation (Chapter 41) as underlying triangulation for the alpha shape computation.

In order to define the original domain and to benefit from the built-in heuristic optimizations of the periodic Delaunay triangulation computation it is recommended to first construct the triangulation and then construct the alpha shape from it. The alpha shape constructor that takes a point range can be used as well but in this case the original domain cannot be specified and the default unit cube will be chosen and no optimizations will be used.

It is also recommended to switch the triangulation to 1-sheeted covering if possible. Note that a periodic triangulation in 27-sheeted covering space is degenerate. In this case an exact constructions kernel needs to be used to compute the alpha shapes. Otherwise the results will suffer from round-off problems.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Periodic_3_triangulation_traits_3.h>
#include <CGAL/Periodic_3_Delaunay_triangulation_3.h>
```

```
#include <CGAL/Alpha_shape_3.h>

#include <CGAL/Random.h>
#include <CGAL/point_generators_3.h>

// Traits
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Periodic_3_triangulation_traits_3<K> PK;

// Vertex type
typedef CGAL::Periodic_3_triangulation_ds_vertex_base_3<> DsVb;
typedef CGAL::Triangulation_vertex_base_3<PK,DsVb> Vb;
typedef CGAL::Alpha_shape_vertex_base_3<PK,Vb> AsVb;
// Cell type
typedef CGAL::Periodic_3_triangulation_ds_cell_base_3<> DsCb;
typedef CGAL::Triangulation_cell_base_3<PK,DsCb> Cb;
typedef CGAL::Alpha_shape_cell_base_3<PK,Cb> AsCb;

typedef CGAL::Triangulation_data_structure_3<AsVb,AsCb> Tds;
typedef CGAL::Periodic_3_Delaunay_triangulation_3<PK,Tds> P3DT3;
typedef CGAL::Alpha_shape_3<P3DT3>  Alpha_shape_3;

typedef PK::Point_3                                 Point;

int main()
{
  typedef CGAL::Creator_uniform_3<double, Point> Creator;
  CGAL::Random random(7);
  CGAL::Random_points_in_cube_3<Point, Creator> in_cube(1, random);
  std::vector<Point> pts;

  // Generating 1000 random points
  for (int i=0 ; i < 1000 ; i++) {
    Point p = *in_cube++;
    pts.push_back(p);
  }

  // Define the periodic cube
  P3DT3 pdt(PK::Iso_cuboid_3(-1,-1,-1,1,1,1));
  // Heuristic for inserting large point sets (if pts is reasonably
   large)
  pdt.insert(pts.begin(), pts.end(), true);
  // As pdt won't be modified anymore switch to 1-sheeted cover if
   possible
  if (pdt.is_triangulation_in_1_sheet())
   pdt.convert_to_1_sheeted_covering();
  std::cout << "Periodic Delaunay computed." << std::endl;

  // compute alpha shape
  Alpha_shape_3 as(pdt);
  std::cout << "Alpha shape computed in REGULARIZED mode by default."
            << std::endl;

   // find optimal alpha values
```

```
  Alpha_shape_3::NT alpha_solid = as.find_alpha_solid();
  Alpha_shape_3::Alpha_iterator opt = as.find_optimal_alpha(1);
  std::cout << "Smallest alpha value to get a solid through data points
     is "
            << alpha_solid << std::endl;
  std::cout << "Optimal alpha value to get one connected component is "
            <<  *opt    << std::endl;
  as.set_alpha(*opt);
  assert(as.number_of_solid_components() == 1);
  return 0;
}
```

3D Alpha Shapes Reference Manual

Tran Kai Frank Da, Sébastien Loriot, and Mariette Yvinec

Alpha shapes definition is based on an underlying triangulation that may be a Delaunay triangulation in case of basic alpha shapes or a regular triangulation (cf. 39.3) in case of weighted alpha shapes.

Let us consider the basic case with a Delaunay triangulation. We first define the alpha complex of the set of points S. The alpha complex is a subcomplex of the Delaunay triangulation. For a given value of α, the alpha complex includes all the simplices in the Delaunay triangulation which have an empty circumscribing sphere with squared radius equal or smaller than α. Here "empty" means that the open sphere do not include any points of S. The alpha shape is then simply the domain covered by the simplices of the alpha complex (see [EM94]).

In general, an alpha complex is a non-connected and non-pure complex. This means in particular that the alpha complex may have singular faces. For $0 \leq k \leq d-1$, a k-simplex of the alpha complex is said to be singular if it is not a facet of a $(k+1)$-simplex of the complex

The alpha shapes of a set of points S form a discrete family, even though they are defined for all real numbers α. The entire family of alpha shapes can be represented through the underlying triangulation of S. In this representation each k-simplex of the underlying triangulation is associated with an interval that specifies for which values of α the k-simplex belongs to the alpha complex. Relying on this fact, the family of alpha shapes can be computed efficiently and relatively easily. Furthermore, we can select the optimal value of α to get an alpha shape including all data points and having less than a given number of connected components.

The definition is analog in the case of weighted alpha shapes. The input set is now a set of weighted points (which can be regarded as spheres) and the underlying triangulation is the regular triangulation of this set. Two spheres, or two weighted points , with centers C_1, C_2 and radii r_1, r_2 are said to be orthogonal iff $C_1C_2^2 = r_1^2 + r_2^2$ and suborthogonal iff $C_1C_2^2 < r_1^2 + r_2^2$. For a given value of α the weighted alpha complex is formed with the simplices of the regular triangulation triangulation such that there is a sphere orthogonal to the weighted points associated with the vertices of the simplex and suborthogonal to all the other input weighted points. Once again the alpha shape is then defined as the domain covered by a the alpha complex.

CGAL provides two versions to compute alpha shapes. The first one gives access to an explicit classification of all the simplices for a fixed alpha value. The second one gives access to the entire family of alpha shapes of a set of points. This latter version comes with two modes. In the general mode, the alpha shapes correspond strictly to the definition previously made. The regularized mode provides a regularized version of the alpha shapes corresponding to the domain covered by a regularized version of the alpha complex where singular faces are removed.

43.6 Classified Reference Pages

Concepts

Classes

43.7 Alphabetical List of Reference Pages

AlphaShapeCell_3

Concept

Definition

This concept describes the requirements for the base cell of an alpha shape.

Refines

TriangulationCellBase_3.

AlphaShapeCell_3:: NT	A number type. Must be the same as the number type used in the traits class of the triangulation underlying the alpha shape.
AlphaShapeCell_3:: Alpha_status_iterator	An iterator with value type *CGAL::Alpha_status<NT>*.

Creation

AlphaShapeCell_3 f; — default constructor.

AlphaShapeCell_3 f(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3);

constructor setting the incident vertices.

AlphaShapeCell_3 f(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3, Cell_handle n0, Cell_handle n1, Cell_handle n2, Cell_handle n3)

constructor setting the incident vertices and the neighboring cells.

Access Functions

NT *f.get_alpha()* — Returns the alpha value of the cell.

Alpha_status_iterator

f.get_facet_status(int i)

Returns an iterator on the *CGAL::Alpha_status<NT>* of the facet i of the cell.

Modifiers

void	*f.set_alpha(NT alpha)*	
		Sets the critical value of the cell.
void	*f.set_facet_status(int i, Alpha_status_iterator as)*	
		Sets the iterator pointing to the *CGAL::Alpha_status<NT>* of the facet *i* of the cell.

See Also

CGAL::Alpha_status

AlphaShapeTraits_3

Concept

Definition

The concept AlphaShapeTraits_3 describes the requirements for the geometric traits class of the underlying Delaunay triangulation of a basic alpha shape.

Refines

DelaunayTriangulationTraits_3

In addition to the requirements described in the concept *DelaunayTriangulationTraits_3*, the geometric traits class of a Delaunay triangulation plugged in a basic alpha shapes provides the following.

Types

AlphaShapeTraits_3:: FT	A number type compatible with the type used for the points coordinate.
AlphaShapeTraits_3:: Compute_squared_radius_3	An object constructor able to compute: the squared radius of the smallest circumscribing sphere of 4 points *p0, p1, p2, p3*, the squared radius of the smallest circumscribing sphere of 3 points *p0, p1, p2*, the squared radius of the smallest circumscribing sphere of 2 points *p0, p1*, and also the squared radius of the smallest circumscribing sphere to a single point *p0* (which is *FT(0)*).

Creation

AlphaShapeTraits_3 traits;	Default constructor.

Access Functions

Compute_squared_radius_3 *traits.compute_squared_radius_3_object()*

Has Models

All *CGAL* kernels.
CGAL::Exact_predicates_inexact_constructions_kernel (recommended)
CGAL::Exact_predicates_exact_constructions_kernel
CGAL::Filtered_kernel
CGAL::Cartesian
CGAL::Simple_cartesian
CGAL::Homogeneous
CGAL::Simple_homogeneous

Concept

AlphaShapeVertex_3

Definition

This concept describe the requirements for the base vertex of an alpha shape.

Refines

TriangulationVertexBase_3.

Types

AlphaShapeVertex_3:: Point	Must be the same as the point type provided by the geometric traits class of the triangulation.
AlphaShapeVertex_3:: Alpha_status	Must be *CGAL::Alpha_status<NT>* where *NT* is the number type used in the geometric traits class of the triangulation.

Creation

AlphaShapeVertex_3 v;	default constructor.
AlphaShapeVertex_3 v(Point p);	constructor setting the point associated to.
AlphaShapeVertex_3 v(Point p, Cell_handle c);	constructor setting the point associated to and an incident cell.

Modifiers

*Alpha_status**	*v.get_alpha_status()*	Returns a pointer the alpha status of the vertex.

See Also

CGAL::Alpha_status

CGAL::Alpha_shape_3<Dt,ExactAlphaComparisonTag>

Class

Definition

The class *Alpha_shape_3<Dt,ExactAlphaComparisonTag>* represents the family of alpha shapes of points in the 3D space for *all* real α. It maintains an underlying triangulation of the class *Dt*. Each k-dimensional face of Dt is associated with an interval that specifies for which values of alpha the face belongs to the alpha shape. The second template parameter *ExactAlphaComparisonTag* is a tag that, when set to *CGAL::Tag_true*, triggers exact comparisons between alpha values. This is useful when the Delaunay triangulation is instantiated with an exact predicates inexact constructions kernel. By default the *ExactAlphaComparisonTag* is set to *CGAL::Tag_false* as it induces a small overhead. Note that since such a strategy does not make sense if used together with a traits class with exact constructions, the tag *ExactAlphaComparisonTag* is not taken into account if *Dt::Geom_traits::FT* is not a floating point number type.

Note that this class is at the same time used for *basic* and for *weighted* Alpha Shapes.

#include <CGAL/Alpha_shape_3.h>

Inherits From

Dt

This class is the underlying triangulation class.

The modifying functions *insert* and *remove* will overwrite the inherited functions. At the moment, only the static version is implemented.

Types

Alpha_shape_3<Dt,ExactAlphaComparisonTag>:: Gt

the alpha shape traits type.

it has to derive from a triangulation traits class. For example *Dt::Point* is a Point class.

Alpha_shape_3<Dt,ExactAlphaComparisonTag>:: FT

the number type of alpha values.
In case *ExactAlphaComparisonTag* is *CGAL::Tag_false*, it is Gt::FT.
In case *ExactAlphaComparisonTag* is *CGAL::Tag_true*, it is a number type allowing filtered exact comparisons (that is, interval arithmetic is first used before resorting to exact arithmetic).
Access to the interval containing the exact value is provided through the function *FT::Approximate_nt approx() const* where *FT::Approximate_nt* is *Interval_nt<Protected>* with *Protected=true*.
Access to the exact value is provided through the function *FT::Exact_nt exact() const* where *FT::Exact_nt* depends on the configuration of CGAL (it is *CGAL::Gmpq* if *gmp* is available and *CGAL::Quotient< CGAL::MP_Float>* otherwise).
It must be noted that an object of type *FT* is valid as long as the alpha shapes class that creates it is valid and has not been modified. For convenience, classical comparison operators are provided for the type *FT*.

Alpha_shape_3<Dt,ExactAlphaComparisonTag>:: size_type

The size type.

Alpha_shape_3<Dt,ExactAlphaComparisonTag>:: Alpha_iterator

A bidirectional and non-mutable iterator that allow to traverse the increasing sequence of different alpha values.
Precondition: Its *value_type* is *FT*

enum Mode { *GENERAL, REGULARIZED*}*;*

In GENERAL mode, the alpha complex can have singular faces, i. e. faces of dimension k, for $k = (0,1,2)$ that are not subfaces of a $k+1$ face of the complex. In REGULARIZED mode, the complex is regularized, that is singular faces are dropped and the alpha complex includes only a subset of the tetrahedral cells of the triangulation and the subfaces of those cells.

enum Classification_type { *EXTERIOR, SINGULAR, REGULAR, INTERIOR*}*;*

Enum to classify the faces of the underlying triangulation with respect to the alpha shape.
In GENERAL mode, for $k = (0,1,2)$, each k-dimensional simplex of the triangulation can be classified as EXTERIOR, SINGULAR, REGULAR or INTERIOR. In GENERAL mode a k simplex is REGULAR if it is on the boundary f the alpha complex and belongs to a $k+1$ simplex in this complex and it is SINGULAR if it is a boundary simplex that is not included in a $k+1$ simplex of the complex.
In REGULARIZED mode, for $k = (0,1,2)$ each k-dimensional simplex of the triangulation can be classified as EXTERIOR, REGULAR or INTERIOR, i.e. there is no singular faces. A k simplex is REGULAR if it is on the boundary of alpha complex and belongs to a tetrahedral cell of the complex.

Creation

Alpha_shape_3<Dt,ExactAlphaComparisonTag> A(FT alpha = 0, Mode m = REGULARIZED);

Introduces an empty alpha shape data structure *A* for and set the current alpha value to *alpha* and the mode to *m*.

Alpha_shape_3<Dt,ExactAlphaComparisonTag> A(Dt& dt, FT alpha = 0, Mode m = REGULARIZED);

Build an alpha shape of mode *m* from the triangulation *dt*. Be careful that this operation destroys the triangulation.

template < class InputIterator >
Alpha_shape_3<Dt,ExactAlphaComparisonTag> A(InputIterator first, InputIterator last, FT alpha = 0, Mode m = REGULARIZED)

Build an alpha shape data structure in mode *m* for the points in the range [*first*, *last*) and set the current alpha value to *alpha*.
Precondition: The *value_type* of *first* and *last* is *Point* (the type point of the underlying triangulation.)

Modifiers

template < class InputIterator >
std::ptrdiff_t A.make_alpha_shape(InputIterator first, InputIterator last)

Initialize the alpha shape data structure for points in the range [*first*, *last*). Returns the number of data points inserted in the underlying triangulation.
If the function is applied to an non-empty alpha shape data structure, it is cleared before initialization.
Precondition: The *value_type* of *first* and *last* is *Point*.

void *A.clear()* Clears the structure.

FT *A.set_alpha(FT alpha)*

Sets the α-value to *alpha*. Returns the previous α-value.
Precondition: $alpha \geq 0$.

Mode *A.set_mode(Mode m = REGULARIZED)*

Sets *A* in GENERAL or REGULARIZED. Returns the previous mode. Changing the mode of an alpha shape data structure entails a partial re-computation of the data structure.

Query Functions

Mode *A.get_mode(void) const*

Returns whether *A* is general or regularized.

FT *A.get_alpha(void) const*

Returns the current α-value.

FT *A.get_nth_alpha(int n) const*

Returns the *n*-th alpha-value, sorted in an increasing order.
Precondition: *n* ¡ number of alphas.

size_type *A.number_of_alphas() const*

Returns the number of different alpha-values.

Classification_type

A.classify(Point p, FT alpha = get_alpha())

Locates a point *p* in the underlying triangulation and Classifies the associated k-face with respect to *alpha*.

Classification_type

A.classify(Cell_handle f, FT alpha = get_alpha())

Classifies the cell *f* of the underlying triangulation with respect to *alpha*.

Classification_type

A.classify(Facet f, FT alpha = get_alpha())

Classifies the facet *f* of the underlying triangulation with respect to *alpha*.

Classification_type

A.classify(Cell_handle f, int i, FT alpha = get_alpha())

Classifies the facet of the cell *f* opposite to the vertex with index *i* of the underlying triangulation with respect to *alpha*.

Classification_type

A.classify(Edge e, FT alpha = get_alpha())

Classifies the edge *e* with respect to *alpha* .

Classification_type

A.classify(Vertex_handle v, FT alpha = get_alpha())

Classifies the vertex *v* of the underlying triangulation with respect to *alpha*.

template<class OutputIterator>
OutputIterator

A.get_alpha_shape_cells(OutputIterator it, Classification_type type, FT alpha = get_alpha())

Write the cells which are of type *type* for the alpha value *alpha* to the sequence pointed to by the output iterator *it*. Returns past the end of the output sequence.

template<class OutputIterator>
OutputIterator

A.get_alpha_shape_facets(OutputIterator it,
Classification_type type,
FT alpha= get_alpha())

Write the facets which are of type *type* for the alpha value *alpha* to the sequence pointed to by the output iterator *it*. Returns past the end of the output sequence.

template<class OutputIterator>
OutputIterator

A.get_alpha_shape_edges(OutputIterator it,
Classification_type type,
FT alpha = get_alpha())

Write the edges which are of type *type* for the alpha value *alpha* to the sequence pointed to by the output iterator *it*. Returns past the end of the output sequence.

template<class OutputIterator>
OutputIterator

A.get_alpha_shape_vertices(OutputIterator it, Classification_type type, FT alpha)

Write the vertices which are of type *type* for the alpha value *alpha* to the sequence pointed to by the output iterator *it*. Returns past the end of the output sequence.

template<class OutputIterator>
OutputIterator

A.filtration(OutputIterator it)

Output all the faces of the triangulation in increasing order of the alpha value for which they appear in the alpha complex. In case of equal alpha value lower dimensional faces are output first. The value type of the OutputIterator has to be a CGAL::Object

Traversal of the α-Values

Alpha_iterator

A.alpha_begin() const

Returns an iterator that allows to traverse the sorted sequence of α-values of the family of alpha shapes.

Alpha_iterator

A.alpha_end() const

Returns the corresponding past-the-end iterator.

Alpha_iterator

A.alpha_find(FT alpha) const

Returns an iterator pointing to an element with α-value *alpha*, or the corresponding past-the-end iterator if such an element is not found.

Alpha_iterator

A.alpha_lower_bound(FT alpha) const

Returns an iterator pointing to the first element with α-value not less than *alpha*.

Alpha_iterator

A.alpha_upper_bound(FT alpha) const

Returns an iterator pointing to the first element with α-value greater than *alpha*.

Operations

size_type *A.number_of_solid_components(FT alpha = get_alpha())*

Returns the number of solid components of *A*, that is, the number of components of its regularized version.

Alpha_iterator

A.find_optimal_alpha(size_type nb_components) const

Returns an iterator pointing to smallest α value such that *A* satisfies the following two properties:
all data points are either on the boundary or in the interior of the regularized version of *A*.
The number of solid component of *A* is equal to or smaller than *nb_components*.

I/O

The I/O operators are defined for *iostream*, and for the window stream provided by CGAL. The format for the iostream is an internal format.

#include <CGAL/IO/io.h>

ostream& *ostream& os << A* Inserts the alpha shape *A* for the current alpha value into the stream *os*.
Precondition: The insert operator must be defined for *Point*.

#include <CGAL/IO/Geomview_stream.h>

#include <CGAL/IO/alpha_shape_geomview_ostream_3.h>

Geomview_stream&

Geomview_stream& W << A

Inserts the alpha shape *A* for the current alpha value into the Geomview stream *W*.
Precondition: The insert operator must be defined for *GT::Point* and *GT::Triangle*.

Implementation

In GENERAL mode, the alpha intervals of each triangulation face is computed and stored at initialization time. In REGULARIZED mode, the alpha shape intervals of edges are not stored nor computed at initialization. Edges are simply classified on the fly upon request. This allows to have much faster building of alpha shapes in REGULARIZED mode.

A.alpha find uses linear search, while *A.alpha lower bound* and *A.alpha upper bound* use binary search. *A.number of solid components* performs a graph traversal and takes time linear in the number of cells of the underlying triangulation. *A.find of optimal alpha* uses binary search and takes time $O(n \log n)$, where n is the number of points.

Class

CGAL::Alpha_shape_cell_base_3<Traits,Fb,ExactAlphaComparisonTag,WeightedTag>

Definition

The class *Alpha_shape_cell_base_3<Traits,Fb,ExactAlphaComparisonTag,WeightedTag>* is the default model for the concept *AlphaShapeCell_3*.

The class has four parameters. The traits class *Traits* is the one that is provided to the *Alpha_shape_3* class. The second parameter *Fb* is a base class instantiated by default with *CGAL::Triangulation_cell_base_3<Traits>* . The third parameter *ExactAlphaComparisonTag* is a tag that, when set to *CGAL::Tag_true*, triggers exact comparisons between alpha values. See the description provided in the documentation of *Alpha_shape_3* for more details. The default value is *CGAL::Tag_false*. The fourth parameter *WeightedTag* is used only if *ExactAlphaComparisonTag* is *CGAL::Tag_true*. It must be *CGAL::Tag_true* if the underlying triangulation of the alpha shape to be used is a regular triangulation and *CGAL::Tag_false* otherwise. The default is *CGAL::Tag_false*.

CGAL::Alpha_status<NT>

Definition

The class *Alpha_status<NT>* is a small data structure to store the critical alpha values of faces of an alpha shape. Each face has three critical alpha values, called *alpha_min*, *alpha_mid* and *alpha_max* in increasing order. The face will be exterior for any $\alpha < alpha\_min$, singular for $alpha\_min \leq \alpha < alpha\_mid$, regular for $alpha\_mid \leq \alpha < alpha\_max$ and interior for $alpha\_max \leq alpha$. The value *alpha_min* is undefined for faces which are not Gabriel faces and therefore do not appear in the alpha complex without any of their including face. The value *alpha_max* is undefined for convex hull faces which can never be interior, The data structure also includes two Boolean to mark if the face is a Gabriel face or a convex hull face.

The class *Alpha_status<NT>* is parameterized by a number type *NT*.

#include <CGAL/Alpha_shape_cell_base_3.h>

Creation

Alpha_status<NT> a;	default constructor.

Modifiers

void	*a.set_is_Gabriel(bool yesorno)*	
		sets Gabriel marker;
void	*a.set_is_on_chull(bool yesorno)*	
		sets convex hull marker;
void	*a.set_alpha_min(NT alpha)*	
		sets *alpha_min*.
void	*a.set_alpha_mid(NT alpha)*	
		sets *alpha_mid*.
void	*a.set_alpha_max(NT alpha)*	
		sets *alpha_max*.

Access Functions

bool	*a.is_Gabriel() const*	Returns true for Gabriel faces;
bool	*a.is_on_chull() const*	Returns true for convex hull faces;
NT	*a.alpha_min() const*	Returns the *alpha_min* *Precondition*: *is_Gabriel()* returns false;
NT	*a.alpha_mid() const*	Returns the *alpha_mid*;
NT	*a.alpha_max() const*	Returns *alpha_max*. *Precondition*: *is_on_chull()* returns false.

Concept

WeightedAlphaShapeTraits_3

Definition

The concept WeightedAlphaShapeTraits_3 describes the requirements for the geometric traits class of the underlying regular triangulation of a weighted alpha shape.

Refines

RegularTriangulationTraits_3

In addition to the requirements described in the concept *RegularTriangulationTraits_3*, the geometric traits class of a Regular triangulation plugged in a basic alpha shapes provides the following.

Types

WeightedAlphaShapeTraits_3:: FT — A number type compatible with the type used for the points coordinates.

WeightedAlphaShapeTraits_3:: Compute_squared_radius_smallest_orthogonal_sphere_3

An object constructor able to compute the squared radius of the smallest sphere orthogonal to four weighted points *p0, p1, p2, p3*, and the squared radius of the smallest sphere orthogonal to three weighted points *p0, p1, p2*, and the squared radius of smallest sphere orthogonal to two weighted points *p0, p1*, and the squared radius of the smallest sphere orthogonal to a single point *p0*.

Creation

WeightedAlphaShapeTraits_3 wast; — default constructor.

Creation

FixedAlphaShapeCell_3 f;   default constructor.

FixedAlphaShapeCell_3 f(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3);

constructor setting the incident vertices.

*FixedAlphaShapeCell_3 f(Vertex_handle v0,
Vertex_handle v1,
Vertex_handle v2,
Vertex_handle v3,
Cell_handle n0,
Cell_handle n1,
Cell_handle n2,
Cell_handle n3)*

constructor setting the incident vertices and the neighboring cells.

Access Functions

Classification_type   *f.get_classification_type()*

Returns the classification of the cell.

Classification_type   *f.get_facet_classification_type(int i)*

Returns the classification of the i-th facet of the cell.

Modifiers

void   *f.set_classification_type(Classification_type type)*

Sets classification of the cell.

void   *f.set_facet_classification_type(int i, Classification_type type)*

Sets the classification of the i-th facet of the cell.

FixedAlphaShapeVertex_3

Definition

This concept describes the requirements for the base vertex of a alpha shape with a fixed value alpha.

Refines

TriangulationVertexBase_3.

Types

FixedAlphaShapeVertex_3:: Point	Must be the same as the point type provided by the geometric traits class of the triangulation.

Creation

FixedAlphaShapeVertex_3	*v*;	default constructor.
FixedAlphaShapeVertex_3	*v(Point p);*	constructor setting the point associated to.
FixedAlphaShapeVertex_3	*v(Point p, Cell_handle c);*	constructor setting the point associated to and an incident cell.

Access Functions

bool	*v.is_on_chull()*	Returns a boolean indicating whether the point is on the convex hull of the point of the triangulation.
Classification_type	*v.get_classification_type()*	Returns the classification of the vertex.

Modifiers

void	*v.set_classification_type(Classification_type type)*	Sets the classification of the vertex.
void	*v.is_on_chull(bool b)*	Sets whether the vertex is on the convex hull.

Class

CGAL::Fixed_alpha_shape_3<Dt>

Definition

The class *Fixed_alpha_shape_3<Dt>* represents one (fixed) alpha shape of points in the 3D space for a real α. It maintains an underlying triangulation of the class *Dt* which represents connectivity and order among its faces. Each k-dimensional face of the *Dt* is associated with a classification that specifies its status in the alpha complex, alpha being fixed.

Note that this class can be used at the same time to build a *basic* or a *weighted* Alpha Shape.

#include <CGAL/Fixed_alpha_shape_3.h>

Inherits From

Dt

This class is the underlying triangulation class.

The modifying functions *insert* and *remove* will overwrite the inherited functions.

Types

Fixed_alpha_shape_3<Dt>:: Gt — the alpha shape traits type.

it has to derive from a triangulation traits class. For example *Dt::Point* is a Point class.

typedef Gt::FT

FT; — the number type of alpha.

enum Classification_type { EXTERIOR, SINGULAR, REGULAR, INTERIOR};

Enum to classify the simplices of the underlying triangulation with respect to a given alpha value.
Each k-dimensional simplex of the triangulation can be classified as EXTERIOR, SINGULAR, REGULAR or INTERIOR. A k simplex is REGULAR if it is on the boundary of the alpha complex and belongs to a $k+1$ simplex in this complex and it is SINGULAR if it is a boundary simplex that is not included in a $k+1$ simplex of the complex.

Creation

Fixed_alpha_shape_3<Dt> A(FT alpha = 0);

Introduces an empty alpha shape data structure *A* and set the alpha value to *alpha*.

Fixed_alpha_shape_3<Dt> A(Dt& dt, FT alpha = 0);

Builds an alpha shape from the triangulation *dt*, and set the alpha value to *alpha*. Be careful that this operation destroys the triangulation.

template < class InputIterator >
Fixed_alpha_shape_3<Dt> A(InputIterator first, InputIterator last, FT alpha = 0);

Builds an alpha shape data structure for the points in the range [*first*, *last*) and set the alpha value to *alpha*.
Requirement: The *value_type* of *first* and *last* is *Point* (the type point of the underlying triangulation.)

Modifiers

Vertex_handle

A.insert(Point p, Cell_handle start = Cell_handle())

Inserts point p in the underlying triangulation and returns the corresponding vertex. The optional argument *start* is used as a starting place for the search. The classification types of the new simplices are computed and that of the simplices incident to the new ones are updated.

void *A.remove(Vertex_handle v)*

Removes the vertex v from the underlying triangulation. The classification types of new simplices and their incident faces are set or reset

void *A.clear()* Clears the structure.

Query Functions

FT *A.get_alpha(void) const*

Returns the α-value.

Classification_type

A.classify(Cell_handle c) const

Classifies the cell *c* of the underlying triangulation in the alpha complex.

Classification_type

A.classify(Facet f) const

Classifies the facet *f* of the underlying triangulation in the alpha complex.

Classification_type

A.classify(Cell_handle f, int i) const

Classifies the facet of the cell *f* opposite to the vertex with index *i* of the underlying triangulation in the alpha complex.

Classification_type

A.classify(Edge e) const

Classifies the edge *e* of the underlying triangulation in the alpha complex.

Classification_type

A.classify(Vertex_handle v) const

Classifies the vertex *v* of the underlying triangulation in the alpha complex.

template<class OutputIterator>
OutputIterator

A.get_alpha_shape_cells(OutputIterator it, Classification_type type)

Writes the cells which are of type *type* in the alpha complex to the sequence pointed to by the output iterator *it*. Returns past the end of the output sequence.

template<class OutputIterator>
OutputIterator

A.get_alpha_shape_facets(OutputIterator it, Classification_type type)

Writes the facets which are of type *type* in the alpha complex to the sequence pointed to by the output iterator *it*. Returns past the end of the output sequence.

template<class OutputIterator>
OutputIterator

A.get_alpha_shape_edges(OutputIterator it, Classification_type type)

Writes the edges which are of type *type* in the alpha complex to the sequence pointed to by the output iterator *it*. Returns past the end of the output sequence.

template<class OutputIterator>

OutputIterator

A.get_alpha_shape_vertices(OutputIterator it, Classification_type type)

Writes the vertices which are of type *type* in the alpha complex to the sequence pointed to by the output iterator *it*. Returns past the end of the output sequence.

I/O

The I/O operators are defined for *iostream*, and for the window stream provided by CGAL. The format for the iostream is an internal format.

#*include* <*CGAL/IO/io.h*>

ostream&	*ostream& os* $<<$ *A*	Inserts the alpha shape *A* into the stream *os*. *Requirement*: The insert operator must be defined for *GT::Point*.

Chapter 44

2D Segment Delaunay Graphs

Menelaos Karavelas

Contents

This chapter describes the two-dimensional segment Delaunay graph package of CGAL. We start with a few definitions in Section 44.1. The software design of the 2D segment Delaunay graph package is described in Section 44.2. In Section 44.3 we discuss the geometric traits of the 2D segment Delaunay graph package and in Section 44.4 the segment Delaunay graph hierarchy, a data structure suitable for fast nearest neighbor queries, is briefly described.

44.1 Definitions

The 2D segment Delaunay graph package of CGAL is designed to compute the Delaunay graph of a set of possibly intersecting segments on the plane. Although we compute the Delaunay graph, we will often refer to its dual, the segment Voronoi diagram, since it is easier to explain and understand. The algorithm that has been implemented is incremental. The corresponding CGAL class is called *Segment_Delaunay_graph_2< SegmentDelaunayGraphTraits_2,SegmentDelaunayGraphStructure_2>* and will be discussed in more detail in the sequel. The interested reader may want to refer to the paper by Karavelas [Kar04] for the general idea as well as the details of the algorithm implemented.

Definitions. Before describing the details of the implementation we make a brief introduction to the theory of segment Delaunay graphs and segment Voronoi diagrams. The segment Voronoi diagram is defined over a set

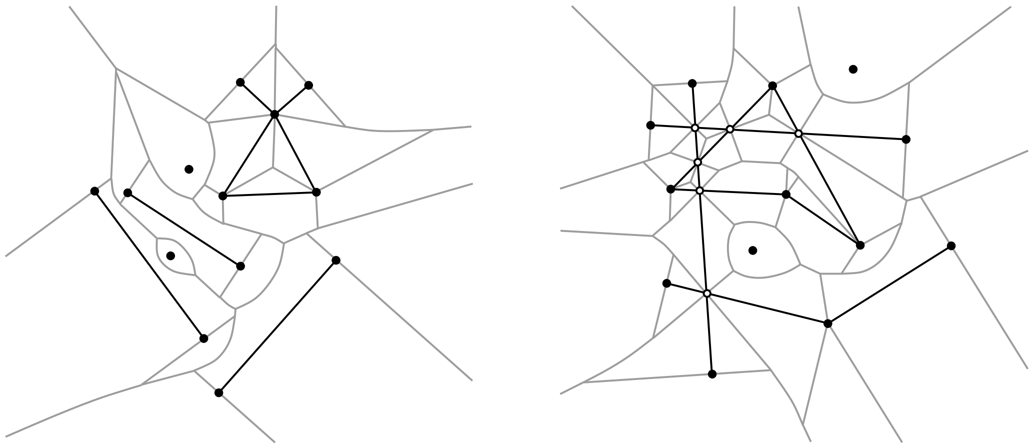

Figure 44.1: The segment Voronoi diagram for a set of weakly (left) and strongly (right) intersecting sites.

of non-intersecting sites, which can either be points or linear segments, which we assume that are given through their endpoints. The segment Voronoi diagram a subdivision of the plane into connected regions, called *cells*, associated with the sites. The dual graph of the segment Voronoi diagram is called the segment Delaunay graph. The cell of a site t_i is the locus of points on the plane that are closer to t_i than any other site t_j, $j \neq i$. The distance $\delta(x,t_i)$ of a point x in the plane to a site t_i is defined as the minimum of the Euclidean distances of x from the points in t_i. Hence, if t_i is a point p_i, then

$$\delta(x,t_i) = \|x - t_i\|,$$

whereas if t_i, is a segment, then

$$\delta(x,t_i) = \min_{y \in t_i} \|x - y\|,$$

where $\|\cdot\|$ denotes the Euclidean norm. It can easily be seen that it is a generalization of the Voronoi diagram for points.

In many applications the restriction that sites are non-intersecting is too strict. Often we want to allow segments that touch at their endpoints, or even segments that overlap or intersect properly at their interior (for example, see Fig. 44.1). Allowing such configurations poses certain problems. More specifically, when we allow segments to touch at their endpoints we may end up with pairs of segments whose bisector is two-dimensional. If we allow pairs of segments that intersect properly at their interior, the interiors of their Voronoi cells are no longer simply connected. In both cases above the resulting Voronoi diagrams are no longer instances of abstract Voronoi diagrams (cf. [Kle89]), which has a direct consequence on the efficient computation of the corresponding Voronoi diagram. The remedy to these problems is to consider linear segments not as one object, but rather as three, namely the two endpoints and the interior. This choice guarantees that all bisectors in the Voronoi diagram are one-dimensional and that all Voronoi cells are simply connected. Moreover, we further distinguish between two cases, according to the type of intersecting pair that our input data set contains. A pair of sites is called *weakly intersecting* if they have a single common point and this common point does not lie in the interior of any of the two sites. A pair of sites is called *strongly intersecting* if they intersect and they either have more than one common point or their common point lies in the interior of at least one of the two sites. As it will be seen later the two cases have different representation (and thus storage) requirements, as well as they require a somehow different treatment on how the predicates are evaluated. Having made the distinction between weakly and strongly intersecting sites, and having said that segment sites are treated as three objects, we are now ready to precisely define the Delaunay graph we compute. Given a set $\mathcal{S}$ of input sites, let $\mathcal{S}_{\mathcal{A}}$ be the set of points and (open) segments in the arrangement $\mathcal{A}(\mathcal{S})$ of $\mathcal{S}$. The 2D segment Delaunay graph package of CGAL computes the (triangulated) Delaunay graph that is dual to the Euclidean Voronoi diagram of the sites in the set $\mathcal{S}_{\mathcal{A}}$.

The segment Delaunay graph is uniquely defined once we have the segment Voronoi diagram. If the all sites are in *general position*, then Delaunay graph is a graph with triangular faces away from the convex hull of the set of sites. To unify our approach and handling of the Delaunay graph we add to the set of (finite) sites a fictitious site at infinity, which we call the *site at infinity*. We can then connect all vertices of the outer face of the Delaunay graph to the site at infinity which gives us a graph with the property that all of its faces are now triangular. However, the Delaunay graph is not a triangulation for two main reasons: we cannot always embed it on the plane with straight line segments that yield a triangulation and, moreover, we may have two faces of the graph that have two edges in common, which is not allowed in a triangulation.

We would like to finish our brief introduction to the theory of segment Delaunay graphs and segment Voronoi diagrams by discussing the concept of general position. We say that a set of sites is in general position if no two triplets of sites have the same tritangent Voronoi circle. This statement is rather technical and it is best understood in the context of points. The equivalent statement for points is that we have no two triplets of points that define the same circumcircle, or equivalently that no four points are co-circular. The statement about general position made above is a direct generalization of the (much simpler to understand) statement about points. On the contrary, when we have sites in degenerate position, the Delaunay graph has faces with more than three edges on their boundary. We can get a triangulated version of the Delaunay graph by simply *triangulating* the corresponding faces in an arbitrary way. In fact the algorithm that has been implemented in CGAL has the property that it always returns a valid *triangulated* version of the segment Delaunay graph. By valid we mean that it contains the actual (non-triangulated) Delaunay graph, and whenever there are faces with more than three faces then they are triangulated. The way that they are triangulated depends on the order of insertion of the sites in the diagram.

One final remark has to be made with respect to the difference between the set of *input sites* and the set of *output sites*. The set of input sites consists of the closed sites that the user inserts in the diagram. Since segment sites are treated as three objects, internally our algorithm sees only points and open segments. As a result, from the point of view of the algorithm, the input sites have no real meaning. What has real meaning is the set of sites that correspond to cells of the Voronoi diagram and this is the set of output sites.

Degenerate Dimensions. The dimension of the segment Delaunay graph is in general 2. The exceptions to this rule are as follows:

- The dimension is -1 if the segment Delaunay graph contains no sites.
- The dimension is 0 if the segment Delaunay graph contains exactly one (output) site.
- The dimension is 1 is the segment Delaunay graph contains exactly two (output) sites.

44.2 Software Design

The 2D segment Delaunay graph class *Segment_Delaunay_graph_2<SegmentDelaunayGraphTraits_2,SegmentDelaunayGraphDataStructure_2>* follows the design of the triangulation package of CGAL. It is parametrized by two arguments:

- the **geometric traits** class. It provides the basic geometric objects involved in the algorithm, such as sites, points etc. It also provides the geometric predicates for the computation of the segment Delaunay graph, as well as some basic constructions that can be used, for example, to visualize the diagram. The geometric traits for the segment Delaunay graph will be discussed in more detail in the next section.
- the **segment Delaunay graph data structure**. This is essentially the same as the Apollonius graph data structure (discussed in Chapter 45.2), augmented with some additional operations that are specific to segment Voronoi diagrams. The corresponding concept is that of *SegmentDelaunayGraphDataStructure_2*,

which in fact is a refinement of the *ApolloniusGraphDataStructure_2* concept. The class *Triangulation_data_structure_2<Vb,Fb>* is a model of the concept *SegmentDelaunayGraphDataStructure_2*. A default value for the corresponding template parameter is provided, so the user does not need to specify it.

Strongly Intersecting Sites and their Representation. As we have mentioned above, the segment Delaunay graph package of CGAL is designed to support the computation of the segment Voronoi diagram even when the input segment sites are intersecting. This choice poses certain issues for the design of the software package. The major concern is the representation of the subsegments that appear in the arrangement of the these sites, because the sites in the arrangement are the ones over which the diagram is actually defined. A direct consequence of the choice of representation is the algebraic degree of the predicates involved in the computation of the segment Delaunay graph, as well as the storage requirements for the subsegments and points on intersection in the arrangement.

The case of weakly intersecting sites does not require any special treatment. We can simply represent points by their coordinates and segments by their endpoints. In the case of strongly intersecting sites, the obvious choice to use the afore-mentioned representation has severe disadvantages. Consider two strongly intersecting segments t_i and t_j, whose endpoints have homogeneous coordinates of size b. Their intersection point will have homogeneous coordinates of bit size $6b+O(1)$. This effect can be cascaded, which implies that after inserting k (input) segments we can arrive at having points of intersection whose bit sizes are exponential with respect to k, i.e., their homogeneous coordinates will have bit size $\Omega(2^k b)$. Not only the points of intersection, but also the adjacent subsegments will be represented by quantities of arbitrarily high bit size, and as a result we would not be able to give a bound on the bit sizes of the coordinates of the points of intersection. As a result, we would not be able to give a bound on the memory needed to store these coordinates. An equally important consequence is that we would also not be able to give a bound on the algebraic degree of the algebraic expressions involved in the evaluation of the predicates.

Such a behavior is obviously undesirable. For robustness, efficiency, and scalability purposes, it is critical that the bit size of the algebraic expressions in the predicates does not depend on the input size. For this reason, as well as for others to be discussed below, we decided to represent sites in a implicit manner, which somehow encodes the history of their construction. In particular, we exploit the fact that points of intersection always lie on two input segments, and that segments that are not part of the input are always supported by input segments.

For example, let us consider the configuration in Fig. 44.2. We assume that the segments $t_i = p_i q_i$, $i = 1,2,3$, are inserted in that order. Upon the insertion of t_2, our algorithm will split the segment t_1 into the subsegments $p_1 s_1$ and $s_1 q_1$, then add s_1, and finally insert the subsegments $p_2 s_1$ and $s_1 q_2$. How do we represent the five new sites? s_1 will be represented by its two defining segments t_1 and t_2. The segment $p_1 s_1$ will be represented by two segments, a point, and a boolean. The first segment is t_1, which is always the segment with the same support as the newly created segment. The second segment is t_2 and the point is p_1. The boolean indicates whether the first endpoint of $p_1 s_1$ is an input point; in this case the boolean is equal to *true*. The segment $s_1 q_1$ will also be represented by two segments, a point, and a boolean, namely, t_1 (the supporting segment of $s_1 q_1$), t_2 and *false* (it is the second endpoint of $s_1 q_1$ that is an input point). Subsegments $p_2 s_1$ and $s_1 q_2$ are represented analogously. Consider now what happens when we insert t_3. The point s_2 will again be represented by two segments, but not $s_1 q_1$ and t_3. In fact, it will be represented by t_1 (the supporting segment of $s_1 q_1$) and t_3. $s_2 q_1$ will be represented by two segments, a point, and a boolean (t_1, t_3, $q1$ and *false*), and similarly for $p_3 s_2$ and $s_2 q_3$. On the other hand, both endpoints of $s_1 s_2$ are non-input points. In such a case we represent the segment by three input segments. More precisely, $s_1 s_2$ is represented by the segments t_1 (the supporting segment of $s_1 q_1$), t_2 (it defines s_1 along with t_1) and t_3 (it defines s_2 along with t_1).

The five different presentations, two for points (coordinates; two input segments) and three for segments (two input points; two input segments, an input point and a boolean; three input segments), form a closed set of representations and thus represent any point of intersection or subsegment regardless of the number of input segments. Moreover, every point (input or intersection) has homogeneous coordinates of bit size at most $3b+O(1)$. The supporting lines of the segments (they are needed in some of the predicates) have coefficients which are always of bit size $2b+O(1)$. As a result, the bit size of the expressions involved in our predicates will always

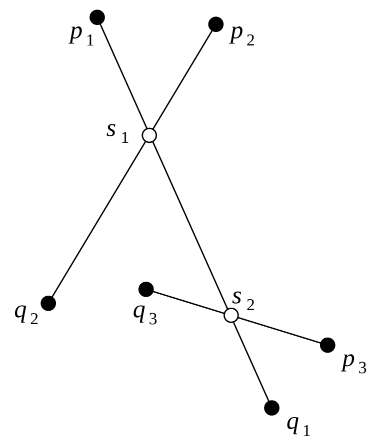

Figure 44.2: Site representation. The point s_1 is represented by the four points p_1, q_1, p_2 and q_2. The segment $p_1 s_1$ is represented by the points p_1, q_1, p_2, q_2 and a boolean which is set to *true* to indicate that the first endpoint in not a point of intersection. The segment $s_1 s_2$ is represented by the six points: p_1, q_1, p_2, q_2, p_3 and q_3. The remaining (non-input) points and segments in the figure are represented similarly.

be $O(b)$, independently of the size of the input. The *SegmentDelaunayGraphSite_2* concept encapsulates the ideas presented above. A site is represented in this concept by up to four points and a boolean, or up to six points, depending on its type. The class *Segment_Delaunay_graph_site_2<K>* implements this concept.

Even this representation, however, has some degree of redundancy. The endpoint of a segment appears in both the representation of the (open) segment site as well as the representation of the point site itself. The situation becomes even worse in the presence of strongly intersecting sites: a point may appear in the representation of multiple subsegments and/or points of intersection. To avoid this redundancy, input points are stored in a container, and the various types of sites (input points and segments, points of intersection, subsegments with one or two points of intersection as endpoints) only store handles to the points in the container. This is achieved by the *Segment_Delaunay_graph_storage_site_2<Gt>* class which is a model of the corresponding concept: *SegmentDelaunayGraphStorageSite_2*. This concept enforces a site to be represented by up to 6 handles (which are very lightweight objects) instead of 6 points, which are, compared to handles of course, very heavy objects.

Optimizing Memory Allocation. There are applications where we know beforehand that the input consists of only weakly intersecting sites. In these cases the site representation described above poses a significant overhead in the memory requirements of our implementation: instead of representing sites with up to two points (or ultimately with to two handles), we require sites to store six points (respectively, six handles). To avoid this overhead we have introduced two series of traits classes:

- One that supports the full-fledged sites, and is suitable when the input consists of strongly intersecting sites. This series consists of the *Segment_Delaunay_graph_traits_2<K,MTag>* and *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* classes.
- One that is customized for input that contain only weakly intersecting sites. This series consists of the *Segment_Delaunay_graph_traits_without_intersections_2<K,MTag>* and *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>* classes.

The advantages of having different traits classes are as follows:

- When the user chooses to use one of the traits classes in the second series we only store two handles per site. This implies a reduction by a factor of three in the memory allocated per site with respect to the first series of traits classes.

- In the case of the first series of traits classes, we can better exploit the knowledge that have strongly intersecting sites, in order to further apply geometric filters (see below) during the evaluation of the predicates. On the contrary, if the second series of traits classes is used, we can avoid geometric filtering tests that have meaning only in the case of strongly intersecting sites.

44.3 The Geometric Traits

The predicates required for the computation of the segment Voronoi diagram are rather complicated. It is not the purpose of this document to discuss them in detail. The interested reader may refer to Burnikel's thesis [Bur96], where it is shown that in the case of weakly intersecting sites represented in homogeneous coordinates of bit size b, the maximum bit size of the algebraic expressions involved in the predicates is $40b+O(1)$. Given our site representation given above we can guarantee that even in the case of strongly intersecting sites, the algebraic degree of the predicates remains $O(b)$, independently of the size of the input. What we want to focus in the remainder of this section are the different kinds of filtering techniques that we have employed in our implementation.

Geometric Filtering. Our representation of sites is coupled very naturally, with what we call *geometric filtering*. The technique amounts to performing simple geometric tests exploiting the representation of our data, as well as the geometric structure inherent in our problem, in order to evaluate predicates in seemingly degenerate configurations. Geometric filtering can be seen as a preprocessing step before performing arithmetic filtering. Roughly speaking, by arithmetic filtering we mean that we first try to evaluate the predicates using a fixed-precision floating-point number type (such as `double`), and at the same time keep error bounds on the numerical errors of the computations we perform. If the numerical errors are too big and do not permit us to evaluate the predicate, we switch to an exact number type, and repeat the evaluation of the predicate. Geometric filtering can help by eliminating situations in which the arithmetic filter will fail, thus decreasing the number of times we need to evaluate a predicate using exact arithmetic.

To illustrate the application and effectiveness of this approach, let us consider a very simple example usage. Suppose we want to determine if two non-input points are identical (we assume here that the input sites are represented by *double*s). In order to do that we need to compute their coordinates and compare them. If the two points are identical, the answer to our question using *double* arithmetic may be wrong (due to numerical errors), in which case we will have to reside to the more expensive exact computation. Instead, before testing the coordinates for equality, we can use the representation of the points to potentially answer the question. More specifically, and this is the geometric filtering part of the computation, we can first test if the defining segments of the two points are the same. If they are not, then we proceed to comparing their coordinates as usual. Testing the defining segments for equality does not involve any arithmetic operations on the input, but rather only comparisons on *double*s. By performing this very simple test we avoid a numerically difficult computation, which could be performed thousands of times during the computation of a Delaunay graph.

Geometric filtering has been implemented in all our models of the *SegmentDelaunayGraphTraits_2* concept. These models are the classes: *Segment_Delaunay_graph_traits_2<K,MTag>*, *Segment_Delaunay_graph_traits_without_intersections_2<K,MTag>*, *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* and *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>*.

Arithmetic Filtering. As mentioned above, performing computations with exact arithmetic can be very costly. For this reason we have devoted considerable effort in implementing different kinds of arithmetic filtering mechanisms. Presently, there two ways of performing arithmetic filtering for the predicates involved in the computation of segment Delaunay graphs:

1. The user can define his/her kernel using as number type, a number type of the form *CGAL::Filtered_exact<CT,ET>*. Then this kernel can be entered as the first template parameter in the *Segment_Delaunay_graph_2<K,MTag>* or *Segment_Delaunay_graph_without_intersections_2<K,MTag>* class.

2. The user can define up to three different kernels *CK*, *FK* and *EK* (default values are provided for most parameters). The first kernel *CK* is used only for constructions. The second kernel *FK* is the filtering kernel: the traits class will attempt to compute the predicates using this kernel. If the filtering kernel fails to successfully compute a predicate, the exact kernel *EK* will be used. These three kernels are then used in the *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* and *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>* classes, which have been implemented using the *Filtered_predicate<EP,FP>* mechanism.

Our experience so far has shown that for all reasonable and valid values of the template parameters, the second method for arithmetic filtering is more efficient among the two.

Let's consider once more the classes *Segment_Delaunay_graph_2<K,MTag>* and *Segment_Delaunay_graph_without_intersections_2<K,MTag>*. The template parameter *MTag* provides another degree of freedom to the user, who can indicate the type of arithmetic operations to be used in the evaluation of the predicates. More specifically, in both classes, *MTag* can be *CGAL::Field_with_sqrt_tag*, in which case the predicates will be evaluated using all four basic arithmetic operations plus square roots; this requires, of course, that the number type used in the kernel *K* supports these operations exactly. The second choices are *CGAL::Field_tag* for the *Segment_Delaunay_graph_2<K,MTag>* class, and *CGAL::Euclidean_ring_tag* for the *Segment_Delaunay_graph_without_intersections_2<K,MTag>* class. In the first case we indicate that we want the predicates to be computed using only the four basic arithmetic operations, whereas in the second case we evaluate the predicates using only ring operations. Again, for the predicates to be evaluated correctly, the number type used in the kernel *K* must support the corresponding operations exactly.

The semantics for the template parameters *CM*, *FM* and *EM* in the *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* and *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>* classes are analogous. With each of these template parameters we can control the type of arithmetic operations that are going to be used in calculations involving each of the corresponding kernels *CK*, *FK* and *EK*. When the *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* is used the possible values for *CM*, *FM* and *EM* are *CGAL::Field_with_sqrt_tag* and *CGAL::Field_tag*, whereas if the *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>* class is used, the possible values are *CGAL::Field_with_sqrt_tag* and *CGAL::Euclidean_ring_tag*. The semantics are the same as in the case of the *Segment_Delaunay_graph_2<K,MTag>* and *Segment_Delaunay_graph_without_intersections_2<K,MTag>* classes.

44.4 The Segment Delaunay Graph Hierarchy

The *Segment_Delaunay_graph_hierarchy_2<SegmentDelaunayGraphTraits_2, SSTag, SegmentDelaunayGraphDataStructure_2>* class is the analogue of the *Triangulation_hierarchy_2* or the *Apollonius_graph_hierarchy_2* classes, applied to the segment Delaunay graph. It consists of a hierarchy of segment Delaunay graphs constructed in a manner analogous to the Delaunay hierarchy by Devillers [Dev02]. Unlike the triangulation hierarchy or the Apollonius graph hierarchy, the situation here is more complicated because of two factors: firstly, segments are treated as three objects instead of one (the two endpoints and the interior of the segments), and secondly, the presence of strongly intersecting sites complicates significantly the way the hierarchy is constructed. The interested reader may refer to the paper by Karavelas [Kar04] for the details of the construction of the hierarchy. Another alternative is to have a hybrid hierarchy that consists of the segment Delaunay graph at the bottom-most level and point Voronoi diagrams at all other levels. This choice seems to work very well in practice , primarily because it avoids the overhead of maintaining a Delaunay graph for segments at the upper levels of the hierarchy. However, it seems much less likely to be possible to give any theoretical guarantees for its performance, in contrast to the hierarchy with segment Delaunay graphs at all levels (cf. [Kar04]). The user can choose between the two types of hierarchies by means of the template parameter *SSTag*. If *SSTag* is set to *false* (which is also the default value), the upper levels of the hierarchy consist of point Delaunay graphs. If *SSTag* is set to *true*, we have segment Delaunay graphs at all levels of the hierarchy.

The class *Segment_Delaunay_graph_hierarchy_2<SegmentDelaunayGraphTraits_2, SSTag, SegmentDelaunayGraphDataStructure_2>* has exactly the same interface and functionality as the *Segment_Delaunay_graph_2<SegmentDelaunayGraphTraits_2,SegmentDelaunayGraphDataStructure_2>* class. Using the segment Delaunay graph hierarchy involves an additional cost in space and time for maintaining the hierarchy. Our experiments have shown that it usually pays off to use the hierarchy for inputs consisting of more than about 1,000 sites.

44.5 Examples

44.5.1 First Example

The following example shows how to use the segment Delaunay graph traits in conjunction with the *Filtered_exact<CT,ET>* mechanism. In addition it shows how to use a few of the iterators provided by the *Segment_Delaunay_graph_2* class in order to count a few site-related quantities.

```
#include <iostream>
#include <fstream>
#include <cassert>

// define the exact number type
#  include <CGAL/Quotient.h>
#  include <CGAL/MP_Float.h>
typedef CGAL::Quotient<CGAL::MP_Float>  ENT;

// define the kernels
#include <CGAL/Simple_cartesian.h>

typedef CGAL::Simple_cartesian<double>     CK;
typedef CGAL::Simple_cartesian<ENT>        EK;

// typedefs for the traits and the algorithm
#include <CGAL/Segment_Delaunay_graph_filtered_traits_2.h>
#include <CGAL/Segment_Delaunay_graph_2.h>

typedef CGAL::Segment_Delaunay_graph_filtered_traits_2<CK,
/* The construction kernel allows for / and sqrt */
   CGAL::Field_with_sqrt_tag,
                                                        EK,
/* The exact kernel supports field ops exactly */      CGAL::Field_tag>
   Gt;

typedef CGAL::Segment_Delaunay_graph_2<Gt>             SDG2;
```

```
using namespace std;

int main() {
  ifstream ifs("data/sitesx.cin");
  assert( ifs );

  SDG2          sdg;
  SDG2::Site_2  site;

  while ( ifs >> site ) { sdg.insert( site ); }

  ifs.close();

  assert( sdg.is_valid(true, 1) );
  cout << endl << endl;

  // print the number of input and output sites
  cout << "# of input sites : " << sdg.number_of_input_sites() << endl;
  cout << "# of output sites: " << sdg.number_of_output_sites() << endl;

  unsigned int n_ipt(0), n_iseg(0), n_opt(0), n_oseg(0), n_ptx(0);

  // count the number of input points and input segments
  SDG2::Input_sites_iterator iit;
  for (iit = sdg.input_sites_begin(); iit != sdg.input_sites_end();
   ++iit)
    {
      if ( iit->is_point() ) { n_ipt++; } else { n_iseg++; }
    }

  // count the number of output points and output segments, as well
  // as the number of points that are points of intersection of pairs
  // of strongly intersecting sites
  SDG2::Output_sites_iterator oit;
  for (oit = sdg.output_sites_begin(); oit != sdg.output_sites_end();
   ++oit)
    {
      if ( oit->is_segment() ) { n_oseg++; } else {
        n_opt++;
        if ( !oit->is_input() ) { n_ptx++; }
      }
    }

  cout << endl << "# of input segments:  " << n_iseg << endl;
  cout << "# of input points:    " << n_ipt << endl << endl;
  cout << "# of output segments: " << n_oseg << endl;
  cout << "# of output points:   " << n_opt << endl << endl;
  cout << "# of intersection points: " << n_ptx << endl;

  return 0;
}
```

File: examples/Segment_Delaunay_graph_2/sdg-count-sites.cpp

44.5.2 Second Example

The following example shows how to use the segment Delaunay graph hierarchy along with the filtered traits class that supports intersecting sites.

```
#include <iostream>
#include <fstream>
#include <cassert>

// example that uses the filtered traits and
// the segment Delaunay graph hierarchy

// choose the kernel
#include <CGAL/Simple_cartesian.h>

struct Rep : public CGAL::Simple_cartesian<double> {};

// typedefs for the traits and the algorithm
#include <CGAL/Segment_Delaunay_graph_hierarchy_2.h>
#include <CGAL/Segment_Delaunay_graph_filtered_traits_2.h>

struct Gt
  : public CGAL::Segment_Delaunay_graph_filtered_traits_2<Rep> {};

typedef CGAL::Segment_Delaunay_graph_hierarchy_2<Gt>  SDG2;

int main()
{
  std::ifstream ifs("data/sites.cin");
  assert( ifs );

  SDG2          sdg;
  SDG2::Site_2  site;

  // read the sites and insert them in the segment Delaunay graph
  while ( ifs >> site ) {
    sdg.insert(site);
  }

  // validate the segment Delaunay graph
  assert( sdg.is_valid(true, 1) );

  return 0;
}
```

File: examples/Segment_Delaunay_graph_2/sdg-filtered-traits.cpp

44.5.3 Third Example

The following example demonstrates how to recover the defining sites for the edges of the Voronoi diagram (which are the duals of the edges of the segment Delaunay graph computed).

```
#include <iostream>
#include <fstream>
#include <cassert>
#include <string>

// define the kernel
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Filtered_kernel.h>

typedef CGAL::Simple_cartesian<double>    CK;
typedef CGAL::Filtered_kernel<CK>         Kernel;

// typedefs for the traits and the algorithm
#include <CGAL/Segment_Delaunay_graph_traits_2.h>
#include <CGAL/Segment_Delaunay_graph_2.h>

typedef CGAL::Segment_Delaunay_graph_traits_2<Kernel>  Gt;
typedef CGAL::Segment_Delaunay_graph_2<Gt>             SDG2;

using namespace std;

int main()
{
  ifstream ifs("data/sites2.cin");
  assert( ifs );

  SDG2          sdg;
  SDG2::Site_2  site;

  // read the sites from the stream and insert them in the diagram
  while ( ifs >> site ) { sdg.insert( site ); }

  ifs.close();

  // validate the diagram
  assert( sdg.is_valid(true, 1) );
  cout << endl << endl;

  /*
  // now walk through the non-infinite edges of the segment Delaunay
  // graphs (which are dual to the edges in the Voronoi diagram) and
  // print the sites defining each Voronoi edge.
  //
  // Each oriented Voronoi edge (horizontal segment in the figure
  // below) is defined by four sites A, B, C and D.
  //
  //       \                     /
  //        \         B         /
  //         \                 /
```

```
  //     C  -----------------  D
  //       /                  \
  //      /         A          \
  //     /                      \
  //
  // The sites A and B define the (oriented) bisector on which the
  // edge lies whereas the sites C and D, along with A and B define
  // the two endpoints of the edge. These endpoints are the Voronoi
  // vertices of the triples A, B, C and B, A, D.
  // If one of these vertices is the vertex at infinity the string
  // "infinite vertex" is printed; the corresponding Voronoi edge is
  // actually a stright-line or parabolic ray.
  // The sites below are printed in the order A, B, C, D.
  */

  string inf_vertex("infinite vertex");
  char vid[] = {'A', 'B', 'C', 'D'};

  SDG2::Finite_edges_iterator eit = sdg.finite_edges_begin();
  for (int k = 1; eit != sdg.finite_edges_end(); ++eit, ++k) {
    SDG2::Edge e = *eit;
    // get the vertices defining the Voronoi edge
    SDG2::Vertex_handle v[] = { e.first->vertex( sdg.ccw(e.second) ),
                                e.first->vertex( sdg.cw(e.second) ),
                                e.first->vertex( e.second ),
                                sdg.tds().mirror_vertex(e.first,
   e.second) };

    cout << "--- Edge " << k << " ---" << endl;
    for (int i = 0; i < 4; i++) {
      // check if the vertex is the vertex at infinity; if yes, print
      // the corresponding string, otherwise print the site
      if ( sdg.is_infinite(v[i]) ) {
        cout << vid[i] << ": " << inf_vertex << endl;
      } else {
        cout << vid[i] << ": " << v[i]->site() << endl;
      }
    }
    cout << endl;
  }

  return 0;
}
```

2D Segment Delaunay Graphs Reference Manual

Menelaos Karavelas

CGAL provides the class *CGAL::Segment_Delaunay_graph_2<Gt,DS>* for computing the 2D Delaunay graph of segments and points. The two template parameters must be models of the *SegmentDelaunayGraphTraits_2* and *SegmentDelaunayGraphDataStructure_2* concepts. The first concept is related to the geometric objects and predicates associated with segment Delaunay graphs, whereas the second concept refers to the data structure used to represent the segment Delaunay graph, which is dual to the 2D Voronoi diagram of segments and points. The classes *Segment_Delaunay_graph_traits_2<K,MTag>*, *Segment_Delaunay_graph_traits_without_intersections_2<K,MTag>* *Segment_Delaunay_graph_filtered_traits_2<K,MTag>* *Segment_Delaunay_graph_filtered_traits_without_intersections_2<K,MTag>* are models of the *SegmentDelaunayGraphTraits_2* concept, whereas the class *Triangulation_data_structure_2<Vb,Fb>* is a model of the *SegmentDelaunayGraphDataStructure_2* concept.

CGAL::Segment_Delaunay_graph_2<Gt,DS>

Definition

The class *Segment_Delaunay_graph_2<Gt,DS>* represents the segment Delaunay graph (which is the dual graph of the 2D segment Voronoi diagram). Currently it supports only insertions of sites. It is templated by two template arguments *Gt*, which must be a model of *SegmentDelaunayGraphTraits_2* and *DS*, which must be a model of *SegmentDelaunayGraphDataStructure_2*. The second template argument defaults to *CGAL::Triangulation_data_structure_2< CGAL::Segment_Delaunay_graph_vertex_base_2<Gt>, CGAL::Triangulation_face_base_2< Gt> >*.

#include <CGAL/Segment_Delaunay_graph_2.h>

Is Model for the Concepts

DelaunayGraph_2

Types

typedef Gt	*Geom_traits;*	A type for the geometric traits.
typedef DS	*Data_structure;*	A type for the underlying data structure.
typedef Data_structure	*Triangulation_data_structure;*	
		This type has been added so that the *Segment_Delaunay_graph_2<Gt,DS>* class is a model of the *DelaunayGraph_2* concept.
typedef typename DS::size_type	*size_type;*	Size type (an unsigned integral type)
typedef typename Gt::Point_2	*Point_2;*	A type for the point defined in the geometric traits.
typedef typename Gt::Site_2	*Site_2;*	A type for the segment Delaunay graph site, defined in the geometric traits.
Segment_Delaunay_graph_2<Gt,DS>:: Point_container		A type for the container of points.
typedef typename Point_container::iterator	*Point_handle;*	A handle for points in the point container.

The vertices and faces of the segment Delaunay graph are accessed through *handles*, *iterators* and *circulators*. The iterators and circulators are all bidirectional and non-mutable. The circulators and iterators are assignable to the corresponding handle types, and they are also convertible to the corresponding handles. The edges of the segment Delaunay graph can also be visited through iterators and circulators, the edge circulators and iterators are also bidirectional and non-mutable. In the following, we call *infinite* any face or edge incident to the infinite vertex and the infinite vertex itself. Any other feature (face, edge or vertex) of the segment Delaunay graph is said to be *finite*. Some iterators (the *All* iterators) allow to visit finite or infinite features while the others (the *Finite* iterators) visit only finite features. Circulators visit both infinite and finite features.

typedef typename DS::Edge	*Edge;*	The edge type. The *Edge(f,i)* is the edge common to faces *f* and *f.neighbor(i)*. It is also the edge joining the vertices *vertex(cw(i))* and *vertex(ccw(i))* of *f*. *Precondition*: *i* must be *0*, *1* or *2*.

typedef typename DS::Vertex	*Vertex;*	A type for a vertex.
typedef typename DS::Face	*Face;*	A type for a face.
typedef typename DS::Vertex_handle	*Vertex_handle;*	A type for a handle to a vertex.
typedef typename DS::Face_handle	*Face_handle;*	A type for a handle to a face.
typedef typename DS::Vertex_circulator	*Vertex_circulator;*	A type for a circulator over vertices incident to a given vertex.
typedef typename DS::Face_circulator	*Face_circulator;*	A type for a circulator over faces incident to a given vertex.
typedef typename DS::Edge_circulator	*Edge_circulator;*	A type for a circulator over edges incident to a given vertex.
typedef typename DS::Vertex_iterator	*All_vertices_iterator;*	A type for an iterator over all vertices.
typedef typename DS::Face_iterator	*All_faces_iterator;*	A type for an iterator over all faces.
typedef typename DS::Edge_iterator	*All_edges_iterator;*	A type for an iterator over all edges.
Segment_Delaunay_graph_2<Gt,DS>:: Finite_vertices_iterator		A type for an iterator over finite vertices.
Segment_Delaunay_graph_2<Gt,DS>:: Finite_faces_iterator		A type for an iterator over finite faces.
Segment_Delaunay_graph_2<Gt,DS>:: Finite_edges_iterator		A type for an iterator over finite edges.

In addition to iterators and circulators for vertices and faces, iterators for sites are provided. In particular there are iterators for the set of input sites and the set of output sites. The set of input sites is the set of sites inserted by the user using the *insert* methods of this class. If a site is inserted multiple times, every instance of this site will be reported. The set of output sites is the set of sites in the segment Delaunay graph. The value type of these iterators is *Site_2*.

Segment_Delaunay_graph_2<Gt,DS>:: Input_sites_iterator

A type for a bidirectional iterator over all input sites.

Segment_Delaunay_graph_2<Gt,DS>:: Output_sites_iterator

A type for a bidirectional iterator over all output sites (the sites in the Delaunay graph).

Creation

In addition to the default and copy constructors the following constructors are defined:

Segment_Delaunay_graph_2<Gt,DS> sdg(Gt gt=Gt());

Creates the segment Delaunay graph using *gt* as geometric traits.

template< class Input_iterator >
Segment_Delaunay_graph_2<Gt,DS> sdg(Input_iterator first, Input_iterator beyond, Gt gt=Gt());

Creates the segment Delaunay graph using *gt* as geometric traits and inserts all sites in the range [*first*, *beyond*).
Precondition: *Input_iterator* must be a model of *InputIterator*. The value type of *Input_iterator* must be either *Point_2* or *Site_2*.

Access Functions

Geom_traits *sdg.geom_traits()*

Returns a reference to the segment Delaunay graph traits object.

int	*sdg.dimension()*	Returns the dimension of the segment Delaunay graph. The dimension is -1 if the graph contains no sites, 0 if the graph contains one site, 1 if it contains two sites and 2 if it contains three or more sites.
size_type	*sdg.number_of_vertices()*	Returns the number of finite vertices of the segment Delaunay graph.
size_type	*sdg.number_of_faces()*	Returns the number of faces (both finite and infinite) of the segment Delaunay graph.
size_type	*sdg.number_of_input_sites()*	Return the number of input sites.
size_type	*sdg.number_of_output_sites()*	Return the number of output sites. This is equal to the number of vertices in the segment Delaunay graph.
Face_handle	*sdg.infinite_face()*	Returns a face incident to the *infinite_vertex*.
Vertex_handle	*sdg.infinite_vertex()*	Returns the *infinite_vertex*.
Vertex_handle	*sdg.finite_vertex()*	Returns a vertex distinct from the *infinite_vertex*. *Precondition*: The number of sites in the segment Delaunay graph must be at least one.
Data_structure	*sdg.data_structure()*	Returns a reference to the segment Delaunay graph data structure object.
Data_structure	*sdg.tds()*	Same as *data_structure()*. It has been added for compliance to the *DelaunayGraph_2* concept.
Point_container	*sdg.point_container()*	Returns a reference to the point container object.

Traversal of the segment Delaunay graph

A segment Delaunay graph can be seen as a container of faces and vertices. Therefore the *Segment_Delaunay_graph_2<Gt,DS>* class provides several iterators and circulators that allow to traverse it (completely or partially).

Face, Edge and Vertex Iterators

The following iterators allow respectively to visit finite faces, finite edges and finite vertices of the segment Delaunay graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the segment Delaunay graph.

Finite_vertices_iterator	*sdg.finite_vertices_begin()*	Starts at an arbitrary finite vertex.
Finite_vertices_iterator	*sdg.finite_vertices_end()*	Past-the-end iterator.
Finite_edges_iterator	*sdg.finite_edges_begin()*	Starts at an arbitrary finite edge.
Finite_edges_iterator	*sdg.finite_edges_end()*	Past-the-end iterator.
Finite_faces_iterator	*sdg.finite_faces_begin()*	Starts at an arbitrary finite face.
Finite_faces_iterator	*sdg.finite_faces_end() const*	Past-the-end iterator.

The following iterators allow respectively to visit all (both finite and infinite) faces, edges and vertices of the segment Delaunay graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the segment Delaunay graph.

All_vertices_iterator	*sdg.all_vertices_begin()*	Starts at an arbitrary vertex.
All_vertices_iterator	*sdg.all_vertices_end()*	Past-the-end iterator.
All_edges_iterator	*sdg.all_edges_begin()*	Starts at an arbitrary edge.

All_edges_iterator	*sdg.all_edges_end()*	Past-the-end iterator.

All_faces_iterator	*sdg.all_faces_begin()*	Starts at an arbitrary face.
All_faces_iterator	*sdg.all_faces_end()*	Past-the-end iterator.

Site iterators

The following iterators allow respectively to visit all sites. These iterators are non-mutable, bidirectional and their value type is *Site_2*. They are all invalidated by any change in the segment Delaunay graph.

Input_sites_iterator	*sdg.input_sites_begin()*	Starts at an arbitrary input site.
Input_sites_iterator	*sdg.input_sites_end()*	Past-the-end iterator.
Output_sites_iterator	*sdg.output_sites_begin()*	Starts at an arbitrary output site.
Output_sites_iterator	*sdg.output_sites_end()*	Past-the-end iterator.

Face, Edge and Vertex Circulators

The *Segment_Delaunay_graph_2<Gt,DS>* class also provides circulators that allow to visit respectively all faces or edges incident to a given vertex or all vertices adjacent to a given vertex. These circulators are non-mutable and bidirectional. The operator *operator++* moves the circulator counterclockwise around the vertex while the *operator--* moves clockwise. A face circulator is invalidated by any modification of the face pointed to. An edge circulator is invalidated by any modification in one of the two faces incident to the edge pointed to. A vertex circulator is invalidated by any modification in any of the faces adjacent to the vertex pointed to.

Face_circulator *sdg.incident_faces(Vertex_handle v)*

Starts at an arbitrary face incident to v.

Face_circulator *sdg.incident_faces(Vertex_handle v, Face_handle f)*

Starts at face f.
Precondition: Face f is incident to vertex v.

Edge_circulator *sdg.incident_edges(Vertex_handle v)*

Starts at an arbitrary edge incident to v.

Edge_circulator *sdg.incident_edges(Vertex_handle v, Face_handle f)*

Starts at the first edge of f incident to v, in counterclockwise order around v.
Precondition: Face f is incident to vertex v.

Vertex_circulator *sdg.incident_vertices(Vertex_handle v)*

Starts at an arbitrary vertex incident to v.

Vertex_circulator *sdg.incident_vertices(Vertex_handle v, Face_handle f)*

Starts at the first vertex of f adjacent to v in counterclockwise order around v.
Precondition: Face f is incident to vertex v.

Traversal of the Convex Hull

Applied on the *infinite_vertex* the above methods allow to visit the vertices on the convex hull and the infinite edges and faces. Note that a counterclockwise traversal of the vertices adjacent to the *infinite_vertex* is a clockwise traversal of the convex hull.

Vertex_circulator *sdg.incident_vertices(sdg.infinite_vertex())*
Vertex_circulator *sdg.incident_vertices(sdg.infinite_vertex(), Face_handle f)*
Face_circulator *sdg.incident_faces(sdg.infinite_vertex())*
Face_circulator *sdg.incident_faces(sdg.infinite_vertex(), Face_handle f)*
Edge_circulator *sdg.incident_edges(sdg.infinite_vertex())*
Edge_circulator *sdg.incident_edges(sdg.infinite_vertex(), Face_handle f)*

Predicates

The class *Segment_Delaunay_graph_2<Gt,DS>* provides methods to test the finite or infinite character of any feature.

bool *sdg.is_infinite(Vertex_handle v) const*

true, iff *v* is the *infinite_vertex*.

bool *sdg.is_infinite(Face_handle f) const* *true*, iff face *f* is infinite.

bool *sdg.is_infinite(Face_handle f, int i) const*

true, iff edge *(f,i)* is infinite.

bool *sdg.is_infinite(Edge e) const* *true*, iff edge *e* is infinite.

bool *sdg.is_infinite(Edge_circulator ec) const*

true, iff edge **ec* is infinite.

Insertion

template< class Input_iterator >
size_type *sdg.insert(Input_iterator first, Input_iterator beyond)*

Inserts the sites in the range [*first*,*beyond*). The number of additional sites inserted in the Delaunay graph is returned. *Input_iterator* must be a model of *InputIterator* and its value type must be either *Point_2* or *Site_2*.

template< class Input_iterator >
size_type *sdg.insert(Input_iterator first, Input_iterator beyond, Tag_false)*

Same as the previous method. *Input_iterator* must be a model of *InputIterator* and its value type must be either *Point_2* or *Site_2*.

template< class Input_iterator >

size_type *sdg.insert(Input_iterator first, Input_iterator beyond, Tag_true)*

Inserts the sites in the range [*first*,*beyond*) after performing a random shuffle on them. The number of additional sites inserted in the Delaunay graph is returned. *Input_iterator* must be a model of *InputIterator* and its value type must be either *Point_2* or *Site_2*.

Vertex_handle *sdg.insert(Point_2 p)* Inserts the point *p* in the segment Delaunay graph. If *p* has already been inserted, then the vertex handle of its already inserted copy is returned. If *p* has not been inserted yet, the vertex handle of *p* is returned.

Vertex_handle *sdg.insert(Point_2 p, Vertex_handle vnear)*

Inserts *p* in the segment Delaunay graph using the site associated with *vnear* as an estimate for the nearest neighbor of *p*. The vertex handle returned has the same semantics as the vertex handle returned by the method *Vertex_handle insert(Point_2 p)*.

Vertex_handle *sdg.insert(Point_2 p1, Point_2 p2)*

Inserts the closed segment with endpoints *p1* and *p2* in the segment Delaunay graph. If the segment has already been inserted in the Delaunay graph then the vertex handle of its already inserted copy is returned. If the segment does not intersect any segment in the existing diagram, the vertex handle corresponding to its corresponding open segment is returned. Finally, if the segment intersects other segments in the existing Delaunay graph, the vertex handle to one of its open subsegments is returned.

Vertex_handle *sdg.insert(Point_2 p1, Point_2 p2, Vertex_handle vnear)*

Inserts the segment whose endpoints are *p1* and *p2* in the segment Delaunay graph using the site associated with *vnear* as an estimate for the nearest neighbor of *p1*. The vertex handle returned has the same semantics as the vertex handle returned by the method *Vertex_handle insert(Point_2 p1, Point_2 p2)*.

Vertex_handle *sdg.insert(Site_2 s)* Inserts the site *s* in the segment Delaunay graph. The vertex handle returned has the same semantics as the vertex handle returned by the methods *Vertex_handle insert(Point_2 p)* and *Vertex_handle insert(Point_2 p1, Point_2 p2)*, depending on whether *s* represents a point or a segment respectively.
Precondition: *s.is_input()* must be *true*.

Vertex_handle *sdg.insert(Site_2 s, Vertex_handle vnear)*

Inserts *s* in the segment Delaunay graph using the site associated with *vnear* as an estimate for the nearest neighbor of *s*, if *s* is a point, or the first endpoint of *s*, if *s* is a segment. The vertex handle returned has the same semantics as the vertex handle returned by the method *Vertex_handle insert(Site_2 s)*.
Precondition: *s.is_input()* must be *true*.

Nearest neighbor location

Vertex_handle *sdg.nearest_neighbor(Point_2 p)*

Finds the nearest neighbor of the point *p*. In other words it finds the site whose segment Voronoi diagram cell contains *p*. Ties are broken arbitrarily and one of the nearest neighbors of *p* is returned. If there are no sites in the segment Delaunay graph *Vertex_handle()* is returned.

Vertex_handle *sdg.nearest_neighbor(Point_2 p, Vertex_handle vnear)*

Finds the nearest neighbor of the point *p* using the site associated with *vnear* as an estimate for the nearest neighbor of *p*. Ties are broken arbitrarily and one of the nearest neighbors of *p* is returned. If there are no sites in the segment Delaunay graph *Vertex_handle()* is returned.

I/O

template < class Stream >
Stream& *sdg.draw_dual(Stream& str)*

Draws the segment Voronoi diagram to the stream *str*. The following operators must be defined:
Stream& operator<<(Stream&, Gt::Segment_2)
Stream& operator<<(Stream&, Gt::Ray_2)
Stream& operator<<(Stream&, Gt::Line_2)

template < class Stream >
Stream& *sdg.draw_skeleton(Stream& str)*

Draws the segment Voronoi diagram to the stream *str*, except the edges of the diagram corresponding to a segment and its endpoints. The following operators must be defined:
Stream& operator<<(Stream&, Gt::Segment_2)
Stream& operator<<(Stream&, Gt::Ray_2)
Stream& operator<<(Stream&, Gt::Line_2)

template< class Stream >
Stream& *sdg.draw_dual_edge(Edge e, Stream& str)*

Draws the edge *e* of the segment Voronoi diagram to the stream *str*. The following operators must be defined:
Stream& operator<<(Stream&, Gt::Segment_2)
Stream& operator<<(Stream&, Gt::Ray_2)
Stream& operator<<(Stream&, Gt::Line_2)
Precondition: *e* must be a finite edge.

template< class Stream >
Stream& *sdg.draw_dual_edge(Edge_circulator ec, Stream& str)*

Draws the edge **ec* of the segment Voronoi diagram to the stream *str*. The following operators must be defined:
Stream& operator<<(Stream&, Gt::Segment_2)
Stream& operator<<(Stream&, Gt::Ray_2)
Stream& operator<<(Stream&, Gt::Line_2)
Precondition: **ec* must be a finite edge.

template< class Stream >

Stream& *sdg.draw_dual_edge(All_edges_iterator eit, Stream& str)*

Draws the edge **eit* of the segment Voronoi diagram to the stream *str*. The following operators must be defined:
Stream& operator<<(Stream&, Gt::Segment_2)
Stream& operator<<(Stream&, Gt::Ray_2)
Stream& operator<<(Stream&, Gt::Line_2)
Precondition: **eit* must be a finite edge.

template< class Stream >
Stream& *sdg.draw_dual_edge(Finite_edges_iterator eit, Stream& str)*

Draws the edge **eit* of the segment Voronoi diagram to the stream *str*. The following operators must be defined:
Stream& operator<<(Stream&, Gt::Segment_2)
Stream& operator<<(Stream&, Gt::Ray_2)
Stream& operator<<(Stream&, Gt::Line_2)

void	*sdg.file_output(std::ostream& os)*	Writes the current state of the segment Delaunay graph to an output stream. In particular, all sites in the diagram are written to the stream (represented through appropriate input sites), as well as the underlying combinatorial data structure.
void	*sdg.file_input(std::istream& is)*	Reads the state of the segment Delaunay graph from an input stream.
std::ostream&	*std::ostream& os << sdg*	Writes the current state of the segment Delaunay graph to an output stream.
std::istream&	*std::istream& is >> sdg*	Reads the state of the segment Delaunay graph from an input stream.

Validity check

bool *sdg.is_valid(bool verbose = false, int level = 1)*

Checks the validity of the segment Delaunay graph. If *verbose* is *true* a short message is sent to *std::cerr*. If *level* is 0, only the data structure is validated. If *level* is 1, then both the data structure and the segment Delaunay graph are validated. Negative values of *level* always return true, and values greater than 1 are equivalent to *level* being 1.

Miscellaneous

void	*sdg.clear()*	Clears all contents of the segment Delaunay graph.
void	*sdg.swap(other)*	The segment Delaunay graphs *other* and *sdg* are swapped. *sdg.swap(other)* should be preferred to *sdg= other* or to *sdg(other)* if *other* is deleted afterwards.

SegmentDelaunayGraphSite_2

Definition

The concept *SegmentDelaunayGraphSite_2* provides the requirements for the sites of a segment Delaunay graph.

Refines

DefaultConstructible
CopyConstructible
Assignable

Types

SegmentDelaunayGraphSite_2:: Point_2	The point type.
SegmentDelaunayGraphSite_2:: Segment_2	The segment type.
SegmentDelaunayGraphSite_2:: FT	The field number type.
SegmentDelaunayGraphSite_2:: RT	The ring number type.

Creation

In addition to the default and copy constructors the following static methods are available for constructing sites:

SegmentDelaunayGraphSite_2 *s.construct_site_2(Point_2 p)*

Constructs a site from a point: the site represents the point *p*.

SegmentDelaunayGraphSite_2 *s.construct_site_2(Point_2 p1, Point_2 p2)*

Constructs a site from two points: the site represents the (open) segment *(p1,p2)*.

SegmentDelaunayGraphSite_2 *s.construct_site_2(Point_2 p1, Point_2 p2, Point_2 q1, Point_2 q2)*

Constructs a site from four points: the site represents the point of intersection of the segments *(p1,p2)* and *(q1,q2)*.

SegmentDelaunayGraphSite_2 *s.construct_site_2(Point_2 p1, Point_2 p2, Point_2 q1, Point_2 q2, bool b)*

Constructs a site from four points and a boolean: the site represents a segment. If *b* is *true* the endpoints are *p1* and $p_\times$, otherwise $p_\times$ and *p2*. $p_\times$ is the point of intersection of the segments *(p1,p2)*,*(q1,q2)*.

SegmentDelaunayGraphSite_2 *s.construct_site_2(Point_2 p1,*
Point_2 p2,
Point_2 q1,
Point_2 q2,
Point_2 r1,

Point_2 r2)

Constructs a site from six points: the site represents the segment with endpoints the points of intersection of the pairs of segments *(p1,p2)*,*(q1,q2)* and *(p1,p2)*,*(r1,r2)*.

Predicates

bool	*s.is_defined()*	Returns *true* if the site represents a valid point or segment.
bool	*s.is_point()*	Returns *true* if the site represents a point.
bool	*s.is_segment()*	Returns *true* if the site represents a segment.
bool	*s.is_input()*	Returns *true* if the site represents an input point or a segment defined by two input points. Returns *false* if it represents a point of intersection of two segments, or if it represents a segment, at least one endpoint of which is a point of intersection of two segments.
bool	*s.is_input(unsigned int i)*	Returns *true* if the *i*-th endpoint of the site is an input point. Returns *false* if the *i*-th endpoint of the site is the intersection of two segments. *Precondition*: *i* must be at most 1, and *s.is_segment()* must be *true*.

Access Functions

Point_2 *s.point() const*

Returns the point represented by the site *s*.
Precondition: *s.is_point()* must be *true*.

Segment_2 *s.segment() const*

Returns the segment represented by the site *s*.
Precondition: *s.is_segment()* must be *true*.

Point_2 *s.source() const*

Returns the source endpoint of the segment. Note that this method can construct an inexact point if the number type used is inexact.
Precondition: *s.is_segment()* must be *true*.

Point_2 *s.target() const*

Returns the target endpoint of the segment. Note that this method can construct an inexact point if the number type used is inexact.
Precondition: *s.is_segment()* must be *true*.

SegmentDelaunayGraphSite_2 *s.supporting_site()*

Returns a segment site object representing the segment that supports the segment represented by the site. Both endpoints of the returned site are input points.
Precondition: *s.is_segment()* must be *true*.

SegmentDelaunayGraphSite_2 *s.supporting_site(unsigned int i)*

Returns a segment site object representing the *i*-th segment that supports the point of intersection represented by the site. Both endpoints of the returned site are input points.
Precondition: *i* must be at most 1, *s.is_point()* must be *true* and *s.is_input()* must be *false*.

SegmentDelaunayGraphSite_2 *s.crossing_site(unsigned int i)*

Returns a segment site object representing the *i*-th segment that supports the *i*-th endpoint of the site which is not the supporting segment of the site. Both endpoints of the returned site are input points.
Precondition: *i* must be at most 1, *s.is_segment()* must be *true* and *s.is_input(i)* must be *false*.

SegmentDelaunayGraphSite_2 *s.source_site()*

Returns a point site object representing the source point of the site.
Precondition: *s.is_segment()* must be *true*.

SegmentDelaunayGraphSite_2 *s.target_site()*

Returns a point site object representing the target point of the site.
Precondition: *s.is_segment()* must be *true*.

Point_2 *s.source_of_supporting_site()*

Returns the source point of the supporting site of the this site.
Precondition: *is_segment()* must be *true*.

Point_2 *s.target_of_supporting_site()*

Returns the target point of the supporting site of the this site.
Precondition: *is_segment()* must be *true*.

Point_2 *s.source_of_supporting_site(unsigned int i)*

Returns the source point of the *i*-th supporting site of the this site.
Precondition: *is_point()* must be *true*, *is_input()* must be *false* and *i* must either be *0* or *1*.

Point_2 *s.target_of_supporting_site(unsigned int i)*

Returns the target point of the *i*-th supporting site of the this site.
Precondition: *is_point()* must be *true*, *is_input()* must be *false* and *i* must either be *0* or *1*.

Point_2 *s.source_of_crossing_site(unsigned int i)*

Returns the source point of the *i*-th crossing site of the this site.
Precondition: *is_segment()* must be *true*, *is_input(i)* must be *false* and *i* must either be *0* or *1*.

Point_2 *s.target_of_crossing_site(unsigned int i)*

Returns the target point of the *i*-th supporting site of the this site.
Precondition: *is_segment()* must be *true*, *is_input(i)* must be *false* and *i* must either be *0* or *1*.

SegmentDelaunayGraphStorageSite_2

Concept

Definition

The concept *SegmentDelaunayGraphStorageSite_2* provides the requirements for the storage sites of a segment Delaunay graph. The storage sites are sites that are used to store the information of a site in a more compact form (that uses less storage). This is achieved by storing handles to points instead of points.

Refines

DefaultConstructible
CopyConstructible
Assignable

Types

SegmentDelaunayGraphStorageSite_2:: Site_2		The site type.
typedef typename std::set<typename Site_2::Point_2>::iterator	*Point_handle;*	The type for a handle to a point.

Creation

In addition to the default and copy constructors, the following static methods should be available for constructing sites:

SegmentDelaunayGraphStorageSite_2 *ss.construct_storage_site_2(Point_handle hp)*

Constructs a storage site from a point handle. The storage site represents the point associated with the point handle *hp*.

SegmentDelaunayGraphStorageSite_2 *ss.construct_storage_site_2(Point_handle hp1, Point_handle hp2)*

Constructs a storage site from two point handles. The storage site represents the segment the endpoints of which are the points associated with the point handles *hp1* and *hp2*.

SegmentDelaunayGraphStorageSite_2 *ss.construct_storage_site_2(Point_handle hp1, Point_handle hp2, Point_handle hq1, Point_handle hq2)*

Constructs a storage site from four point handles. The storage site represents the point of intersection of the segments the endpoints of which are the points associated with the point handles *hp1*, *hp2* and *hq1* and *hq2*, respectively.

SegmentDelaunayGraphStorageSite_2 *ss.construct_storage_site_2(Point_handle hp1, Point_handle hp2, Point_handle hq1, Point_handle hq2, bool b)*

Constructs a site from four point handles and a boolean. The storage site represents a segment. If *b* is *true*, the first endpoint of the segment is the point associated with the handle *hp1* and the second endpoint is the point of intersection of the segments the endpoints of which are the point associated with the point handles *hp1*, *hp2* and *hq1*, *hq2*, respectively. If *b* is *false*, the first endpoint of the represented segment is the one mentioned above, whereas the second endpoint if the point associated with the point handle *hp2*.

SegmentDelaunayGraphStorageSite_2 *ss.construct_storage_site_2(Point_handle hp1, Point_handle hp2, Point_handle hq1, Point_handle hq2, Point_handle hr1, Point_handle hr2)*

Constructs a storage site from six point handles. The storage site represents of segment the endpoints of which are points of intersection of two pairs of segments, the endpoints of which are *hp1*, *hp2*/*hq1*, *hq2* and *hp1*, *hp2*/*hr1*, *hr2*, respectively.

Predicates

bool	*ss.is_defined()*	Returns *true* if the storage site represents a valid point or segment.
bool	*ss.is_point()*	Returns *true* if the storage site represents a point.
bool	*ss.is_segment()*	Returns *true* if the storage site represents a segment.
bool	*ss.is_input()*	Returns *true* if the storage site represents an input point or a segment defined by two input points. Returns *false* if it represents a point of intersection of two segments, or if it represents a segment, at least one endpoint of which is a point of intersection of two segments.
bool	*ss.is_input(unsigned int i)*	Returns *true* if the *i*-th endpoint of the corresponding site is an input point. Returns *false* if the *i*-th endpoint of the corresponding site is the intersection of two segments. *Precondition*: *i* must be at most 1, and *ss.is_segment()* must be *true*.

Access Functions

SegmentDelaunayGraphStorageSite_2 *ss.supporting_site()*

Returns a storage site object representing the segment that supports the segment represented by the storage site. The returned storage site represents a site, both endpoints of which are input points.
Precondition: *ss.is_segment()* must be *true*.

SegmentDelaunayGraphStorageSite_2 *ss.source_site()*

Returns a storage site that represents the first endpoint of the represented segment.
Precondition: *ss.is_segment()* must be *true*.

SegmentDelaunayGraphStorageSite_2 *ss.target_site()*

Returns a storage site that represents the second endpoint of the represented segment.
Precondition: *ss.is_segment()* must be *true*.

SegmentDelaunayGraphStorageSite_2 *ss.supporting_site(unsigned int i)*

Returns a storage site object representing the i-th segment that supports the point of intersection represented by the storage site. The returned storage site represents a site, both endpoints of which are input points.
Precondition: i must be at most 1, *ss.is_point()* must be *true* and *ss.is_input()* must be *false*.

SegmentDelaunayGraphStorageSite_2 *ss.crossing_site(unsigned int i)*

Returns a storage site object representing the i-th segment that supports the i-th endpoint of the site which is not the supporting segment of the site. The returned storage site represents a site, both endpoints of which are input points.
Precondition: i must be at most 1, *ss.is_segment()* must be *true* and *ss.is_input(i)* must be *false*.

Site_2 *ss.site()*

Returns the site represented by the storage site.

Point_handle *ss.point()*

Returns a handle associated with the represented point.
Precondition: *is_point()* and *is_input()* must both be *true*.

Point_handle *ss.source_of_supporting_site()*

Returns a handle to the source point of the supporting site of the this site.
Precondition: *is_segment()* must be *true*.

Point_handle *ss.target_of_supporting_site()*

Returns a handle to the target point of the supporting site of the this site.
Precondition: *is_segment()* must be *true*.

Point_handle *ss.source_of_supporting_site(unsigned int i)*

Returns a handle to the source point of the i-th supporting site of the this site.
Precondition: *is_point()* must be *true*, *is_input()* must be *false* and i must either be *0* or *1*.

Point_handle *ss.target_of_supporting_site(unsigned int i)*

Returns a handle to the target point of the i-th supporting site of the this site.
Precondition: *is_point()* must be *true*, *is_input()* must be *false* and i must either be *0* or *1*.

Point_handle *ss.source_of_crossing_site(unsigned int i)*

Returns a handle to the source point of the *i*-th crossing site of the this site.
Precondition: *is_segment()* must be *true*, *is_input(i)* must be *false* and *i* must either be *0* or *1*.

Point_handle *ss.target_of_crossing_site(unsigned int i)*

Returns a handle to the target point of the *i*-th supporting site of the this site.
Precondition: *is_segment()* must be *true*, *is_input(i)* must be *false* and *i* must either be *0* or *1*.

SegmentDelaunayGraphDataStructure_2

Definition

The concept *SegmentDelaunayGraphDataStructure_2* refines the concept *ApolloniusGraphDataStructure_2*. In addition it provides two methods for the merging of two vertices joined by an edge of the data structure, and the splitting of a vertex into two. The method that merges two vertices, called *join_vertices* identifies the two vertices and deletes their common two faces. The method that splits a vertex, called *split_vertex* introduces a new vertex that shares an edge and two faces with the old vertex (see figure below). Notice that the *join_vertices* and *split_vertex* operations are complementary, in the sense that one reverses the action of the other.

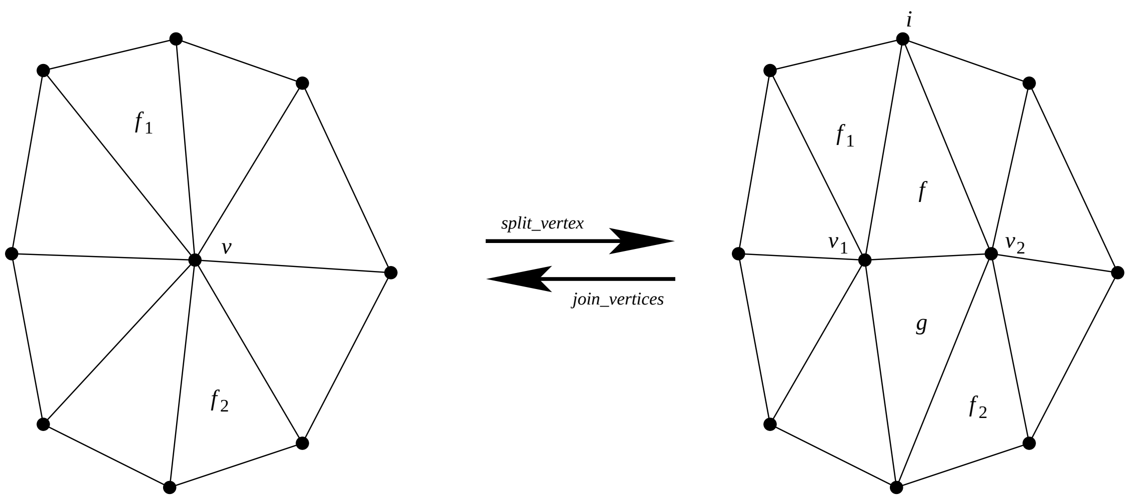

Figure 44.3: The join and split operations. Left to right: The vertex v is split into v_1 and v_2. The faces f and g are inserted after f_1 and f_2, respectively, in the counter-clockwise sense. The vertices v_1, v_2 and the faces f and g are returned as a *boost tuple* in that order. Right to left: The edge *(f,i)* is collapsed, and thus the vertices v_1 and v_2 are joined. The vertex v is returned.

We only describe the additional requirements with respect to the *ApolloniusGraphDataStructure_2* concept.

Refines

ApolloniusGraphDataStructure_2

Modification

Vertex_handle	*sdgds.join_vertices(Face_handle f, int i)*	Joins the vertices that are endpoints of the edge *(f,i)*. It returns a vertex handle to common vertex.

boost::tuples::tuple<Vertex_handle, Vertex_handle, Face_handle, Face_handle>

sdgds.split_vertex(Vertex_handle v, Face_handle f1, Face_handle f2)

Splits the vertex *v* into two vertices *v1* and *v2*. The common faces *f* and *g* of *v1* and *v2* are created after (in the counter-clockwise sense) the faces *f1* and *f2*. The 4-tuple *(v1,v2,f,g)* is returned (see Fig. 44.6).

Concept

SegmentDelaunayGraphVertexBase_2

Definition

The concept *SegmentDelaunayGraphVertexBase_2* describes the requirements for the vertex base class of the *SegmentDelaunayGraphDataStructure_2* concept. A vertex stores a site of the segment Delaunay graph and provides access to one of its incident faces through a *Face_handle*.

Refines

DefaultConstructible
CopyConstructible
Assignable

Types

SegmentDelaunayGraphVertexBase_2:: Geom_traits	A type for the geometric traits that defines the site. *Precondition*: The type *Geom_traits* must define the type *Site_2*.
SegmentDelaunayGraphVertexBase_2:: Site_2	A type for the site. This type must coincide with the type *Geom_traits::Site_2*.
SegmentDelaunayGraphVertexBase_2:: Storage_site_tag	A type that indicates what kind of storage type to use. *Storage_site_tag* must either be *CGAL::Tag_true* or *CGAL::Tag_false*.
SegmentDelaunayGraphVertexBase_2:: Storage_site_2	A type for the internal representation of sites. This type must satisfy the requirements of the concept *SegmentDelaunayGraphStorageSite_2*.
SegmentDelaunayGraphVertexBase_2:: Data_structure	A type for the underlying data structure, to which the vertex belongs to.
SegmentDelaunayGraphVertexBase_2:: Vertex_handle	A type for the vertex handle of the segment Delaunay graph data structure.
SegmentDelaunayGraphVertexBase_2:: Face_handle	A type for the face handle of the segment Delaunay graph data structure.

Creation

In addition to the default and copy constructors and following constructors are required:

SegmentDelaunayGraphVertexBase_2 v(Storage_site_2 ss);

Constructs a vertex associated with the site represented by the storage site *ss*.

SegmentDelaunayGraphVertexBase_2 v(Storage_site_2 ss, Face_handle f);

Constructs a vertex associated with the site represented by the storage site *ss*, and pointing to the face associated with the face handle *f*.

Access Functions

Storage_site_2	*v.storage_site()*	Returns the storage site representing the site.
Site_2	*v.site()*	Returns the site.
Face_handle	*v.face()*	Returns a handle to an incident face.

Setting

void	*v.set_site(Storage_site_2 ss)*	Sets the storage site.
void	*v.set_face(Face_handle f)*	Sets the incident face.

Checking

bool *v.is_valid(bool verbose, int level) const*

Performs any required tests on a vertex.

Class

CGAL::Segment_Delaunay_graph_vertex_base_2<Gt,SSTag>

Definition

The class *Segment_Delaunay_graph_vertex_base_2<Gt,SSTag>* provides a model for the *SegmentDelaunayGraphVertexBase_2* concept which is the vertex base required by the *SegmentDelaunayGraphDataStructure_2* concept. The class *Segment_Delaunay_graph_vertex_base_2<Gt,SSTag>* has two template arguments, the first being the geometric traits of the segment Delaunay graph and should be a model of the concept *SegmentDelaunayGraphTraits_2*. The second template argument indicates whether or not to use the simple storage site that does not support intersecting segments, or the full storage site, that supports intersecting segments. The possible values are *CGAL::Tag_true* and *CGAL::Tag_false*. *CGAL::Tag_true* indicates that the full storage site is to be used, whereas *CGAL::Tag_false* indicates that the simple storage site is to be used.

SegmentDelaunayGraphTraits_2

Definition

The concept *SegmentDelaunayGraphTraits_2* provides the traits requirements for the *Segment_Delaunay_graph_2<Gt,DS>* and *Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS>* classes. In particular, it provides a type *Site_2*, which must be a model of the concept *SegmentDelaunayGraphSite_2*. It also provides constructions for sites and several function object types for the predicates.

Refines

DefaultConstructible
CopyConstructible
Assignable

Types

SegmentDelaunayGraphTraits_2:: Intersections_tag	Indicates or not whether the intersecting segments are to be supported. The tag must either be *CGAL::Tag_true* or *CGAL::Tag_false*.
SegmentDelaunayGraphTraits_2:: Site_2	A type for a site of the segment Delaunay graph. Must be a model of the concept *SegmentDelaunayGraphSite_2*.
SegmentDelaunayGraphTraits_2:: Point_2	A type for a point.
SegmentDelaunayGraphTraits_2:: Line_2	A type for a line. Only required if the segment Delaunay graph is inserted in a stream.
SegmentDelaunayGraphTraits_2:: Ray_2	A type for a ray. Only required if the segment Delaunay graph is inserted in a stream.
SegmentDelaunayGraphTraits_2:: Segment_2	A type for a segment. Only required if if the segment Delaunay graph is inserted in a stream.
SegmentDelaunayGraphTraits_2:: FT	A type for the field number type of sites, points, etc..
SegmentDelaunayGraphTraits_2:: RT	A type for the ring number type of sites, points, etc.
SegmentDelaunayGraphTraits_2:: Arrangement_type	An enumeration type that indicates the type of the arrangement of two sites. The possible values are *DISJOINT*, *IDENTICAL*, *CROSSING*, *TOUCHING_1*, *TOUCHING_2*, *TOUCHING_11*, *TOUCHING_12*, *TOUCHING_21*, *TOUCHING_22*, *OVERLAPPING_11*, *OVERLAPPING_12*, *OVERLAPPING_21*, *OVERLAPPING_22*, *INTERIOR*, *INTERIOR_1*, *INTERIOR_2*, *TOUCHING_11_INTERIOR_1*, *TOUCHING_11_INTERIOR_2*, *TOUCHING_12_INTERIOR_1*, *TOUCHING_12_INTERIOR_2*, *TOUCHING_21_INTERIOR_1*, *TOUCHING_21_INTERIOR_2*, *TOUCHING_22_INTERIOR_1*, *TOUCHING_22_INTERIOR_2*. A detailed description of the meaning of these values is shown the end of the reference manual for this concept. **(to be done)**

SegmentDelaunayGraphTraits_2:: Object_2 — A type representing different types of objects in two dimensions, namely: *Point_2*, *Site_2*, *Line_2*, *Ray_2* and *Segment_2*.

SegmentDelaunayGraphTraits_2:: Assign_2 — Must provide *template <class T> bool operator() (T& t, Object_2 o)* which assigns *o* to *t* if *o* was constructed from an object of type *T*. Returns *true*, if the assignment was possible.

SegmentDelaunayGraphTraits_2:: Construct_object_2 — Must provide *template <class T> Object_2 operator()(T t)* that constructs an object of type *Object_2* that contains *t* and returns it.

SegmentDelaunayGraphTraits_2:: Construct_svd_vertex_2

A constructor for a point of the segment Voronoi diagram equidistant from three sites. Must provide *Point_2 operator()(Site_2 s1, Site_2 s2, Site_2 s3)*, which constructs a point equidistant from the sites *s1*, *s2* and *s3*.

SegmentDelaunayGraphTraits_2:: Compare_x_2

A predicate object type. Must provide *Comparison_result operator()(Site_2 s1, Site_2 s2)*, which compares the *x*-coordinates of the points represented by the sites *s1* and *s2*.
Precondition: *s1* and *s2* must be points.

SegmentDelaunayGraphTraits_2:: Compare_y_2

A predicate object type. Must provide *Comparison_result operator()(Site_2 s1, Site_2 s2)*, which compares the *y*-coordinates of the points represented by the sites *s1* and *s2*.
Precondition: *s1* and *s2* must be points.

SegmentDelaunayGraphTraits_2:: Orientation_2

A predicate object type. Must provide *Orientation operator()(Site_2 s1, Site_2 s2, Site_2 s3)*, which performs the usual orientation test for three points. *s1*, *s2* and *s3*.
Precondition: the sites *s1*, *s2* and *s3* must be points.

SegmentDelaunayGraphTraits_2:: Equal_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2)*, which determines is the points represented by the sites *s1* and *s2* are identical.
Precondition: *s1* and *s2* must be points.

SegmentDelaunayGraphTraits_2:: Are_parallel_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2)*, which determines is the segments represented by the sites *s1* and *s2* are parallel.
Precondition: *s1* and *s2* must be segments.

SegmentDelaunayGraphTraits_2:: Oriented_side_of_bisector_2

A predicate object type. Must provide *Oriented_side operator()(Site_2 s1, Site_2 s2, Point_2 p)*, which returns the oriented side of the bisector of *s1* and *s2* that contains *p*. Returns *ON_POSITIVE_SIDE* if *p* lies in the half-space of *s1* (i.e., *p* is closer to *s1* than *s2*); returns *ON_NEGATIVE_SIDE* if *p* lies in the half-space of *s2*; returns *ON_ORIENTED_BOUNDARY* if *p* lies on the bisector of *s1* and *s2*.

SegmentDelaunayGraphTraits_2:: Vertex_conflict_2

A predicate object type. Must provide *Sign operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q)*, which returns the sign of the distance of q from the Voronoi circle of *s1*, *s2*, *s3* (the Voronoi circle of three sites *s1*, *s2*, *s3* is a circle co-tangent to all three sites, that touches them in that order as we walk on its circumference in the counter-clockwise sense).
Precondition: the Voronoi circle of *s1*, *s2*, *s3* must exist.
Must also provide *Sign operator()(Site_2 s1, Site_2 s2, Site_2 q)*, which returns the sign of the distance of q from the bitangent line of *s1*, *s2* (a degenerate Voronoi circle, with its center at infinity).

SegmentDelaunayGraphTraits_2:: Finite_edge_interior_conflict_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 s4, Site_2 q, Sign sgn)*. The sites *s1*, *s2*, *s3* and *s4* define a Voronoi edge that lies on the bisector of *s1* and *s2* and has as endpoints the Voronoi vertices defined by the triplets *s1*, *s2*, *s3* and *s1*, *s4* and *s2*. The sign *sgn* is the common sign of the distance of the site q from the Voronoi circle of the triplets *s1*, *s2*, *s3* and *s1*, *s4* and *s2*. In case that *sgn* is equal to *NEGATIVE*, the predicate returns *true* if and only if the entire Voronoi edge is in conflict with q. If *sgn* is equal to *POSITIVE* or *ZERO*, the predicate returns *false* if and only if q is not in conflict with the Voronoi edge.
Precondition: the Voronoi vertices of *s1*, *s2*, *s3*, and *s1*, *s4*, *s2* must exist.
Must also provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q, Sign sgn)*. The sites *s1*, *s2*, *s3* and the site at infinity s_∞ define a Voronoi edge that lies on the bisector of *s1* and *s2* and has as endpoints the Voronoi vertices v_{123} and $v_{1\infty2}$ defined by the triplets *s1*, *s2*, *s3* and *s1*, s_∞ and *s2* (the second vertex is actually at infinity). The sign *sgn* is the common sign of the distance of the site q from the two Voronoi circles centered at the Voronoi vertices v_{123} and $v_{1\infty2}$. In case that *sgn* is *NEGATIVE*, the predicate returns *true* if and only if the entire Voronoi edge is in conflict with q. If *sgn* is *POSITIVE* or *ZERO*, the predicate returns *false* if and only if q is not in conflict with the Voronoi edge.
Precondition: the Voronoi vertex v_{123} of *s1*, *s2*, *s3* must exist.
Must finally provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 q, Sign sgn)*. The sites *s1*, *s2* and the site at infinity s_∞ define a Voronoi edge that lies on the bisector of $v_{12\infty}$ and $v_{1\infty2}$ *s1* and *s2* and has as endpoints the Voronoi vertices defined by the triplets *s1*, *s2*, s_∞ and *s1*, s_∞ and *s2* (both vertices are actually at infinity). The sign *sgn* denotes the common sign of the distance of the site q from the Voronoi circles centered at $v_{12\infty}$ and $v_{1\infty2}$. If *sgn* is *NEGATIVE*, the predicate returns *true* if and only if the entire Voronoi edge is in conflict with q. If *POSITIVE* or *ZERO* is *false*, the predicate returns *false* if and only if q is not in conflict with the Voronoi edge.

SegmentDelaunayGraphTraits_2:: Infinite_edge_interior_conflict_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q, Sign sgn)*. The sites s_∞, *s1*, *s2* and *s3* define a Voronoi edge that lies on the bisector of s_∞ and *s1* and has as endpoints the Voronoi vertices $v_{\infty12}$ and $v_{\infty31}$ defined by the triplets s_∞, *s1*, *s2* and s_∞, *s3* and *s1*. The sign *sgn* is the common sign of the distances of q from the Voronoi circles centered at the vertices $v_{\infty12}$ and $v_{\infty31}$. If *sgn* is *NEGATIVE*, the predicate returns *true* if and only if the entire Voronoi edge is in conflict with q. If *sgn* is *POSITIVE* or *ZERO*, the predicate returns *false* if and only if q is not in conflict with the Voronoi edge.

SegmentDelaunayGraphTraits_2:: Oriented_side_2

A predicate object type. Must provide *Oriented_side operator()(Site_1 s1, Site_2 s2, Site_2 s3, Site_2 s, Site_2 p)*. Determines the oriented side of the line ℓ that contains the point site p, where ℓ is the line that passes through the Voronoi vertex of the sites *s1*, *s2*, *s3* and is perpendicular to the segment site s.
Precondition: s must be a segment and p must be a point.

SegmentDelaunayGraphTraits_2:: Arrangement_type_2

A predicate object type. Must provide *Arrangement_type operator()(Site_2 s1, Site_2 s2)* that returns the type of the arrangement of the two sites *s1* and *s2*.

Class

CGAL::Segment_Delaunay_graph_traits_2<K,MTag>

Definition

The class *Segment_Delaunay_graph_traits_2<K,MTag>* provides a model for the *SegmentDelaunayGraphTraits_2* concept. This class has two template parameters. The first template parameter must be a model of the *Kernel* concept. The second template parameter corresponds to how predicates are evaluated. There are two possible values for *MTag*, namely *CGAL::Field_with_sqrt_tag* and *CGAL::Field_tag*. The first one must be used when the number type used in the representation supports the exact evaluation of signs of expressions involving all four basic operations and square roots, whereas the second one requires the exact evaluation of signs of field-type expressions, i.e., expressions involving additions, subtractions, multiplications and divisions. The default value for *MTag* is *CGAL::Field_tag*. The way the predicates are evaluated is discussed in [Bur96] and [Kar04] (the geometric filtering part).

Class

CGAL::Segment_Delaunay_graph_filtered_traits_2< CK,CM,EK,EM,FK,FM>

Definition

The class *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* provides a model for the *SegmentDelaunayGraphTraits_2* concept.

The class *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* uses the filtering technique [BBP01] to achieve traits for the *Segment_Delaunay_graph_2<Gt,DS>* class with efficient and exact predicates given an exact kernel *EK* and a filtering kernel *FK*. The geometric constructions associated provided by this class are equivalent to those provided by the traits class *Segment_Delaunay_graph_traits_2<CK,CM>*, which means that they may be inexact depending on the choice of the *CK* kernel.

This class has six template parameters. The first, third and fifth template parameters must be a models of the *Kernel* concept. The parameter *CK* is the construction kernel and it is the kernel that will be used for constructions. The parameter *FK* is the filtering kernel; this kernel will be used for performing the arithmetic filtering for the predicates involved in the computation of the segment Delaunay graph. Finally, the parameter *EK* is the exact kernel; this kernel will be used for computing the predicates if the filtering kernel fails to produce an answer.

The second, fourth and sixth template parameters correspond to how predicates are evaluated. There are two predefined possible values for these parameters, namely *CGAL::Field_with_sqrt_tag* and *CGAL::Field_tag*. The first one must be used when the number type used in the representation supports the exact evaluation of signs of expressions involving all four basic operations and square roots, whereas the second one requires that only field operations are exact. Finally, in order to get exact constructions *CM* must be set to *CGAL::Field_with_sqrt_tag* and the number type in *CK* must support operations involing divisions and square roots (as well as the other three basic operations of course). The way the predicates are evaluated is discussed in [Bur96] and [Kar04] (the geometric filtering part).

The default values for the template parameters are as follows: *CM = CGAL::Field_with_sqrt_tag* (it is assumed that *CGAL::Cartesian<double>* or *CGAL::Simple_cartesian<double>* will be the entry for the template parameter *CK*), *EM = CGAL::Field_tag*, *FK = CGAL::Simple_cartesian<CGAL::Interval_nt<false> >*, *FM = CGAL::Field_with_sqrt_tag*. If the GMP package is installed with CGAL, the template parameter *EK* has the default value: *EK = CGAL::Simple_cartesian<CGAL::Gmpq>*, otherwise its default value is *EK = CGAL::Simple_cartesian<CGAL::Quotient<CGAL::MP_Float> >*.

Definition

The class *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>* provides a model for the *SegmentDelaunayGraphTraits_2* concept.

The class *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>* uses the filtering technique [BBP01] to achieve traits for the *Segment_Delaunay_graph_2<Gt,DS>* class with efficient and exact predicates given an exact kernel *EK* and a filtering kernel *FK*. The geometric constructions associated provided by this class are equivalent to those provided by the traits class *Segment_Delaunay_graph_traits_without_intersections_2<CK,CM>*, which means that they may be inexact, depending on the choice of the *CK* kernel.

This class has six template parameters. The first, third and fifth template parameters must be a models of the *Kernel* concept. The parameter *CK* is the construction kernel and it is the kernel that will be used for constructions. The parameter *FK* is the filtering kernel; this kernel will be used for performing the arithmetic filtering for the predicates involved in the computation of the segment Delaunay graph. Finally, the parameter *EK* is the exact kernel; this kernel will be used for computing the predicates if the filtering kernel fails to produce an answer.

The second, fourth and sixth template parameters correspond to how predicates are evaluated. There are two predefined possible values for these parameters, namely *CGAL::Field_with_sqrt_tag* and *CGAL::Euclidean_ring_tag*. The first one must be used when the number type used in the representation supports the exact evaluation of signs of expressions involving all four basic operations and square roots, whereas the second requires the exact evaluation of signs of ring-type expressions, i.e., expressions involving only additions, subtractions and multiplications. Finally, in order to get exact constructions *CM* must be set to *CGAL::Field_with_sqrt_tag* and the number type in *CK* must support operations involing divisions and square roots (as well as the other three basic operations of course). The way the predicates are evaluated is discussed in [Bur96] and [Kar04] (the geometric filtering part).

The default values for the template parameters are as follows: *CM = CGAL::Field_with_sqrt_tag* (it is assumed that *CGAL::Cartesian<double>* or *CGAL::Simple_cartesian<double>* will be the entry for the template parameter *CK*), *EM = CGAL::Euclidean_ring_tag*, *FK = CGAL::Simple_cartesian<CGAL::Interval_nt<false> >*, *FM = CGAL::Field_with_sqrt_tag*. If the GMP package is installed with CGAL, the template parameter *EK* has the default value: *EK = CGAL::Simple_cartesian<CGAL::Gmpq>*, otherwise its default value is *EK = CGAL::Simple_cartesian<CGAL::MP_Float>*.

CGAL::Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS>

Definition

We provide an alternative to the class *Segment_Delaunay_graph_2<Gt,DS>* for the incremental construction of the segment Delaunay graph. The *Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS>* class maintains a hierarchy of Delaunay graphs. There are two possibilities as to how this hierarchy is constructed.

In the first case the bottom-most level of the hierarchy contains the full segment Delaunay graph. The upper levels of the hierarchy contain only points that are either point sites or endpoints of segment sites in the bottom-most Delaunay graph. A point that is in level i (either as an individdual point or as the endpoint of a segment), is inserted in level $i+1$ with probability $1/\alpha$ where $\alpha > 1$ is some constant. In the second case the upper levels of the hierarchy contains not only points but also segments. A site that is in level i, is in level $i+1$ with probability $1/\beta$ where $\beta > 1$ is some constant.

The difference between the *Segment_Delaunay_graph_2<Gt,DS>* class and the *Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS>* class (both versions of it) is on how the nearest neighbor location is done. Given a point p the location is done as follows: at the top most level we find the nearest neighbor of p as in the *Segment_Delaunay_graph_2<Gt,DS>* class. At every subsequent level i we use the nearest neighbor found at level $i+1$ to find the nearest neighbor at level i. This is a variant of the corresponding hierarchy for points found in [Dev02]. The details are described in [Kar04].

The class has three template parameters. The first and third have essentially the same semantics as in the *Segment_Delaunay_graph_2<Gt,DS>* class. The first template parameter must be a model of the *SegmentDelaunayGraphTraits_2* concept. The third template parameter must be a model of the *SegmentDelaunayGraphDataStructure_2* concept. However, the vertex base class that is to be used in the segment Delaunay graph data structure must be a model of the *SegmentDelaunayGraphHierarchyVertexBase_2* concept. The third template parameter defaults to *Triangulation_data_structure_2< Segment_Delaunay_graph_hierarchy_vertex_base_2< Segment_Delaunay_graph_vertex_base_2<Gt> >, Triangulation_face_base_2<Gt> >*. The second template parameter controls whether or not segments are added in the upper levels of the hierarchy. It's possible values are *CGAL::Tag_true* and *CGAL::Tag_false*. If it is set to *CGAL::Tag_true*, segments are also inserted in the upper levels of the hierarchy. The value *CGAL::Tag_false* indicates that only points are to be inserted in the upper levels of the hierarchy. The default value for the second template parameter is *CGAL::Tag_false*.

The *Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS>* class derives publicly from the *Segment_Delaunay_graph_2<Gt,DS>* class. The interface is the same with its base class. In the sequel only additional types and methods defined are documented.

Types

Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS> introduces the following types in addition to those introduced by its base class *Segment_Delaunay_graph_2<Gt,DS>*.

typedef STag	*Segments_in_hierarchy_tag;*	A type for the *STag* template parameter.
typedef CGAL::Segment_Delaunay_graph_2<Gt,DS>	*Base;*	A type for the base class.

Creation

In addition to the default and copy constructors, the following constructors are defined:

Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS> sdgh(Gt gt=Gt());

Creates a hierarchy of segment Delaunay graphs using *gt* as geometric traits.

template< class Input_iterator >
Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS> sdgh(Input_iterator first, Input_iterator beyond, Gt gt=Gt())

Creates a segment Delaunay graph hierarchy using *gt* as geometric traits and inserts all sites in the range [*first*, *beyond*). *Input_iterator* must be a model of *InputIterator*. The value type of *Input_iterator* must be either *Point_2* or *Site_2*.

I/O

std::ostream&	*std::ostream& os << svdh*	Writes the current state of the segment Delaunay graph hierarchy to an output stream. In particular, all sites in the diagram are written to the stream (represented through appropriate input sites), as well as the underlying combinatorial hierarchical data structure.
std::istream&	*std::istream& is >> svdh*	Reads the state of the segment Delaunay graph hierarchy from an input stream.

SegmentDelaunayGraphHierarchyVertexBase_2

Definition

The vertex of a segment Delaunay graph included in a segment Delaunay graph hierarchy has to provide some pointers to the corresponding vertices in the graphs of the next and preceeding levels. Therefore, the concept *SegmentDelaunayGraphHierarchyVertexBase_2* refines the concept *SegmentDelaunayGraphVertexBase_2*, by adding two vertex handles to the correponding vertices for the next and previous level graphs.

Refines

SegmentDelaunayGraphVertexBase_2

Types

SegmentDelaunayGraphHierarchyVertexBase_2 does not introduce any types in addition to those of *SegmentDelaunayGraphVertexBase_2*.

Creation

The *SegmentDelaunayGraphHierarchyVertexBase_2* concept does not introduce any constructors in addition to those of the *SegmentDelaunayGraphVertexBase_2* concept.

Operations

Vertex_handle	*v.up()*	Returns a handle to the corresponding vertex of the next level segment Delaunay graph. If such a vertex does not exist *Vertex_handle()* is returned.
Vertex_handle	*v.down()*	Returns a handle to the corresponding vertex of the previous level segment Delaunay graph. If such a vertex does not exist *Vertex_handle()* is returned.
void	*v.set_up(Vertex_handle u)*	Sets the handle for the vertex of the next level segment Delaunay graph.
void	*v.set_down(Vertex_handle d)*	Sets the handle for the vertex of the previous level segment Delaunay graph.

Chapter 45

2D Apollonius Graphs (Delaunay Graphs of Disks)

Menelaos Karavelas and Mariette Yvinec

Contents

This chapter describes the two-dimensional Apollonius graph of CGAL. We start with a few definitions in Section 45.1. The software design of the 2D Apollonius graph package is described in Section 45.2. In Section 45.3 we discuss the geometric traits of the 2D Apollonius graph package and in Section 45.4 the Apollonius graph hierarchy, a data structure suitable for fast nearest neighbor queries, is briefly described.

45.1 Definitions

The 2D Apollonius graph class of CGAL is designed to compute the dual of the *Apollonius diagram* or, as it is also known, the *Additively weighted Voronoi diagram*. The algorithm that has been implemented is dynamic, which means that we can perform insertions and deletions on line. The corresponding CGAL class is called *Apollonius_graph_2<ApolloniusGraphTraits_2,ApolloniusGraphDataStructure_2>* and will be discussed in more detail in the sequel. The interested reader may want to refer to the paper by Karavelas and Yvinec [KY02] for the general idea as well as the details of the algorithm implemented.

Before describing the details of the implementation we make a brief introduction to the theory of Apollonius diagrams. The Apollonius diagram is defined over a set of sites $P_i = (c_i, w_i)$, $i = 1, \ldots, n$, where c_i is the point

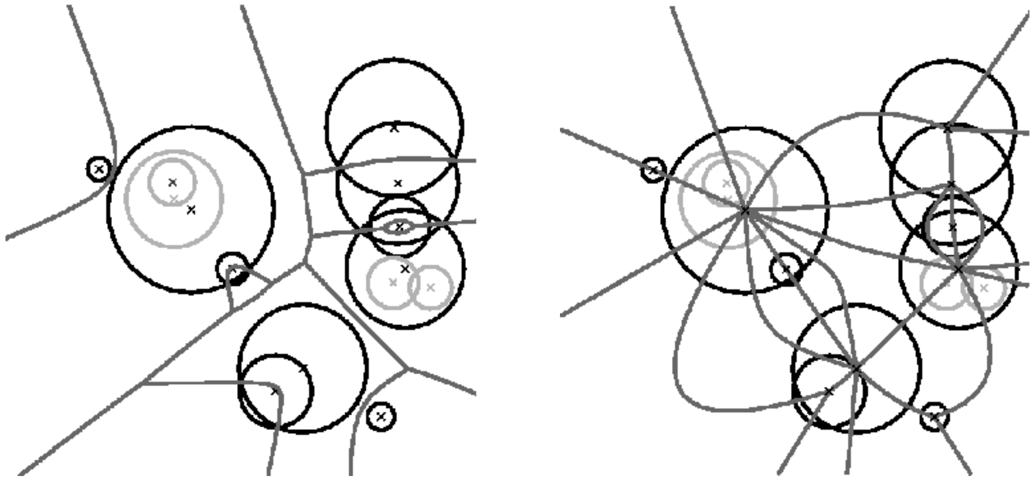

Figure 45.1: The Apollonius diagram (left) and its dual the Apollonius graph (right).

and w_i the weight of P_i. It is a subdivision of the plane into connected regions, called *cells*, associated with the sites (see Fig. 45.1(left)). The cell of a site P_i is the locus of points on the plane that are closer to P_i than any other site P_j, $j \neq i$. The distance $\delta(x, P_i)$ of a point x in the plane to a site P_i is defined as:

$$\delta(x, P_i) = \|x - c_i\| - w_i,$$

where $\|\cdot\|$ denotes the Euclidean norm. It can easily be seen that it is a generalization of the Voronoi diagram for points, which can actually be obtained if all the weights w_i are equal. Unlike the case of points, however, it is possible that a site P_i might have an empty cell. This can also happen in the case of the power diagram, whose dual is the regular triangulation (see Section 37.6). If this is the case we call the site *hidden* (these are the black circles in Fig. 45.1). A site which is not hidden will be referred to as *visible*.

If all weights w_i are non-negative, the Apollonius diagram can be viewed as the Voronoi diagram of the set of circles $\{P_1, \ldots, P_n\}$, where c_i is the center of the circle P_i and w_i its radius. If the weights are allowed to be negative, we need to go to 3D in order to explain what the Apollonius diagram means geometrically. We identify the 2D Euclidean plane with the xy-plane in 3D. Then the Voronoi diagram of a set of points can be seen as the vertical projection on the xy-plane of the lower envelope of a set of 3D cones defined as follows: for each point p in the set of 2D points we have a cone C_p whose apex is the point p. The axis of C_p is a line parallel to the z-axis passing through p, the angle of C_p is $45°$ and, finally C_p is facing in the positive z-direction (that is, C_p is contained in the positive z-halfspace). The Apollonius diagram corresponds to shifting the apexes of these cones in the z-direction by a quantity equal to the weight. Sites with negative weight will give rise to cones whose apex is in the negative z-halfspace and sites with positive weight will give rise to cones whose apex is in the positive z-halfspace. In a manner analogous to the case of points, the Apollonius diagram can then be defined as the vertical projection on the xy-plane of the lower envelope of the set of shifted cones. Notice that when all apexes are translated along the z-direction by the same amount, the projection of the lower envelope of the set of cones does not change. In particular, we can translate all cones by a large enough amount so that all apexes are in the positive z-halfspace. Algebraically, this means that the Apollonius diagram does not change if we add to all weights the same quantity, which in particular, implies that we can assume without loss of generality that all weights are positive. Given the observations above and in order to simplify our discussion of Apollonius diagrams, we will, from now on, assume that all weights are positive, and we will refer to the sites as circles.

The Apollonius diagram is a planar graph, and so is its dual, the Apollonius graph. There are many ways to embed it on the plane and one such way is shown in Fig. 45.1(right). The Apollonius graph is uniquely defined once we have the Apollonius diagram. If the circles are in *general position* (see precise definition below), then the Apollonius graph is a graph with triangular faces away from the convex hull of the set of circles (by triangular we mean that every face has exactly three edges). Near the convex hull we may have some spikes (i.e., vertices of degree 1). To unify our approach and handling of the Apollonius graph we add to the set of (finite) circles a fictitious circle at infinity, which we call the *site at infinity*. We can then connect all vertices of the outer face of the Apollonius graph to the site at infinity which gives us a graph with the property that all of its faces are now triangular. However, the Apollonius graph is not a triangulation for two main reasons: we cannot always embed it on the plane with straight line segments that yield a triangulation and, moreover, we may have two faces of the graph that have two edges in common, which is not allowed in a triangulation. Both of these particularities appear when we consider the Apollonius graph of the set of circles in Fig. 45.1(right).

We would like to finish our brief introduction to the theory of Apollonius graphs by discussing the concept of general position. We say that a set of circles is in general position if no two triplets of circles have the same tritangent circle. This statement is rather technical and it is best understood in the context of points. The equivalent statement for points is that we have no two triplets of points that define the same circumcircle, or equivalently that no four points are co-circular. The statement about general position made above is a direct generalization of the (much simpler to understand) statement about points. On the contrary, when we have circles in degenerate position, the Apollonius graph has faces with more than three edges on their boundary. We can get a triangulated version of the graph by simply *triangulating* the corresponding faces in an arbitrary way. In fact the algorithm that has been implemented in CGAL has the property that it always returns a valid *triangulated* version of the Apollonius graph. By valid we mean that it contains the actual Apollonius graph (i.e., the actual dual of the Apollonius diagram) and whenever there are faces with more than three faces then they are triangulated. The way that they are triangulated depends on the order of insertion and deletion of the circles in the diagram.

One final point has to be made about hidden circles. First of all we would like to be more precise about our definition of hidden circles: we say that a circle is hidden if its cell has empty interior. This definition allows us to guarantee that all visible circles have cells that are two-dimensional regions. Geometrically the fact that a circle is hidden means that it is contained in the closure of the disk of another circle (see again Fig. 45.1). Note that a circle contained in the union of several disks, but not in the closure of any one of them, is not hidden.

Hidden circles pose an additional difficulty to our algorithm and software design. Since we allow circles to be inserted and deleted at wish, it is possible that a circle that was hidden at some point in time, may become visible at a later point in time; for example this can happen if we delete the circle that hides it. For this purpose we store hidden circles and have them reappear when they become visible. We will discuss this issue in detail below. For the time being it suffices to say that the user has the ability to control this behavior. More specifically it is possible to discard the circles that become hidden. This choice is totally natural when for example we expect to do only insertions, since in this case a circle that becomes hidden will never reappear. On the other hand if deletions are expected as well, then we lose the ability to have the hidden circles reappear.

Degenerate Dimensions. The dimension of the Apollonius graph is in general 2. The exceptions to this rule are as follows:

- The dimension is -1 if the Apollonius graph contains no circles.
- The dimension is 0 if the Apollonius graph contains exactly one visible circle.
- The dimension is 1 is the Apollonius graph contains exactly two visible circles.

45.2 Software Design

The 2D Apollonius graph class *Apollonius_graph_2<ApolloniusGraphTraits_2,ApolloniusGraphDataStructure_2>* follows the design of the triangulation package of CGAL. It is parametrized by two arguments:

- the **geometric traits** class. It provides the basic geometric objects involved in the algorithm, such as sites, points etc. It also provides the geometric predicates for the computation of the Apollonius graph, as well as some basic constructions that can be used, for example, to visualize the Apollonius graph or the Apollonius diagram. The geometric traits for the Apollonius graph will be discussed in more detail in the next section.
- the **Apollonius graph data structure**. This is essentially the same as the triangulation data structure (discussed in Chapter 38), augmented with some additional operations that are specific to Apollonius graphs. The corresponding concept is that of *ApolloniusGraphDataStructure_2*, which in fact is a refinement of the *TriangulationDataStructure_2* concept. The class *Triangulation_data_structure_2<Vb,Fb>* is a model of the concept *ApolloniusGraphDataStructure_2*. A default value for the corresponding template parameter is provided, so the user does not need to specify it.

Storing Hidden Sites. As we have already mentioned a circle is hidden if it is contained inside some visible circle. This creates a parent-child relationship between visible and hidden circles: the parent of a hidden circle is the visible circle that contains it. If more than one visible circles contain a hidden circle then the hidden circle can be assigned to any of the visible circles arbitrarily.

To store hidden circles we assign to every visible circle a list. This list comprises the hidden circles that are contained in the visible circle. The user can access the hidden circles associated with a visible circle through an iterator called *Hidden_sites_iterator*. This iterator is defined in the *ApolloniusGraphVertexBase_2* concept and is implemented by its model, the *Apollonius_graph_vertex_base_2<Gt,StoreHidden>* class. It is also possible to iterate through the entire set of hidden sites using an homonymous iterator defined by the *Apollonius_graph_2< Gt,Agds>* class.

Since storing hidden sites may not be of interest in some cases (e.g., for example this is the case if we only perform insertions in the Apollonius graph), the user has the possibility of controlling this behavior. More precisely, the class *Apollonius_graph_vertex_base_2<Gt,StoreHidden>* has two template parameters, the second of which is a Boolean value. This value is by default *true* and it indicates that hidden sites should be stored. The user can indicate that hidden sites may be discarded by setting this value to *false*.

45.3 The Geometric Traits

The predicates required for the computation of the Apollonius graph are rather complicated. It is not the purpose of this document to discuss them in detail. The interested reader may refer to the papers by Karavelas and Emiris for the details [KE02, KE03]. However, we would like to give a brief overview of what they compute. There are several predicates needed by this algorithm. We will discuss the most important/complicated ones. It turns out that it is much easier to describe them in terms of the Apollonius diagram, rather than the Apollonius graph. Whenever it is applicable we will also describe their meaning in terms of the Apollonius graph.

The first two geometric predicates are called *Is_hidden_2* and *Oriented_side_of_bisector_2*. The first one involves two circles, say P_1 and P_2. It determines if P_1 is hidden with respect to P_2; more precisely it checks whether the circle P_1 is contained in the closure of the disk defined by the circle P_2. As its name indicates, it determines if a circle is hidden or not. The second predicate involves two circles P_1 and P_2 and a point q. It answers the question whether q is closer to P_1 or P_2. Its name stems from the fact that answering the aforementioned question is equivalent to determining the oriented side of the bisector of P_1 and P_2 that contains the query point q. This predicate is used by the algorithm for closest neighbor queries for points.

The next geometric predicate is called *Vertex_conflict_2* and it involves four circles P_1, P_2, P_3, and P_4 (see Fig. 45.3). The first three (red circles in Fig. 45.3) define a tritangent circle (yellow circle in Fig. 45.3). What we want to determine is the sign of the distance of the green circle from the yellow circle. The distance between two circles $K_1 = (c_1, r_1)$ and $K_2 = (c_2, r_2)$ is defined as the distance of their centers minus their radii:

$$\delta(K_1, K_2) = \|c_1 - c_2\| - r_1 - r_2.$$

This predicate determines if a vertex in the Apollonius diagram (the center of the yellow circle) is destroyed when a new circle is inserted in the diagram (the green circle). In the Apollonius graph it tells us if a triangular face of the diagram is to be destroyed or not.

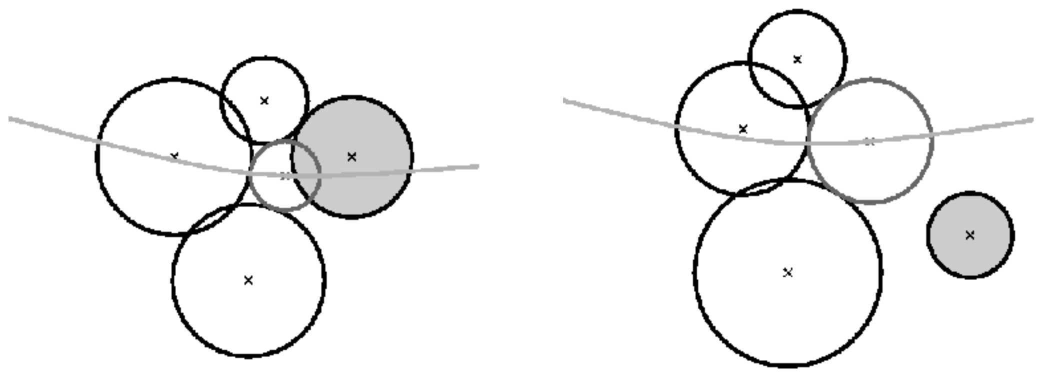

Figure 45.2: The *Vertex_conflict_2* predicate. The left-most, bottom-most and top-most circles define the tritangent circle in the middle. We want to determine the sign of the distance of the left-most circle from the one in the middle. The almost horizontal curve is the bisector of the top-most and bottom-most circles. Left: the predicate returns *CGAL::NEGATIVE*. Right: the predicate returns *CGAL::POSITIVE*.

What we essentially want to compute when we construct incrementally a Voronoi diagram, is whether the object to be inserted destroys an edge of the Voronoi diagram or not. In the case of points this is really easy and it amounts to the well known *incircle* test. In the case of circles the situation is more complicated. We can have six possible outcomes as to what portion of an edge of the Apollonius diagram the new circle destroys (see Fig. 45.3). The first two can be answered directly by the *Vertex_conflict_2* predicate evaluated for the two endpoints of the Apollonius diagram edge. This is due to the fact that the value of the *Vertex_conflict_2* predicate is different for the two endpoints. If the two values are the same then we need an additional test which determines if the interior of the Apollonius diagram edge is destroyed by the new circle. This is what the *Finite_edge_interior_conflict_2* and *Infinite_edge_interior_conflict_2* predicates do. In essence, it is the same predicate (same idea) applied to two different types of edges in the Apollonius diagram: a finite or an infinite edge. An edge is infinite if its dual edge in the Apollonius graph connects the site at infinity with the vertex corresponding to a (finite) circle; otherwise it is a finite edge.

The last predicate that we want to discuss is called *Is_degenerate_edge_2*. It tells us whether an edge in the Apollonius diagram is degenerate, that is if its two endpoints coincide. In the Apollonius graph such an edge corresponds to one of the additional edges that we use to triangulate the non-triangular faces.

The aforementioned predicates are part of the *ApolloniusGraphTraits_2* concept of CGAL. CGAL also provides a model for this concept, the *Apollonius_graph_traits_2<K,Method_tag>* class. The first template parameter of this class must be a model of the *Kernel* concept. The second template parameter is a tag that indicates what operations are allowed in the computations that take place within the traits class. The two possible values of the *Method_tag* parameter are *CGAL::Ring_tag* and *CGAL::Sqrt_field_tag*. When *CGAL::Ring_tag* is used, only ring operations are used during the evaluation of the predicates, whereas if *CGAL::Sqrt_field_tag* is chosen, all four field operations, as well as square roots, are used during the predicate evaluation.

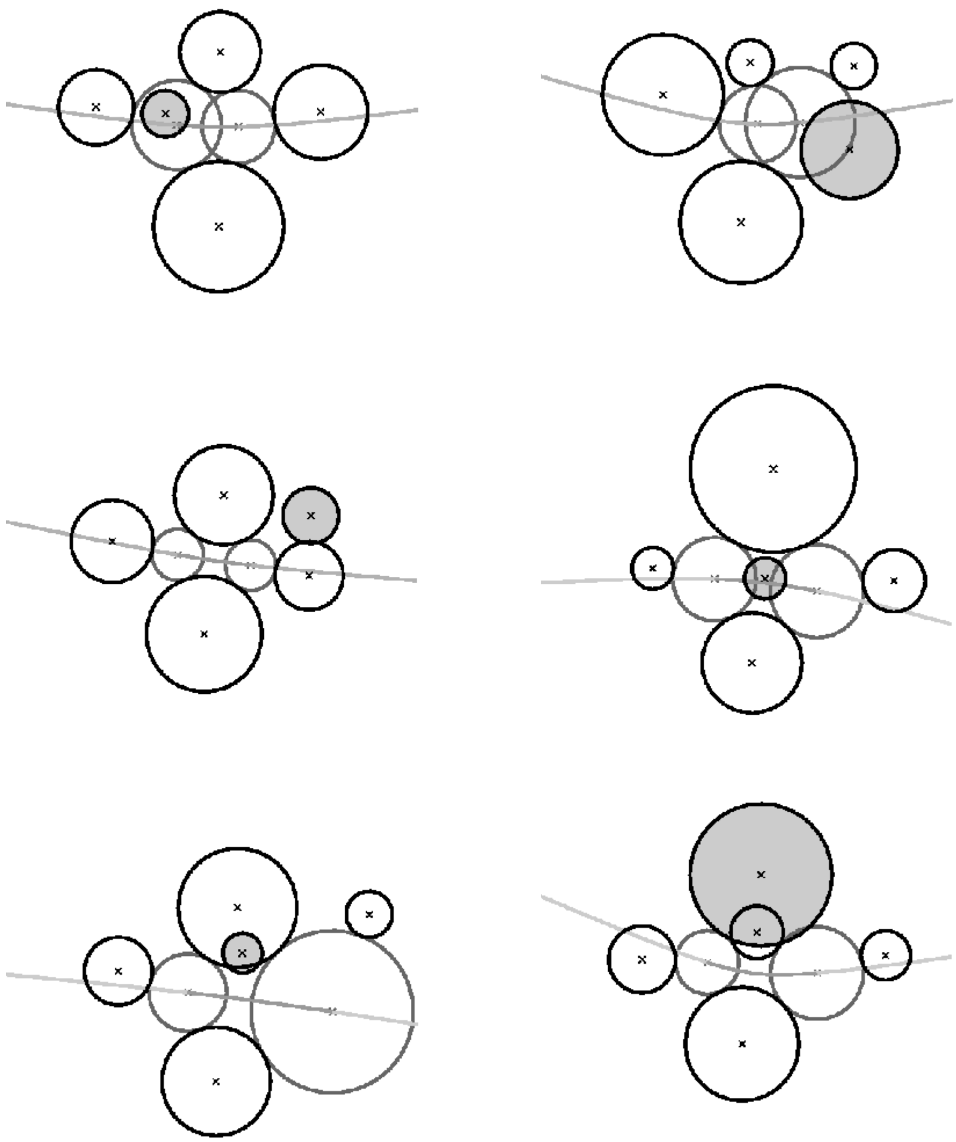

Figure 45.3: The 6 possible outcomes of the *Finite_edge_interior_conflict_2* predicate. Top left: only a neighborhood around the left-most endpoint of the edge will be destroyed. Top right: only a neighborhood around the right-most endpoint of the edge will be destroyed. Middle left: no portion of the edge is destroyed. Middle right: the entire edge will be destroyed. Bottom left: a neighborhood in the interior of the edge will be destroyed; the regions near the endpoints remain unaffected. Bottom right: The neighborhood around the two endpoints will be destroyed, but an interval in the interior of the edge will remain in the new diagram.

The *Apollonius_graph_traits_2<K,Method_tag>* class provides exact predicates if the number type in the kernel *K* is an exact number type. This is to be associated with the type of operations allowed for the predicate evaluation. For example *CGAL::MP_Float* as number type, with *CGAL::Ring_tag* as tag will give exact predicates, whereas *CGAL::MP_Float* with *CGAL::Sqrt_field_tag* will give inexact predicates.

Since using an exact number type may be too slow, the *Apollonius_graph_traits_2<K,Method_tag>* class is designed to support the dynamic filtering of CGAL through the *CGAL::Filtered_exact<CT,ET>* mechanism. In particular if *CT* is an inexact number type that supports the operations denoted by the tag *Method_tag* and *ET* is an exact number type for these operations, then kernel with number type *CGAL::Filtered_exact<CT,ET>* will yield exact predicates for the Apollonius graph traits. To give a concrete example, *CGAL::Filtered_exact< double,CGAL::MP_Float>* with *CGAL::Ring_tag* will produce exact predicates.

Another possibility for fast and exact predicate evaluation is to use the *Apollonius_graph_filtered_traits_2< CK,CM,EK,EM,FK,FM>* class. This class is the analog of a filtered kernel. It takes a constructions kernel *CK*, a filtering kernel *FK* and an exact kernel *EK*, as well as the corresponding tags (*CM*, *FM* and *EM*, respectively). It evaluates the predicates by first using the filtering kernel, and if this fails the evaluation is performed using the exact kernel. The constructions are done using the kernel *CK*, which means that they are not necessarily exact. All template parameters except *CK* have default values, which are explained in the reference manual.

45.4 The Apollonius Graph Hierarchy

The *Apollonius_graph_hierarchy_2<ApolloniusGraphTraits_2,ApolloniusGraphDataStructure_2>* class is nothing but the equivalent of the *Triangulation_hierarchy_2* class, applied to the Apollonius graph. It consists of a series of Apollonius graphs constructed in a manner analogous to the Delaunay hierarchy by Devillers [Dev98]. The class *Apollonius_graph_hierarchy_2<ApolloniusGraphTraits_2,ApolloniusGraphDataStructure_2>* has exactly the same interface and functionality as the *Apollonius_graph_2<ApolloniusGraphTraits_2,ApolloniusGraphDataStructure_2>* class. Using the Apollonius graph hierarchy involves an additional cost in space and time for maintaining the hierarchy. Our experiments have shown that it usually pays off to use the hierarchy for inputs consisting of more than 1,000 circles. This threshold holds for both the construction of the Apollonius diagram itself, as well as for nearest neighbor queries.

45.5 Examples

45.5.1 First Example

```
#include <iostream>
#include <fstream>
#include <cassert>

// the number type
#include <CGAL/MP_Float.h>

// example that uses an exact number type

typedef CGAL::MP_Float NT;

// choose the kernel
#include <CGAL/Simple_cartesian.h>

typedef CGAL::Simple_cartesian<NT>  Kernel;

// typedefs for the traits and the algorithm

#include <CGAL/Apollonius_graph_2.h>
```

```
#include <CGAL/Apollonius_graph_traits_2.h>

typedef CGAL::Apollonius_graph_traits_2<Kernel>   Traits;
typedef CGAL::Apollonius_graph_2<Traits>          Apollonius_graph;

int main()
{
  std::ifstream ifs("data/sites.cin");
  assert( ifs );

  Apollonius_graph ag;
  Apollonius_graph::Site_2 site;

  // read the sites and insert them in the Apollonius graph
  while ( ifs >> site ) {
    ag.insert(site);
  }

  // validate the Apollonius graph
  assert( ag.is_valid(true, 1) );
  std::cout << std::endl;

  return 0;
}
```

File: examples/Apollonius_graph_2/ag2_exact_traits.cpp

45.5.2 Second Example

```
#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

#if defined CGAL_USE_LEDA
#  include <CGAL/leda_real.h>
#elif defined CGAL_USE_CORE
#  include <CGAL/CORE_Expr.h>
#endif

#if defined CGAL_USE_LEDA
// If LEDA is present use leda_real as the exact number type
typedef leda_real NT;

#elif defined CGAL_USE_CORE
// Otherwise if CORE is present use CORE's Expr as the exact number type
```

```
typedef CORE::Expr NT;

#else

// Otherwise just use double. This may cause numerical errors but it
// is still worth doing it to show how to define correctly the traits
// class
typedef double NT;

#endif

#include <CGAL/Simple_cartesian.h>

typedef CGAL::Simple_cartesian<NT>  Kernel;

// typedefs for the traits and the algorithm

#include <CGAL/Apollonius_graph_2.h>
#include <CGAL/Apollonius_graph_traits_2.h>

// the traits class is now going to assume that the operations
// +,-,*,/ and sqrt are supported exactly
typedef
CGAL::Apollonius_graph_traits_2<Kernel,CGAL::Field_with_sqrt_tag> Traits;

typedef CGAL::Apollonius_graph_2<Traits> Apollonius_graph;

int main()
{
  std::ifstream ifs("data/sites.cin");
  assert( ifs );

  Apollonius_graph ag;
  Apollonius_graph::Site_2 site;

  // read the sites and insert them in the Apollonius graph
  while ( ifs >> site ) {
    ag.insert(site);
  }

  // validate the Apollonius graph
  assert( ag.is_valid(true, 1) );
  std::cout << std::endl;

  return 0;
}
```

File: examples/Apollonius_graph_2/ag2_exact_traits_sqrt.cpp

45.5.3 Third Example

```
#include <iostream>
#include <fstream>
#include <cassert>

// example that uses the filtered traits

// choose the representation
#include <CGAL/Simple_cartesian.h>

typedef CGAL::Simple_cartesian<double> Rep;

#include <CGAL/Apollonius_graph_2.h>
#include <CGAL/Triangulation_data_structure_2.h>
#include <CGAL/Apollonius_graph_vertex_base_2.h>
#include <CGAL/Triangulation_face_base_2.h>
#include <CGAL/Apollonius_graph_filtered_traits_2.h>

// typedef for the traits; the filtered traits class is used
typedef CGAL::Apollonius_graph_filtered_traits_2<Rep> Traits;

// typedefs for the algorithm

// With the second template argument in the vertex base class being
// false, we indicate that there is no need to store the hidden sites.
// One case where this is indeed not needed is when we only do
// insertions, like in the main program below.
typedef CGAL::Apollonius_graph_vertex_base_2<Traits,false>   Vb;
typedef CGAL::Triangulation_face_base_2<Traits>              Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb>       Agds;
typedef CGAL::Apollonius_graph_2<Traits,Agds>    Apollonius_graph;

int main()
{
  std::ifstream ifs("data/sites.cin");
  assert( ifs );

  Apollonius_graph ag;
  Apollonius_graph::Site_2 site;

  // read the sites and insert them in the Apollonius graph
  while ( ifs >> site ) {
    ag.insert(site);
  }

  // validate the Apollonius graph
  assert( ag.is_valid(true, 1) );
  std::cout << std::endl;

  // now remove all sites
  std::cout << "Removing all sites... " << std::flush;
  while ( ag.number_of_vertices() > 0 ) {
```

```
    ag.remove( ag.finite_vertex() );
  }
  std::cout << "done!" << std::endl << std::endl;

  return 0;
}
```

File: examples/Apollonius_graph_2/ag2_filtered_traits_no_hidden.cpp

45.5.4 Fourth Example

```
#include <iostream>
#include <fstream>
#include <cassert>

// example that uses the filtered traits

#include <CGAL/MP_Float.h>
#include <CGAL/Simple_cartesian.h>

// constructions kernel (inexact)
typedef CGAL::Simple_cartesian<double> CK;

// exact kernel
typedef CGAL::Simple_cartesian<CGAL::MP_Float> EK;

// typedefs for the traits and the algorithm

#include <CGAL/Apollonius_graph_hierarchy_2.h>
#include <CGAL/Apollonius_graph_filtered_traits_2.h>

// Type definition for the traits class.
// In this example we explicitly define the exact kernel. We also
// explicitly define what operations to use for the evaluation of the
// predicates and constructions, when the filtering and the exact
// kernels are used respectively.
// Note that the operations allowed for the filtering and the
// constructions (field operations plus square roots) are different
// from the operations allowed when the exact kernel is used (ring
// operations).
typedef CGAL::Field_with_sqrt_tag  CM;
typedef CGAL::Integral_domain_without_division_tag        EM;
typedef CGAL::Apollonius_graph_filtered_traits_2<CK,CM,EK,EM> Traits;

// Now we use the Apollonius graph hierarchy.
// The hierarchy is faster for inputs consisting of about more than
// 1,000 sites
typedef CGAL::Apollonius_graph_hierarchy_2<Traits> Apollonius_graph;
```

```
int main()
{
  std::ifstream ifs("data/hierarchy.cin");
  assert( ifs );

  Apollonius_graph ag;
  Apollonius_graph::Site_2 site;

  // read the sites and insert them in the Apollonius graph
  while ( ifs >> site ) {
    ag.insert(site);
  }

  // validate the Apollonius graph
  assert( ag.is_valid(true, 1) );

  return 0;
}
```

File: examples/Apollonius_graph_2/ag2_hierarchy.cpp

2D Apollonius Graphs (Delaunay Graphs of Disks) Reference Manual

Menelaos Karavelas and Mariette Yvinec

An Apollonius graph is the dual of the Apollonius diagram, also known as the *additively weighted Voronoi diagram*. It is essentially the Voronoi diagram of a set of disks, where the distance of a point of the plane from a disk is defined as the Euclidean distance of the point and the center of the circle, minus the radius of the disk.

CGAL provides the class *CGAL::Apollonius_graph_2<Gt,Agds>* for computing the 2D Apollonius graph. The two template parameters must be models of the *ApolloniusGraphTraits_2* and *ApolloniusGraphDataStructure_2* concepts. The first concept is related to the geometric objects and predicates associated with Apollonius graphs, whereas the second concept refers to the data structure used to represent the Apollonius graph. The classes *Apollonius_graph_traits_2<K,Method_tag>* and *Triangulation_data_structure_2<Vb,Fb>* are models of the aforementioned concepts.

CGAL::Apollonius_graph_2<Gt,Agds>

Definition

The class *Apollonius_graph_2<Gt,Agds>* represents the Apollonius graph. It supports insertions and deletions of sites. It is templated by two template arguments *Gt*, which must be a model of *ApolloniusGraphTraits_2*, and *Agds*, which must be a model of *ApolloniusGraphDataStructure_2*. The second template argument defaults to *CGAL::Triangulation_data_structure_2< CGAL::Apollonius_graph_vertex_base_2<Gt,true>, CGAL::Triangulation_face_base_2<Gt> >*.

#include <CGAL/Apollonius_graph_2.h>

Is Model for the Concepts

DelaunayGraph_2

Types

typedef Agds	*Data_structure;*	A type for the underlying data structure.
typedef Data_structure	*Triangulation_data_structure;*	Same as the *Data_structure* type. This type has been introduced in order for the *Apollonius_graph_2<Gt,Agds>* class to be a model of the *DelaunayGraph_2* concept.
typedef Gt	*Geom_traits;*	A type for the geometric traits.
typedef Gt::Point_2	*Point_2;*	A type for the point defined in the geometric traits.
typedef Gt::Site_2	*Site_2;*	A type for the Apollonius site, defined in the geometric traits.

The vertices and faces of the Apollonius graph are accessed through *handles*, *iterators* and *circulators*. The iterators and circulators are all bidirectional and non-mutable. The circulators and iterators are assignable to the corresponding handle types, and they are also convertible to the corresponding handles. The edges of the Apollonius graph can also be visited through iterators and circulators, the edge circulators and iterators are also bidirectional and non-mutable. In the following, we call *infinite* any face or edge incident to the infinite vertex and the infinite vertex itself. Any other feature (face, edge or vertex) of the Apollonius graph is said to be *finite*. Some iterators (the *All* iterators) allow to visit finite or infinite features while the others (the *Finite* iterators) visit only finite features. Circulators visit both infinite and finite features.

typedef Data_structure::Edge	*Edge;*	the edge type. The *Edge(f,i)* is the edge common to faces *f* and *f.neighbor(i)*. It is also the edge joining the vertices *vertex(cw(i))* and *vertex(ccw(i))* of *f*. *Precondition*: *i* must be *0*, *1* or *2*.
typedef Data_structure::Vertex	*Vertex;*	A type for a vertex.
typedef Data_structure::Face	*Face;*	A type for a face.
typedef Data_structure::Vertex_handle	*Vertex_handle;*	A type for a handle to a vertex.
typedef Data_structure::Face_handle	*Face_handle;*	A type for a handle to a face.
typedef Data_structure::Vertex_circulator	*Vertex_circulator;*	A type for a circulator over vertices incident to a given vertex.

typedef Data_structure::Face_circulator	*Face_circulator;*	A type for a circulator over faces incident to a given vertex.
typedef Data_structure::Edge_circulator	*Edge_circulator;*	A type for a circulator over edges incident to a given vertex.
typedef Data_structure::Vertex_iterator	*All_vertices_iterator;*	A type for an iterator over all vertices.
typedef Data_structure::Face_iterator	*All_faces_iterator;*	A type for an iterator over all faces.
typedef Data_structure::Edge_iterator	*All_edges_iterator;*	A type for an iterator over all edges.
typedef Data_structure::size_type	*size_type;*	An unsigned integral type.

Apollonius_graph_2<Gt,Agds>:: Finite_vertices_iterator	A type for an iterator over finite vertices.
Apollonius_graph_2<Gt,Agds>:: Finite_faces_iterator	A type for an iterator over finite faces.
Apollonius_graph_2<Gt,Agds>:: Finite_edges_iterator	A type for an iterator over finite edges.

In addition to iterators and circulators for vertices and faces, iterators for sites are provided. In particular there are iterators for the entire set of sites, the hidden sites and the visible sites of the Apollonius graph.

Apollonius_graph_2<Gt,Agds>:: Sites_iterator	A type for an iterator over all sites.
Apollonius_graph_2<Gt,Agds>:: Visible_sites_iterator	A type for an iterator over all visible sites.
Apollonius_graph_2<Gt,Agds>:: Hidden_sites_iterator	A type for an iterator over all hidden sites.

Creation

Apollonius_graph_2<Gt,Agds> ag(Gt gt=Gt()); Creates an Apollonius graph using *gt* as geometric traits.

template< class Input_iterator >
Apollonius_graph_2<Gt,Agds> ag(Input_iterator first, Input_iterator beyond, Gt gt=Gt());

Creates an Apollonius graph using *gt* as geometric traits and inserts all sites in the range [*first*, *beyond*).
Precondition: *Input_iterator* must be a model of *InputIterator*. The value type of *Input_iterator* must be *Site_2*.

Apollonius_graph_2<Gt,Agds> ag(other); Copy constructor. All faces and vertices are duplicated. After the construction, *ag* and *other* refer to two different Apollonius graphs : if *other* is modified, *ag* is not.

Apollonius_graph_2<Gt,Agds> ag = other Assignment. If *ag* and *other* are the same object nothing is done. Otherwise, all the vertices and faces are duplicated. After the assignment, *ag* and *other* refer to different Apollonius graphs : if *other* is modified, *ag* is not.

Access Functions

Geom_traits	*ag.geom_traits()*	Returns a reference to the Apollonius graph traits object.
Data_structure	*ag.data_structure()*	Returns a reference to the underlying data structure.
Data_structure	*ag.tds()*	Same as *data_structure()*. This method has been added in compliance with the *DelaunayGraph_2* concept.
int	*ag.dimension()*	Returns the dimension of the Apollonius graph.
size_type	*ag.number_of_vertices()*	Returns the number of finite vertices.
size_type	*ag.number_of_visible_sites()*	Returns the number of visible sites.

size_type	*ag.number_of_hidden_sites()*	Returns the number of hidden sites.
size_type	*ag.number_of_faces()*	Returns the number of faces (both finite and infinite) of the Apollonius graph.
Face_handle	*ag.infinite_face()*	Returns a face incident to the *infinite_vertex*.
Vertex_handle	*ag.infinite_vertex()*	Returns the *infinite_vertex*.
Vertex_handle	*ag.finite_vertex()*	Returns a vertex distinct from the *infinite_vertex*. *Precondition*: The number of (visible) vertices in the Apollonius graph must be at least one.

Traversal of the Apollonius graph

An Apollonius graph can be seen as a container of faces and vertices. Therefore the Apollonius graph provides several iterators and circulators that allow to traverse it (completely or partially).

Face, Edge and Vertex Iterators

The following iterators allow respectively to visit finite faces, finite edges and finite vertices of the Apollonius graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the Apollonius graph.

Finite_vertices_iterator	*ag.finite_vertices_begin()*	Starts at an arbitrary finite vertex.
Finite_vertices_iterator	*ag.finite_vertices_end()*	Past-the-end iterator.
Finite_edges_iterator	*ag.finite_edges_begin()*	Starts at an arbitrary finite edge.
Finite_edges_iterator	*ag.finite_edges_end()*	Past-the-end iterator.
Finite_faces_iterator	*ag.finite_faces_begin()*	Starts at an arbitrary finite face.
Finite_faces_iterator	*ag.finite_faces_end() const*	Past-the-end iterator.

The following iterators allow respectively to visit all (both finite and infinite) faces, edges and vertices of the Apollonius graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the Apollonius graph.

All_vertices_iterator	*ag.all_vertices_begin()*	Starts at an arbitrary vertex.
All_vertices_iterator	*ag.all_vertices_end()*	Past-the-end iterator.
All_edges_iterator	*ag.all_edges_begin()*	Starts at an arbitrary edge.
All_edges_iterator	*ag.all_edges_end()*	Past-the-end iterator.
All_faces_iterator	*ag.all_faces_begin()*	Starts at an arbitrary face.
All_faces_iterator	*ag.all_faces_end()*	Past-the-end iterator.

Site iterators

The following iterators allow respectively to visit all sites, the visible sites and the hidden sites. These iterators are non-mutable, bidirectional and their value type is *Site_2*. They are all invalidated by any change in the Apollonius graph.

Sites_iterator	*ag.sites_begin()*	Starts at an arbitrary site.

Sites_iterator	*ag.sites_end()*	Past-the-end iterator.
Visible_sites_iterator	*ag.visible_sites_begin()*	Starts at an arbitrary visible site.
Visible_sites_iterator	*ag.visible_sites_end()*	Past-the-end iterator.
Hidden_sites_iterator	*ag.hidden_sites_begin()*	Starts at an arbitrary hidden site.
Hidden_sites_iterator	*ag.hidden_sites_end()*	Past-the-end iterator.

Face, Edge and Vertex Circulators

The Apollonius graph also provides circulators that allow to visit respectively all faces or edges incident to a given vertex or all vertices adjacent to a given vertex. These circulators are non-mutable and bidirectional. The operator *operator++* moves the circulator counterclockwise around the vertex while the *operator--* moves clockwise. A face circulator is invalidated by any modification of the face pointed to. An edge circulator is invalidated by any modification in one of the two faces incident to the edge pointed to. A vertex circulator is invalidated by any modification in any of the faces adjacent to the vertex pointed to.

Face_circulator *ag.incident_faces(Vertex_handle v)*

Starts at an arbitrary face incident to v.

Face_circulator *ag.incident_faces(Vertex_handle v, Face_handle f)*

Starts at face f.
Precondition: Face f is incident to vertex v.

Edge_circulator *ag.incident_edges(Vertex_handle v)*

Starts at an arbitrary edge incident to v.

Edge_circulator *ag.incident_edges(Vertex_handle v, Face_handle f)*

Starts at the first edge of f incident to v, in counterclockwise order around v.
Precondition: Face f is incident to vertex v.

Vertex_circulator *ag.incident_vertices(Vertex_handle v)*

Starts at an arbitrary vertex incident to v.

Vertex_circulator *ag.incident_vertices(Vertex_handle v, Face_handle f)*

Starts at the first vertex of f adjacent to v in counterclockwise order around v.
Precondition: Face f is incident to vertex v.

Traversal of the Convex Hull

Applied on the *infinite_vertex* the above functions allow to visit the vertices on the convex hull and the infinite edges and faces. Note that a counterclockwise traversal of the vertices adjacent to the *infinite_vertex* is a clockwise traversal of the convex hull.

Vertex_circulator *ag.incident_vertices(ag.infinite_vertex())*
Vertex_circulator *ag.incident_vertices(ag.infinite_vertex(), Face_handle f)*
Face_circulator *ag.incident_faces(ag.infinite_vertex())*

Face_circulator *ag.incident_faces(ag.infinite_vertex(), Face_handle f)*
Edge_circulator *ag.incident_edges(ag.infinite_vertex())*
Edge_circulator *ag.incident_edges(ag.infinite_vertex(), Face_handle f)*

Predicates

The class *Apollonius_graph_2<Gt,Agds>* provides methods to test the finite or infinite character of any feature.

bool *ag.is_infinite(Vertex_handle v) const*

true, iff *v* is the *infinite_vertex*.

bool *ag.is_infinite(Face_handle f) const* *true*, iff face *f* is infinite.

bool *ag.is_infinite(Face_handle f, int i) const*

true, iff edge *(f,i)* is infinite.

bool *ag.is_infinite(Edge e) const* *true*, iff edge *e* is infinite.

bool *ag.is_infinite(Edge_circulator ec) const*

true, iff edge **ec* is infinite.

Insertion

template< class Input_iterator >
unsigned int *ag.insert(Input_iterator first, Input_iterator beyond)*

Inserts the sites in the range [*first*,*beyond*). The number of sites in the range [*first*, *beyond*) is returned.
Precondition: *Input_iterator* must be a model of *InputIterator* and its value type must be *Site_2*.

Vertex_handle *ag.insert(Site_2 s)* Inserts the site *s* in the Apollonius graph. If *s* is visible then the vertex handle of *s* is returned, otherwise *Vertex_handle(NULL)* is returned.

Vertex_handle *ag.insert(Site_2 s, Vertex_handle vnear)*

Inserts *s* in the Apollonius graph using the site associated with *vnear* as an estimate for the nearest neighbor of the center of *s*. If *s* is visible then the vertex handle of *s* is returned, otherwise *Vertex_handle(NULL)* is returned.

Removal

void *ag.remove(Vertex_handle v)* Removes the site associated to the vertex handle *v* from the Apollonius graph.
Precondition: *v* must correspond to a valid finite vertex of the Apollonius graph.

Nearest neighbor location

Vertex_handle	*ag.nearest_neighbor(Point_2 p)*	Finds the nearest neighbor of the point p. In other words it finds the site whose Apollonius cell contains p. Ties are broken arbitrarily and one of the nearest neighbors of p is returned. If there are no visible sites in the Apollonius diagram *Vertex_handle(NULL)* is returned.
Vertex_handle	*ag.nearest_neighbor(Point_2 p, Vertex_handle vnear)*	Finds the nearest neighbor of the point p using the site associated with *vnear* as an estimate for the nearest neighbor of p. Ties are broken arbitrarily and one of the nearest neighbors of p is returned. If there are no visible sites in the Apollonius diagram *Vertex_handle(NULL)* is returned.

Access to the dual

The *Apollonius_graph_2* class provides access to the duals of the faces of the graph. The dual of a face of the Apollonius graph is a site. If the originating face is infinite, its dual is a site with center at infinity (or equivalently with infinite weight), which means that it can be represented geometrically as a line. If the originating face is finite, its dual is a site with finite center and weight. In the following three methods the returned object is assignable to either *Site_2* or *Gt::Line_2*, depending on whether the corresponding face of the Apollonius graph is finite or infinite, respectively.

Gt::Object_2	*ag.dual(Face_handle f) const*	Returns the dual corresponding to the face handle f. The returned object can be assignable to one of the following: *Site_2*, *Gt::Line_2*.
Gt::Object_2	*ag.dual(All_faces_iterator it) const*	Returns the dual of the face to which *it* points to. The returned object can be assignable to one of the following: *Site_2*, *Gt::Line_2*.
Gt::Object_2	*ag.dual(Finite_faces_iterator it) const*	Returns the dual of the face to which *it* points to. The returned object can be assignable to one of the following: *Site_2*, *Gt::Line_2*.

I/O

template< class Stream >

Stream&	*ag.draw_primal(Stream& str)*	Draws the Apollonius graph to the stream *str*. *Precondition*: The following operators must be defined: *Stream& operator<<(Stream&, Gt::Segment_2)*, *Stream& operator<<(Stream&, Gt::Ray_2)*.

template < class Stream >

Stream&	*ag.draw_dual(Stream& str)*	Draws the dual of the Apollonius graph, i.e., the Apollonius diagram, to the stream *str*. *Precondition*: The following operators must be defined: *Stream& operator<<(Stream&, Gt::Segment_2)*, *Stream& operator<<(Stream&, Gt::Ray_2)*, *Stream& operator<<(Stream&, Gt::Line_2)*.

template< class Stream >

Stream&	*ag.draw_primal_edge(Edge e, Stream& str)*	Draws the edge *e* of the Apollonius graph to the stream *str*. *Precondition*: The following operators must be defined: *Stream& operator<<(Stream&, Gt::Segment_2)*, *Stream& operator<<(Stream&, Gt::Ray_2)*.

template< class Stream >

Stream&	*ag.draw_dual_edge(Edge e, Stream& str)*	Draws the dual of the edge *e* to the stream *str*. The dual of *e* is an edge of the Apollonius diagram. *Precondition*: The following operators must be defined: *Stream& operator<<(Stream&, Gt::Segment_2)*, *Stream& operator<<(Stream&, Gt::Ray_2)*, *Stream& operator<<(Stream&, Gt::Line_2)*.
void	*ag.file_output(std::ostream& os)*	Writes the current state of the Apollonius graph to an output stream. In particular, all visible and hidden sites are written as well as the underlying combinatorial data structure.
void	*ag.file_input(std::istream& is)*	Reads the state of the Apollonius graph from an input stream.
std::ostream&	*std::ostream& os << ag*	Writes the current state of the Apollonius graph to an output stream.
std::istream&	*std::istream& is >> ag*	Reads the state of the Apollonius graph from an input stream.

Validity check

bool	*ag.is_valid(bool verbose = false, int level = 1)*	Checks the validity of the Apollonius graph. If *verbose* is *true* a short message is sent to *std::cerr*. If *level* is 0, only the data structure is validated. If *level* is 1, then both the data structure and the Apollonius graph are validated. Negative values of *level* always return true, and values greater then 1 are equivalent to *level* being 1.

Miscellaneous

void	*ag.clear()*	Clears all contents of the Apollonius graph.
void	*ag.swap(other)*	The Apollonius graphs *other* and *ag* are swapped. *ag.swap(other)* should be preferred to *ag= other* or to *ag(other)* if *other* is deleted afterwards.

Concept

ApolloniusSite_2

Definition

The concept *ApolloniusSite_2* provides the requirements for an Apollonius site class.

Types

ApolloniusSite_2:: Point_2	The point type.
ApolloniusSite_2:: FT	The field number type.
ApolloniusSite_2:: RT	The ring number type.
ApolloniusSite_2:: Weight	The weight type. *Precondition*: It must be the same as *FT*.

Creation

ApolloniusSite_2 s(Point_2 p=Point_2(), Weight w= Weight(0));

ApolloniusSite_2 s(other);	Copy constructor.

Access Functions

Point_2	*s.point() const*	Returns the center of the Apollonius site.
Weight	*s.weight() const*	Returns the weight of the Apollonius site.

CGAL::Apollonius_site_2<K>

Class

Definition

The class *Apollonius_site_2<K>* is a model for the concept *ApolloniusSite_2*. It is parametrized by a template parameter *K* which must be a model of the *Kernel* concept.

#include <CGAL/Apollonius_site_2.h>

Is Model for the Concepts

ApolloniusSite_2

Types

The class *Apollonius_site_2<K>* does not introduce any types in addition to the concept *ApolloniusSite_2*.

Creation

Apollonius_site_2<K>	*s(Point_2 p=Point_2(), Weight w= Weight(0));*	
Apollonius_site_2<K>	*s(other);*	Copy constructor.

I/O

The I/O operators are defined for *iostream*.

std::ostream&	*std::ostream& os << s*	Inserts the Apollonius site *s* into the stream *os*. *Precondition*: The insert operator must be defined for *Point_2* and *Weight*.
std::istream&	*std::istream& is >> s*	Reads an Apollonius site from the stream *is* and assigns it to *s*. *Precondition*: The extract operator must be defined for *Point_2* and *Weight*.

The information output in the *iostream* is: the point of the Apollonius site and its weight.

#include <CGAL/IO/Qt_widget_Apollonius_site_2.h>

Qt_widget&	*Qt_widget& w << s*	Inserts the Apollonius site *s* into the *Qt_widget* stream *w*. *Precondition*: The insert operator must be defined for *K::Circle_2*.

ApolloniusGraphDataStructure_2

Definition

The concept *ApolloniusGraphDataStructure_2* refines the concept *TriangulationDataStructure_2*. In addition it provides two methods for the insertion and removal of a degree 2 vertex in the data structure. The insertion method adds a new vertex to the specified edge, thus creating two new edges. Moreover, it creates two new faces that have the two newly created edges in common (see figure below). The removal method performs the reverse operation.

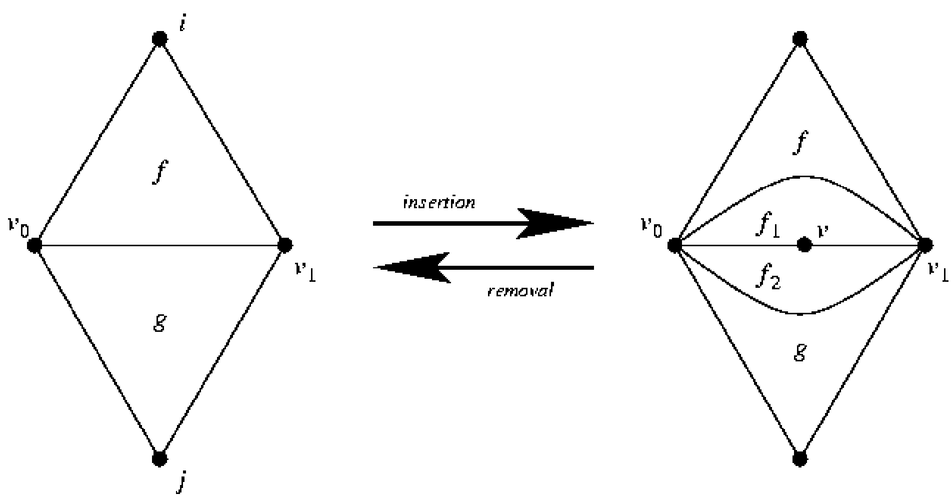

Figure 45.4: Insertion and removal of degree 2 vertices. Left to right: The edge *(f,i)* is replaced by two edges by means of inserting a vertex v on the edge. The faces f_1 and f_2 are created. Right to left: the faces f_1 and f_2 are destroyed. The vertex v is deleted and its two adjacent edges are merged.

We only describe the additional requirements with respect to the *TriangulationDataStructure_2* concept.

Refines

TriangulationDataStructure_2

Insertion

Vertex_handle	*agds.insert_degree_2(Face_handle f, int i)*	Inserts a degree two vertex and two faces adjacent to it that have two common edges. The edge defined by the face handle f and the integer i is duplicated. It returns a handle to the vertex created.

Removal

void	*agds.remove_degree_2(Vertex_handle v)*	Removes a degree 2 vertex and the two faces adjacent to it. The two edges of the star of *v* that are not incident to it are collapsed. *Precondition*: The degree of *v* must be equal to 2.

Concept

ApolloniusGraphVertexBase_2

Definition

The concept *ApolloniusGraphVertexBase_2* describes the requirements for the vertex base class of the *ApolloniusGraphDataStructure_2* concept. A vertex stores an Apollonius site and provides access to one of its incident faces through a *Face_handle*. In addition, it maintains a container of sites. The container stores the hidden sites related to the vertex.

Types

ApolloniusGraphVertexBase_2:: Geom_traits	A type for the geometric traits that defines the site stored. *Precondition*: The type *Geom_traits* must define the type *Site_2*.
ApolloniusGraphVertexBase_2:: Store_hidden	A Boolean that indicates if hidden sites are actually stored or not. Its value is *true* if hidden sites are stored, *false* otherwise.
ApolloniusGraphVertexBase_2:: Site_2	A type for the site stored. *Precondition*: This type must coincide with the type *Geom_traits::Site_2*.
ApolloniusGraphVertexBase_2:: Apollonius_graph_data_structure_2	A type for the Apollonius graph data structure, to which the vertex belongs to.
ApolloniusGraphVertexBase_2:: Vertex_handle	A type for the vertex handle of the Apollonius graph data structure.
ApolloniusGraphVertexBase_2:: Face_handle	A type for the face handle of the Apollonius graph data structure.
ApolloniusGraphVertexBase_2:: Hidden_sites_iterator	An iterator that iterates over the hidden sites in the hidden sites container of the vertex. *Precondition*: Must be a model of *Iterator*.

Creation

ApolloniusGraphVertexBase_2 v;	Default constructor.
ApolloniusGraphVertexBase_2 v(Site_2 s);	Constructs a vertex associated with the Apollonius site *s* and embedded at the center of *s*.
ApolloniusGraphVertexBase_2 v(Site_2 s, Face_handle f);	Constructs a vertex associated with the site *s*, embedded at the center of *s*, and pointing to the face associated with the face handle *f*.

Access Functions

Site_2	*v.site()*	Returns the Apollonius site.
Face_handle	*v.face()*	Returns a handle to an incident face.
unsigned int	*v.number_of_hidden_sites()*	Returns the number of hidden sites in the hidden sites container.

Hidden_sites_iterator	*v.hidden_sites_begin()*	Starts at an arbitrary hidden site.
Hidden_sites_iterator	*v.hidden_sites_end()*	Past-the-end iterator.

Setting and unsetting

void	*v.set_site(Site_2 s)*	Sets the Apollonius site.
void	*v.set_face(Face_handle f)*	Sets the incident face.
void	*v.add_hidden_site(Site_2 s)*	Adds a hidden site to the container of hidden sites.
void	*v.clear_hidden_sites_container()*	Clears the container of hidden sites.

Checking

bool

v.is_valid(bool verbose, int level) const

Performs any required tests on a vertex.

Class

CGAL::Apollonius_graph_vertex_base_2<Gt,StoreHidden>

Definition

The class *Apollonius_graph_vertex_base_2<Gt,StoreHidden>* provides a model for the *ApolloniusGraphVertexBase_2* concept which is the vertex base required by the *ApolloniusGraphDataStructure_2* concept. The class *Apollonius_graph_vertex_base_2<Gt,StoreHidden>* has two template arguments, the first being the geometric traits of the Apollonius graph and should be a model of the concept *ApolloniusGraphTraits_2*. The second is a Boolean which controls whether hidden sites are actually stored. Such a control is important if the user is not interested in hidden sites and/or if only insertions are made, in which case no hidden site can become visible. If *StoreHidden* is set to *true*, hidden sites are stored, otherwise they are discarded. By default *StoreHidden* is set to *true*.

#include <CGAL/Apollonius_graph_vertex_base_2.h>

Is Model for the Concepts

ApolloniusGraphVertexBase_2

Creation

Apollonius_graph_vertex_base_2<Gt,StoreHidden> vb;	Default constructor.
Apollonius_graph_vertex_base_2<Gt,StoreHidden> vb(Site_2 s);	Constructs a vertex associated with the site *s* and embedded at the center of *s*.
Apollonius_graph_vertex_base_2<Gt,StoreHidden> vb(Site_2 s, Face_handle f);	Constructs a vertex associated with the site *s*, embedded at the center of *s*, and pointing to the face associated with the face handle *f*.

ApolloniusGraphTraits_2

Definition

The concept *ApolloniusGraphTraits_2* provides the traits requirements for the *Apollonius_graph_2* class. In particular, it provides a type *Site_2*, which must be a model of the concept *ApolloniusSite_2*. It also provides constructions for sites and several function object types for the predicates.

Types

ApolloniusGraphTraits_2:: Point_2	A type for a point.
ApolloniusGraphTraits_2:: Site_2	A type for an Apollonius site. Must be a model of the concept *ApolloniusSite_2*.
ApolloniusGraphTraits_2:: Line_2	A type for a line. Only required if access to the dual of the Apollonius graph is required or if the primal or dual diagram are inserted in a stream.
ApolloniusGraphTraits_2:: Ray_2	A type for a ray. Only required if access to the dual of the Apollonius graph is required or if the primal or dual diagram are inserted in a stream.
ApolloniusGraphTraits_2:: Segment_2	A type for a segment. Only required if access to the dual of the Apollonius graph is required or if the primal or dual diagram are inserted in a stream.
ApolloniusGraphTraits_2:: Object_2	A type representing different types of objects in two dimensions, namely: *Point_2*, *Site_2*, *Line_2*, *Ray_2* and *Segment_2*.
ApolloniusGraphTraits_2:: FT	A type for the field number type of sites.
ApolloniusGraphTraits_2:: RT	A type for the ring number type of sites.
ApolloniusGraphTraits_2:: Assign_2	Must provide *template <class T> bool operator() (T& t, Object_2 o)* which assigns *o* to *t* if *o* was constructed from an object of type *T*. Returns *true*, if the assignment was possible.

ApolloniusGraphTraits_2:: Construct_object_2

Must provide *template <class T> Object_2 operator()(T t)* that constructs an object of type *Object_2* that contains *t* and returns it.

ApolloniusGraphTraits_2:: Construct_Apollonius_vertex_2

A constructor for a point of the Apollonius diagram equidistant from three sites. Must provide *Point_2 operator()(Site_2 s1, Site_2 s2, Site_2 s3)*, which constructs a point equidistant from the sites *s1*, *s2* and *s3*.

ApolloniusGraphTraits_2:: Construct_Apollonius_site_2

A constructor for a dual Apollonius site (a site whose center is a vertex of the Apollonius diagram and its weight is the common distance of its center from the three defining sites). Must provide *Site_2 operator()(Site_2 s1, Site_2 s2, Site_2 s3)*, which constructs a dual site whose center *c* is equidistant from *s1*, *s2* and *s3*, and its weight is equal to the (signed) distance of *c* from *s1* (or *s2* or *s3*).
Must also provide *Line_2 operator()(Site_2 s1, Site_2 s2)*, which constructs a line bitangent to *s1* and *s2*. This line is the dual site of *s1*, *s2* and the site at infinity; it can be viewed as a dual Apollonius site whose center is at infinity and its weight is infinite.

ApolloniusGraphTraits_2:: Compare_x_2

A predicate object type. Must provide *Comparison_result operator()(Site_2 s1, Site_2 s2)*, which compares the x-coordinates of the centers of *s1* and *s2*.

ApolloniusGraphTraits_2:: Compare_y_2

A predicate object type. Must provide *Comparison_result operator()(Site_2 s1, Site_2 s2)*, which compares the y-coordinates of the centers of *s1* and *s2*.

ApolloniusGraphTraits_2:: Compare_weight_2

A predicate object type. Must provide *Comparison_result operator()(Site_2 s1, Site_2 s2)*, which compares the weights of *s1* and *s2*.

ApolloniusGraphTraits_2:: Orientation_2

A predicate object type. Must provide *Orientation operator()(Site_2 s1, Site_2 s2, Site_2 s3)*, which performs the usual orientation test for the centers of the three sites *s1*, *s2* and *s3*.
Must also provide *Orientation operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 p1, Site_2 p2)*, which performs the usual orientation test for the Apollonius vertex of *s1*, *s2*, *s3* and the centers of *p1* and *p2*.
Precondition: the Apollonius vertex of *s1*, *s2* and *s3* must exist.

ApolloniusGraphTraits_2:: Is_hidden_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2)*, which returns *true* if the circle corresponding to *s2* is contained in the closure of the disk corresponding to *s1*, *false* otherwise.

ApolloniusGraphTraits_2:: Oriented_side_of_bisector_2

A predicate object type. Must provide *Oriented_side operator()(Site_2 s1, Site_2 s2, Point_2 p)*, which returns the oriented side of the bisector of *s1* and *s2* that contains *p*. Returns *ON_POSITIVE_SIDE* if *p* lies in the half-space of *s1* (i.e., *p* is closer to *s1* than *s2*); returns *ON_NEGATIVE_SIDE* if *p* lies in the half-space of *s2*; returns *ON_ORIENTED_BOUNDARY* if *p* lies on the bisector of *s1* and *s2*.

ApolloniusGraphTraits_2:: Vertex_conflict_2

A predicate object type. Must provide *Sign operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q)*, which returns the sign of the distance of *q* from the dual Apollonius site of *s1*, *s2*, *s3*.
Precondition: the dual Apollonius site of *s1*, *s2*, *s3* must exist.
Must also provide *Sign operator()(Site_2 s1, Site_2 s2, Site_2 q)*, which returns the sign of the distance of *q* from the bitangent line of *s1*, *s2* (a degenerate dual Apollonius site, with its center at infinity).

ApolloniusGraphTraits_2:: Finite_edge_interior_conflict_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 s4, Site_2 q, bool b)*. The sites *s1*, *s2*, *s3* and *s4* define an Apollonius edge that lies on the bisector of *s1* and *s2* and has as endpoints the Apollonius vertices defined by the triplets *s1*, *s2*, *s3* and *s1*, *s4* and *s2*. The Boolean *b* denotes if the two Apollonius vertices are in conflict with the site *q* (in which case *b* should be *true*, otherwise *false*). In case that *b* is *true*, the predicate returns *true* if and only if the entire Apollonius edge is in conflict with *q*. If *b* is *false*, the predicate returns *false* if and only if *q* is not in conflict with the Apollonius edge.
Precondition: the Apollonius vertices of *s1*, *s2*, *s3*, and *s1*, *s4*, *s2* must exist.
Must also provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q, bool b)*. The sites *s1*, *s2*, *s3* and the site at infinity s_∞ define an Apollonius edge that lies on the bisector of *s1* and *s2* and has as endpoints the Apollonius vertices defined by the triplets *s1*, *s2*, *s3* and *s1*, s_∞ and *s2* (the second Apollonius vertex is actually at infinity). The Boolean *b* denotes if the two Apollonius vertices are in conflict with the site *q* (in which case *b* should be *true*, otherwise *false*). In case that *b* is *true*, the predicate returns *true* if and only if the entire Apollonius edge is in conflict with *q*. If *b* is *false*, the predicate returns *false* if and only if *q* is not in conflict with the Apollonius edge.
Precondition: the Apollonius vertex of *s1*, *s2*, *s3* must exist.
Must finally provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 q, bool b)*. The sites *s1*, *s2* and the site at infinity s_∞ define an Apollonius edge that lies on the bisector of *s1* and *s2* and has as endpoints the Apollonius vertices defined by the triplets *s1*, *s2*, s_∞ and *s1*, s_∞ and *s2* (both Apollonius vertices are actually at infinity). The Boolean *b* denotes if the two Apollonius vertices are in conflict with the site *q* (in which case *b* should be *true*, otherwise *false*). In case that *b* is *true*, the predicate returns *true* if and only if the entire Apollonius edge is in conflict with *q*. If *b* is *false*, the predicate returns *false* if and only if *q* is not in conflict with the Apollonius edge.

ApolloniusGraphTraits_2:: Infinite_edge_interior_conflict_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q, bool b)*. The sites s_∞, *s1*, *s2* and *s3* define an Apollonius edge that lies on the bisector of s_∞ and *s1* and has as endpoints the Apollonius vertices defined by the triplets s_∞, *s1*, *s2* and s_∞, *s3* and *s1*. The Boolean *b* denotes if the two Apollonius vertices are in conflict with the site *q* (in which case *b* should be *true*, otherwise *false*. In case that *b* is *true*, the predicate returns *true* if and only if the entire Apollonius edge is in conflict with *q*. If *b* is *false*, the predicate returns *false* if and only if *q* is not in conflict with the Apollonius edge.

ApolloniusGraphTraits_2:: Is_degenerate_edge_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 s4)*. It returns *true* if the Apollonius edge defined by *s1*, *s2*, *s3* and *s4* is degenerate, *false* otherwise. An Apollonius edge is called degenerate if its two endpoints coincide.
Precondition: the Apollonius vertices of *s1*, *s2*, *s3*, and *s1*, *s4*, *s2* must exist.

CGAL::Apollonius_graph_traits_2<K,Method_tag>

Definition

The class *Apollonius_graph_traits_2<K,Method_tag>* provides a model for the *ApolloniusGraphTraits_2* concept. This class has two template parameters. The first template parameter must be a model of the *Kernel* concept. The second template parameter corresponds to how predicates are evaluated. There are two predefined possible values for *Method_tag*, namely *CGAL::Sqrt_field_tag* and *CGAL::Ring_tag*. The first one must be used when the number type used in the representation supports the exact evaluation of signs of expressions involving all four basic operations and square roots, whereas the second one requires the exact evaluation of signs of ring-type expressions, i.e., expressions involving only additions, subtractions and multiplications. The default value for *Method_tag* is *CGAL::Ring_tag*. The way the predicates are evaluated is discussed in [KE02, KE03].

Class

CGAL::Apollonius_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>

Definition

The class *Apollonius_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* provides a model for the *ApolloniusGraphTraits_2* concept.

The class *Apollonius_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* uses the filtering technique [BBP01] to achieve traits for the *Apollonius_graph_2<Gt,Agds>* class with efficient and exact predicates given an exact kernel *EK* and a filtering kernel *FK*. The geometric constructions associated provided by this class are equivalent to those provided by the traits class *Apollonius_graph_traits_2<CK,CM>*, which means that they may be inexact.

This class has six template parameters. The first, third and fifth template parameters must be a models of the *Kernel* concept. The second, fourth and sixth template parameters correspond to how predicates are evaluated. There are two predefined possible values for *Method_tag*, namely *CGAL::Sqrt_field_tag* and *CGAL::Ring_tag*. The first one must be used when the number type used in the representation supports the exact evaluation of signs of expressions involving all four basic operations and square roots, whereas the second one requires the exact evaluation of signs of ring-type expressions, i.e., expressions involving only additions, subtractions and multiplications. The way the predicates are evaluated is discussed in [KE02, KE03].

The default values for the template parameters are as follows: *CM = CGAL::Ring_tag*, *EK = CGAL::Simple_cartesian<CGAL::MP_Float>*, *EM = CM*, *FK = CGAL::Simple_cartesian<CGAL::Interval_nt<false> >*, *FM = CM*.

#include <CGAL/Apollonius_graph_filtered_traits_2.h>

CGAL::Apollonius_graph_hierarchy_2<Gt,Agds>

Definition

We provide an alternative to the class *Apollonius_graph_2<Gt,Agds>* for the dynamic construction of the Apollonius graph. The *Apollonius_graph_hierarchy_2<Gt,Agds>* class maintains a hierarchy of Apollonius graphs. The bottom-most level of the hierarchy contains the full Apollonius diagram. A site that is in level i, is in level $i+1$ with probability $1/\alpha$ where $\alpha > 1$ is some constant. The difference between the *Apollonius_graph_2<Gt,Agds>* class and the *Apollonius_graph_hierarchy_2<Gt,Agds>* is on how the nearest neighbor location is done. Given a point p the location is done as follows: at the top most level we find the nearest neighbor of p as in the *Apollonius_graph_2<Gt,Agds>* class. At every subsequent level i we use the nearest neighbor found at level $i+1$ to find the nearest neighbor at level i. This is a variant of the corresponding hierarchy for points found in [Dev98]. The class has two template parameters which have essentially the same meaning as in the *Apollonius_graph_2<Gt,Agds>* class. The first template parameter must be a model of the *ApolloniusGraphTraits_2* concept. The second template parameter must be a model of the *ApolloniusGraphDataStructure_2* concept. However, the vertex base class that is to be used in the Apollonius graph data structure must be a model of the *ApolloniusGraphHierarchyVertexBase_2* concept. The second template parameter defaults to *Triangulation_data_structure_2< Apollonius_graph_hierarchy_vertex_base_2< Apollonius_graph_vertex_base_2<Gt,true> >, Triangulation_face_base_2<Gt> >*.

The *Apollonius_graph_hierarchy_2<Gt,Agds>* class derives publicly from the *Apollonius_graph_2<Gt,Agds>* class. The interface is the same with its base class. In the sequel only the methods overridden are documented.

#include <CGAL/Apollonius_graph_hierarchy_2.h>

Inherits From

CGAL::Apollonius_graph_2<Gt,Agds>

Types

Apollonius_graph_hierarchy_2<Gt,Agds> does not introduce other types than those introduced by its base class *Apollonius_graph_2<Gt,Agds>*.

Creation

Apollonius_graph_hierarchy_2<Gt,Agds> agh(Gt gt=Gt());

Creates an hierarchy of Apollonius graphs using *gt* as geometric traits.

template< class Input_iterator >
Apollonius_graph_hierarchy_2<Gt,Agds> agh(Input_iterator first, Input_iterator beyond, Gt gt=Gt());

Creates an Apollonius graph hierarchy using *gt* as geometric traits and inserts all sites in the range [*first*, *beyond*).

Apollonius_graph_hierarchy_2<Gt,Agds> agh(other);

Copy constructor. All faces, vertices and inter-level pointers are duplicated. After the construction, *agh* and *other* refer to two different Apollonius graph hierarchies: if *other* is modified, *agh* is not.

Apollonius_graph_hierarchy_2<Gt,Agds> *agh = other*

Assignment. All faces, vertices and inter-level pointers are duplicated. After the construction, *agh* and *other* refer to two different Apollonius graph hierarchies: if *other* is modified, *agh* is not.

Insertion

template< class Input_iterator >
unsigned int *agh.insert(Input_iterator first, Input_iterator beyond)*

Inserts the sites in the range [*first*,*beyond*). The number of sites in the range [*first*, *beyond*) is returned.
Precondition: *Input_iterator* must be a model of *InputIterator* and its value type must be *Site_2*.

Vertex_handle *agh.insert(Site_2 s)*

Inserts the site *s* in the Apollonius graph hierarchy. If *s* is visible then the vertex handle of *s* is returned, otherwise *Vertex_handle(NULL)* is returned.

Vertex_handle *agh.insert(Site_2 s, Vertex_handle vnear)*

Inserts *s* in the Apollonius graph hierarchy using the site associated with *vnear* as an estimate for the nearest neighbor of the center of *s*. If *s* is visible then the vertex handle of *s* is returned, otherwise *Vertex_handle(NULL)* is returned. A call to this method is equivalent to *agh.insert(s);* and it has been added for the sake of conformity with the interface of the *Apollonius_graph_2<Gt,Agds>* class.

Removal

void *agh.remove(Vertex_handle v)*

Removes the site associated to the vertex handle *v* from the Apollonius graph hierarchy.
Precondition: *v* must correspond to a valid finite vertex of the Apollonius graph hierarchy.

Nearest neighbor location

Vertex_handle *agh.nearest_neighbor(Point p)*

Finds the nearest neighbor of the point *p*. In other words it finds the site whose Apollonius cell contains *p*. Ties are broken arbitrarily and one of the nearest neighbors of *p* is returned. If there are no visible sites in the Apollonius diagram *Vertex_handle(NULL)* is returned.

Vertex_handle *agh.nearest_neighbor(Point p, Vertex_handle vnear)*

Finds the nearest neighbor of the point *p*. If there are no visible sites in the Apollonius diagram *Vertex_handle(NULL)* is returned. A call to this method is equivalent to *agh.nearest_neighbor(p);* and it has been added for the sake of conformity with the interface of the *Apollonius_graph_2<Gt,Agds>* class.

I/O

void	*agh.file_output(std::ostream& os)*	Writes the current state of the Apollonius graph hierarchy to an output stream. In particular, all visible and hidden sites are written as well as the underlying combinatorial hierarchical data structure.
void	*agh.file_input(std::istream& is)*	Reads the state of the Apollonius graph hierarchy from an input stream.
std::ostream&	*std::ostream& os << agh*	Writes the current state of the Apollonius graph hierarchy to an output stream.
std::istream&	*std::istream& is >> agh*	Reads the state of the Apollonius graph hierarchy from an input stream.

Validity check

bool *agh.is_valid(bool verbose = false, int level = 1) const*

Checks the validity of the Apollonius graph hierarchy. If *verbose* is *true* a short message is sent to *std::cerr*. If *level* is 0, the data structure at all levels is validated, as well as the inter-level pointers. If *level* is 1, then the data structure at all levels is validated, the inter-level pointers are validated and all levels of the Apollonius graph hierarchy are also validated. Negative values of *level* always return *true*, and values greater then 1 are equivalent to *level* being 1.

Miscellaneous

void	*agh.clear()*	Clears all contents of the Apollonius graph hierarchy.
void	*agh.swap(other)*	The Apollonius graph hierarchies *other* and *agh* are swapped. *agh.swap(other)* should be preferred to *agh*= *other* or to *agh(other)* if *other* is deleted afterwards.

Concept

ApolloniusGraphHierarchyVertexBase_2

Definition

The vertex of an Apollonius graph included in an Apollonius graph hierarchy has to provide some pointers to the corresponding vertices in the graphs of the next and preceding levels. Therefore, the concept *ApolloniusGraphHierarchyVertexBase_2* refines the concept *ApolloniusGraphVertexBase_2*, by adding two vertex handles to the corresponding vertices for the next and previous level graphs.

Refines

ApolloniusGraphVertexBase_2

Types

ApolloniusGraphHierarchyVertexBase_2 does not introduce any types in addition to those of *ApolloniusGraphVertexBase_2*.

Creation

ApolloniusGraphHierarchyVertexBase_2 v;	Default constructor.
ApolloniusGraphHierarchyVertexBase_2 v(Site_2 s);	Constructs a vertex associated with the site s and embedded at the center of s.
ApolloniusGraphHierarchyVertexBase_2 v(Site_2 s, Face_handle f);	Constructs a vertex associated with the site s, embedded at the center of s, and pointing to face f.

Operations

Vertex_handle	*v.up()*	Returns a handle to the corresponding vertex of the next level Apollonius graph. If such a vertex does not exist *Vertex_handle(NULL)* is returned.
Vertex_handle	*v.down()*	Returns a handle to the corresponding vertex of the previous level Apollonius graph.
void	*v.set_up(Vertex_handle u)*	Sets the handle for the vertex of the next level Apollonius graph.
void	*v.set_down(Vertex_handle d)*	Sets the handle for the vertex of the previous level Apollonius graph;

Chapter 46

2D Voronoi Diagram Adaptor

Menelaos Karavelas

Contents

This chapter describes an adaptor that adapts two-dimensional triangulated Delaunay graphs to the corresponding Voronoi diagrams. We start with a few definitions and a description of the issues that this adaptor addresses in Section 46.1. The software design of the Voronoi diagram adaptor package is described in Section 46.2. In Section 46.3 we discuss the traits required for performing the adaptation, and finally in Section 46.5 we present a few examples using this adaptor.

46.1 Introduction

A Voronoi diagram is typically defined for a set of objects, also called sites in the sequel, that lie in some space Σ and a distance function that measures the distance of a point x in Σ from an object in the object set. In this package we are interested in planar Voronoi diagrams, so in the sequel the space Σ will be the space $\mathbb{R}^2$. Let $\mathcal{S} = \{S_1, S_2, \ldots, S_n\}$ be our set of sites and let $\delta(x, S_i)$ denote the distance of a point $x \in \mathbb{R}^2$ from the site S_i. Given two sites S_i and S_j, the set V_{ij} of points that are closer to S_i than to S_j with respect to the distance function $\delta(x, \cdot)$ is simply the set:

$$V_{ij} = \{x \in \mathbb{R}^2 : \delta(x, S_i) < \delta(x, S_j)\}.$$

We can then define the set V_i of points on the plane that are closer to S_i than to any other object in $\mathcal{S}$ as:

$$V_i = \bigcap_{i \neq j} V_{ij}.$$

The set V_i is said to be the *Voronoi cell* or *Voronoi face* of the site S_i. The locus of points on the plane that are equidistant from exactly two sites S_i and S_j is called a *Voronoi bisector*. A point that is equidistant to three or more objects in $\mathcal{S}$ is called a *Voronoi vertex*. A simply connected subset of a Voronoi bisector is called a *Voronoi edge*. The collection of Voronoi faces, edges and vertices is called the *Voronoi diagram* of the set $\mathcal{S}$ with respect to the distance function $\delta(x,\cdot)$, and it turns out that it is a subdivision of the plane, i.e., it is a planar graph.

We typically think of faces as 2-dimensional objects, edges as 1-dimensional objects and vertices as 0-dimensional objects. However, this may not be the case for several combinations of sites and distance functions (for example points in $\mathbb{R}^2$ under the L_1 or the L_∞ distance can produce 2-dimensional Voronoi edges). We call a Voronoi diagram *nice* if no such artifacts exist, i.e., if all vertices edges and faces are 0-, 1- and 2-dimensional, respectively.

Even nice Voronoi diagrams can end up being not so nice. The cell of a site can in general consist of several disconnected components. Such a case can happen, for example, when we consider weighted points $Q_i = (p_i, \lambda_i)$, where $p_i \in \mathbb{R}^2$, $\lambda_i \in \mathbb{R}$, and the distance function is the Euclidean distance multiplied by the weight of each site, i.e., $\delta_M(x, Q_i) = \lambda_i \|x - p_i\|$, where $\|\cdot\|$ denotes the Euclidean norm. In this package we are going to restrict ourselves to nice Voronoi diagrams that have the property that the Voronoi cell of each site is a simply connected region of the plane. We are going to call such Voronoi diagrams *simple Voronoi diagrams*. Examples of simple Voronoi diagrams include the usual Euclidean Voronoi diagram of points, the Euclidean Voronoi diagram of a set of disks on the plane (i.e., the Apollonius diagram), the Euclidean Voronoi diagram of a set of disjoint convex objects on the plane, or the power or (Laguerre) diagram for a set of circles on the plane. In fact every instance of an *abstract Voronoi diagram* in the sense of Klein [Kle89] is a simple Voronoi diagram in our setting. In the sequel when we refer to Voronoi diagrams we will refer to simple Voronoi diagrams.

In many cases we are not really interested in computing the Voronoi diagram itself, but rather its dual graph, called the *Delaunay graph*. In general the Delaunay graph is a planar graph, each face of which consists of at least three edges. Under the non-degeneracy assumption that no point on the plane is equidistant, under the distance function, to more than three sites, the Delaunay graph is a planar graph with triangular faces. In certain cases this graph can actually be embedded with straight line segments in which case we talk about a triangulation. This is the case, for example, for the Euclidean Voronoi diagram of points, or the power diagram of a set of circles. The dual graphs are, respectively, the Delaunay triangulation and the regular triangulation of the corresponding site sets. Graphs of non-constant non-uniform face complexity can be undesirable in many applications, so typically we end up triangulating the non-triangular faces of the Delaunay graph. Intuitively this amounts to imposing an implicit or explicit perturbation scheme during the construction of the Delaunay graph, that perturbs the input sites in such a way so as not to have degenerate configurations.

Choosing between computing the Voronoi diagram or the (triangulated) Delaunay graph is a major decision while implementing an algorithm. It heavily affects the design and choice of the different data structures involved. Although in theory the two approaches are entirely equivalent, it is not so straightforward to go from one representation to the other. The objective of this package is to provide a generic way of going from triangulated Delaunay graphs to planar subdivisions represented through a DCEL data structure. The goal is to provide an adaptor that gives the look and feel of a DCEL data structure, although internally it keeps a graph data structure representing triangular graphs.

The adaptation might seem straightforward at a first glance, and more or less this is case; after all one graph is the dual of the other. The situation becomes complicated whenever we want to treat artifacts of the representation used. Suppose for example that we have a set of sites that contains subsets of sites in degenerate positions. The computed triangulated Delaunay graph has triangular faces that may be the result of an implicit or explicit perturbation scheme. The dual of such a triangulated Delaunay graph is a Voronoi diagram that has all its vertices of degree 3, and for that purpose we are going to call it a *degree-3 Voronoi diagram* in order to distinguish it from the true Voronoi diagram of the input sites. A degree-3 Voronoi diagram can have degenerate features, namely Voronoi edges of zero length, and/or Voronoi faces of zero area. Although we can potentially treat such artifacts, they are nonetheless artifacts of the algorithm we used and do not correspond to the true geometry of the Voronoi diagram.

The manner that we treat such issues in this package in a generic way is by defining an *adaptation policy*. The adaptation policy is responsible for determining which features in the degree-3 Voronoi diagram are to be rejected and which not. The policy to be used can vary depending on the application or the intended usage of the resulting Voronoi diagram. What we care about is that firstly the policy itself is consistent and, secondly, that the adaptation is also done in a consistent manner. The latter is the responsibility of the adaptor provided by this package, whereas the former is the responsibility of the implementor of a policy.

In this package we currently provide two types of adaptation policies. The first one is the simplest: we reject no feature of the degree-3 Voronoi diagram; we call such a policy an *identity policy* since the Voronoi diagram produced is identical to the degree-3 Voronoi diagram. The second type of policy eliminates the degenerate features from the degree-3 Voronoi diagram yielding the true geometry of the Voronoi diagram of the input sites; we call such policies *degeneracy removal policies*.

Delaunay graphs can be mutable or non-mutable. By mutable we mean that sites can be inserted or removed at any time, in an entirely on-line fashion. By non-mutable we mean that once the Delaunay graph has been created, no changes, with respect to the set of sites defining it, are allowed. If the Delaunay graph is a non-mutable one, then the Voronoi diagram adaptor is a non-mutable adaptor as well.

If the Delaunay graph is mutable then the question of whether the Voronoi diagram adaptor is also mutable is slightly more complex to answer. As long as the adaptation policy used does not maintain a state, the Voronoi diagram adaptor is a mutable one; this is the case, for example, with our identity policy or the degeneracy removal policies. If, however, the adaptor maintains a state, then whether it is mutable or non-mutable really depends on whether its state can be updated after every change in the Delaunay graph. Such policies are our caching degeneracy removal policies: some of them result in mutable adaptors others result in non-mutable ones. In Section 46.4 we discuss the issue in more detail.

46.2 Software Design

The *Voronoi_diagram_2<DG,AT,AP>* class is parameterized by three template parameters. The first one must be a model of the *DelaunayGraph_2* concept. It corresponds to the API required by an object representing a Delaunay graph. All classes of CGAL that represent Delaunay diagrams are models of this concept, namely, Delaunay triangulations, regular triangulations, Apollonius graphs and segment Delaunay graphs. The second template parameter must be a model of the *AdaptationTraits_2* concept. We discuss this concept in detail in Section 46.3. The third template parameter must be model of the *AdaptationPolicy_2* concept, which we discuss in detail in Section 46.4.

The *Voronoi_diagram_2<DG,AT,AP>* class has been intentionally designed to provide an API similar to the arrangements class in CGAL: Voronoi diagrams are special cases of arrangements after all. The API of the two classes, however, could not be identical. The reason is that arrangements in CGAL do not yet support more than one unbounded faces, or equivalently, cannot handle unbounded curves. On the contrary, a Voronoi diagram defined over at least two generating sites, has at least two unbounded faces.

On a more technical level, the *Voronoi_diagram_2<DG,AT,AP>* class imitates the representation of the Voronoi diagram (seen as a planar subdivision) by a DCEL (Doubly Connected Edge List) data structure. We have vertices (the Voronoi vertices), halfedges (oriented versions of the Voronoi edges) and faces (the Voronoi cells). In particular, we can basically perform every operation we can perform in a standard DCEL data structure:

- go from a halfedge to its next and previous in the face;
- go from one face to an adjacent one through a halfedge and its twin (opposite) halfedge;
- walk around the boundary of a face;
- enumerate/traverse the halfedges incident to a vertex
- from a halfedge, access the adjacent face;

- from a face, access an adjacent halfedges;
- from a halfedges, access its source and target vertices;
- from a vertex, access an incident halfedge.

In addition to the above possibilities for traversal, we can also traverse the following features through iterators:

- the vertices of the Voronoi diagram;
- the edges or halfedges of the Voronoi diagram;
- the faces of the Voronoi diagram;
- the bounded faces of the Voronoi diagram;
- the bounded halfedges of the Voronoi diagram;
- the unbounded faces of the Voronoi diagram;
- the unbounded halfedges of the Voronoi diagram;
- the sites defining the Voronoi diagram.

Finally, depending on the adaptation traits passed to the Voronoi diagram adaptor, we can perform point location queries, namely given a point p we can determine the feature of the Voronoi diagram (vertex, edge, face) on which p lies.

46.3 The Adaptation Traits

The *AdaptationTraits_2* concept defines the types and functors required by the adaptor in order to access geometric information in the Delaunay graph that is needed by the *Voronoi_diagram_2<DG,AT,AP>* class. In particular, it provides functors for accessing sites in the Delaunay graph and constructing Voronoi vertices from their dual faces in the Delaunay graph. Finally, it defines a tag that indicates whether nearest site queries are to be supported by the Voronoi diagram adaptor. If such queries are to be supported, a functor is required.

Given a query point, the nearest site functor should return information related to how many and which sites of the Voronoi diagram are at equal and minimal distance from the query point. In particular, if the query point is closest to a single site, the vertex handle of the Delaunay graph corresponding to this site is returned. If the query point is closest to exactly two site, the edge of the Delaunay graph that is dual to the Voronoi edges on which the query point lies is returned. If three (or more) sites are closest to the query point, then the query point coincides with a vertex in the Voronoi diagram, and the face handle of the face in the Delaunay graph that is dual to the Voronoi vertex is returned. This way of abstracting the point location mechanism allows for multiple different point location strategies, which are passed to the Voronoi diagram adaptor through different models of the *AdaptationTraits_2* concept. The point location and nearest sites queries of the *Voronoi_diagram_2< DG,AT,AP>* class use internally this nearest site query functor.

In this package we provide four adaptation traits classes, all of which support nearest site queries:

- The *Apollonius_graph_adaptation_traits_2<AG2>* class: it provides the adaptation traits for Apollonius graphs.
- The *Delaunay_triangulation_adaptation_traits_2<DT2>* class: it provides the adaptation traits for Delaunay triangulations.

- The *Regular_triangulation_adaptation_traits_2<RT2>* class: it provides the adaptation traits for regular triangulations.
- The *Segment_Delaunay_graph_adaptation_traits_2<SDG2>* class: it provides the adaptation traits for segment Delaunay graphs.

46.4 The Adaptation Policy

As mentioned above, when we perform the adaptation of a triangulated Delaunay graph to a Voronoi diagram, a question that arises is whether we want to eliminate certain features of the Delaunay graph when we construct its Voronoi diagram representation (such features could be the Voronoi edges of zero length or, for the Voronoi diagram of a set of segments forming a polygon, all edges outside the polygon). The manner that we treat such issues in this package in a generic way is by defining an adaptation policy. The adaptation policy is responsible for determining which features in the degree-3 Voronoi diagram are to be rejected and which not. The policy to be used can vary depending on the application or the intended usage of the resulting Voronoi diagram.

The concept *AdaptationPolicy_2* defines the requirements on the predicate functors that determine whether a feature of the triangulated Delaunay graph should be rejected or not. More specifically it defines an *Edge_rejector* and a *Face_rejector* functor that answer the question: "should this edge (face) of the Voronoi diagram be rejected?". In addition to the edge and face rejectors the adaptation policy defines a tag, the *Has_inserter* tag. This tag is either set to *CGAL::Tag_true* or to *CGAL::Tag_false*. Semantically it determines if the adaptor is allowed to insert sites in an on-line fashion (on-line removals are not yet supported). In the former case, i.e., when on-line site insertions are allowed, an additional functor is required, the *Site_inserter* functor. This functor takes a reference to a Delaunay graph and a site, and inserts the site in the Delaunay graph. Upon successful insertion, a handle to the vertex representing the site in the Delaunay graph is returned.

We have implemented two types of policies that provide two different ways for answering the question of which features of the Voronoi diagram to keep and which to discard. The first one is called the *identity policy* and corresponds to the *Identity_policy_2<DG,VT>* class. This policy is in some sense the simplest possible one, since it does not reject any feature of the Delaunay graph. The Voronoi diagram provided by the adaptor is the true dual (from the graph-theoretical point of view) of the triangulated Delaunay graph adapted. This policy assumes that the Delaunay graph adapted allows for on-line insertions, and the *Has_inserter* tag is set to *CGAL::Tag_true*. A default site inserter functor is also provided.

The second type of policy we provide is called *degeneracy removal policy*. If the set of sites defining the triangulated Delaunay graph contains subsets of sites in degenerate configurations, the graph-theoretical dual of the triangulated Delaunay graph has edges and potentially faces that are geometrically degenerate. By that we mean that the dual of the triangulated Delaunay graph can have Voronoi edges of zero length or Voronoi faces/cells of zero area. Such features may not be desirable and ideally we would like to eliminate them. The degeneracy removal policies eliminate exactly these features and provide a Voronoi diagram where all edges have non-zero length and all cells have non-zero area. More specifically, in these policies the *Edge_rejector* and *Face_rejector* functors reject the edges and vertices of the Delaunay graph that correspond to dual edges and faces that have zero length and area, respectively. In this package we provide four degeneracy removal policies, namely:

- The *Apollonius_graph_degeneracy_removal_policy_2<AG2>* class: it provides an adaptation policy for removing degeneracies when adapting an Apollonius graph to an Apollonius diagram.
- The *Delaunay_triangulation_degeneracy_removal_policy_2<DT2>* class: it provides an adaptation policy for removing degeneracies when adapting a Delaunay triangulation to a point Voronoi diagram.
- The *Regular_triangulation_degeneracy_removal_policy_2<RT2>* class: it provides an adaptation policy for removing degeneracies when adapting a regular triangulation to a power diagram

- The *Segment_Delaunay_graph_degeneracy_removal_policy_2<SDG2>* class: it provides an adaptation policy for removing degeneracies when adapting a segment Delaunay graph to a segment Voronoi diagram.

A variation of the degeneracy removal policies are the *caching degeneracy removal policies*. In these policies we cache the results of the edge and face rejectors. In particular, every time we want to determine, for example, if an edge of the Delaunay graph has, as dual edge in the Voronoi diagram, an edge of zero length, we check if the result has already been computed. If yes, we simply return the outcome. If not, we perform the necessary geometric tests, compute the answer, cache it and return it. Such a policy really pays off when we have a lot of degenerate data in our input set of sites. Verifying whether a Voronoi edge is degenerate or not implies computing the outcome of a predicate in a possibly degenerate or near degenerate configuration, which is typically very costly (compared to computing the same predicate in a generic configuration). To avoid this cost every single time we want to check if a Voronoi edge is degenerate or not, we compute the result of the geometric predicate the first time the adaptor asks for it, and simply lookup the answer in the future. In this package we provide four caching degeneracy removal policies, one per degeneracy removal policy mentioned above. Intentionally, we have not indicated the value of the *Has_inserter* tag for the degeneracy removal and caching degeneracy removal policies. The issue is discussed in detail in the sequel.

We raised the question above, as to whether the adaptor is a mutable or non-mutable one, in the sense of whether we can add/remove sites in an on-line fashion. The answer to this question depends on: (1) whether the Delaunay graph adapted allows for on-line insertions/removals and (2) whether the adaptation policies maintains a state and whether this state is easily maintainable when we want to allow for on-line modifications.

The way we indicate if we allow on-line insertions of sites is via the *Has_inserter* tag (as mentioned, on-line removals are currently not supported). The *Has_inserter* tag has two possible values, namely, *CGAL::Tag_true* and *CGAL::Tag_false*. The value *CGAL::Tag_true* indicates that the Delaunay graph allows for on-line insertions, whereas the value *CGAL::Tag_false* indicates the opposite. Note that these values *do not* indicate if the Delaunay graph supports on-line insertions, but rather whether the Voronoi diagram adaptor should be able to perform on-line insertions or not. This delicate point will be become clearer below.

Let us consider the various scenarios. If the Delaunay graph is non-mutable, the Voronoi diagram adaptor cannot perform on-line insertions of sites. In this case not only degeneracy removal policies, but rather every single adaptation policy for adapting the Delaunay graph in question should have the *Has_inserter* tag set to *CGAL::Tag_false*.

If the Delaunay graph is mutable, i.e., on-line site insertions as are allowed, we can choose between two types of adaptation policies, those that allow these on-line insertions and those that do not. In the former case the *Has_inserter* tag should be set to *CGAL::Tag_true*, whereas in the latter to *CGAL::Tag_false*. In other words, even if the Delaunay graph is mutable, we can choose (by properly determining the value of the *Has_inserter* tag) if the adaptor should be mutable as well. At a first glance it may seem excessive to restrict existing functionality. There are situations, however, where such a choice is necessary.

Consider a caching degeneracy removal policy. If we do not allow for on-line insertions then the cached quantities are always valid since the Voronoi diagram never changes. If we allow for on-line insertions the Voronoi diagram can change, which implies that the results of the edge and faces degeneracy testers that we have cached are no longer valid or relevant. In these cases, we need to somehow update these cached results, and ideally we would like to do this in an efficient manner. The inherent dilemma in the above discussion is whether the Voronoi diagram adaptor should be able to perform on-line insertions of sites. The answer to this question in this framework is given by the *Has_inserter* tag. If the tag is set to *CGAL::Tag_false* the adaptor cannot insert sites on-line, whereas if the tag is set to *CGAL::Tag_true* the adaptor can add sites on-line. In other words, the *Has_inserter* tag determines how the Voronoi diagram adaptor should behave, and this is enough from the adaptor's point of view.

From the point of a view of a policy writer the dilemma is still there: should the policy allow for on-line insertions or not? The answer really depends on what are the consequences of such a choice. For a policy that has no state, such as our degeneracy removal policies, it is natural to set the *Has_inserter* tag to *CGAL::Tag_true*. For our caching degeneracy removal policies, our choice was made on the grounds of whether we can update the cached results efficiently when insertions are performed. For CGAL's Apollonius graphs, Delaunay triangulation and regular triangulations it is possible to ask what are the edges and faces of the Delaunay graph that are to be destroyed when a query site is inserted. This is done via the *get_conflicts* method provided by these classes. Using the outcome of the *get_conflicts* method the site inserter can first update the cached results (i.e., indicate which are invalidated) and then perform the actual insertion. Such a method does not yet exist for segment Delaunay graphs. We have thus chosen to support on-line insertions for all non-caching degeneracy removal policies. The caching degeneracy removal policy for segment Delaunay graphs does not support on-line insertions, whereas the remaining three caching degeneracy removal policies support on-line insertions.

Efficiency Considerations

One last item that merits some discussion are the different choices from the point of view of time- and space-efficiency.

As far as the Voronoi diagram adaptor is concerned, only a copy of the adaptation traits and a copy of the adaptation policy are stored in it. The various adaptation traits classes we provide are empty classes (i.e., they do not store anything). The major time and space efficiency issues arise from the various implementations of the adaptation policies. Clearly, the identity policy has no dominant effect on neither the time or space efficiency. The costs when choosing this policy are due to the underlying Delaunay graph.

The non-caching degeneracy removal policies create a significant time overhead since every time we want to access a feature of the Voronoi diagram, we need to perform geometric tests in order to see if this feature or one of its neighboring ones has been rejected. Such a policy is acceptable if we know we are away from degeneracies or for small input sizes. In the case of the segment Delaunay graph, it is also the only policy we provide that at the same time removes degeneracies and allows for on-line insertion of sites. Caching policies seem to be the best choice for moderate to large input sizes (1000 sites and more). They do not suffer from the problem of dealing with degenerate configurations, but since they cache the results, they increase the space requirements by linear additive factor. To conclude, if the user is interested in getting a Voronoi diagram without degenerate features and knows all sites in advance, the best course of action is to insert all sites at construction time and use a caching degeneracy removal policy. This strategy avoids the updates of the cached results after each individual insertion, due to the features of the Voronoi diagram destroyed because of the site inserted.

46.5 Examples

In this section we present an example that shows how to perform point location queries.

```
#include <iostream>
#include <fstream>
#include <cassert>

// includes for defining the Voronoi diagram adaptor
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Voronoi_diagram_2.h>
#include <CGAL/Delaunay_triangulation_adaptation_traits_2.h>
#include <CGAL/Delaunay_triangulation_adaptation_policies_2.h>

// typedefs for defining the adaptor
```

```

2D Voronoi Diagram Adaptor Reference Manual

Menelaos Karavelas

CGAL provides the class *CGAL::Voronoi_diagram_2<DG,AT,AP>* for adapting the various (triangulated) Delaunay graphs to Voronoi diagrams according to some adaptation policy. In particular, the class *CGAL::Voronoi_diagram_2<DG,AT,AP>* provides an API for the duals of (triangulated) Delaunay graphs, that makes them look like planar subdivisions. The adaptation policy is responsible for deciding which edges and faces of these duals should be eliminated. This is especially important when, for instance, we want to eliminate degenerate features in the Voronoi diagram that are the result of the fact that Delaunay graphs are always triangulated and are due to degenerate configurations in the generating data.

The three template parameters must be models of the *DelaunayGraph_2*, *AdaptationTraits_2* and *AdaptationPolicy_2* concepts, respectively. The first concept is related to the Delaunay graphs that are to be adapted, whereas the second one is responsible for manipulating/accessing in a unified way the geometry of a specific Voronoi diagram as well as for performing nearest site queries. The third template parameter corresponds to the chosen adaptation policy and provides the necessary types and functors needed for performing this adaptation.

CGAL::Voronoi_diagram_2<DG,AT,AP>

Class

Definition

The class *Voronoi_diagram_2<DG,AT,AP>* provides an adaptor that enables us to view a triangulated Delaunay graph as their dual subdivision, the Voronoi diagram. The class *Voronoi_diagram_2<DG,AT,AP>* is designed to provide an API that is similar to that of CGAL's arrangements.
The first template parameter of the *Voronoi_diagram_2<DG,AT,AP>* class corresponds to the triangulated Delaunay graph and must be a model of the *DelaunayGraph_2* concept. The second template parameter must be a model of the *AdaptationTraits_2* concept. The third template parameter must be a model of the *AdaptationPolicy_2* concept. The third template parameter defaults to *CGAL::Identity_policy_2<DG,AT>*.

#include <CGAL/Voronoi_diagram_2.h>

Refines

DefaultConstructible, *CopyConstructible*, *Assignable*

Types

typedef DG	*Delaunay_graph;*	A type for the dual Delaunay graph.
typedef AT	*Adaptation_traits;*	A type for the adaptation traits needed by the Voronoi diagram adaptor.
typedef AP	*Adaptation_policy;*	A type for the adaptation policy used.
typedef Adaptation_traits::Point_2	*Point_2;*	A type a point.
typedef Adaptation_traits::Site_2	*Site_2;*	A type for the sites of the Voronoi diagram.
typedef Delaunay_graph::size_type	*size_type;*	A type for sizes.
typedef Delaunay_graph::Geom_traits	*Delaunay_geom_traits;*	A type for the geometric traits of the Delaunay graph.
typedef Delaunay_graph::Vertex_handle	*Delaunay_vertex_handle;*	A type for the vertex handles of the Delaunay graph.
typedef Delaunay_graph::Face_handle	*Delaunay_face_handle;*	A type for the face handles of the Delaunay graph.
typedef Delaunay_graph::Edge	*Delaunay_edge;*	A type for the edges of the Delaunay graph.

Voronoi_diagram_2<DG,AT,AP>:: Halfedge	A type for the halfedges of the Voronoi diagram.
Voronoi_diagram_2<DG,AT,AP>:: Vertex	A type for the vertices of the Voronoi diagram.
Voronoi_diagram_2<DG,AT,AP>:: Face	A type for the faces of the Voronoi diagram.

The vertices, edges and faces of the Voronoi diagram are accessed through *handles*, *iterators* and *circulators*. The iterators and circulators are all bidirectional and non-mutable. The circulators and iterators are assignable to the corresponding handle types, and they are also convertible to the corresponding handles.

Voronoi_diagram_2<DG,AT,AP>:: Halfedge_handle	Handle for halfedges.

Voronoi_diagram_2<DG,AT,AP>:: Vertex_handle	Handle for vertices.
Voronoi_diagram_2<DG,AT,AP>:: Face_handle	Handle for faces.
Voronoi_diagram_2<DG,AT,AP>:: Edge_iterator	A type for an iterator over Voronoi edges. Edges are considered non-oriented. Its value type is *Halfedge*.
Voronoi_diagram_2<DG,AT,AP>:: Halfedge_iterator	A type for an iterator over Voronoi halfedges. Halfedges are oriented and come in pairs. Its value type is *Halfedge*.
Voronoi_diagram_2<DG,AT,AP>:: Face_iterator	A type for an iterator over Voronoi faces. Its value type is *Face*.
Voronoi_diagram_2<DG,AT,AP>:: Vertex_iterator	A type for an iterator over Voronoi vertices. Its value type is *Vertex*.
Voronoi_diagram_2<DG,AT,AP>:: Halfedge_around_vertex_circulator	A type for a circulator over the halfedges that have a common vertex as their target. Its value type is *Halfedge*.
Voronoi_diagram_2<DG,AT,AP>:: Ccb_halfedge_circulator	A type for a circulator over the halfedges on the boundary of a Voronoi face. Its value type of is *Halfedge*.
Voronoi_diagram_2<DG,AT,AP>:: Unbounded_faces_iterator	A type for an iterator over the unbounded faces of the Voronoi diagram. Its value type is *Face*.
Voronoi_diagram_2<DG,AT,AP>:: Bounded_faces_iterator	A type for an iterator over the bounded faces of the Voronoi diagram. Its value type is *Face*.
Voronoi_diagram_2<DG,AT,AP>:: Unbounded_halfedges_iterator	A type for an iterator over the unbounded halfedges of the Voronoi diagram. Its value type is *Halfedge*.
Voronoi_diagram_2<DG,AT,AP>:: Bounded_halfedges_iterator	A type for an iterator over the bounded halfedges of the Voronoi diagram. Its value type is *Halfedge*.
Voronoi_diagram_2<DG,AT,AP>:: Site_iterator	A type for an iterator over the sites of the Voronoi diagram. Its value type is *Site_2*.

typedef boost::variant<Face_handle,Halfedge_handle,Vertex_handle>	*Locate_result;*	The result type of the point location queries.

Creation

Voronoi_diagram_2<DG,AT,AP> vd(Adaptation_traits at = Adaptation_traits(),
Adaptation_policy ap = Adaptation_policy(),
Delaunay_geom_traits gt = Delaunay_geom_traits())

Creates a Voronoi diagram using *at* as adaptation traits and *ap* as adaptation policy; the underlying Delaunay graph is created using *gt* as geometric traits.

Voronoi_diagram_2<DG,AT,AP> vd(Delaunay_graph dg,
bool swap_dg = false,
Adaptation_traits at = Adaptation_traits(),
Adaptation_policy ap = Adaptation_policy())

Creates a Voronoi diagram from the Delaunay graph *dg* and using *at* as adaptation traits and *ap* as adaptation policy. The Delaunay graph *dg* is fully copied if *swap_dg* is set to *false*, or swapped with the one stored internally if *swap_dg* is set to *true*.

template<class Iterator>
Voronoi_diagram_2<DG,AT,AP> vd(Iterator first,
Iterator beyond,
Adaptation_traits at = Adaptation_traits(),
Adaptation_policy ap = Adaptation_policy(),
Delaunay_geom_traits gt = Delaunay_geom_traits())

Creates a Voronoi diagram using as sites the sites in the iterator range *[first, beyond)*, *at* as adaptation traits and *ap* as adaptation policy; the underlying Delaunay graph is created using *gt* as geometric traits. *Iterator* must be a model of the *InputIterator* concept and its value type must be *Site_2*.

Access Methods

Delaunay_graph	*vd.dual()*	Returns a const reference to the dual graph, i.e., the Delaunay graph.
Halfedge_handle	*vd.dual(Delaunay_edge e)*	Returns a handle to the halfedge in the Voronoi diagram that is dual to the edge *e* in the Delaunay graph.
Face_handle	*vd.dual(Delaunay_vertex_handle v)*	Returns a handle to the face in the Voronoi diagram that is dual to the vertex corresponding to the vertex handle *v* in the Delaunay graph.
Vertex_handle	*vd.dual(Delaunay_face_handle f)*	Returns a handle to the vertex in the Voronoi diagram that is dual to the face corresponding to the face handle *f* in the Delaunay graph.
Adaptation_traits	*vd.adaptation_traits()*	Returns a reference to the Voronoi traits.
Adaptation_policy	*vd.adaptation_policy()*	Returns a reference to the adaptation policy.
size_type	*vd.number_of_vertices()*	Returns the number of Voronoi vertices.
size_type	*vd.number_of_faces()*	Returns the number of Voronoi faces (bounded and unbounded).
size_type	*vd.number_of_halfedges()*	Returns the number of halfedges (bounded and unbounded) in the Voronoi diagram. This is always an even number.
size_type	*vd.number_of_connected_components()*	Returns the number of connected components of the Voronoi skeleton.
Face_handle	*vd.unbounded_face()*	Returns one of the unbounded faces of the Voronoi diagram. If no unbounded faces exist (this can happen if the number of sites is zero) the default constructed face handle is returned.

Face_handle	*vd.bounded_face()*	Returns one of the bounded faces of the Voronoi diagram. If no bounded faces exist the default constructed face handle is returned.
Halfedge_handle	*vd.unbounded_halfedge()*	Returns one of the unbounded halfedges of the Voronoi diagram. If no unbounded halfedges exist the default constructed halfedge handle is returned.
Halfedge_handle	*vd.bounded_halfedge()*	Returns one of the bounded halfedges of the Voronoi diagram. If no bounded halfedges exist the default constructed halfedge handle is returned.

Traversal of the Voronoi diagram

A Voronoi diagram can be seen as a container of faces, vertices and halfedges. Therefore the Voronoi diagram provides several iterators and circulators that allow to traverse it.

Iterators

The following iterators allow respectively to visit the faces (all or only the unbounded/bounded ones), edges, halfedges (all or only the unbounded/bounded ones) and vertices of the Voronoi diagram. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Halfedge*, *Halfedge* and *Vertex*. All iterators are convertible to the corresponding handles and are invalidated by any change in the Voronoi diagram.

Face_iterator	*vd.faces_begin()*	Starts at an arbitrary Voronoi face.
Face_iterator	*vd.faces_end()*	Past-the-end iterator.
Unbounded_faces_iterator	*vd.unbounded_faces_begin()*	Starts at an arbitrary unbounded Voronoi face.
Unbounded_faces_iterator	*vd.unbounded_faces_end()*	Past-the-end iterator.
Bounded_faces_iterator	*vd.bounded_faces_begin()*	Starts at an arbitrary bounded Voronoi face.
Bounded_faces_iterator	*vd.bounded_faces_end()*	Past-the-end iterator.
Edge_iterator	*vd.edges_begin()*	Starts at an arbitrary Voronoi edge.
Edge_iterator	*vd.edges_end()*	Past-the-end iterator.
Halfedge_iterator	*vd.halfedges_begin()*	Starts at an arbitrary Voronoi halfedge.
Halfedge_iterator	*vd.halfedges_end()*	Past-the-end iterator.
Unbounded_halfedges_iterator	*vd.unbounded_halfedges_begin()*	Starts at an arbitrary unbounded Voronoi edge.
Unbounded_halfedges_iterator	*vd.unbounded_halfedges_end()*	Past-the-end iterator.
Bounded_halfedges_iterator	*vd.bounded_halfedges_begin()*	Starts at an arbitrary bounded Voronoi edge.
Bounded_halfedges_iterator	*vd.bounded_halfedges_end()*	Past-the-end iterator.

Vertex_iterator	*vd.vertices_begin()*	Starts at an arbitrary Voronoi vertex.
Vertex_iterator	*vd.vertices_end()*	Past-the-end iterator.

The following iterator provides access to the sites that define the Voronoi diagram. Its value type is *Site_2*. It is invalidated by any change in the Voronoi diagram.

Site_iterator	*vd.sites_begin()*	Starts at an arbitrary site.
Site_iterator	*vd.sites_end()*	Past-the-end iterator.

Circulators

The Voronoi diagram adaptor also provides circulators that allow to visit all halfedges whose target is a given vertex – this is the *Halfedge_around_vertex_circulator*, as well as all halfedges on the boundary of a Voronoi face – this is the *Ccb_halfedge_circulator*. These circulators are non-mutable and bidirectional. The operator *operator++* moves the former circulator counterclockwise around the vertex while the *operator--* moves clockwise. The latter circulator is moved by the operator *operator++* to the next halfedge on the boundary in the counterclockwise sense, while *operator--* moves clockwise. When the *Ccb_halfedge_circulator* is defined over an infinite Voronoi face f, then applying *operator++* to a circulator corresponding to a halfedge whose target is not finite moves to the next infinite (or semi-infinite) halfedge of f in the counterclockwise sense. Similarly, applying *operator++* to a circulator corresponding to a halfedge whose source is not finite, moves to the previous infinite (or semi-infinite) halfedge of f in the clockwise sense. The *Halfedge_around_vertex_circulator* circulator is invalidated by any modification in the faces adjacent to the vertex over which it is defined. The *Ccb_halfedge_circulator* is invalidated by any modification in the face over which it is defined.

Ccb_halfedge_circulator	*vd.ccb_halfedges(Face_handle f)*	Returns a circulator over the halfedges on the boundary of f. The circulator is initialized to an arbitrary halfedge on the boundary of the Voronoi face f.
Ccb_halfedge_circulator	*vd.ccb_halfedges(Face_handle f, Halfedge_handle h)*	Returns a circulator over the halfedges on the boundary of f. The circulator is initialized with the halfedge h. *Precondition*: The halfedge h must lie on the boundary of f.
Halfedge_around_vertex_circulator	*vd.incident_halfedges(Vertex_handle v)*	Returns a circulator over the halfedges whose target is the Voronoi vertex v. The circulator is initialized to an arbitrary halfedge incident to v.
Halfedge_around_vertex_circulator	*vd.incident_halfedges(Vertex_handle v, Halfedge_handle h)*	Returns a circulator over the halfedges whose target is the Voronoi vertex v. The circulator is initialized with the halfedge h. *Precondition*: The vertex v must be the target vertex of the halfedge h.

Insertion

Face_handle	*vd.insert(Site_2 t)*	Inserts the site *t* in the Voronoi diagram. A handle to the face corresponding to the Voronoi face of *t* in the Voronoi diagram is returned. If *t* has an empty Voronoi cell, the default constructed face handle is returned. This method is supported only if *Voronoi_traits::Has_inserter* is set to *CGAL::Tag_true*.

template<class Iterator>
size_type *vd.insert(Iterator first, Iterator beyond)*

Inserts, in the Voronoi diagram, the sites in the iterator range *[first, beyond)*. The value type of *Iterator* must be *Site_2*. The number of sites in the iterator range is returned. This method is supported only if *Voronoi_traits::Has_inserter* is set to *CGAL::Tag_true*.

Queries

Locate_result	*vd.locate(Point_2 p)*	Performs point location for the query point *p*. In other words, the face, halfedge or vertex of the Voronoi diagram is found on which the point *p* lies. This method is supported only if *Voronoi_traits::Has_nearest_site_2* is set to *CGAL::Tag_true*. *Precondition*: The Voronoi diagram must contain at least one face.

I/O

void	*vd.file_output(std::ostream& os)*	Writes the current state of the Voronoi diagram to the output stream *os*. The following operator must be defined: *std::ostream& operator<<(std::ostream&, Delaunay_graph)*
void	*vd.file_input(std::istream& is)*	Reads the current state of the Voronoi diagram from the input stream *is*. The following operator must be defined: *std::istream& operator>>(std::istream&, Delaunay_graph)*
std::ostream&	*std::ostream& os << vd*	Writes the current state of the Voronoi diagram to the output stream *os*. The following operator must be defined: *std::ostream& operator<<(std::ostream&, Delaunay_graph)*
std::istream&	*std::istream& is >> vd*	Reads the current state of the Voronoi diagram from the input stream *is*. The following operator must be defined: *std::istream& operator>>(std::istream&, Delaunay_graph)*

Validity check

bool	*vd.is_valid()*	Checks the validity of the dual Delaunay graph and the Voronoi diagram adaptor.

Miscellaneous

void	*vd.clear()*	Clears all contents of the Voronoi diagram.
void	*vd.swap(other)*	The Voronoi diagrams *other* and *vd* are swapped. *vd.swap(other)* should be preferred to *vd= other* or to *vd(other)* if *other* is deleted afterwards.

Class

CGAL::Voronoi_diagram_2<DG,AT,AP>::Halfedge

Definition

The class *Halfedge* is the class provided by the *Voronoi_diagram_2<DG,AT,AP>* class for Voronoi halfedges. Below we present its interface.

Is Model for the Concepts

DefaultConstructible, *CopyConstructible*, *Assignable*, *EqualityComparable*, *LessThanComparable*

Types

Halfedge:: Vertex		A type for the vertices of the Voronoi diagram.
Halfedge:: Face		A type for the faces of the Voronoi diagram.
Halfedge:: Vertex_handle		Handle for the vertices of the Voronoi diagram.
Halfedge:: Face_handle		Handle for the faces of the Voronoi diagram.
Halfedge:: Halfedge_handle		Handle for the halfedges of the Voronoi diagram.
Halfedge:: Ccb_halfedge_circulator		A type for a bidirectional circulator over the halfedges of the boundary of a Voronoi face. The value type of the circulator is *CGAL::Voronoi_diagram_2< DG,AT,AP>::Halfedge* and is convertible to *Halfedge_handle*.
Halfedge:: Delaunay_graph		A type for the Delaunay graph. It is a model of the *DelaunayGraph_2* concept.
typedef Delaunay_graph::Edge	*Delaunay_edge;*	A type for the dual edge in the Delaunay graph.
typedef Delaunay_graph::Vertex_handle	*Delaunay_vertex_handle;*	A type for vertex handles in the Delaunay graph.

Access Methods

Halfedge_handle	*e.twin()*	Returns the twin halfedge.
Halfedge_handle	*e.opposite()*	Same as *e.twin()*.
Halfedge_handle	*e.next()*	Returns the next halfedge in the counterclockwise sense around the boundary of the face that *e* is incident to.
Halfedge_handle	*e.previous()*	Returns the previous halfedge in the counterclockwise sense around the boundary of the adjacent face.

Face_handle	*e.face()*	Returns the face that *e* is incident to.
Vertex_handle	*e.source()*	Returns the source vertex of *e*. *Precondition*: The source vertex must exist, i.e., *has_source()* must return *true*.
Vertex_handle	*e.target()*	Returns the target vertex of *e*. *Precondition*: The target vertex must exist, i.e., *has_target()* must return *true*.
Ccb_halfedge_circulator	*e.ccb()*	Returns a bidirectional circulator to traverse the halfedges on the boundary of the Voronoi face containing *e*. The circulator is initialized to *e*. Applying *operator++* (resp. *operator--*) to this circulator returns the next halfedge on the boundary of the face containing *e* in the counterclockwise (resp. clockwise) sense.
Delaunay_edge	*e.dual()*	Returns the corresponding dual edge in the Delaunay graph.

In the four methods below we consider Voronoi halfedges to be "parallel" to the *x*-axis, oriented from left to right.

Delaunay_vertex_handle	*e.up()*	Returns a handle to the vertex in the Delaunay graph corresponding to the defining site above the Voronoi edge.
Delaunay_vertex_handle	*e.down()*	Returns a handle to the vertex in the Delaunay graph corresponding to the defining site below the Voronoi edge.
Delaunay_vertex_handle	*e.left()*	Returns a handle to the vertex in the Delaunay graph corresponding to the defining site to the left of the Voronoi edge. *Precondition*: *has_source()* must be *true*.
Delaunay_vertex_handle	*e.right()*	Returns a handle to the vertex in the Delaunay graph corresponding to the defining site to the right of the Voronoi edge. *Precondition*: *has_target()* must be *true*.

Predicate Methods

bool	*e.has_source()*	Returns *true* iff the halfedge corresponds to a bisecting segment or a bisecting ray oriented appropriately so that its apex is its source.
bool	*e.has_target()*	Returns *true* iff the halfedge corresponds to a bisecting segment or a bisecting ray oriented appropriately so that its apex is its target.
bool	*e.is_unbounded()*	Returns *true* iff the source or the target of the halfedge does not exist, i.e., if either of *has_source()* or *has_target()* return *false*.
bool	*e.is_bisector()*	Returns *true* iff the Voronoi edge is an entire bisector.
bool	*e.is_segment()*	Returns *true* iff the Voronoi edge has both a source and a target Voronoi vertex.
bool	*e.is_ray()*	Returns *true* iff the Voronoi edge has either a source or a target Voronoi vertex, but not both; in other words it is a bisecting ray.
bool	*e.is_valid()*	Returns *true* if the following conditions are met: the halfedge is not a rejected edge with respect to the chosen adaptation policy; the twin edge of its twin edge is itself; its adjacent face is not a rejected face with respect to the chosen adaptation policy; its source and target vertices are valid (provided they exist, of course); the previous of its next halfedge is itself and the next of its previous halfedge is itself.

Class

CGAL::Voronoi_diagram_2<DG,AT,AP>::Vertex

Definition

The class *Vertex* is the Voronoi vertex class provided by the class *Voronoi_diagram_2<DG,AT,AP>* class. Below we present its interface.

Is Model for the Concepts

DefaultConstructible, *CopyConstructible*, *Assignable*, *EqualityComparable*, *LessThanComparable*

Types

Vertex:: Halfedge		A type for the halfedges of the Voronoi diagram.
Vertex:: Face		A type for the faces of the Voronoi diagram.
Vertex:: Vertex_handle		Handle for the vertices of the Voronoi diagram.
Vertex:: Face_handle		Handle for the faces of the Voronoi diagram.
Vertex:: Halfedge_handle		Handle for the halfedges of the Voronoi diagram.
Vertex:: Point_2		A type for the point represented by the vertex.
Vertex:: size_type		A type for sizes.
Vertex:: Halfedge_around_vertex_circulator		A type for a bidirectional circulator that allows to traverse all incident halfedges, i.e., all halfedges that have the vertex as their target. The value type of the circulator is *CGAL::Voronoi_diagram_2< DG,AT,AP>::Halfedge* and is convertible to *Halfedge_handle*.
Vertex:: Delaunay_graph		A type for the Delaunay graph. It is a model of the *DelaunayGraph_2* concept.
typedef Delaunay_graph::Face_handle	*Delaunay_face_handle;*	A type for the handle of the dual face.
typedef Delaunay_graph::Vertex_handle	*Delaunay_vertex_handle;*	A type for the vertex handles in the Delaunay graph.

Access Methods

Halfedge_handle	*v.halfedge()*	Returns an incident halfedge that has *v* as its target.
size_type	*v.degree()*	Returns the in-degree of the vertex, i.e. the number of halfedges that have *v* as their target.
Point_2	*v.point()*	Returns the point represented by the vertex.
Delaunay_face_handle	*v.dual()*	Returns a handle to the corresponding dual face in the Delaunay graph.

Delaunay_vertex_handle	*v.site(unsigned int i)*	Returns a handle to the vertex in the Delaunay graph corresponding to the $(i+1)$-th generating site of the Voronoi vertex. *Precondition*: *i* must be smaller or equal to 2.
Halfedge_around_vertex_circulator	*v.incident_halfedges()*	Returns a bidirectional circulator that allows the traversal of the halfedges that have *v* as their target. Applying *operator++* (resp. *operator--*) to this circulator returns the next incident halfedge in the counterclockwise (resp. clockwise) sense.

Predicate Methods

bool	*v.is_incident_edge(Halfedge_handle e)*	Returns *true* if the halfedge *e* is incident to *v*.
bool	*v.is_incident_face(Face_handle e)*	Returns *true* if the face *f* is incident to *v*.
bool	*v.is_valid()*	Returns *true* if the following conditions are met: the dual face is not an infinite face; all incident halfedges have the vertex as their target.

Class

CGAL::Voronoi_diagram_2<DG,AT,AP>::Face

Definition

The class *Face* is the class provided by the *Voronoi_diagram_2<DG,AT,AP>* class for Voronoi faces. Below we present its interface.

Is Model for the Concepts

DefaultConstructible, *CopyConstructible*, *Assignable*, *EqualityComparable*, *LessThanComparable*

Types

Face:: Vertex	A type for the vertices of the Voronoi diagram.
Face:: Halfedge	A type for the halfedges of the Voronoi diagram.
Face:: Vertex_handle	Handle for the vertices of the Voronoi diagram.
Face:: Face_handle	Handle for the faces of the Voronoi diagram.
Face:: Halfedge_handle	Handle for the halfedges of the Voronoi diagram.
Face:: Ccb_halfedge_circulator	A type for a bidirectional circulator over the halfedges on the boundary of the face. The value type of the circulator is *CGAL::Voronoi_diagram_2<DG,AT,AP>::Halfedge*, and is convertible to *Halfedge_handle*.
Face:: Delaunay_graph	A type for the Delaunay graph. It is a model of the *DelaunayGraph_2* concept.
typedef Delaunay_graph::Vertex_handle Delaunay_vertex_handle;	A type for the handle of the dual vertex.

Access Methods

Halfedge_handle	*f.halfedge()*	Returns an incident halfedge on the boundary of *f*.
Ccb_halfedge_circulator	*f.ccb()*	Returns a bidirectional circulator for traversing the halfedges on the boundary of *f*. The halfedges are traversed in counterclockwise order.
Delaunay_vertex_handle	*f.dual()*	Returns a handle to the corresponding dual vertex in the Delaunay graph.

Predicate Methods

bool	*f.is_unbounded()*	Returns *true* iff the face is an unbounded face in the Voronoi diagram.
bool	*f.is_halfedge_on_ccb(Halfedge e)*	Returns *true* iff *e* is a halfedge of the boundary of *f*.

bool	*f.is_valid()*	Returns *true* iff the following conditions are met: the face is not rejected by the chosen adaptation policy; all its adjacent halfedges do not have zero length; all its adjacent halfedges return the face as their adjacent face.

DelaunayGraph_2

Definition

The concept *DelaunayGraph_2* defines the requirements for the first template parameter of the *Voronoi_diagram_2<DG,AT,AP>* class. The *DelaunayGraph_2* concept essentially defines the requirements that a class representing a Delaunay graph must obey so that the Voronoi diagram adaptor can adapt it.

Refines

DefaultConstructible, *CopyConstructible*, *Assignable*

Types

DelaunayGraph_2:: size_type	A type for sizes.
DelaunayGraph_2:: Geom_traits	A type for the geometric traits associated with the Delaunay graph.
DelaunayGraph_2:: Triangulation_data_structure	A type for the underlying triangulation data structure. It must be a model of the concept *TriangulationDataStructure_2*.
DelaunayGraph_2:: Vertex	A type for the vertices of the Delaunay graph.
DelaunayGraph_2:: Face	A type for the faces of the Delaunay graph.
typedef std::pair<Face_handle,int> Edge;	The type of the edges of the Delaunay graph.
DelaunayGraph_2:: Vertex_handle	Handle to the vertices of the Delaunay graph.
DelaunayGraph_2:: Face_handle	Handle to the faces of the Delaunay graph.

The following iterators and circulators must be defined. All iterators and circulators must be assignable and convertible to their corresponding handles.

DelaunayGraph_2:: All_edges_iterator	A type for an iterator over all edges of the Delaunay graph. Its value type must be *Edge*.
DelaunayGraph_2:: Finite_edges_iterator	A type for an iterator over the finite edges of the Delaunay graph. Its value type must be *Edge*.
DelaunayGraph_2:: All_faces_iterator	A type for an iterator over all faces of the Delaunay graph. Its value type must be *Face*.
DelaunayGraph_2:: Finite_faces_iterator	A type for an iterator over the finite faces of the Delaunay graph. Its value type must be *Face*.
DelaunayGraph_2:: All_vertices_iterator	A type for an iterator over all vertices of the Delaunay graph. Its value type must be *Vertex*.
DelaunayGraph_2:: Finite_vertices_iterator	A type for an iterator over the finite vertices of the Delaunay graph. Its value type must be *Vertex*.
DelaunayGraph_2:: Face_circulator	A type for a circulator over the adjacent faces of a vertex of the Delaunay graph. Its value type must be *Face*.
DelaunayGraph_2:: Vertex_circulator	A type for a circulator over the adjacent vertices of a vertex of the Delaunay graph. Its value type must be *Vertex*.
DelaunayGraph_2:: Edge_circulator	A type for a circulator over the adjacent edges of a vertex of the Delaunay graph. Its value type must be *Edge*.

Creation

In addition to the default and copy constructors, as well as the assignment operator, the following constructors are required.

DelaunayGraph_2 dg(Geom_traits gt);	Constructor that takes an instance of the geometric traits.
template<class It> *DelaunayGraph_2 dg(It first, It beyond);*	Constructor that takes an iterator range. The value type of the iterator must be the type of the sites of the Delaunay graph.
template<class It> *DelaunayGraph_2 dg(It first, It beyond, Geom_traits gt);*	Constructor that takes an iterator range and an instance of the geometric traits. The value type of the iterator must be the type of the sites of the Delaunay graph.

Access methods

Triangulation_data_structure	*dg.tds()*	Returns a reference to the underlying triangulation data structure.
Geom_traits	*dg.geom_traits()*	Returns a reference to the geometric traits object.
Vertex_handle	*dg.infinite_vertex()*	Returns a handle to the infinite vertex.
Vertex_handle	*dg.finite_vertex()*	Returns a handle to a finite vertex, provided there exists one.
Face_handle	*dg.infinite_face()*	Returns a handle to a face incident to the infinite vertex.
int	*dg.dimension()*	Returns the dimension of the Delaunay graph.
size_type	*dg.number_of_vertices()*	Returns the number of finite vertices.
size_type	*dg.number_of_faces()*	Returns the number of faces (both finite and infinite).

Traversal of the Delaunay graph

A model of the *DelaunayGraph_2* concept must provide several iterators and circulators that allow to traverse it (completely or partially). All iterators and circulators must be convertible to the corresponding handles.

Face, Edge and Vertex Iterators

The following iterators must allow, respectively, to visit finite faces, finite edges and finite vertices of the Delaunay graph. These iterators must be non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*.

Finite_vertices_iterator	*dg.finite_vertices_begin()*	Starts at an arbitrary finite vertex.
Finite_vertices_iterator	*dg.finite_vertices_end()*	Past-the-end iterator.
Finite_edges_iterator	*dg.finite_edges_begin()*	Starts at an arbitrary finite edge.
Finite_edges_iterator	*dg.finite_edges_end()*	Past-the-end iterator.
Finite_faces_iterator	*dg.finite_faces_begin()*	Starts at an arbitrary finite face.

Finite_faces_iterator	*dg.finite_faces_end() const*	Past-the-end iterator.

The following iterators must allow, respectively, to visit all (both finite and infinite) faces, edges and vertices of the Delaunay graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*.

All_vertices_iterator	*dg.all_vertices_begin()*	Starts at an arbitrary vertex.
All_vertices_iterator	*dg.all_vertices_end()*	Past-the-end iterator.
All_edges_iterator	*dg.all_edges_begin()*	Starts at an arbitrary edge.
All_edges_iterator	*dg.all_edges_end()*	Past-the-end iterator.
All_faces_iterator	*dg.all_faces_begin()*	Starts at an arbitrary face.
All_faces_iterator	*dg.all_faces_end()*	Past-the-end iterator.

Face, Edge and Vertex Circulators

A model of the *DelaunayGraph_2* concept must also provide circulators that allow to visit, respectively, all faces or edges incident to a given vertex or all vertices adjacent to a given vertex. These circulators are non-mutable and bidirectional. The operator *operator++* must move the circulator counterclockwise around the vertex while the *operator--* must move the circulator clockwise.

Face_circulator	*dg.incident_faces(Vertex_handle v)*	Starts at an arbitrary face incident to v.
Face_circulator	*dg.incident_faces(Vertex_handle v, Face_handle f)*	Starts at face f. *Precondition*: Face f must be incident to vertex v.
Edge_circulator	*dg.incident_edges(Vertex_handle v)*	Starts at an arbitrary edge incident to v.
Edge_circulator	*dg.incident_edges(Vertex_handle v, Face_handle f)*	Starts at the first edge of f incident to v, in counterclockwise order around v. *Precondition*: Face f must be incident to vertex v.
Vertex_circulator	*dg.incident_vertices(Vertex_handle v)*	Starts at an arbitrary vertex incident to v.
Vertex_circulator	*dg.incident_vertices(Vertex_handle v, Face_handle f)*	Starts at the first vertex of f adjacent to v in counterclockwise order around v. *Precondition*: Face f must be incident to vertex v.

Predicates

A model of the *DelaunayGraph_2* concept must provide methods to test the finite or infinite character of any feature.

bool	*dg.is_infinite(Vertex_handle v)*	*true*, iff *v* is the *infinite_vertex*.
bool	*dg.is_infinite(Face_handle f)*	*true*, iff face *f* is infinite.
bool	*dg.is_infinite(Face_handle f, int i)*	*true*, iff edge *(f,i)* is infinite.
bool	*dg.is_infinite(Edge e)*	*true*, iff edge *e* is infinite.
bool	*dg.is_infinite(Edge_circulator ec)*	*true*, iff edge **ec* is infinite.

Validity check

bool	*dg.is_valid(bool verbose = false)*	Checks the validity of the Delaunay graph. If *verbose* is *true* a short message is sent to *std::cerr*.

Miscellaneous

void	*dg.clear()*	Clears all contents of the Delaunay graph.
void	*dg.swap(other)*	The Delaunay graphs *other* and *dg* are swapped. *dg.swap(other)* should be preferred to *dg= other* or to *dg(other)* if *other* is deleted afterwards.

Has Models

CGAL::Delaunay_triangulation_2<Traits,Tds>
CGAL::Regular_triangulation_2<Traits,Tds>

Concept

AdaptationTraits_2

Definition

The concept *AdaptationTraits_2* defines the functors required for accessing geometric information in the Delaunay graph that is needed by the *Voronoi_diagram_2<DG,AT,AP>* class. It optionally defines a functor for performing nearest site queries. A tag is provided for determining whether this functor is defined or not.

Refines

DefaultConstructible, *CopyConstructible*, *Assignable*

Types

AdaptationTraits_2:: Point_2	A type for a point.
AdaptationTraits_2:: Site_2	A type for the sites of the Voronoi diagram.
AdaptationTraits_2:: Delaunay_graph	A type for the triangulated Delaunay graph. The type *Delaunay_graph* must be a model of the *DelaunayGraph_2* concept.

typedef Delaunay_graph::Edge	*Delaunay_edge;*	The type of the edges of the Delaunay graph
typedef Delaunay_graph::Face_handle	*Delaunay_face_handle;*	The type of the face handles of the Delaunay graph
typedef Delaunay_graph::Vertex_handle	*Delaunay_vertex_handle;*	The type of the vertex handles of the Delaunay graph.

AdaptationTraits_2:: Access_site_2

A type for a functor that accesses the site associated with a vertex. The functor should be a model of the concepts *DefaultConstructible*, *CopyConstructible*, *Assignable* and *AdaptableFunctor* (with one argument). The functor must provide the following operator:
result_type operator()(Delaunay_vertex_handle v)
where the result type *result_type* must be either *Site_2* or *const Site_2*`&`.

AdaptationTraits_2:: Construct_Voronoi_point_2

A type for a functor that constructs the dual point of a (triangular) face in the Delaunay graph. This point is the Voronoi vertex of the three sites defining the face in the Delaunay graph. The functor must be a model of the concepts *DefaultConstructible*, *CopyConstructible*, *Assignable*, *AdaptableFunctor* (with one argument). It must provide the following operator:
Point_2 operator()(Delaunay_face_handle f) .
The face handle *f* must not correspond to an infinite face.

AdaptationTraits_2:: Has_nearest_site_2

A tag for determining if the adaptation traits class provides a functor for performing nearest site queries. This tag is equal to either *CGAL::Tag_true* (a nearest site query functor is available) or *CGAL::Tag_false* (a nearest site query functor is not available).

AdaptationTraits_2:: Nearest_site_2

A type for a functor that performs nearest site queries. Semantically, the result of the query is either a face, edge or vertex of the Delaunay graph. It is a face if the query point has at least three closest sites; the returned face has closest sites as vertices. It is an edge if the query point is equidistant to exactly two vertices of the Delaunay graph, which are the source and target vertices of the edge. In all other cases, the search result is a vertex, namely, the unique vertex of the Delaunay graph closest to the query point. The functor must be a model of the concepts *DefaultConstructible*, *CopyConstructible*, *Assignable*, *AdaptableFunctor* (with two arguments). It must provide the following operator:
result_type operator()(Delaunay_graph dg, Point_2 p)
where the result type *result_type* is *boost::variant< Delaunay_vertex_handle,Delaunay_edge,Delaunay_face_handle>*.
This type is required only if *Has_nearest_site_2* is equal to *CGAL::Tag_true*.

Access to objects

Access_site_2	*at.access_site_2_object()*	
Construct_Voronoi_point_2	*at.construct_Voronoi_point_2_object()*	
Nearest_site_2	*at.nearest_site_2_object()*	This method is required only if *Has_nearest_site_2* is equal to *CGAL::Tag_true*.

Has Models

Concept

AdaptationPolicy_2

Definition

The concept *AdaptationPolicy_2* defines the requirements on the predicate functors that determine whether a feature of the triangulated Delaunay graph should be rejected or not. It also provides a functor for inserting sites in the Delaunay graph. The last functor is optional and a tag determines whether it is provided or not. Note that while the first two functors do not modify the Delaunay graph they take as an argument, the last ones does.

Refines

DefaultConstructible, *CopyConstructible*, *Assignable*

Types

AdaptationPolicy_2:: Site_2 — A type for the sites of the Voronoi diagram.

AdaptationPolicy_2:: Delaunay_graph — A type for the triangulated Delaunay graph. The type *Delaunay_graph* must be a model of the *DelaunayGraph_2* concept.

typedef Delaunay_graph::Vertex_handle	*Delaunay_vertex_handle;*
typedef Delaunay_graph::Face_handle	*Delaunay_face_handle;*
typedef Delaunay_graph::Edge	*Delaunay_edge;*
typedef Delaunay_graph::All_edges_iterator	*All_Delaunay_edges_iterator;*
typedef Delaunay_graph::Finite_edges_iterator	*Finite_Delaunay_edges_iterator;*
typedef Delaunay_graph::Edge_circulator	*Delaunay_edge_circulator;*

AdaptationPolicy_2:: Edge_rejector — A type for the predicate functor that is responsible for rejecting an edge of the Delaunay graph (or equivalently rejecting its dual edge in the Voronoi diagram). It must be model of the concepts *DefaultConstructible*, *CopyConstructible*, *Assignable*, and *AdaptableFunctor* (with two arguments). It must provide the following operators:

bool operator()(Delaunay_graph dg, Delaunay_edge e)
bool operator()(Delaunay_graph dg, Delaunay_face_handle f, int i)
bool operator()(Delaunay_graph dg, Delaunay_edge_circulator ec)
bool operator()(Delaunay_graph dg, All_Delaunay_edges_iterator eit)
bool operator()(Delaunay_graph dg, Finite_Delaunay_edges_iterator eit)

The functor returns *true* iff the edge is rejected.

AdaptationPolicy_2:: Face_rejector — A type for the predicate functor that is responsible for rejecting a vertex of the Delaunay graph (or equivalently its dual face in the Voronoi diagram – hence the name of the functor). It must be model of the concepts *DefaultConstructible*, *CopyConstructible*, *Assignable*, *AdaptableFunctor* (with two arguments). It must provide the following operator:

bool operator()(Delaunay graph dg, Delaunay_vertex_handle v)

The functor returns *true* iff the face is rejected.

AdaptationPolicy_2:: Has_inserter — A tag for determining if the adaptation policy class provides a functor for inserting sites in the Delaunay graph. This tag is equal to either *CGAL::Tag_true* (a site inserter functor is available) or *CGAL::Tag_false* (a site inserter functor is not available).

AdaptationPolicy_2:: Site_inserter	A type for a functor that inserts sites in the Delaunay graph. It must be model of the concepts *DefaultConstructible*, *CopyConstructible*, *Assignable*, *AdaptableFunctor* (with two arguments). It must provide the following operator *Delaunay_vertex_handle operator()(Delaunay_graph& dg, Site_2 t)* The vertex handle returned either points to the vertex of the Delaunay graph corresponding to the site just inserted or is the default constructed vertex handle. The latter case can happen if the site inserted is *hidden*, i.e., it has an empty Voronoi cell. This type is required only if the *Has_inserter* tag is equal to *CGAL::Tag_true*.

Access to objects

Edge_rejector	*ap.edge_rejector_object()*	
Face_rejector	*ap.face_rejector_object()*	
Site_inserter	*ap.site_inserter_object()*	This method is required only if *Has_inserter* is equal to *CGAL::Tag_true*.

Miscellaneous

The following methods are important when the adaptation policy maintains a state. This can happen if we have a caching adaptation policy, i.e., when we cache the results of the edge and face rejectors.

void	*ap.clear()*	Clears the state of the adaptation policy.
void	*ap.swap(other)*	The adaptation policies *ap* and *other* are swapped. This method should be preferred to *ap=other* or *ap(other)* if *other* is deleted afterwards.
bool	*ap.is_valid()*	Tests the validity of the adaptation policy.
bool	*ap.is_valid(Delaunay_graph dg)*	Tests the validity of the adaptation policy using extra information from the Delaunay graph *dg*.

Class

CGAL::Identity_policy_2<DG,AT>

Definition

The class *Identity_policy_2<DG,AT>* provides a model for the *AdaptationPolicy_2* concept. The first template parameter of the *Identity_policy_2<DG,AT>* class must be a model of the *DelaunayGraph_2* concept, whereas as the second template parameter must be a model of the *AdaptationTraits_2* concept. This policy rejects no edge and no face of the Delaunay graph, thus giving a Voronoi diagram which is the true dual of the triangulation Delaunay graph. The Voronoi diagram created with this adaptation policy may have degenerate features, such as Voronoi edges of zero length, or Voronoi faces of zero area. This policy assumes that the Delaunay graph, that is adapted, allows for site insertions through an *insert* method that takes as argument an object of type *AT::Site_2*. The site inserter functor provided by this policy uses the aforementioned *insert* method.

Class

CGAL::Segment_Delaunay_graph_caching_degeneracy_removal_policy_2<SDG2>

Definition

The class *Segment_Delaunay_graph_caching_degeneracy_removal_policy_2<SDG2>* provides a model for the *AdaptationPolicy_2* concept. The template parameter of the *Segment_Delaunay_graph_caching_degeneracy_removal_policy_2<SDG2>* class must be a model of the *DelaunayGraph_2* concept, and in particular it has the semantics of a (triangulated) 2D segment Delaunay graph. This policy caches the results of the edge and face rejectors and results in a Voronoi diagram that has no degenerate features, i.e., no Voronoi edges of zero length and no Voronoi faces of zero area.

#include <CGAL/Segment_Delaunay_graph_adaptation_policies_2.h>

Mesh Generation

Chapter 47

2D Conforming Triangulations and Meshes

Laurent Rineau

Contents

This package implements Shewchuk's algorithm [She00] to construct conforming triangulations and 2D meshes. Conforming triangulations will be described in Section 47.1 and meshes in Section 47.2.

47.1 Conforming Triangulations

47.1.1 Definitions

A triangulation is a *Delaunay triangulation* if the circumscribing circle of any facet of the triangulation contains no vertex in its interior. A *constrained* Delaunay triangulation is a constrained triangulation which is as much Delaunay as possible. The circumscribing circle of any facet of a constrained Delaunay triangulation contains in its interior no data point *visible* from the facet.

An edge is said to be a *Delaunay edge* if it is inscribed in an empty circle (containing no data point in its interior). This edge is said to be a *Gabriel edge* if its diametrical circle is empty.

A constrained Delaunay triangulation is said to be a *conforming Delaunay triangulation* if every constrained edge is a Delaunay edge. Because any edge in a constrained Delaunay triangulation is either a Delaunay edge or a constrained edge, a conforming Delaunay triangulation is in fact a Delaunay triangulation. The only difference is that some of the edges are marked as constrained edges.

A constrained Delaunay triangulation is said to be a *conforming Gabriel triangulation* if every constrained edge is a Gabriel edge. The Gabriel property is stronger than the Delaunay property and each Gabriel edge is a Delaunay edge. Conforming Gabriel triangulations are thus also conforming Delaunay triangulations.

Any constrained Delaunay triangulation can be refined into a conforming Delaunay triangulation or into a conforming Gabriel triangulation by adding vertices, called *Steiner vertices*, on constrained edges until they are decomposed into subconstraints small enough to be Delaunay or Gabriel edges.

47.1.2 Building Conforming Triangulations

Constrained Delaunay triangulations can be refined into conforming triangulations by the two following global functions:
template<class CDT> void make_conforming_Delaunay_2 (CDT& t) and
template<class CDT> void make_conforming_Gabriel_2 (CDT& t).

In both cases, the template parameter *CDT* must be instantiated by a constrained Delaunay triangulation class. Such a class must be a model of the concept *ConstrainedDelaunayTriangulation_2*.

The geometric traits of the constrained Delaunay triangulation used to instantiate the parameter *CDT* has to be a model of the concept *ConformingDelaunayTriangulationTraits_2*.

The constrained Delaunay triangulation *t* is passed by reference and is refined into a conforming Delaunay triangulation or into a conforming Gabriel triangulation by adding vertices. The user is advised to make a copy of the input triangulation in the case where the original triangulation has to be preserved for other computations

The algorithm used by *make_conforming_Delaunay_2* and *make_conforming_Gabriel_2* builds internal data structures that would be computed twice if the two functions are called consecutively on the same triangulation. In order to avoid these data to be constructed twice, the advanced user can use the class *Triangulation_conformer_2<CDT>* to refine a constrained Delaunay triangulation into a conforming Delaunay triangulation and then into a conforming Gabriel triangulation. For additional control of the refinement algorithm, this class also provides separate functions to insert one Steiner point at a time.

47.1.3 Example: Making a Triangulation Conforming Delaunay and Then Conforming Gabriel

This example inserts several segments into a constrained Delaunay triangulation, makes it conforming Delaunay, and then conforming Gabriel. At each step, the number of vertices of the triangulation is printed.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_conformer_2.h>

#include <iostream>
```

```
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Constrained_Delaunay_triangulation_2<K> CDT;
typedef CDT::Point Point;
typedef CDT::Vertex_handle Vertex_handle;

int main()
{
  CDT cdt;

  // construct a constrained triangulation
  Vertex_handle
    va = cdt.insert(Point( 5., 5.)),
    vb = cdt.insert(Point(-5., 5.)),
    vc = cdt.insert(Point( 4., 3.)),
    vd = cdt.insert(Point( 5.,-5.)),
    ve = cdt.insert(Point( 6., 6.)),
    vf = cdt.insert(Point(-6., 6.)),
    vg = cdt.insert(Point(-6.,-6.)),
    vh = cdt.insert(Point( 6.,-6.));

  cdt.insert_constraint(va,vb);
  cdt.insert_constraint(vb,vc);
  cdt.insert_constraint(vc,vd);
  cdt.insert_constraint(vd,va);
  cdt.insert_constraint(ve,vf);
  cdt.insert_constraint(vf,vg);
  cdt.insert_constraint(vg,vh);
  cdt.insert_constraint(vh,ve);

  std::cout << "Number of vertices before: "
            << cdt.number_of_vertices() << std::endl;

  // make it conforming Delaunay
  CGAL::make_conforming_Delaunay_2(cdt);

  std::cout << "Number of vertices after make_conforming_Delaunay_2: "
            << cdt.number_of_vertices() << std::endl;

  // then make it conforming Gabriel
  CGAL::make_conforming_Gabriel_2(cdt);

  std::cout << "Number of vertices after make_conforming_Gabriel_2: "
            << cdt.number_of_vertices() << std::endl;
}
```

47.2 Meshes

47.2.1 Definitions

A mesh is a partition of a given region into simplices whose shapes and sizes satisfy several criteria.

The domain is the region that the user wants to mesh. It has to be a bounded region of the plane. The domain is defined by a *planar straight line graph*, PSLG for short, which is a set of segments such that two segments in the set are either disjoint or share an endpoint. The segments of the PSLG are constraints that will be represented by a union of edges in the mesh. The PSLG can also contain isolated points that will appear as vertices of the mesh.

The segments of the PSLG are either segments of the boundary or internals constraints. The segments of the PSLG have to cover the boundary of the domain.

The PSLG divides the plane into several connected components. By default, the domain is the union of the bounded connected components. The user can override this default by providing a set of seed points. Either seed points mark components to be meshed or they mark components not to be meshed (holes).

See figures 47.4 and 47.5 for an example of a domain defined without using seed points, and a possible mesh of it. See figure 47.6 for another domain defined with the same PSLG and two seed points used to define holes. In the corresponding mesh (figure 47.7), these two holes are triangulated but not meshed.

47.2.2 Shape and Size Criteria

The shape criterion for triangles is a lower bound B on the ratio between the circumradius and the shortest edge length. Such a bound implies a lower bound of $\arcsin\frac{1}{2B}$ on the minimum angle of the triangle and an upper

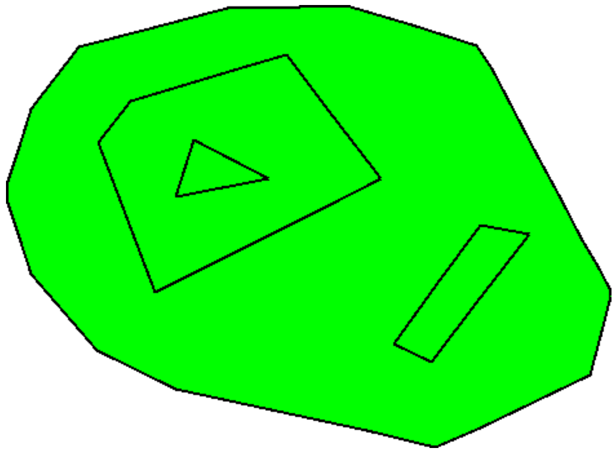

Figure 47.4: A domain defined without seed points.

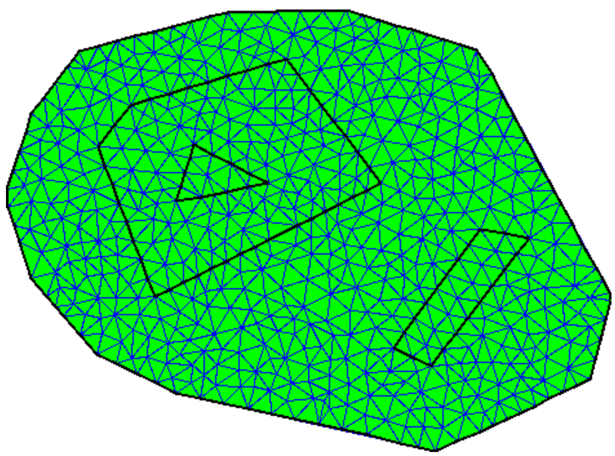

Figure 47.5: A mesh of the domain defined without seed points.

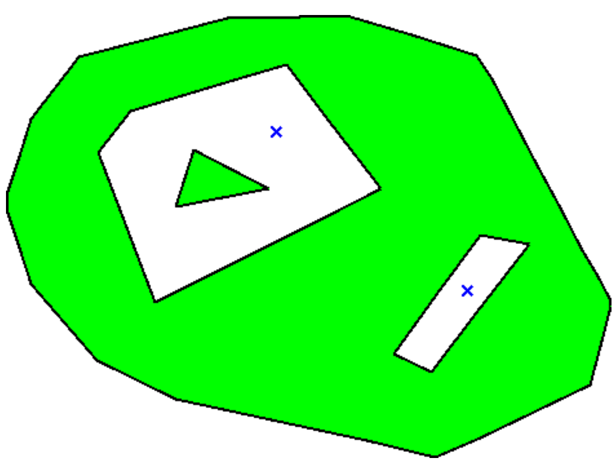

Figure 47.6: A domain with two seeds points defining holes.

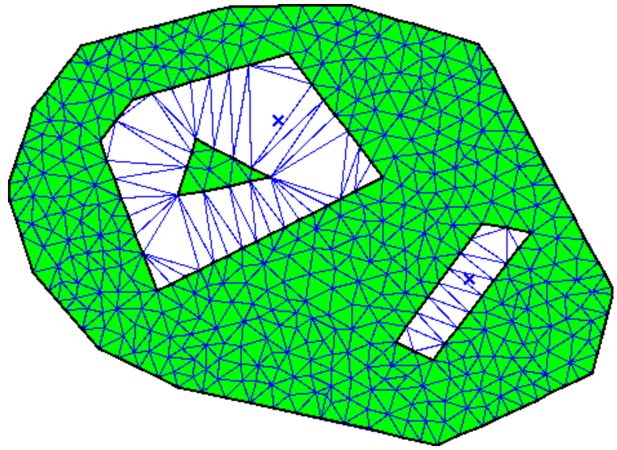

Figure 47.7: A mesh of the domain with two seeds defining holes.

bound of $\pi - 2 * \arcsin \frac{1}{2B}$ on the maximum angle. Unfortunately, the termination of the algorithm is guaranteed only if $B \geq \sqrt{2}$, which corresponds to a lower bound of 20.7 degrees over the angles.

The size criterion can be any criterion that tends to prefer small triangles. For example, the size criterion can be an upper bound on the length of longest edge of triangles, or an upper bound on the radius of the circumcircle. The size bound can vary over the domain. For example, the size criterion could impose a small size for the triangles intersecting a given line.

Both types of criteria are defined in an object *criteria* passed as parameter of the meshing functions.

47.2.3 The Meshing Algorithm

The input to a meshing problem is a PSLG and a set of seeds describing the domain to be meshed, and a set of size and shape criteria. The algorithm implemented in this package starts with a constrained Delaunay triangulation of the input PSLG and produces a mesh using the Delaunay refinement method. This method inserts new vertices to the triangulation, as far as possible from other vertices, and stops when the criteria are satisfied.

If all angles between incident segments of the input PSLG are greater than 60 degrees and if the bound on the circumradius/edge ratio is greater than $\sqrt{2}$, the algorithm is guaranteed to terminate with a mesh satisfying the size and shape criteria.

If some input angles are smaller than 60 degrees, the algorithm will end up with a mesh in which some triangles violate the criteria near small input angles. This is unavoidable since small angles formed by input segments cannot be suppressed. Furthermore, it has been shown ([She00]), that some domains with small input angles cannot be meshed with angles even smaller than the small input angles. Note that if the domain is a polygonal region, the resulting mesh will satisfy size and shape criteria except for the small input angles. In addition, the algorithm may succeed in producing meshes with a lower angle bound greater than 20.7 degrees, but there is no such guarantee.

47.2.4 Building Meshes

Meshes are obtained from constrained Delaunay triangulations by calling the global function
template<class CDT, class Criteria> void refine_Delaunay_mesh_2 (CDT &t, const Criteria& criteria).
The template parameter *CDT* must be instantiated by a constrained Delaunay triangulation class, which is a model of the concept *ConstrainedDelaunayTriangulation_2*. In order to override the domain, a version of this function has two more arguments that define a sequence of seed points.

The geometric traits class of *CDT* has to be a model of the concept *DelaunayMeshTraits_2*. This concept refines the concept *ConformingDelaunayTriangulationTraits_2* adding the geometric predicates and constructors. The template parameter *Criteria* must be a model of *MeshingCriteria_2*. This concept defines criteria that the triangles have to satisfy. CGAL provides two models for this concept:

- *Delaunay_mesh_criteria_2<CDT>*, that defines a shape criterion that bounds the minimum angle of triangles,
- *Delaunay_mesh_size_criteria_2<CDT>*, that adds to the previous criterion a bound on the maximum edge length.

If the function *refine_Delaunay_mesh_2* is called several times on the same triangulation with different criteria, the algorithm rebuilds the internal data structure used for meshing at every call. In order to avoid rebuild the data structure at every call, the advanced user can use the class *Delaunay_mesher_2<CDT>*. This class provides also step by step functions. Those functions insert one vertex at a time.

Any object of type *Delaunay_mesher_2<CDT>* is constructed from a reference to a *CDT*, and has several member functions to define the domain to be meshed and to mesh the *CDT*. See the example given below and the reference manual for details. Note that the *CDT* should not be externally modified during the life time of the *Delaunay_mesher_2<CDT>* object.

Once the mesh is constructed, one can determine which faces of the triangulation are in the mesh domain using the *is_in_domain()* member function of the face type (see the concept *DelaunayMeshFaceBase_2*).

47.2.5 Example Using the Global Function

The following example inserts several segments into a constrained triangulation and then meshes it using the global function *refine_Delaunay_mesh_2*. The size and shape criteria are the default ones provided by the criteria class *Delaunay_mesh_criteria_2<K>*. No seeds are given, meaning that the mesh domain covers the whole plane except the unbounded component.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Delaunay_mesher_2.h>
#include <CGAL/Delaunay_mesh_face_base_2.h>
#include <CGAL/Delaunay_mesh_size_criteria_2.h>

#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Delaunay_mesh_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb, Fb> Tds;
typedef CGAL::Constrained_Delaunay_triangulation_2<K, Tds> CDT;
```

```
typedef CGAL::Delaunay_mesh_size_criteria_2<CDT> Criteria;

typedef CDT::Vertex_handle Vertex_handle;
typedef CDT::Point Point;

int main()
{
  CDT cdt;

  Vertex_handle va = cdt.insert(Point(-4,0));
  Vertex_handle vb = cdt.insert(Point(0,-1));
  Vertex_handle vc = cdt.insert(Point(4,0));
  Vertex_handle vd = cdt.insert(Point(0,1));
  cdt.insert(Point(2, 0.6));

  cdt.insert_constraint(va, vb);
  cdt.insert_constraint(vb, vc);
  cdt.insert_constraint(vc, vd);
  cdt.insert_constraint(vd, va);

  std::cout << "Number of vertices: " << cdt.number_of_vertices() <<
   std::endl;

  std::cout << "Meshing the triangulation..." << std::endl;
  CGAL::refine_Delaunay_mesh_2(cdt, Criteria(0.125, 0.5));

  std::cout << "Number of vertices: " << cdt.number_of_vertices() <<
   std::endl;
}
```

File: examples/Mesh_2/mesh_global.cpp

47.2.6 Example Using the Class Delaunay_mesher_2<CDT>

This example uses the class *Delaunay_mesher_2<CDT>* and calls the *refine_mesh()* member function twice, changing the size and shape criteria in between. In such a case, using twice the global function *refine_Delaunay_mesh_2* would be less efficient, because some internal structures needed by the algorithm would be built twice.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Delaunay_mesher_2.h>
#include <CGAL/Delaunay_mesh_face_base_2.h>
#include <CGAL/Delaunay_mesh_size_criteria_2.h>

#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Delaunay_mesh_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb, Fb> Tds;
typedef CGAL::Constrained_Delaunay_triangulation_2<K, Tds> CDT;
typedef CGAL::Delaunay_mesh_size_criteria_2<CDT> Criteria;
```

```
typedef CGAL::Delaunay_mesher_2<CDT, Criteria> Mesher;

typedef CDT::Vertex_handle Vertex_handle;
typedef CDT::Point Point;

int main()
{
  CDT cdt;

  Vertex_handle va = cdt.insert(Point(-4,0));
  Vertex_handle vb = cdt.insert(Point(0,-1));
  Vertex_handle vc = cdt.insert(Point(4,0));
  Vertex_handle vd = cdt.insert(Point(0,1));
  cdt.insert(Point(2, 0.6));

  cdt.insert_constraint(va, vb);
  cdt.insert_constraint(vb, vc);
  cdt.insert_constraint(vc, vd);
  cdt.insert_constraint(vd, va);

  std::cout << "Number of vertices: " << cdt.number_of_vertices() <<
    std::endl;

  std::cout << "Meshing the triangulation with default criterias..."
            << std::endl;

  Mesher mesher(cdt);
  mesher.refine_mesh();

  std::cout << "Number of vertices: " << cdt.number_of_vertices() <<
    std::endl;

  std::cout << "Meshing with new criterias..." << std::endl;
  // 0.125 is the default shape bound. It corresponds to abound 20.6
    degree.
  // 0.5 is the upper bound on the length of the longuest edge.
  // See reference manual for Delaunay_mesh_size_traits_2<K>.
  mesher.set_criteria(Criteria(0.125, 0.5));
  mesher.refine_mesh();

  std::cout << "Number of vertices: " << cdt.number_of_vertices() <<
    std::endl;
}
```

File: examples/Mesh_2/mesh_class.cpp

47.2.7 Example Using Seeds

This example uses the global function *refine_Delaunay_mesh_2* but defines a domain by using one seed. The size and shape criteria are the default ones provided by the criteria class *Delaunay_mesh_criteria_2<K>*.

Once the mesh is constructed, the *is_in_domain()* member function of faces is used to count them.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Delaunay_mesher_2.h>
#include <CGAL/Delaunay_mesh_face_base_2.h>
#include <CGAL/Delaunay_mesh_size_criteria_2.h>

#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Delaunay_mesh_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb, Fb> Tds;
typedef CGAL::Constrained_Delaunay_triangulation_2<K, Tds> CDT;
typedef CGAL::Delaunay_mesh_size_criteria_2<CDT> Criteria;

typedef CDT::Vertex_handle Vertex_handle;
typedef CDT::Point Point;

int main()
{
  CDT cdt;
  Vertex_handle va = cdt.insert(Point(2,0));
  Vertex_handle vb = cdt.insert(Point(0,2));
  Vertex_handle vc = cdt.insert(Point(-2,0));
  Vertex_handle vd = cdt.insert(Point(0,-2));

  cdt.insert_constraint(va, vb);
  cdt.insert_constraint(vb, vc);
  cdt.insert_constraint(vc, vd);
  cdt.insert_constraint(vd, va);

  va = cdt.insert(Point(3,3));
  vb = cdt.insert(Point(-3,3));
  vc = cdt.insert(Point(-3,-3));
  vd = cdt.insert(Point(3,0-3));

  cdt.insert_constraint(va, vb);
  cdt.insert_constraint(vb, vc);
  cdt.insert_constraint(vc, vd);
  cdt.insert_constraint(vd, va);

  std::list<Point> list_of_seeds;

  list_of_seeds.push_back(Point(0, 0));

  std::cout << "Number of vertices: " << cdt.number_of_vertices() <<
   std::endl;

  std::cout << "Meshing the domain..." << std::endl;
  CGAL::refine_Delaunay_mesh_2(cdt, list_of_seeds.begin(),
   list_of_seeds.end(),
                              Criteria());

  std::cout << "Number of vertices: " << cdt.number_of_vertices() <<
```

```
    std::endl;
  std::cout << "Number of finite faces: " << cdt.number_of_faces() <<
    std::endl;
  int mesh_faces_counter = 0;
  for(CDT::Finite_faces_iterator fit = cdt.finite_faces_begin();
      fit != cdt.finite_faces_end(); ++fit)
  {
    if(fit->is_in_domain()) ++mesh_faces_counter;
  }
  std::cout << "Number of faces in the mesh domain: " <<
    mesh_faces_counter << std::endl;
}
```

ConformingDelaunayTriangulationTraits_2

Concept

Definition

The concept ConformingDelaunayTriangulationTraits_2 refines the concept *ConstrainedDelaunayTriangulationTraits_2* by providing a numeric field type *FT*, a type *Vector_2* and several constructors on *Vector_2*, *Point_2*, and a predicate on angles. The field type has to be a model of the concept *SqrtFieldNumberType*. This field type and the constructors are used by the conforming algorithm to compute Steiner points on constrained edges.

Refines

DelaunayTriangulationTraits_2

Types

ConformingDelaunayTriangulationTraits_2:: FT

The field type. It must be a model of *SqrtFieldNumberType*, that is must be a number type supporting the operations $+$, $-$, $*$, $/$, and $\sqrt{\cdot}$.

ConformingDelaunayTriangulationTraits_2:: Vector_2

The vector type.

ConformingDelaunayTriangulationTraits_2:: Construct_vector_2

Constructor object. Must provide the operator *Vector_2 operator()(Point a, Point b)* that computes the vector $b-a$.

ConformingDelaunayTriangulationTraits_2:: Construct_scaled_vector_2

Constructor object. Must provide the operator *Vector_2 operator()(Vector_2 v, FT scale)* that computes the vector $scale \cdot \mathbf{v}$.

ConformingDelaunayTriangulationTraits_2:: Construct_translated_point_2

Constructor object. Must provide the operator *Point_2 operator()(Point_2 p, Vector_2 v)* that computes the point $p+\mathbf{v}$.

ConformingDelaunayTriangulationTraits_2:: Construct_midpoint_2

Constructor object. Must provide the operator *Point_2 operator()(Point_2 a, Point_2 b)* that computes the midpoint of the segment ab.

ConformingDelaunayTriangulationTraits_2:: Compute_squared_distance_2

Constructor object. Must provide the operator *FT operator()(Point_2 a, Point_2 b)* that computes the squared distance between *a* and *b*.

ConformingDelaunayTriangulationTraits_2:: Angle_2

Predicate object. Must provide the operator *CGAL::Angle operator()(Point_2 p, Point_2 q, Point_2 r)* that returns OBTUSE, RIGHT or ACUTE depending on the angle formed by the three points p, q, r (q being the vertex of the angle).

Access to predicate and constructor objects

Construct_vector_2	*traits.construct_vector_2_object()*
Construct_scaled_vector_2	*traits.construct_scaled_vector_2_object()*
Construct_translated_point_2	*traits.construct_translated_point_2_object()*
Constructor_midpoint_2	*traits.construct_midpoint_2_object()*
Compute_squared_distance_2	*traits.compute_squared_distance_2_object()*
Angle_2	*traits.angle_2_object()*

Has Models

Any model of *Kernel* concept. In particular, all CGAL kernels.

DelaunayMeshFaceBase_2

Definition

The concept DelaunayMeshFaceBase_2 refines the concept *TriangulationFaceBase_2*. It adds two functions giving access to a Boolean marker, that indicates if the face is in the meshing domain or not.

Refines

ConstrainedTriangulationFaceBase_2

Access Functions

bool	*f.is_in_domain() const*	
		returns true if this face is in the domain to be refined.
void	*f.set_in_domain(const bool b)*	
		sets if this face is in the domain.

Has Models

Delaunay_mesh_face_base_2<Traits, Fb>

Concept

Concept

DelaunayMeshTraits_2

Definition

The concept DelaunayMeshTraits_2 refines the concept *ConformingDelaunayTriangulationTraits_2*. It provides a construction object *Construct_circumcenter_2*.

Refines

ConformingDelaunayTriangulationTraits_2

Types

DelaunayMeshTraits_2:: Construct_circumcenter_2	
	Constructor object. Must provide an operator *Point_2 operator()(Point_2 p, Point_2 q, Point_2 r);* that constructs the center of the circle passing through the points p, q, and r. *Precondition*: p, q, and r are not collinear.
DelaunayMeshTraits_2:: Compute_area_2	Constructor object. Must provide an operator *FT operator()(Point_2 p, Point_2 q, Point_2 r);* that computes the signed area of the triangle defined by the points p, q, and r.

Access to predicate and constructor objects

Construct_circumcenter_2	*traits.construct_circumcenter_2_object()*
Compute_area_2	*traits.compute_area_2_object()*

Has Models

Any model of the *Kernel* concept. In particular, all CGAL kernels.

CGAL::Delaunay_mesher_2<CDT, Criteria>

Class

This class implements a 2D mesh generator.

#include <CGAL/Delaunay_mesher_2.h>

Parameters

The template parameter *CDT* should be a model of the concept *ConstrainedDelaunayTriangulation_2*, and type *CDT::Face* should be a model of the concept *MeshFaceBase_2*.

The geometric traits class of the instance of *CDT* has to be a model of the concept *DelaunayMeshTraits_2*.

The template parameter *Criteria* should be a model of the concept *MeshingCriteria_2*. This traits class defines the shape and size criteria for the triangles of the mesh. *Criteria::Face_handle* has to be the same as *CDT::Face_handle*.

Using this class

The constructor of the class *Delaunay_mesher_2<CDT, Criteria>* takes a reference to a *CDT* as an argument. A call to the refinement method *refine_mesh()* will refine the constrained Delaunay triangulation into a mesh satisfying the size and shape criteria specified in the traits class. Note that if, during the life time of the *Delaunay_mesher_2<CDT, Criteria>* object, the triangulation is externally modified, any further call to its member methods may crash. Consider constructing a new *Delaunay_mesher_2<CDT, Criteria>* object if the triangulation has been modified.

Meshing domain

The domain to be mesh is defined by the constrained edges and a set of seed points. The constrained edges divides the plane into several connected components. The mesh domain is either the union of the bounded connected components including at least one seed, or the union of the bounded connected components that do no contain any seed. Note that the unbounded component of the plane is never meshed.

Types

typedef CDT::Geom_traits

Geom_traits; the geometric traits class.

Delaunay_mesher_2<CDT, Criteria>:: Seeds_iterator

const iterator over defined seeds. Its value type is *Geom_traits::Point_2*.

Creation

Delaunay_mesher_2<CDT, Criteria> mesher(CDT& t, Criteria criteria = Criteria());

Create a new mesher, working on *t*, with meshing criteria *criteria*.

Seeds functions

The following functions are used to define seeds.

void	*mesher.clear_seeds()*	Sets seeds to the empty set. All finite connected components of the constrained triangulation will be refined.

template<class InputIterator>
void *mesher.set_seeds(InputIterator begin, InputIterator end, const bool mark=false)*

Sets seeds to the sequence [*begin*, *end*]. If *mark=true*, the mesh domain is the union of the bounded connected components including at least one seed. If *mark=false*, the domain is the union of the bounded components including no seed. Note that the unbounded component of the plane is never meshed.
Requirement: The *value_type* of *begin* and *end* is *Geom_traits::Point_2*.

Seeds_const_iterator *mesher.seeds_begin() const*

Start of the seeds sequence.

Seeds_const_iterator *mesher.seeds_end() const*

Past the end of the seeds sequence.

Meshing methods

void	*mesher.refine_mesh()*	Refines the constrained Delaunay triangulation into a mesh satisfying the criteria defined by the traits.
Criteria	*mesher.get_criteria()*	Returns a const reference to the criteria traits object.

void *mesher.set_criteria(Criteria criteria)*

Assigns *criteria* to the criteria traits object.

advanced

The function *set_criteria* scans all faces to recalculate the list of *bad faces*, that are faces not conforming to the meshing criteria. This function actually has an optional argument that permits to prevent this recalculation. The filling of the list of bad faces can then be done by a call to *set_bad_faces*.

void *mesher.set_criteria(Criteria criteria, bool recalculate_bad_faces)*

Assigns *criteria* to the criteria traits object. If *recalculate_bad_faces* is *false*, the list of bad faces is let empty and the function *set_bad_faces* should be called before *refine_mesh*.

template <class InputIterator>

void *mesher.set_bad_faces(InputIterator begin, InputIterator end)*

This method permits to set the list of bad triangles directly, from the sequence [begin, end], so that the algorithm will not scan the whole set of triangles to find bad ones. To use if there is a non-naive way to find bad triangles.
Requirement: The *value_type* of *begin* and *end* is *Face_handle*.

advanced

advanced

Step by step operations

The *Delaunay_mesher_2<CDT, Criteria>* class allows, for debugging or demos, to play the meshing algorithm step by step, using the following methods.

void *mesher.init()*

This method must be called just before the first call to the following step by step refinement method, that is when all vertices and constrained edges have been inserted into the constrained Delaunay triangulation. It must be called again before any subsequent calls to the step by step refinement method if new vertices or constrained edges have been inserted since the last call.

bool *mesher.is_refinement_done()*

Tests if the step by step refinement algorithm is done. If it returns *true*, the following calls to *step_by_step_refine_mesh* will not insert any points, until some new constrained segments or points are inserted in the triangulation and *init* is called again.

bool *mesher.step_by_step_refine_mesh()*

Applies one step of the algorithm, by inserting one point, if the algorithm is not done. Returns *false* iff no point has been inserted because the algorithm is done.

advanced

Class

CGAL::Delaunay_mesh_criteria_2<CDT>

Definition

The class *Delaunay_mesh_criteria_2<CDT>* is a model for the *MeshingCriteria_2* concept. The shape criterion on triangles is given by a bound B such that for good triangles $\frac{r}{l} \leq B$ where l is the shortest edge length and r is the circumradius of the triangle. By default, $B = \sqrt{2}$, which is the best bound one can use with the guarantee that the refinement algorithm will terminate. The upper bound B is related to a lower bound α_{min} on the minimum angle in the triangle:

$$\sin \alpha_{min} = \frac{1}{2B}$$

so $B = \sqrt{2}$ corresponds to $\alpha_{min} \geq 20.7$ degrees.

#include <CGAL/Delaunay_mesh_criteria_2.h>

Is Model for the Concepts

MeshingCriteria_2

Creation

Delaunay_mesh_criteria_2<CDT> traits; Default constructor. $B = \sqrt{2}$.

Delaunay_mesh_criteria_2<CDT> traits(double b = 0.125);

Construct a traits class with bound $B = \sqrt{\frac{1}{4b}}$.

CGAL::Delaunay_mesh_face_base_2<Traits, Fb>

Class

Definition

The class *Delaunay_mesh_face_base_2<Traits, Fb>* is a model for the concept *DelaunayMeshFaceBase_2*.

This class can be used directly or it can serve as a base to derive other classes with some additional attributes (a color for example) tuned to a specific application.

#include <CGAL/Delaunay_mesh_face_base_2.h>

Parameters

- The first parameter *Traits* is the geometric traits class. It must be the same as the one used for the Delaunay mesh.
- The second parameter *Fb* is the base class from which *Delaunay_mesh_face_base_2<Traits, Fb>* derives. It must be a model of the *TriangulationFaceBase_2* concept.

DelaunayMeshFaceBase_2

Class

CGAL::Delaunay_mesh_size_criteria_2<CDT>

Definition

The class *Delaunay_mesh_size_criteria_2<CDT>* is a model for the *MeshingCriteria_2* concept. The shape criterion on triangles is given by a bound B such that for good triangles $\frac{r}{l} \leq B$ where l is the shortest edge length and r is the circumradius of the triangle. By default, $B = \sqrt{2}$, which is the best bound one can use with the guarantee that the refinement algorithm will terminate. The upper bound B is related to a lower bound α_{min} on the minimum angle in the triangle:

$$\sin \alpha_{min} = \frac{1}{2B}$$

so $B = \sqrt{2}$ corresponds to $\alpha_{min} \geq 20.7$ degrees.

This traits class defines also a size criteria: all segments of all triangles must be shorter than a bound S.

#include <CGAL/Delaunay_mesh_size_criteria_2.h>

Is Model for the Concepts

MeshingCriteria_2

Creation

Delaunay_mesh_size_criteria_2<CDT> traits; Default constructor. $B = \sqrt{2}$. No bound on size

Delaunay_mesh_size_criteria_2<CDT> traits(double b = 0.125, double S = 0);

Construct a traits class with bound $B = \sqrt{\frac{1}{4b}}$. If $S \neq 0$, the size bound is S. If $S = 0$, there is no bound on size.

CGAL::Mesh_2::Face_badness

#include <CGAL/Mesh_2/Face_badness.h>

enum Mesh_2::Face_badness { *NOT_BAD, BAD, IMPERATIVELY_BAD*}*;*

Function

CGAL::make_conforming_Delaunay_2

#include <CGAL/Triangulation_conformer_2.h>

template<class CDT>
void *make_conforming_Delaunay_2(CDT &t)*

Refines the constrained Delaunay triangulation *t* into a conforming Delaunay triangulation. After a call to this function, all edges of *t* are Delaunay edges.
Requirement: The template parameter *CDT* should be a model of the concept *ConstrainedDelaunayTriangulation_2*. The geometric traits class of into the constrained Delaunay triangulation must be a model of *ConformingDelaunayTriangulationTraits_2*.

Function

CGAL::make_conforming_Gabriel_2

#include <CGAL/Triangulation_conformer_2.h>

template<class CDT>
void *make_conforming_Gabriel_2(CDT &t)*

Refines the constrained Delaunay triangulation *t* into a conforming Gabriel triangulation. After a call to this function, all constrained edges of *t* have the *Gabriel property*: the circle that has *e* as diameter does not contain any vertex from the triangulation.
Requirement: The template parameter *CDT* should be a model of the concept *ConstrainedDelaunayTriangulation_2*. The geometric traits class of the constrained Delaunay triangulation must be a model of *ConformingDelaunayTriangulationTraits_2*.

Concept

MeshingCriteria_2

Definition

The concept MeshingCriteria_2 defines the meshing criteria to be used in the algorithm. It provides a predicate *Is_bad* that tests a triangle according to criteria. The return type of *Is_bad* is an enum *Mesh_2::Face_badness*.

The possible values of *Mesh_2::Face_badness* are *NOT_BAD*, *BAD* and *IMPERATIVELY_BAD*. If the predicate returns *BAD*, the triangle is marked as bad and the algorithm will try to destroy it. If the predicates returns *IMPERATIVELY_BAD*, the algorithm will destroy the triangle unconditionally during its execution.

The termination of the algorithm is guaranteed when criteria are shape criteria corresponding to a bound on smallest angles not less than 20.7 degrees (this corresponds to a radius-edge ratio bound not less than $\sqrt{2}$). Any size criteria that are satisfied by small enough triangle can be added to the set of criteria without compromising the termination.

Note that, in the presence of input angles smaller than 60 degrees, some bad shaped triangles can appear in the final mesh in the neighboring of small angles. To achieve termination and the respect of size criteria everywhere, the *Is_bad* predicate has to return *IMPERATIVELY_BAD* when size criteria are not satisfied, and *BAD* when shape criteria are not satisfied.

MeshingCriteria_2 also provides a type *Quality* designed to code a quality measure for triangles. The type *Quality* must be *less-than comparable* as the meshing algorithm will order bad triangles by quality, to split those with smallest quality first. The predicate *Is_bad* computes the quality of the triangle as a by-product.

Types

MeshingCriteria_2:: Face_handle	Handle to a face of the triangulation.
MeshingCriteria_2:: Quality	Default constructible, copy constructible, assignable, and less-than comparable type.
MeshingCriteria_2:: Is_bad	Predicate object. Must provide two operators. The first operator *Mesh_2::Face_badness operator()(Face_handle fh, Quality& q)* returns *NOT_BAD* if it satisfies the desired criteria for mesh triangles, *BAD* if it does not, and *IMPERATIVELY_BAD* if it does not and should be refined unconditionally. In addition, this operator assigns to q a value measuring the quality of the triangle pointed by *fh*. The second operator *Mesh_2::Face_badness operator()(Quality q)* returns *NOT_BAD* if q is the quality of a good triangle, *BAD* if the q represents a poor quality, and *IMPERATIVELY_BAD* if q represents the quality of a bad triangle that should be refined unconditionally.

Access to predicate and constructor objects

Is_bad *traits.is_bad_object()*

Has Models

Delaunay_mesh_criteria_2<CDT>
Delaunay_mesh_size_criteria_2<CDT>

Function

CGAL::refine_Delaunay_mesh_2

template<class CDT, class Criteria>
void *refine_Delaunay_mesh_2(CDT &t, Criteria criteria = Criteria())*

Refines the default domain defined by a constrained Delaunay triangulation without seeds into a mesh satisfying the criteria defined by the traits *criteria*. The domain of the mesh covers all the connected components of the plane defined by the constrained edges of *t*, except for the unbounded component.

Precondition: The template parameter *CDT* must be a model of the concept *ConstrainedDelaunayTriangulation_2*. The geometric traits class of the constrained Delaunay triangulation must be a model of *DelaunayMeshTraits_2*.

Requirement: The face of the constrained Delaunay triangulation must be a model of the concept *DelaunayMeshFaceBase_2*. *Criteria* must be a model of the concept *MeshingCriteria_2* and *CDT::Face_handle* must be the same as *Criteria::Face_handle*.

template <class CDT, class Criteria, class InputIterator>
void *refine_Delaunay_mesh_2(CDT& t,*
InputIterator begin,
InputIterator end,
Criteria criteria = Criteria(),
bool mark = false)

Refines the default domain defined by a constrained Delaunay triangulation into a mesh satisfying the criteria defined by the traits *criteria*.The sequence [*begin*, *end*] gives a set of seeds points, that defines the domain to be meshed as follows. The constrained edges of *t* partition the plane into connected components. If *mark=true*, the mesh domain is the union of the bounded connected components including at least one seed. If *mark=false*, the domain is the union of the bounded components including no seed. Note that the unbounded component of the plane is never meshed.

Requirement: The *value_type* of *begin* and *end* is *CDT::Geom_traits::Point_2*.

CGAL::Triangulation_conformer_2<CDT>

Class

The class *Triangulation_conformer_2<CDT>* is an auxiliary class of *Delaunay_mesher_2<CDT>*. It permits to refine a constrained Delaunay triangulation into a conforming Delaunay or conforming Gabriel triangulation. For standard needs, consider using the global functions *make_conforming_Gabriel_2* and *make_conforming_Delaunay_2*.

#include <CGAL/Triangulation_conformer_2.h>

Parameters

The template parameter *CDT* should be a model of the concept *ConstrainedDelaunayTriangulation_2*.

The geometric traits class of the instance of *CDT* has to be a model of the concept *ConformingDelaunayTriangulationTraits_2*.

Using this class

The constructor of the class *Triangulation_conformer_2<CDT>* takes a reference to a *CDT* as an argument. A call to the method *make_conforming_Delaunay()* or *make_conforming_Gabriel()* will refine this constrained Delaunay triangulation into a conforming Delaunay or conforming Gabriel triangulation. Note that if, during the life time of the *Triangulation_conformer_2<CDT>* object, the triangulation is externally modified, any further call to its member methods may lead to undefined behavior. Consider reconstructing a new *Triangulation_conformer_2<CDT>* object if the triangulation has been modified.

The conforming methods insert points into constrained edges, thereby splitting them into several subconstraints. You have access to the initial inserted constraints if you instantiate the template parameter by a *CGAL::Constrained_triangulation_plus_2<CDT>*.

Creation

Triangulation_conformer_2<CDT> m(CDT& t);

Create a new conforming maker, working on *t*.

Operations

Conforming methods

void	*m.make_conforming_Delaunay()*	Refines the triangulation into a conforming Delaunay triangulation. After a call to this method, all triangles fulfill the Delaunay property, that is the empty circle property.

void *m.make_conforming_Gabriel()*

Refines the triangulation into a conforming Gabriel triangulation. After a call to this method, all constrained edges *e* have the *Gabriel property*: the circle with diameter *e* does not contain any vertex of the triangulation.

Checking

The following methods verify that the constrained triangulation is conforming Delaunay or conforming Gabriel. These methods scan the whole triangulation and their complexity is proportional to the number of edges.

bool *m.is_conforming_Delaunay()*

Returns *true* iff all triangles fulfill the Delaunay property.

bool *m.is_conforming_Gabriel()*

Returns *true* iff all constrained edges have the Gabriel property: their circumsphere is empty.

advanced

Step by step operations

The *Triangulation_conformer_2<CDT>* class allows, for debugging or demos, to play the conforming algorithm step by step, using the following methods. They exist in two versions, depending on whether you want the triangulation to be conforming Delaunay or conforming Gabriel, respectively. Any call to a *step_by_step_conforming_XX* function requires a previous call to the corresponding function *init_XX* and Gabriel and Delaunay methods can not be mixed between two calls of *init_XX*.

void *m.init_Delaunay()* The method must be called after all points and constrained segments are inserted and before any call to the following methods. If some points or segments are then inserted in the triangulation, this method must be called again.

bool *m.step_by_step_conforming_Delaunay()*

Applies one step of the algorithm, by inserting one point, if the algorithm is not done. Returns *false* iff no point has been inserted because the algorithm is done.

void *m.init_Gabriel()* Analog to *init_Delaunay* for Gabriel conforming.

bool *m.step_by_step_conforming_Gabriel()*

Analog to *step_by_step_conforming_Delaunay()* for Gabriel conforming.

bool *m.is_conforming_done()*

Tests if the step by step conforming algorithm is done. If it returns *true*, the following calls to *step_by_step_conforming_XX* will not insert any points, until some new constrained segments or points are inserted in the triangulation and *init_XX* is called again.

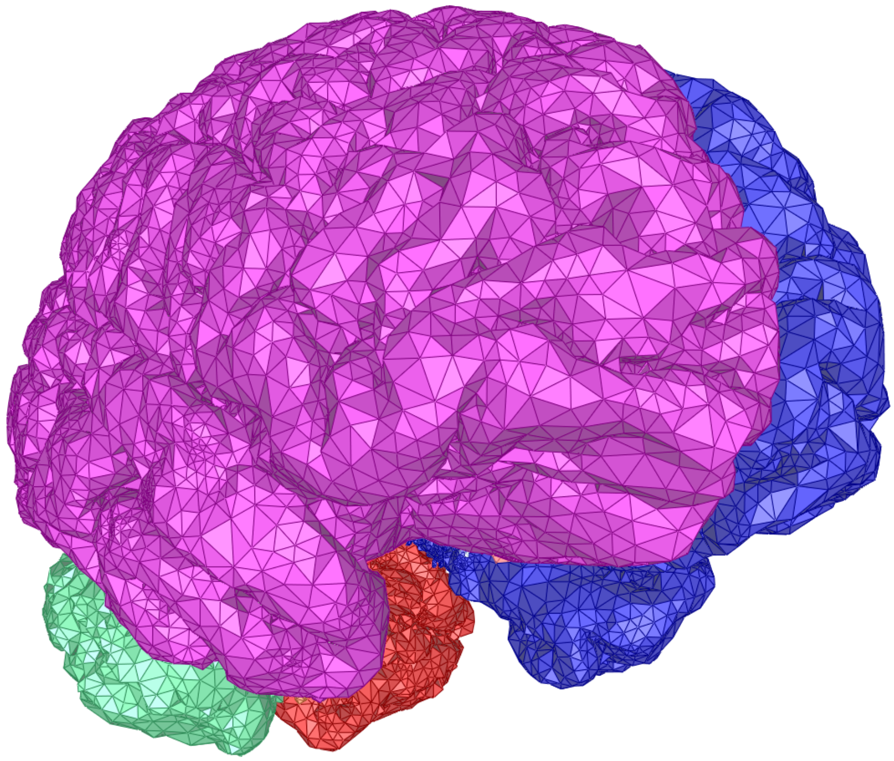
Chapter 48

3D Surface Mesh Generation

Laurent Rineau and Mariette Yvinec

Contents



48.1 Introduction

This package provides a function template to compute a triangular mesh approximating a surface.

The meshing algorithm requires to know the surface to be meshed only through an oracle able to tell whether a given segment, line or ray intersects the surface or not and to compute an intersection point if any. This feature makes the package generic enough to be applied in a wide variety of situations. For instance, it can be used to mesh implicit surfaces described as the zero level set of some function. It may also be used in the field of medical imaging to mesh surfaces described as a gray level set in a three dimensional image.

The meshing algorithm is based on the notion of the restricted Delaunay triangulation. Basically the algorithm computes a set of sample points on the surface, and extract an interpolating surface mesh from the three dimensional triangulation of these sample points. Points are iteratively added to the sample, as in a Delaunay refinement process, until some size and shape criteria on the elements of the surface mesh are satisfied.

The size and shape criteria guide the behavior of the refinement process and control its termination. They also condition the size and shape of the elements in the final mesh. Naturally, those criteria can be customized to satisfy the user needs. The *Surface mesh generation* package offers a set of standard criteria that can be scaled through three numerical values. Also the user can also plug in its own set of refinement criteria.

There is no restriction on the topology and number of components of the surface provided that the oracle (or the user) is able to provide one initial sample point on each connected component. If the surface is smooth enough, and if the size criteria are small enough, the algorithm guarantees that the output mesh is homeomorphic to the surface, and is within a small bounded distance (Hausdorff or even Frechet distance) from the surface. The algorithm can also be used for non smooth surfaces but then there is no guarantee.

48.2 The Surface Mesh Generator Interface for Smooth Surfaces

The meshing process is launched through a call to a function template. There are two overloaded versions of the meshing function whose signatures are the following:

template <class SurfaceMeshC2T3, class Surface, class FacetsCriteria, class Tag >
void make_surface_mesh(
SurfaceMeshC2T3& c2t3,
Surface surface,
FacetsCriteria criteria,
Tag)

template <class SurfaceMeshC2T3, class SurfaceMeshTraits, class FacetsCriteria, class Tag >
void make_surface_mesh(
SurfaceMeshC2T3& c2t3,
SurfaceMeshTraits::Surface_3 surface,
SurfaceMeshTraits traits,
FacetsCriteria criteria,
Tag)

The template parameter *SurfaceMeshC2T3* stands for a data structure type that is used to store the surface mesh. This type is required to be a model of the concept *SurfaceMeshComplex_2InTriangulation_3*. Such a data structure has a pointer to a three dimensional triangulation and encodes the surface mesh as a subset of facets in this triangulation. An argument of type *SurfaceMeshC2T3* is passed by reference to the meshing function. This argument holds the output mesh at the end of the process.

The template parameter *Surface* stands for the surface type. This type has to be a model of the concept *Surface_3*.

The knowledge on the surface, required by the surface mesh generator is encapsulated in a traits class. Actually, the mesh generator accesses the surface to be meshed through this traits class only. The traits class is required to be a model of the concept *SurfaceMeshTraits_3*. The difference between the two overloaded versions of *make_surface_mesh* can be explained as follows

- In the first overloaded version of *make_surface_mesh*, the surface type is given as template parameter (*Surface*) and the *surface* to be meshed is passed as parameter to the mesh generator. In that case the surface mesh generator traits type is automatically generated from the surface type by an auxiliary class called the *Surface_mesh_traits_generator_3*.
- In the second overloaded version of *make_surface_mesh*, the surface mesh generator traits type is provided by the template parameter *SurfaceMeshTraits_3* and the surface type is obtained from this traits type. Both a surface and a traits are passed to the mesh generator as arguments.

The first overloaded version can be used whenever the surface type either provides a nested type *Surface::Surface_mesher_traits_3* that is a model of *SurfaceMeshTraits_3* or is a surface type for which a specialization of the traits generator *Surface_mesh_traits_generator_3<Surface>* is provided. Currently, the library provides partial specializations of *Surface_mesher_traits_generator_3<Surface>* for implicit surfaces (*Implicit_surface_3<Traits, Function>*) and gray level images (*Gray_level_image_3<FT, Point>*).

The parameter *criteria* handles the description of the size and shape criteria driving the meshing process. The template parameter *FacetsCriteria* has to be instantiated by a model of the concept *SurfaceMeshFacetsCriteria*.

The parameter *Tag* is a tag whose type influences the behavior of the meshing algorithm. For instance, this parameter can be used to enforce the manifold property of the output mesh while avoiding an over-refinement of the mesh. Further details on this subject are given in Section 48.4.

A call to *make_surface_mesh(c2t3,surface, criteria, tag)* launches the meshing process with an initial set of points which is the union of two subsets: the set of vertices in the initial triangulation pointed to by *c2t3*, and a set of points provided by the *Construct_initial_points()* functor of the traits class. This initial set of points is required to include at least one point on each connected component of the surface to be meshed.

48.3 Examples

48.3.1 Meshing Isosurfaces defined by Implicit Functions

The first code example meshes a sphere given as the zero level set of a function $\mathbb{R}^3 \longrightarrow \mathbb{R}$. More precisely, the surface to be meshed is created by the constructor of the class *Implicit_surface_3<Kernel, Function>* from a pointer to the function (*sphere_function*) and a bounding sphere.

The default meshing criteria are determined by three numerical values:

- *angular_bound* is a lower bound in degrees for the angles of mesh facets.
- *radius_bound* is an upper bound on the radii of surface Delaunay balls. A surface Delaunay ball is a ball circumscribing a mesh facet and centered on the surface.
- *distance_bound* is an upper bound for the distance between the circumcenter of a mesh facet and the center of a surface Delaunay ball of this facet.

Given this surface type, the surface mesh generator will use an automatically generated traits class.

The resulting mesh is shown in Figure 48.1.

```
#include <CGAL/Surface_mesh_default_triangulation_3.h>
#include <CGAL/Complex_2_in_triangulation_3.h>
#include <CGAL/make_surface_mesh.h>
#include <CGAL/Implicit_surface_3.h>

// default triangulation for Surface_mesher
typedef CGAL::Surface_mesh_default_triangulation_3 Tr;

// c2t3
typedef CGAL::Complex_2_in_triangulation_3<Tr> C2t3;

typedef Tr::Geom_traits GT;
typedef GT::Sphere_3 Sphere_3;
typedef GT::Point_3 Point_3;
typedef GT::FT FT;

typedef FT (*Function)(Point_3);

typedef CGAL::Implicit_surface_3<GT, Function> Surface_3;

FT sphere_function (Point_3 p) {
```

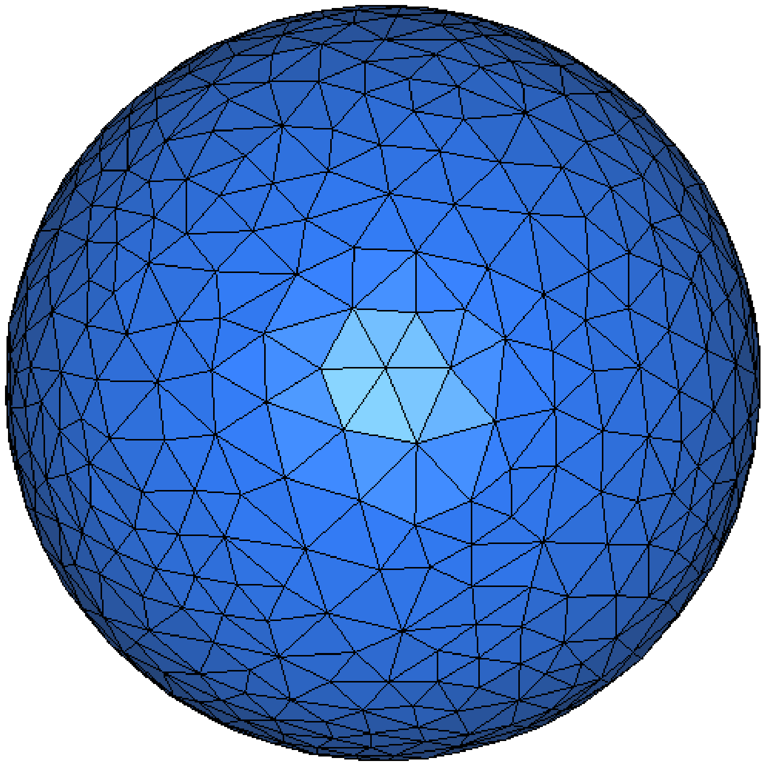


Figure 48.1: Surface mesh of a sphere

```
  const FT x2=p.x()*p.x(), y2=p.y()*p.y(), z2=p.z()*p.z();
  return x2+y2+z2-1;
}

int main() {
  Tr tr;            // 3D-Delaunay triangulation
  C2t3 c2t3 (tr);   // 2D-complex in 3D-Delaunay triangulation

  // defining the surface
  Surface_3 surface(sphere_function,             // pointer to function
                    Sphere_3(CGAL::ORIGIN, 2.)); // bounding sphere
  // Note that "2." above is the *squared* radius of the bounding sphere!

  // defining meshing criteria
  CGAL::Surface_mesh_default_criteria_3<Tr> criteria(30.,  // angular
   bound
                                                     0.1,  // radius
   bound
                                                     0.1); // distance
   bound
  // meshing surface
  CGAL::make_surface_mesh(c2t3, surface, criteria,
   CGAL::Non_manifold_tag());

   "\n";
```

```
}
```

File: examples/Surface_mesher/mesh_an_implicit_function.cpp

48.3.2 Meshing Isosurfaces Defined as Gray Levels in 3D Images

In this example the surface to be meshed is defined as the locus of points with a given gray level in a 3D image. The code is quite similar to the previous example.

The main difference with the previous code is that the function used to define the surface is an object of type *CGAL::Gray_level_image_3* created from an image file and a numerical value that is the gray value of the level one wishes to mesh.

Note that surface, which is still an object of type *Implicit_surface_3* is now, defined by three parameters that are the function, the bounding sphere and a numerical value called *the precision*. This precision, whose value is relative to the bounding sphere radius, is used in the intersection computation. This parameter has a default which was used in the previous example. Also note that the center of the bounding sphere is required to be internal a point where the function has a negative value.

The chosen iso-value of this 3D image corresponds to a head skull. The resulting mesh is shown in Figure 48.2.

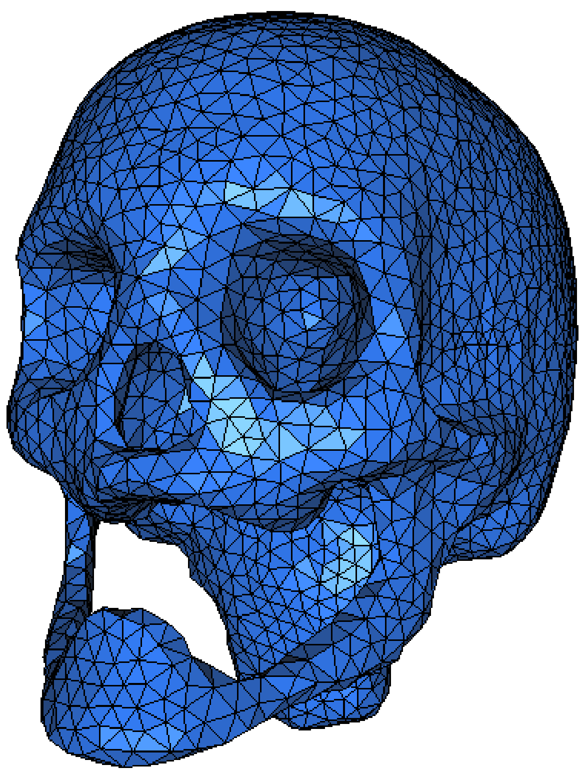

Figure 48.2: Surface mesh of an iso-contour extracted from a gray level 3D image

```
#include <CGAL/Surface_mesh_default_triangulation_3.h>
#include <CGAL/Surface_mesh_default_criteria_3.h>
#include <CGAL/Complex_2_in_triangulation_3.h>
```

```
#include <CGAL/IO/Complex_2_in_triangulation_3_file_writer.h>
#include <fstream>
#include <CGAL/make_surface_mesh.h>
#include <CGAL/Gray_level_image_3.h>
#include <CGAL/Implicit_surface_3.h>

// default triangulation for Surface_mesher
typedef CGAL::Surface_mesh_default_triangulation_3 Tr;

// c2t3
typedef CGAL::Complex_2_in_triangulation_3<Tr> C2t3;

typedef Tr::Geom_traits GT;
typedef CGAL::Gray_level_image_3<GT::FT, GT::Point_3> Gray_level_image;
typedef CGAL::Implicit_surface_3<GT, Gray_level_image> Surface_3;

int main() {
  Tr tr;            // 3D-Delaunay triangulation
  C2t3 c2t3 (tr);   // 2D-complex in 3D-Delaunay triangulation

  // the 'function' is a 3D gray level image
  Gray_level_image image("data/skull_2.9.inr", 2.9f);

  // Carefully choosen bounding sphere: the center must be inside the
  // surface defined by 'image' and the radius must be high enough so
   that
  // the sphere actually bounds the whole image.
  GT::Point_3 bounding_sphere_center(122., 102., 117.);
  GT::FT bounding_sphere_squared_radius = 200.*200.*2.;
  GT::Sphere_3 bounding_sphere(bounding_sphere_center,
                                   bounding_sphere_squared_radius);

  // definition of the surface, with 10^-5 as relative precision
  Surface_3 surface(image, bounding_sphere, 1e-5);

  // defining meshing criteria
  CGAL::Surface_mesh_default_criteria_3<Tr> criteria(30.,
                                                      5.,
                                                      5.);

  // meshing surface, with the "manifold without boundary" algorithm
  CGAL::make_surface_mesh(c2t3, surface, criteria, CGAL::Manifold_tag());
  std::ofstream out("out.off");
  CGAL::output_surface_facets_to_off (out, c2t3);
  std::cout << "Final number of points: " << tr.number_of_vertices() <<
   "\n";
}
```

File: examples/Surface_mesher/mesh_a_3d_gray_image.cpp

48.4 Meshing Criteria, Guarantees and Variations

The guarantees on the output mesh depend on the mesh criteria. Theoretical guarantees are given in [BO05]. First, the meshing algorithm is proved to terminate if the lower bound on facets angles is not bigger than 30 degrees. Furthermore, the output mesh is guaranteed to be homeomorphic to the surface, and there is a guaranteed bound on the distance (Hausdorff and even Frechet distance) between the mesh and the surface if the radius bound is everywhere smaller than ε times the local feature size. Here ε is a constant that has to be less than 0.16, and the local feature size $lfs(x)$ is defined on each point x of the surface as the distance from x to the medial axis. Note that the radius bound need not be uniform, although it is a uniform bound in the default criteria.

Naturally, such a theoretical guarantee can be only achieved for smooth surfaces that have a finite, non zero reach value. (The reach of a surface is the minimum value of local feature size on this surface).

The value of the local feature size on any point of the surface or its minimum on the surface it usually unknown although it can sometimes be guessed. Also it happens frequently that setting the meshing criteria so as to fulfill the theoretical conditions yields an over refined mesh. On the other hand, when the size criteria are relaxed, no homeomorphism with the input surface is guaranteed, and the output mesh is not even guaranteed to be manifold. To remedy this problem and give a more flexible meshing algorithm, the function template *make_surface_mesh* has a tag template parameter allowing to slightly change the behavior of the refinement process. This feature allows, for instance, to run the meshing algorithm with a relaxed size criteria, more coherent with the size of the mesh expected by the user, and still have a guarantee that the output mesh forms a manifold surface. The function *make_surface_mesh* has specialized versions for the following tag types:
Manifold_tag: the output mesh is guaranteed to be a manifold surface without boundary.
Manifold_with_boundary_tag: the output mesh is guaranteed to be manifold but may have boundaries.
Non_manifold_tag: the algorithm relies on the given criteria and guarantees nothing else.

48.5 Output

This CGAL component also provides functions to write the reconstructed surface mesh to the Object File Format (OFF) [Phi96] and to convert it to a polyhedron (when it is manifold):
CGAL::output_surface_facets_to_off
CGAL::output_surface_facets_to_polyhedron

48.6 Undocumented Features Available in Demos

The Polyhedron demo has a feature that allows to remesh a polyhedral surface, using the 3D Surface Mesh Generator. That has been implemented as a special model of *SurfaceMeshTraits_3*, for polyhedra. That traits class is not yet documented because its interface and code have not yet been stabilized. It will probably be shipped with next release of CGAL.

The Surface Mesh Generator demo allows to mesh not only gray level images, but also segmented images, when voxels are labelled with a domain index. Such images are for example the result of a segmentation of 3D medical images. This feature is not yet ready to be documented in current release, but will probably be in next release of CGAL.

48.7 Design and Implementation History

The algorithm implemented in this package is mainly based on the work of Jean-Daniel Boissonnat and Steve Oudot [BO05]. Steve Oudot implemented a first working prototype of the algorithm during his PhD thesis.

The meshing algorithm is implemented using the design of mesher levels described in [RY07].

David Rey, Steve Oudot and Andreas Fabri have participated in the development of this package.

3D Surface Mesh Generation Reference Manual

Laurent Rineau and Mariette Yvinec

The surface mesh generation package offers a function template which builds a triangular mesh approximating a surface.

The meshing algorithms requires to know the surface to be meshed through an oracle that mainly can tell whether a given segment, ray or line intersects the surface or not and can compute the compute the intersections point if any. The oracle is represented by a traits class which can be passed to the meshing function or automatically generated for certain types of surfaces. The current implementation provides traits classes to mesh implicit surfaces as well as surfaces described as a gray level in a three dimensional image.

The output mesh conforms to some size and shape criteria which are customizable. The criteria are passed to the mesher through a parameter whose type is a model of the concept *SurfaceMeshFacetsCriteria_3*.

The meshing algorithm is a Delaunay refinement process which is mainly guided by the criteria. The output mesh may offer some guarantees, as being manifold, homeomorphic to the surface or within a given Hausdorff distance. However, these guarantees depend on the quality of the input surface (smoothness, with or without boundary, manifold or not), the type and values of the given criteria. The behavior of the refinement process can also be influenced through a tag, which allows for instance to enforce the manifold property of the output mesh while avoiding an over-refinement of the mesh.

Class

CGAL::Gray_level_image_3<FT, Point>

Definition

A 3D gray image is a tri-dimensional array that associates a scalar value to each triple of integer (x, y, z) in the range of the image. A trilinear interpolation algorithm provides a map $f : \mathbb{R}^3 \longrightarrow \mathbb{R}$.

The class *Gray_level_image_3<FT, Point>* is a 3D gray image loader and a model of the concept *ImplicitFunction*. An object of the class *Gray_level_image_3<FT, Point>* is created with a parameter *iso* and then its *operator()* implements the function *sign of (f(p) - iso)*, for $p \in \mathbb{R}^3$. Plugging such a function in the creation of the *Implicit_surface_3* object given as parameter to *make_surface_mesh* yields a mesh approximating the level with value *iso* in the input 3D gray image.

Gray_level_image_3<FT, Point> provides an interface with an auxiliary library called *CGALimageIO*. An executable that uses *Gray_level_image_3<FT, Point>* must be linked with the *CGALimageIO* library. This library is shipped with CGAL and will be linked automatically by any makefile created by the script *cgal_create_makefile*.

The library *CGALimageIO* and therefore *Gray_level_image_3<FT, Point>* support several types of 3D images: INRIMAGE (extension .inr[.gz]), GIS (extension .dim, of .ima[.gz]), and ANALYZE (extension .hdr, or .img[.gz]).

#include <CGAL/Gray_level_image_3.h>

Is Model for the Concepts

ImplicitFunction

Types

Gray_level_image_3<FT, Point>:: FT	the numerical type *FT*
Gray_level_image_3<FT, Point>:: FT	the point type *Point*

Creation

Gray_level_image_3<FT, Point> image(const char filename, FT iso_value);*

filename is the path to a file of a type supported by *ImageIO*.
iso_value is an isovalue of f.

ImplicitFunction

Concept

Definition

The concept ImplicitFunction describes a function object whose *operator()* computes the values of a function $f : \mathbb{R}^3 \longrightarrow \mathbb{R}$.

Types

ImplicitFunction:: FT	Number type
ImplicitFunction:: Point	Point type

Operations

FT	*function(Point p)*	Returns the value $f(p)$, where $p \in \mathbb{R}^3$.

Has Models

Gray_level_image_function,
any pointer to a function of type *FT (*)(Point)*.

Class

CGAL::Implicit_surface_3<Traits, Function>

Definition

The class *Implicit_surface_3<Traits, Function>* implements a surface described as the zero level set of a function $f : \mathbb{R}^3 \longrightarrow \mathbb{R}$.

For this type of surface, the library provides a partial specialization of the surface mesher traits generator: *Surface_mesh_traits_generator_3<Implicit_surface_3<Traits, Function> >*, that provides a traits class, model of the concept *SurfaceMeshTraits_3*, to be used by the surface mesher.

The parameter *Traits* is a traits class that has to be implemented with a model of *ImplicitSurfaceTraits_3*. Actually, this traits class implements the oracle needed by the surface mesher: the types, predicates and constructors provided in *Traits* are passed by the surface mesher traits generator to the generated the traits class used by the surface mesh generator.

The template parameter *Function* stands for a model of the concept *ImplicitFunction*. The number type *Function::FT* has to match the type *Traits::FT*.

#include <CGAL/Implicit_surface_3.h>

Creation

Implicit_surface_3<Traits, Function> surface(Function f, Sphere_3 bounding_sphere, FT error_bound = FT(1e-3))

f is the object of type *Function* that represents the implicit surface.
bounding_sphere is a bounding sphere of the implicit surface. The evaluation of f at the center c of this sphere must be negative: $f(c) < 0$.
error_bound is a relative error bound used to compute intersection points between the implicit surface and query segments. This bound is used in the default generated traits class. In this traits class, the intersection points between the surface and segments/rays/line are constructed by dichotomy. The dichotomy is stopped when the size of the intersected segment is less than the product of *error_bound* by the radius of *bounding_sphere*.

ImplicitSurfaceTraits_3

Definition

The concept ImplicitSurfaceTraits_3 describes the requirements of the traits class to be plugged as *Traits* in *Implicit_surface_3<Traits, Function>*.

When *make_surface_mesh* is called with a surface of type *Implicit_surface_3<Traits,Function>*, the surface mesher traits generator generates automatically a traits class that is a model of *SurfaceMeshTraits_3*. Actually, the concept ImplicitSurfaceTraits_3 provides the types, predicates and constructors that are passed to the generated model of *SurfaceMeshTraits_3*.

Types

ImplicitSurfaceTraits_3:: FT	The numerical type. It must be model of *SqrtFieldNumberType* and constructible from a *double*.
ImplicitSurfaceTraits_3:: Point_3	The point type. This point type must have a constructor *Point_3(FT, FT, FT)*.
ImplicitSurfaceTraits_3:: Line_3	The line type.
ImplicitSurfaceTraits_3:: Ray_3	The ray type.
ImplicitSurfaceTraits_3:: Segment_3	The segment type.
ImplicitSurfaceTraits_3:: Vector_3	The vector type.
ImplicitSurfaceTraits_3:: Sphere_3	The sphere type.

ImplicitSurfaceTraits_3:: Compute_scalar_product_3

A function object that provides the operator
FT operator()(Vector_3 v, Vector_3 w) which returns the scalar (inner) product of the two vectors *v* and *w*.

ImplicitSurfaceTraits_3:: Compute_squared_distance_3

A function object that provides the operator
FT operator()(Point_3, Point_3) which returns the squared distance between two points.

ImplicitSurfaceTraits_3:: Compute_squared_radius_3

A function object providing the operator
FT operator()(const Sphere_3& s) which returns the squared radius of *s*.

ImplicitSurfaceTraits_3:: Construct_center_3

A function object providing the operator
Point_3 operator()(const Sphere_3& s) which computes the center of the sphere *s*.

ImplicitSurfaceTraits_3:: Construct_midpoint_3

A function object providing the operator
Point_3 operator()(const Point_3& p, const Point_3& q) which computes the midpoint of the segment *pq*.

ImplicitSurfaceTraits_3:: Construct_point_on_3

A function object providing the following operators:
Point_3 operator()(const Line_3& l,int i); which returns an arbitrary point on *l*. It holds *point(i) == point(j)*, iff *i==j*. Furthermore, is directed from *point(i)* to *point(j)*, for all $i < j$.
Point_3 operator()(const Ray_3& r,int i); which returns a point on *r*. *point(0)* is the source, *point(i)*, with $i > 0$, is different from the source.
Precondition: $i \geq 0$.
Point_3 operator()(const Segment_3& s,int i); which returns source or target of *s*: *point(0)* returns the source of *s*, *point(1)* returns the target of *s*. The parameter *i* is taken modulo 2, which gives easy access to the other end point.

ImplicitSurfaceTraits_3:: Construct_segment_3

A function object providing the operators
Segment_3 operator()(const Point_3 &p, const Point_3 &q); which returns a segment with source *p* and target *q*. It is directed from the source towards the target.

ImplicitSurfaceTraits_3:: Construct_scaled_vector_3

A function object providing the operator
Vector_3 operator()(const Vector_3 &v, const FT& scale) which returns the vector *v* scaled by a factor *scale*.

ImplicitSurfaceTraits_3:: Construct_translated_point_3

A function object providing the operator
Point_3 operator()(const Point_3& p, const Vector_3& v) which returns the point obtained by translating *p* by the vector *v*.

ImplicitSurfaceTraits_3:: Construct_vector_3

A function object providing the operator
Vector_3 operator()(const Point_3 &a, const Point_3 &b) which returns the vector *b-a*.

ImplicitSurfaceTraits_3:: Has_on_bounded_side_3

A function object providing the operator
bool operator()(const Sphere_3&s, const Point_3&p); which returns true iff *p* lies on the bounded side of *s*.

Operations

The following functions give access to the predicate and construction objects:

Compute_scalar_product_3	*traits.compute_scalar_product_3_object()*
Compute_squared_distance_3	*traits.compute_squared_distance_3_object()*
Compute_squared_radius_3	*traits.compute_squared_radius_3_object()*
Construct_center_3	*traits.construct_center_3_object()*
Construct_midpoint_3	*traits.construct_midpoint_3_object()*
Construct_point_on_3	*traits.construct_point_on_3_object()*
Construct_scaled_vector_3	*traits.construct_scaled_vector_3_object()*
Construct_segment_3	*traits.construct_segment_3_object()*
Construct_translated_point_3	*traits.construct_translated_point_3_object()*
Construct_vector_3	*traits.construct_vector_3_object()*
Has_on_bounded_side_3	*traits.has_on_bounded_side_3_object()*

CGAL::make_surface_mesh

#include <CGAL/make_surface_mesh.h>

Definition

The function *make_surface_mesh* is a surface mesh generator, that is a function to build a two dimensional mesh approximating a surface.

The library provides two overloaded version of this function:

template <class SurfaceMeshC2T3, class Surface, class FacetsCriteria, class Tag >
void make_surface_mesh(SurfaceMeshC2T3& c2t3,
Surface surface,
FacetsCriteria criteria,
Tag,
int initial_number_of_points = 20)

template <class SurfaceMeshC2T3, class SurfaceMeshTraits, class FacetsCriteria, class Tag >
void make_surface_mesh(SurfaceMeshC2T3& c2t3,
SurfaceMeshTraits::Surface_3 surface,
SurfaceMeshTraits traits,
FacetsCriteria criteria,
Tag,
int initial_number_of_points = 20)

Parameters

The template parameter *SurfaceMeshC2T3* is required to be a model of the concept *SurfaceMeshComplex_2InTriangulation_3*, a data structure able to represent a two dimensional complex embedded in a three dimensional triangulation. The argument *c2t3* of type *SurfaceMeshC2T3*, passed by reference to the surface mesh generator, is used to maintain the current approximating mesh and it stores the final mesh at the end of the procedure. The type *SurfaceMeshC2T3* is in particular required to provide a type *SurfaceMeshC2T3::Triangulation_3* for the three dimensional triangulation embedding the surface mesh. The vertex and cell base classes of the triangulation *SurfaceMeshC2T3::Triangulation_3* are required to be models of the concepts *SurfaceMeshVertexBase_3* and *SurfaceMeshCellBase_3* respectively.

The template parameter *Surface* stands for the surface type. This type has to be a model of the concept *Surface_3*.

The knowledge on the surface, required by the surface mesh generator is encapsulated in a traits class. Actually, the mesh generator accesses the surface to be meshed through this traits class only. The traits class is required to be a model of the concept *SurfaceMeshTraits_3*.

In the first version of *make_surface_mesh* the surface type is a template parameter *Surface* and the surface mesh generator traits type is automatically generated form the surface type through the class *Surface_mesh_traits_generator_3<Surface>*.

The difference between the two overloaded versions of *make_surface_mesh* can be explained as follows

- In the first overloaded version of of *make_surface_mesh*, the surface type is given as template parameter (*Surface*) and the *surface* to be meshed is passed as parameter to the mesh generator. In that case the surface mesh generator traits type is automatically generated form the surface type by an auxiliary class called the *Surface_mesh_traits_generator_3*.
- In the second overloaded version of *make_surface_mesh*, the surface mesh generator traits type is provided by the template parameter *SurfaceMeshTraits_3* and the surface type is obtained from this traits type. Both the surface and the traits are passed to the mesh generator as arguments.

The first overloaded version can be used whenever the surface type either provides a nested type *Surface::Surface_mesher_traits_3* that is a model of *SurfaceMeshTraits_3* or is a surface type for which a specialization of the traits generator *Surface_mesh_traits_generator_3*<*Surface*> is provided. Currently, the library provides partial specializations of *Surface_mesher_traits_generator_3*<*Surface*> for implicit surfaces (*Implicit_surface_3*<*Traits, Function*>) and gray level images (*Gray_level_image_3*<*FT, Point*>).

The template parameter *FacetsCriteria* has to be a model of the concept *SurfaceMeshFacetsCriteria_3*. The argument of type *FacetsCriteria* passed to the surface mesh generator specifies the size and shape requirements on the output surface mesh.

The template parameter *Tag* is a tag whose type affects the behavior of the meshing algorithm. The function *make_surface_mesh* has specialized versions for the following tag types:
- *Manifold_tag*: the output mesh is guaranteed to be a manifold surface without boundary.
- *Manifold_with_boundary_tag*: the output mesh is guaranteed to be manifold but may have boundaries.
- *Non_manifold_tag*: the algorithm relies on the given criteria and guarantees nothing else.

The Delaunay refinement process is started with an initial set of points which is the union of two sets: the set of vertices in the initial triangulation pointed to by the *c2t3* argument and a set of points provided by the traits class. The optional parameter *initial_number_of_points* allows to monitor the number of points in this second set. (This parameter is passed to the *operator()* of the constructor object *Construct_initial_points* in the traits class.) The meshing algorithm requires that the initial set of points includes at least one point on each connected components of the surface to be meshed. one.

Surface_3

Concept

Definition

The concept Surface_3 describes the types of surfaces to be meshed. The surface types are required to be copy constructible and assignable.

Types

In addition, surface types are required

- either to provide a nested type: *Surface_3:: Surface_mesher_traits_3* a model of *SurfaceMesherTraits_3*
- or to be a surface type for which a specialization of the traits generator *Surface_mesh_traits_generator_3<Surface>* exists.

SurfaceMeshCellBase_3

Concept

Definition

The concept SurfaceMeshCellBase_3 describes the cell base type of the three dimensional triangulation used to embed the surface mesh.

More precisely, the first template parameter *SurfaceMeshC2T3* of the surface mesher *make_surface_mesh* is a model of the concept *SurfaceMeshComplex_2InTriangulation_3* which describes a data structure to store a pure two dimensional complex embedded in a three dimensional triangulation. In particular, the type *SurfaceMeshC2T3* is required to provide a three dimensional triangulation type *SurfaceMeshC2T3::Triangulation_3*. The concept SurfaceMeshCellBase_3 describes the cell base type required in this triangulation type.

Refines

TriangulationCellBase_3

The concept SurfaceMeshCellBase_3 adds four markers to mark the facets of the triangulation that belong to the two dimensional complex, and four markers that are helpers used in some operations to mark for instance the facets that have been visited.

This concept also provides storage for the center of a Delaunay surface ball. Given a surface and a 3D Delaunay triangulation, a Delaunay surface ball is a ball circumscribed to a facet of the triangulation and centered on the surface and empty of triangulation vertices. Such a ball does exist when the facet is part of the restriction to the surface of a three dimensional triangulation. In the following we call *surface center* of a facet, the center of its biggest Delaunay surface ball.

Types

SurfaceMeshCellBase_3:: Point	The point type, required to match the point type of the three dimensional triangulation in which the surface mesh is embedded.

Creation

Operations

bool *cell.is_facet_on_surface(int i)*

returns *true*, if *facet(i)* is in the 2D complex.

void *cell.set_facet_on_surface(int i, bool b)*

Sets *facet(i)* as part of the 2D complex, if *b* is *true*, and *NOT_IN_COMPLEX*, otherwise.

bool *cell.is_facet_visited(int i)*

Returns *true*, if *facet(i)* has been visited, *false* otherwise.

void	*cell.set_facet_visited(int i, bool b)*	
		Marks *facet(i)* as visited, if *b* is *true*, and non visited otherwise.
Point	*cell.get_facet_surface_center(int i)*	
		Returns a const reference to the surface center of *facet(i)*.
void	*cell.set_facet_surface_center(int i, Point p)*	
		Sets point *p* as the surface center of *facet(i)*.

CGAL::Surface_mesh_complex_2_in_triangulation_3<Tr, Edge_info = void>

Class

Definition

The class *Surface_mesh_complex_2_in_triangulation_3<Tr, Edge_info = void>* implements a data structure to store the restricted Delaunay triangulation used by the surface mesh generator. The restricted Delaunay triangulation is stored as a two dimensional complex embedded in a three dimensional triangulation.

The class *Surface_mesh_complex_2_in_triangulation_3<Tr, Edge_info = void>* is a model of the concept *SurfaceMeshComplex_2InTriangulation_3* and can be plugged as the template parameter *C2T3* in the function template *make_surface_mesh*.

The template parameter *Tr* has to be instantiated with a model of the concept *SurfaceMeshTriangulation_3*. (Any three dimensional triangulation of CGAL is a model of *Triangulation_3* provided that its vertex and cell base class be models of the concept *SurfaceMeshVertexBase_3* and *SurfaceMeshCellBase_3* respectively.)

SurfaceMeshComplex_2InTriangulation_3

Definition

The concept SurfaceMeshComplex_2InTriangulation_3 describes a data structure designed to represent a two dimensional pure complex embedded in a three dimensional triangulation.

A *complex* is a set C of faces such that:
- any subface of a face in C is a face of C
- two faces of C are disjoint or share a common subface
The complex is *two dimensional*, if its faces have dimension at most two. It is *pure* if any face in the complex is a subface of some face of maximal dimension. Thus, a two dimensional pure complex is a set of facets together with their edges and vertices. A two dimensional pure complex embedded in a three dimensional triangulation is a subset of the facets of this triangulation, together with their edges and vertices.

The concept SurfaceMeshComplex_2InTriangulation_3 is particularly suited to handle surface meshes obtained as the restriction to a surface of a three dimensional Delaunay triangulation. A model of this concept is a type to be plugged as first template parameter in the function template *make_surface_mesh*.

Types

SurfaceMeshComplex_2InTriangulation_3 provides the following types.

SurfaceMeshComplex_2InTriangulation_3:: Triangulation

The type of the embedding 3D triangulation. Must be a model of *SurfaceMeshTriangulation_3*.

typedef Triangulation::Vertex_handle

Vertex_handle; The type of the embedding triangulation vertex handles.

typedef Triangulation::Cell_handle

Cell_handle; The type of the embedding triangulation cell handles.

typedef Triangulation::Facet

Facet; The type of the embedding triangulation facets.

typedef Triangulation::Edge

Edge; The type of the embedding triangulation edges.

typedef Triangulation::size_type

size_type; Size type (an unsigned integral type) *enum Face_status* { *NOT_IN_COMPLEX, BOUNDARY, REGULAR, SINGULAR*}*;*

A type to describe the status of a face (facet, edge, or vertex) with respect to the 2D pure complex. A *NOT_IN_COMPLEX* face does not belong to the 2D complex. Facets can only be *NOT_IN_COMPLEX* or *REGULAR* depending on whether they belong to the 2D complex on not. Edges and vertices can be *NOT_IN_COMPLEX*, *BOUNDARY*, *REGULAR* or *SINGULAR*. An edge in the complex is *BOUNDARY*, *REGULAR*, or *SINGULAR*, if it is incident to respectively 1, 2, or 3 or more facets in the complex. The status of a vertex is determined by the adjacency graph of the facets of the 2D complex incident to that vertex. The vertex of the 2D complex is *BOUNDARY*, if this adjacency graph is a simple path, it is *REGULAR*, if the adjacency graph is cyclic, and *SINGULAR* in any other case.

SurfaceMeshComplex_2InTriangulation_3:: Facet_iterator

An iterator type to visit the facets of the 2D complex.

SurfaceMeshComplex_2InTriangulation_3:: Edge_iterator

An iterator type to visit the edges of the 2D complex.

SurfaceMeshComplex_2InTriangulation_3:: Vertex_iterator

An iterator type to visit vertices of the 2D complex.

SurfaceMeshComplex_2InTriangulation_3:: Boundary_edges_iterator

An iterator type to visit the boundary edges of the 2D complex.

Creation

SurfaceMeshComplex_2InTriangulation_3 c2t3(Triangulation& t3);

Builds an empty 2D complex embedded in the triangulation *t3*

template < class FacetSelector>
SurfaceMeshComplex_2InTriangulation_3 c2t3(Triangulation& t3, FacetSelector select);

Builds a 2D complex embedded in the triangulation *t3*, including in the 2D complex the facets of *t3* for which the predicate *select* returns *true*.
The type *FacetSelector* must be a function object with an operator to select facets: *bool operator()(Facet f);*.

Member access

Triangulation&	*c2t3.triangulation()*	Returns the reference to the triangulation.

Modifications

void *c2t3.add_to_complex(Facet f)*

Adds facet *f* to the 2D complex.

void *c2t3.add_to_complex(Cell_handle c, int i)*

Adds facet *(c,i)* to the 2D complex.

void *c2t3.remove_from_complex(Facet f)*

Removes facet *f* from the 2D complex.

void *c2t3.remove_from_complex(Cell_handle c, int i)*

Removes facet *(c,i)* from the 2D complex.

Queries

Queries on the status of individual face with respect to the 2D complex.

size_type *c2t3.number_of_facets() const*

Returns the number of facets that belong to the 2D complex.

Face_status *c2t3.face_status(Facet f)*

Returns the status of the facet *f* with respect to the 2D complex.

Face_status *c2t3.face_status(Cell_handle c, int i)*

Returns the status of the facet *(c,i)* with respect to the 2D complex.

Face_status *c2t3.face_status(Edge e)*

Returns the status of edge *e* in the 2D complex.

Face_status *c2t3.face_status(Cell_handle c, int i, int j)*

Returns the status of edge *(c,i,j)* in the 2D complex.

Face_status *c2t3.face_status(Vertex_handle v)*

Returns the status of vertex *v* in the 2D complex.

bool *c2t3.is_in_complex(Facet f)*

Returns *true*, if the facet *f* belongs to the 2D complex.

bool	*c2t3.is_in_complex(Cell_handle c, int i)*	
		Returns *true*, if the facet *(c,i)* belongs to the 2D complex.
bool	*c2t3.is_in_complex(Edge e)*	
		Returns *true*, if the edge *e* belongs to the 2D complex.
bool	*c2t3.is_in_complex(Cell_handle c, int i, int j)*	
		Returns *true*, if the edge *(c,i,j)* belongs to the 2D complex.
bool	*c2t3.is_in_complex(Vertex_handle v)*	
		Returns *true*, if the vertex *v* belongs to the 2D complex.
bool	*c2t3.is_regular_or_boundary_for_vertices(Vertex_handle v)*	
		Returns true if the status of vertex *v* is *REGULAR* or *BOUNDARY*. *Precondition*: All the edges of the complex incident to *v* are *REGULAR* or *BOUNDARY*.

Traversal of the complex

The data structure provides iterators to visit the facets, edges and vertices of the complex. All those iterators are bidirectional and non mutable.

Facet_iterator	*c2t3.facets_begin()*	Returns an iterator with value type *Facet* to visit the facets of the 2D complex.
Facet_iterator	*c2t3.facets_end()*	Returns the past the end iterator for the above iterator.
Edge_iterator	*c2t3.edges_begin()*	Returns an iterator with value type *Edge* to visit the edges of the 2D complex which are not isolated.
Edge_iterator	*c2t3.edges_end()*	Returns the past the end iterator for the above iterator.
Boundary_edges_iterator		
	c2t3.boundary_edges_begin()	
		Returns an iterator with value type *Edge* to visit the boundary edges of the complex.
Boundary_edges_iterator		
	c2t3.boundary_edges_end()	
		Returns the past the end iterator for the above iterator.
Vertex_iterator	*c2t3.vertices_begin()*	Returns an iterator with value type *Vertex_handle* to visit the vertices of the 2D complex.
Vertex_iterator	*c2t3.vertices_end()*	Returns the past the end iterator for the above iterator.

template <class OutputIterator>

OutputIterator *c2t3.incident_facets(Vertex_handle v, OutputIterator facets)*

Copies the *Facet*s of the complex incident to v to the output iterator *facets*. Returns the resulting output iterator.
Precondition: *c2t3.triangulation().dimension()* $= 3$, $v \neq$ *Vertex_handle()*, *c2t3.triangulation().is_vertex(v)*.

The following function is the basic function to walk on the 2D complex

Facet *c2t3.neighbor(Facet f, int j)*

Returns the facet of the complex which is the neighbor of the facet f opposite to the vertex with index j of f. The vertices of the facet f = *(cell c, i)* are numbered (0,1,2) (according to the *vertex_triple_index(i,j)* member function of *Triangulation_3*) in such a way that facet f is oriented by the outward normal of tetraedra c. If there is no such neighbor, or if the edge is singular the functions returns *Facet()*.

Facet *c2t3.neighbor(Cell_handle c, int i, int j)*

Returns the facet of the complex which is the neighbor of the facet f opposite to the vertex with index j of f. See above.

SurfaceMeshFacetsCriteria_3

Concept

Definition

The Delaunay refinement process involved in the function template *make_surface_mesh* is guided by a set of refinement criteria. The concept SurfaceMeshFacetsCriteria_3 describes the type which handles those criteria. It corresponds to the requirements for the template parameter *FacetsCriteria* of the surface mesher function *make_surface_mesh<SurfaceMeshC2T3,Surface,FacetsCriteria,Tag>* .

Typically the meshing criteria are a set of elementary criteria, each of which has to be met by the facets of the final mesh. The meshing algorithm eliminates in turn *bad* facets, i.e., facets that do not meet all the criteria.

The size and quality of the final mesh depends on the order according to which bad facets are handled. Therefore, the meshing algorithm needs to be able to quantify the facet qualities and to compare the qualities of different faces. The concept SurfaceMeshFacetsCriteria_3 defines a type *Quality* designed to measure the quality of a mesh facet. Typically this quality is a multicomponent variable. Each component corresponds to one criterion and measures how much the facet deviates from meeting this criterion. Then, the comparison operator on qualities is just a lexicographical comparison. The meshing algorithm handles facets with lowest quality first. The qualities are computed by a function *is_bad(Facet f, Quality& q)*.

Types

SurfaceMeshFacetsCriteria_3:: Facet	The type of facets. This type has to match the *Facet* type in the triangulation type used by the mesher function. (This triangulation type is the type *SurfaceMeshC2T3::Triangulation* provided by the model of *SurfaceMeshComplex_2InTriangulation_3* plugged as first template parameter of *make_surface_mesh*).
SurfaceMeshFacetsCriteria_3:: Quality	Default constructible, copy constructible, assignable, and less-than comparable type.

Operations

bool *criteria.is_bad(Facet f, Quality& q)*

Assigns the quality of the facet *f* to *q*, and returns *true* is *f* does not meet the criteria.

make_surface_mesh<SurfaceMeshC2T3,Surface,FacetsCriteria,Tag>

Class

CGAL::Surface_mesh_default_criteria_3<Tr>

Definition

The class *Surface_mesh_default_criteria_3<Tr>* implements the most commonly used combination of meshing criteria. It involves mainly three criteria which are in order:

- a lower bound on the minimum angle in degrees of the surface mesh facets.
- an upper bound on the radius of surface Delaunay balls. A surface Delaunay ball is a ball circumscribing a facet, centered on the surface and empty of vertices. Such a ball exists for each facet of the current surface mesh. Indeed the current surface mesh is the Delaunay triangulation of the current sampling restricted to the surface which is just the set of facets in the three dimensional Delaunay triangulation of the sampling that have a Delaunay surface ball.
- an upper bound on the center-center distances of the surface mesh facets. The center-center distance of a surface mesh facet is the distance between the facet circumcenter and the center of its surface Delaunay ball.

#include <CGAL/Surface_mesh_default_criteria_3.h>

Class

Concept

SurfaceMeshTraits_3

Definition

The concept SurfaceMeshTraits_3 describes the knowledge that is required on the surface to be meshed. A model of this concept implements an oracle that is able to tell whether a segment (or a ray, or a line) intersects the surface or not and to compute some intersection points if any. The concept SurfaceMeshTraits_3 also includes a constructor able to provide a small set of initial points on the surface.

Types

SurfaceMeshTraits_3:: Point_3	The type of points. This type is required to match the point type of the three dimensional embedding triangulation *C2T3::Triangulation_3*.
SurfaceMeshTraits_3:: Segment_3	The type of segments.
SurfaceMeshTraits_3:: Ray_3	The type of rays.
SurfaceMeshTraits_3:: Line_3	The type of lines.
SurfaceMeshTraits_3:: Surface_3	The surface type.
SurfaceMeshTraits_3:: Intersect_3	A model of this type provides the operator *CGAL::Object operator()(Surface_3 surface, Type1 type1)* to compute the intersection of the surface with an object of type *Type1* which may be *Segment_3*, *Ray_3* or *Line_3* .

SurfaceMeshTraits_3:: Construct_initial_points

A model of this type provides the following operators to construct initial points on the surface:
template <class OutputIteratorPoints>
OutputIteratorPoints operator()(OutputIteratorPoints pts)
which outputs a set of points on the surface,
template <class OutputIteratorPoints>
OutputIteratorPoints operator() (OutputIteratorPoints pts, int n)
which outputs a set of *n* points on the surface.

Operations

The following functions give access to the construction objects:

Intersect_3	*traits.intersect_3_object()*
Construct_initial_points	*traits.construct_initial_points_object()*

Class

CGAL::Surface_mesh_traits_generator_3<Surface>

Definition

The class *Surface_mesh_traits_generator_3<Surface>* provides a type *Type*, that is a model of the concept *SurfaceMeshTraits_3* for the surface type *Surface*.

The type *Surface* is required to be a model of the concept *Surface_3*, which means that it is copy constructible and assignable. In addition, a *Surface* type is required

- either to provide a nested type *Surface::Surface_mesher_traits_3* that is a model of *SurfaceMeshTraits_3*
- or to be a surface type for which a specialization of the traits generator *Surface_mesh_traits_generator_3<Surface>* exists.

Currently, the library provides partial specializations of the traits generator for implicit surfaces (*Implicit_surface_3<Traits, Function>*) and gray level images (*Gray_level_image_3<FT, Point>*).

#include <CGAL/Surface_mesh_traits_generator_3.h>

Surface_mesh_traits_generator_3<Surface>:: Type

SurfaceMeshTriangulation_3

Concept

Definition

The concept SurfaceMeshTriangulation_3 describes the triangulation type used by the surface mesher *make_surface_mesh* to represent the three dimensional triangulation embedding the surface mesh. Thus, this concept describes the requirements for the triangulation type *SurfaceMeshC2T3::Triangulation* nested in the model of *SurfaceMeshComplex2InTriangulation3* plugged as the template parameter *SurfaceMeshC2T3* of *make_surface_mesh*. It also describes the requirements for the triangulation type plugged in the class *Surface_mesh_complex_2_in_triangulation_3<Tr>*.

Types

SurfaceMeshTriangulation_3:: Point — The point type. It must be DefaultConstructible, CopyConstructible and Assignable.

Vertices and *cells* of the triangulation are manipulated via handles, which support the two dereference operators *operator** and *operator->*.

SurfaceMeshTriangulation_3:: Vertex_handle — Handle to a data representing a *vertex*. *Vertex_handle* must be a model of *Handle* and its *value type* must be model of *TriangulationDataStructure_3::Vertex*.

SurfaceMeshTriangulation_3:: Cell_handle — Handle to a data representing a *cell*. *Cell_handle* must be a model of *Handle* and its *value type* must be model of *TriangulationDataStructure_3::Cell*.

typedef CGAL::Triple<Cell_handle, int, int>
Edge; — The edge type.

typedef std::pair<Cell_handle, int>
Facet; — The facet type.

The following iterators allow one to visit all finite vertices, edges and facets of the triangulation.

SurfaceMeshTriangulation_3:: Finite_vertices_iterator

Iterator over finite vertices

SurfaceMeshTriangulation_3:: Finite_edges_iterator

Iterator over finite edges

SurfaceMeshTriangulation_3:: Finite_facets_iterator

Iterator over finite facets

SurfaceMeshTriangulation_3:: Geom_traits — The geometric traits class. Must be a model of *DelaunayTriangulationTraits_3*.

Creation

SurfaceMeshTriangulation_3 t;	default constructor.
SurfaceMeshTriangulation_3 t(tr);	Copy constructor. All vertices and faces are duplicated.

Assignment

SurfaceMeshTriangulation_3 &

	$t = tr$	The triangulation *tr* is duplicated, and modifying the copy after the duplication does not modify the original. The previous triangulation held by *t* is deleted.
void	*t.clear()*	Deletes all finite vertices and all cells of *t*.

Access Functions

int	*t.dimension() const*	Returns the dimension of the affine hull.

DelaunayTriangulationTraits_3

	t.geom_traits() const	Returns a const reference to a model of *DelaunayTriangulationTraits_3*.

Voronoi diagram

Object	*t.dual(Facet f) const*	Returns the dual of facet *f*, which is in dimension 3: either a segment, if the two cells incident to *f* are finite, or a ray, if one of them is infinite; in dimension 2: a point.

Queries

A point *p* is said to be in conflict with a cell *c* in dimension 3 (resp. a facet *f* in dimension 2) iff *t.side_of_sphere(c, p)* (resp. *t.side_of_circle(f, p)*) returns *ON_BOUNDED_SIDE*. The set of cells (resp. facets in dimension 2) which are in conflict with *p* is connected, and it forms a hole.

template <class OutputIteratorBoundaryFacets, class OutputIteratorCells, class OutputIteratorInternalFacets>

Triple<OutputIteratorBoundaryFacets, OutputIteratorCells, OutputIteratorInternalFacets>

t.find_conflicts(Point p,
Cell_handle c,
OutputIteratorBoundaryFacets bfit,
OutputIteratorCells cit,

OutputIteratorInternalFacets ifit)

Computes the conflict hole induced by p. The starting cell (resp. facet) c must be in conflict. Then this function returns respectively in the output iterators:
– *cit*: the cells (resp. facets) in conflict.
– *bfit*: the facets (resp. edges) on the boundary, that is, the facets (resp. edges) *(t, i)* where the cell (resp. facet) t is in conflict, but *t->neighbor(i)* is not.
– *ifit*: the facets (resp. edges) inside the hole, that is, delimiting two cells (resp facets) in conflict.
Returns the *Triple* composed of the resulting output iterators.

The following iterators allow the user to visit facets, edges and vertices of the triangulation.

Finite_vertices_iterator

t.finite_vertices_begin() const

Starts at an arbitrary finite vertex. Then ++ and -- will iterate over finite vertices. Returns *finite_vertices_end()* when *t.number_of_vertices()* $= 0$.

Finite_vertices_iterator

t.finite_vertices_end() const

Past-the-end iterator

Finite_edges_iterator *t.finite_edges_begin() const*

Starts at an arbitrary finite edge. Then ++ and -- will iterate over finite edges. Returns *finite_edges_end()* when *t.dimension()* < 1.

Finite_edges_iterator *t.finite_edges_end() const*

Past-the-end iterator

Finite_facets_iterator

t.finite_facets_begin() const

Starts at an arbitrary finite facet. Then ++ and -- will iterate over finite facets. Returns *finite_facets_end()* when *t.dimension()* < 2.

Finite_facets_iterator

t.finite_facets_end() const

Past-the-end iterator

template <class OutputIterator>

OutputIterator *t.incident_cells(Vertex_handle v, OutputIterator cells) const*

Copies the *Cell_handle*s of all cells incident to v to the output iterator *cells*. If *t.dimension()* < 3, then do nothing. Returns the resulting output iterator.
Precondition: $v \neq$ *Vertex_handle()*, *t.is_vertex(v)*.

template <class OutputIterator>
OutputIterator *t.incident_cells(Vertex_handle v, OutputIterator cells) const*

Copies the *Cell_handle*s of all cells incident to v to the output iterator *cells*. If *t.dimension()* < 3, then do nothing. Returns the resulting output iterator.

bool *t.is_vertex(Point p, Vertex_handle & v) const*

Tests whether p is a vertex of t by locating p in the triangulation. If p is found, the associated vertex v is given.

bool *t.is_edge(Vertex_handle u, Vertex_handle v, Cell_handle & c, int & i, int & j) const*

Tests whether *(u,v)* is an edge of t. If the edge is found, it gives a cell c having this edge and the indices i and j of the vertices u and v in c, in this order.
Precondition: u and v are vertices of t.

bool *t.is_infinite(const Vertex_handle v) const*

true, iff vertex v is the infinite vertex.

bool *t.is_infinite(const Cell_handle c) const*

true, iff c is incident to the infinite vertex.
Precondition: *t.dimension()* $= 3$.

Facet *t.mirror_facet(Facet f) const*

Returns the same facet viewed from the other adjacent cell.

int *t.vertex_triple_index(const int i, const int j)*

Return the indexes of the jth vertex of the facet of a cell opposite to vertex i.

Point location

Cell_handle *t.locate(Point query, Cell_handle start = Cell_handle())*

If the point *query* lies inside the convex hull of the points, the cell that contains the query in its interior is returned. If *query* lies on a facet, an edge or on a vertex, one of the cells having *query* on its boundary is returned.
If the point *query* lies outside the convex hull of the points, an infinite cell with vertices $\{p,q,r,\infty\}$ is returned such that the tetrahedron $(p,q,r,query)$ is positively oriented (the rest of the triangulation lies on the other side of facet (p,q,r)).
Note that locate works even in degenerate dimensions: in dimension 2 (resp. 1, 0) the *Cell_handle* returned is the one that represents the facet (resp. edge, vertex) containing the query point.
The optional argument *start* is used as a starting place for the search.

Cell_handle *t.locate(Point query,*
Locate_type & lt,
int & li,
int & lj,
Cell_handle start = Cell_handle())

If *query* lies inside the affine hull of the points, the *k*-face (finite or infinite) that contains *query* in its interior is returned, by means of the cell returned together with *lt*, which is set to the locate type of the query (*VERTEX, EDGE, FACET, CELL*, or *OUTSIDE_CONVEX_HULL* if the cell is infinite and *query* lies strictly in it) and two indices *li* and *lj* that specify the *k*-face of the cell containing *query*.
If the *k*-face is a cell, *li* and *lj* have no meaning; if it is a facet (resp. vertex), *li* gives the index of the facet (resp. vertex) and *lj* has no meaning; if it is and edge, *li* and *lj* give the indices of its vertices.
If the point *query* lies outside the affine hull of the points, which can happen in case of degenerate dimensions, *lt* is set to *OUTSIDE_AFFINE_HULL*, and the cell returned has no meaning. As a particular case, if there is no finite vertex yet in the triangulation, *lt* is set to *OUTSIDE_AFFINE_HULL* and *locate* returns the default constructed handle.
The optional argument *start* is used as a starting place for the search.

template <class CellIt>

Vertex_handle *t.insert_in_hole(Point p, CellIt cell_begin, CellIt cell_end, Cell_handle begin, int i)*

Creates a new vertex by starring a hole. It takes an iterator range [*cell_begin*; *cell_end*[of *Cell_handle*s which specifies a hole: a set of connected cells (resp. facets in dimension 2) which is star-shaped wrt p. (*begin*, i) is a facet (resp. an edge) on the boundary of the hole, that is, *begin* belongs to the set of cells (resp. facets) previously described, and *begin->neighbor(i)* does not. Then this function deletes all the cells (resp. facets) describing the hole, creates a new vertex v, and for each facet (resp. edge) on the boundary of the hole, creates a new cell (resp. facet) with v as vertex. Then *v->set_point(p)* is called and v is returned.

Precondition: *t.dimension()* ≥ 2, the set of cells (resp. facets in dimension 2) is connected, its boundary is connected, and p lies inside the hole, which is star-shaped wrt p.

SurfaceMeshVertexBase_3

Definition

The concept SurfaceMeshVertexBase_3 describes the vertex base type of the three dimensional triangulation used to embed the surface mesh.

More precisely, the first template parameter *SurfaceMeshC2T3* of the surface mesher *make_surface_mesh* is a model of the concept *SurfaceMeshComplex_2InTriangulation_3* which describes a data structure to store a pure two dimensional complex embedded in a three dimensional triangulation. In particular, the type *SurfaceMeshC2T3* is required to provide a three dimensional triangulation type *SurfaceMeshC2T3::Triangulation_3* The concept SurfaceMeshVertexBase_3 describes the vertex base type required in this triangulation type.

Refines

TriangulationVertexBase_3

The surface mesher algorithm issues frequent queries about the status of the vertices with respect to the two dimensional complex that represents the current surface approximation. The class SurfaceMeshVertexBase_3 offers a caching mechanism to answer more efficiently these queries. The caching mechanism includes two cached integers, which, when they are valid, store respectively the number of complex facets incident to the vertex and the number of connected components of the adjacency graph of those facets.

Creation

Operations

bool *vb.is_c2t3_cache_valid()*

Returns *true* if the cache is valid.

void *vb.invalidate_c2t3_cache()*

Invalidates the cache.

int *vb.cached_number_of_incident_facets()*

Returns the cached number of facets of the complex incident to the vertex.

int *vb.cached_number_of_components()*

This method concerns the adjacency graph of the facets of the complex incident to the vertex and returns a cached value for the number of connected components this graph.

Function

CGAL::output_surface_facets_to_polyhedron

Definition

output_surface_facets_to_polyhedron() converts a surface reconstructed by *make_surface_mesh()* to a *Polyhedron_3<Traits>*.

#include <CGAL/IO/output_surface_facets_to_polyhedron.h>

template<class SurfaceMeshComplex_2InTriangulation_3, class Polyhedron>
bool *output_surface_facets_to_polyhedron(SurfaceMeshComplex_2InTriangulation_3 c2t3, Polyhedron& output_polyhedron)*

Gets reconstructed surface out of a *SurfaceMeshComplex_2InTriangulation_3* object.
This variant exports the surface as a polyhedron. It requires the surface to be manifold. For this purpose, you may call *make_surface_mesh*() with *Manifold_tag* or *Manifold_with_boundary_tag* parameter.
Template Parameters:
SurfaceMeshComplex_2InTriangulation_3: model of the *SurfaceMeshComplex_2InTriangulation_3* concept. *Polyhedron*: an instance of *Polyhedron_3<Traits>*.
Returns: true if the surface is manifold and orientable.
Parameters:
c2t3: Input surface. *output_polyhedron*: Output polyhedron.

Chapter 49

Surface Reconstruction from Point Sets

Pierre Alliez, Laurent Saboret, Gaël Guennebaud

Contents

49.1 Introduction

This CGAL component implements a surface reconstruction method which takes as input point sets with oriented normals and computes an implicit function. We assume that the input points contain no outliers and little noise. The output surface mesh is generated by extracting an isosurface of this function with the CGAL Surface Mesh Generator [RY07] or potentially with any other surface contouring algorithm.

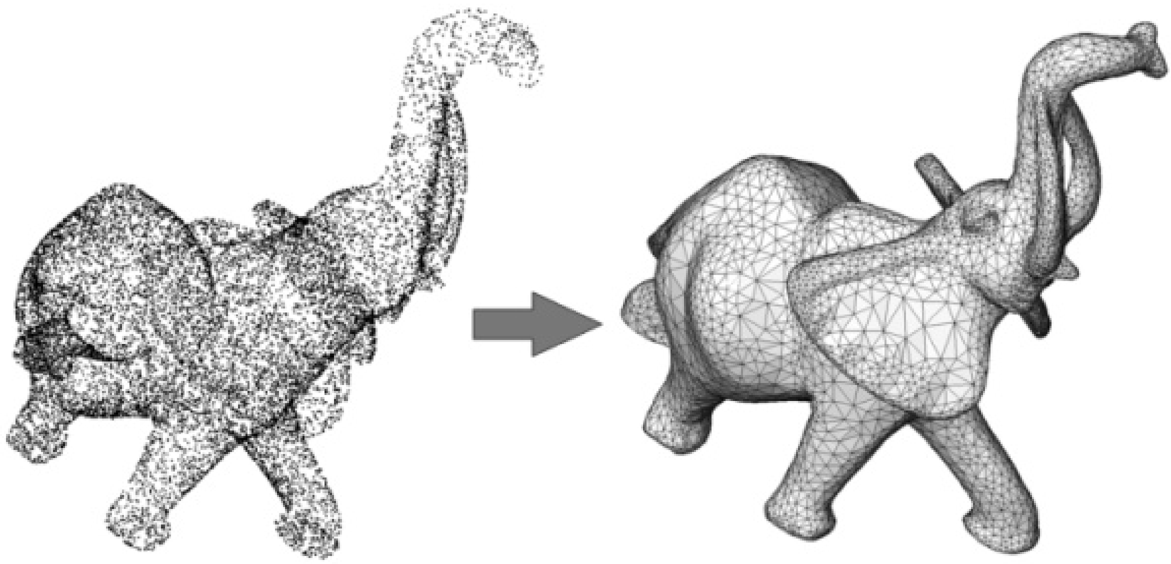

Figure 49.1: Poisson surface reconstruction. Left: 17K points sampled on the statue of an elephant with a Minolta laser scanner. Right: reconstructed surface mesh.

More specifically, the core surface reconstruction algorithm consists of computing an implicit function which is an approximate indicator function of the inferred solid (Poisson Surface Reconstruction - referred to as Poisson). Poisson is a two steps process: it requires solving for the implicit function before function evaluation.

49.2 Common Reconstruction Pipeline

Surface reconstruction from point sets is often a sequential process with the following steps: 1) Scanning and scan alignment produce a set of points or points with normals; 2) Outlier removal; 3) Simplification to reduce the number of input points; 4) Smoothing to reduce noise in the input data; 5) Normal estimation and orientation when the normals are not already provided by the acquisition device; and 6) Surface reconstruction.
CGAL provides algorithms for all steps listed above except alignment.
Chapter *Point_set_processing_3* 58 describes algorithms to pre-process the point set before reconstruction with functions devoted to the simplification, outlier removal, smoothing, normal estimation and normal orientation.

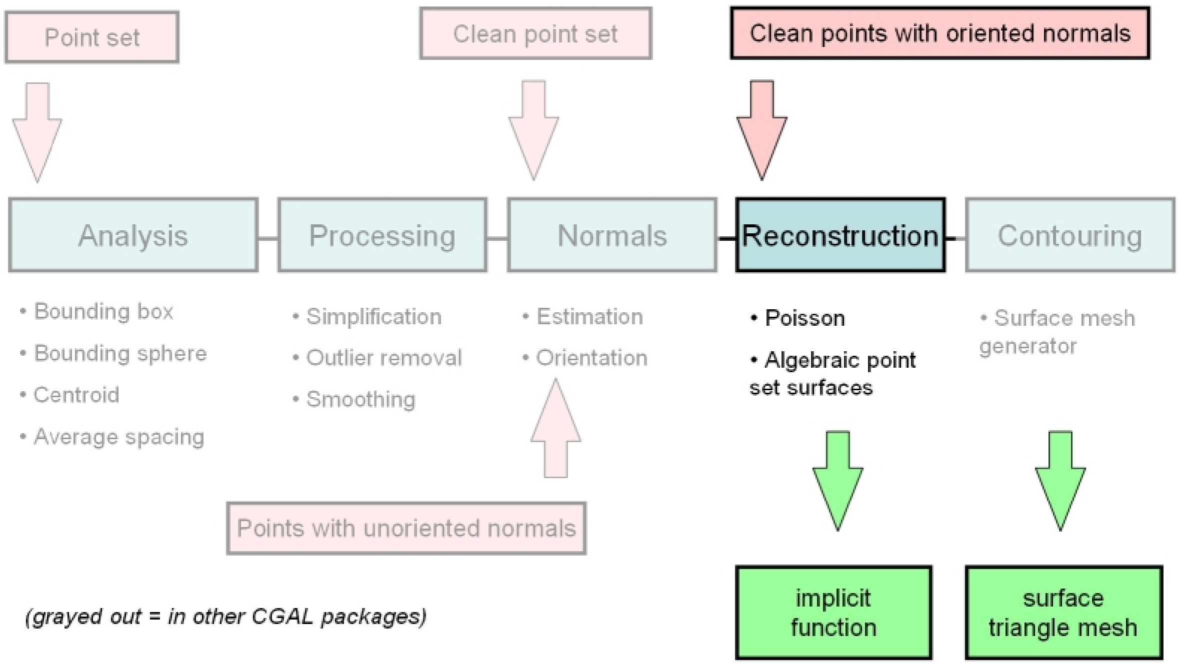

Figure 49.2: Common surface reconstruction pipeline.

49.3 Poisson

Given a set of 3D points with oriented normals (denoted oriented points in the sequel) sampled on the boundary of a 3D solid, the Poisson Surface Reconstruction method [KBH06] solves for an approximate indicator function of the inferred solid, whose gradient best matches the input normals. The output scalar function, represented in an adaptive octree, is then iso-contoured using an adaptive marching cubes.

CGAL implements a variant of this algorithm which solves for a piecewise linear function on a 3D Delaunay triangulation instead of an adaptive octree. The algorithm takes as input a set of 3D oriented points. It builds a 3D Delaunay triangulation from these points and refines it by Delaunay refinement so as to remove all badly shaped (non isotropic) tetrahedra and to tessellate a loose bounding box of the input oriented points. The normal of each Steiner point added during refinement is set to zero. It then solves for a scalar indicator function f represented as a piecewise linear function over the refined triangulation. More specifically, it solves for the Poisson equation $\Delta f = div(\mathbf{n})$ at each vertex of the triangulation using a sparse linear solver. Eventually, the CGAL surface mesh generator extracts an isosurface with function value set by default to be the median value of f at all input points.

49.3.1 Interface

The class template declaration is:

template<
class Gt>
class *Poisson_reconstruction_function*;

with
Gt: Geometric traits class.

Creation:

template<typename InputIterator, typename PointPMap, typename NormalPMap>
Poisson_reconstruction_function(InputIterator first, InputIterator beyond, PointPMap point_pmap, NormalPMap normal_pmap)

Creates a Poisson implicit function from the [first, beyond) range of points.
Template Parameters:
InputIterator: iterator over input points. *PointPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type* = *Point_3*. It can be omitted if *InputIterator value_type* is convertible to *Point_3*. *NormalPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type* = *Vector_3*.
Parameters:
first: iterator over the first input point. *beyond*: past-the-end iterator over the input points. *point_pmap*: property map to access the position of an input point. *normal_pmap*: property map to access the **oriented** normal of an input point.

The main operations are:

Sphere *bounding_sphere() const*

Returns a sphere bounding the inferred surface.

bool *compute_implicit_function()*

The function *compute_implicit_function*() must be called after each insertion of oriented points. It computes the piecewise linear scalar function operator() by: applying Delaunay refinement, solving for operator() at each vertex of the triangulation with a sparse linear solver, and shifting and orienting operator() such that it is 0 at all input points and negative inside the inferred surface.
Returns false if the linear solver fails.
The sparse solver used for this step is a parameter of the function. We recommend to use the class *CGAL::Eigen_solver_traits<T>* instantiated with the iterative conjugate gradient solver *Eigen::ConjugateGradient* for *double* (which is the default when Eigen (Page 28) is available and *CGAL_EIGEN3_ENABLED* is defined).

FT *value(Point p) const* Evaluates the implicit function at a given 3D query point.

Point *get_inner_point() const*

Returns an arbitrary point located inside the inferred surface.

See details in
CGAL::Poisson_reconstruction_function<GeomTraits>

49.3.2 Example

poisson_reconstruction_example.cpp reads a point set, creates a Poisson implicit function and reconstructs a surface.

49.4 Contouring

The computed implicit functions can be iso-contoured to reconstruct a surface by using the CGAL surface mesh generator [RY07, BO05]:
CGAL::make_surface_mesh

The parameter *Tag* affects the behavior of *make_surface_mesh()*:
- *Manifold_tag*: the output mesh is guaranteed to be a manifold surface without boundary.
- *Manifold_with_boundary_tag*: the output mesh is guaranteed to be manifold and may have boundaries.
- *Non_manifold_tag*: the output mesh has no guarantee and hence is outputted as a polygon soup.

49.5 Output

The surface reconstructed by *make_surface_mesh()* is required to be a model of the concept *SurfaceMeshComplex_2InTriangulation_3*, a data structure devised to represent a two dimensional complex embedded into a three dimensional triangulation.

SurfaceMeshComplex_2InTriangulation_3 defines the methods to traverse the reconstructed surface, and e.g. convert it to a triangle soup.

Other CGAL components provide functions to write the reconstructed surface mesh to the Object File Format (OFF) [Phi96] and to convert it to a polyhedron (when it is manifold):
CGAL::output_surface_facets_to_off
CGAL::output_surface_facets_to_polyhedron

See *poisson_reconstruction_example.cpp* example above.

49.6 Case Studies

The surface reconstruction problem being inherently ill-posed, the proposed algorithm does not pretend to reconstruct all kinds of surfaces with arbitrary sampling conditions. This section provides the user with some hints about the ideal sampling and contouring conditions, and depicts some failure cases when these conditions are not matched.

49.6.1 Ideal Conditions

The user must keep in mind that the poisson surface reconstruction algorithm comprises two phases (computing the implicit function from the input point set and contouring an iso-surface of this function). Both require some care in terms of sampling conditions and parameter tuning.

Point Set

Ideally the current implementation of the Poisson surface reconstruction method expects a dense 3D oriented point set (typically matching the epsilon-sampling condition [BO05]) and sampled over a closed, smooth surface. Oriented herein means that all 3D points must come with consistently oriented normals to the inferred surface. Figures 49.3 and 49.4 illustrate cases where these ideal conditions are met.

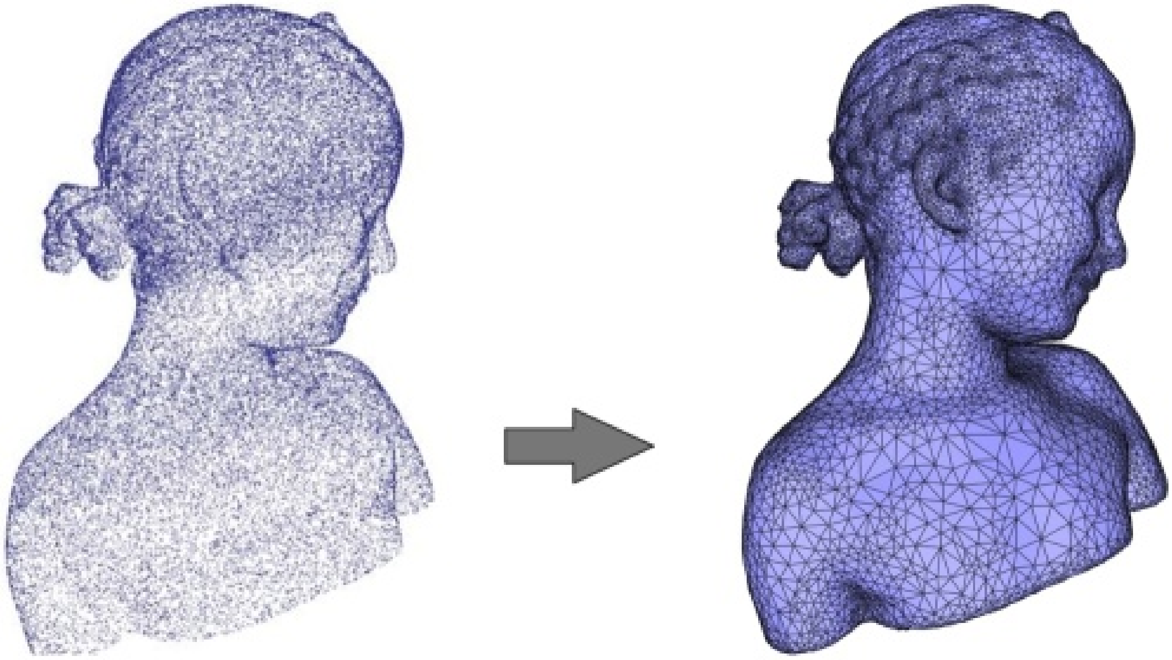

Figure 49.3: Poisson reconstruction. Left: 120K points sampled on a statue (Minolta laser scanner). Right: reconstructed surface mesh.

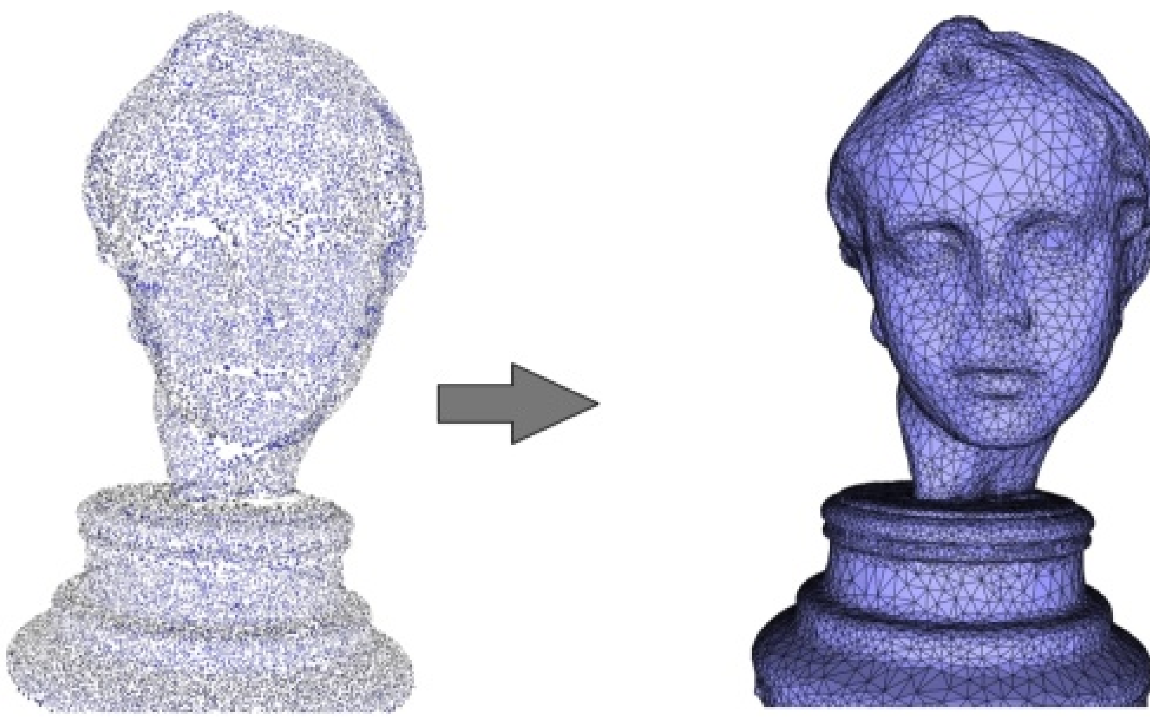

Figure 49.4: Left: 120K points sampled on a statue (Minolta laser scanner). Right: reconstructed surface mesh.

The algorithm is fairly robust to anisotropic sampling and to noise. It is also robust to missing data through filling the corresponding holes as the algorithm is designed to reconstruct the indicator function of an inferred solid (see Figure 49.5).

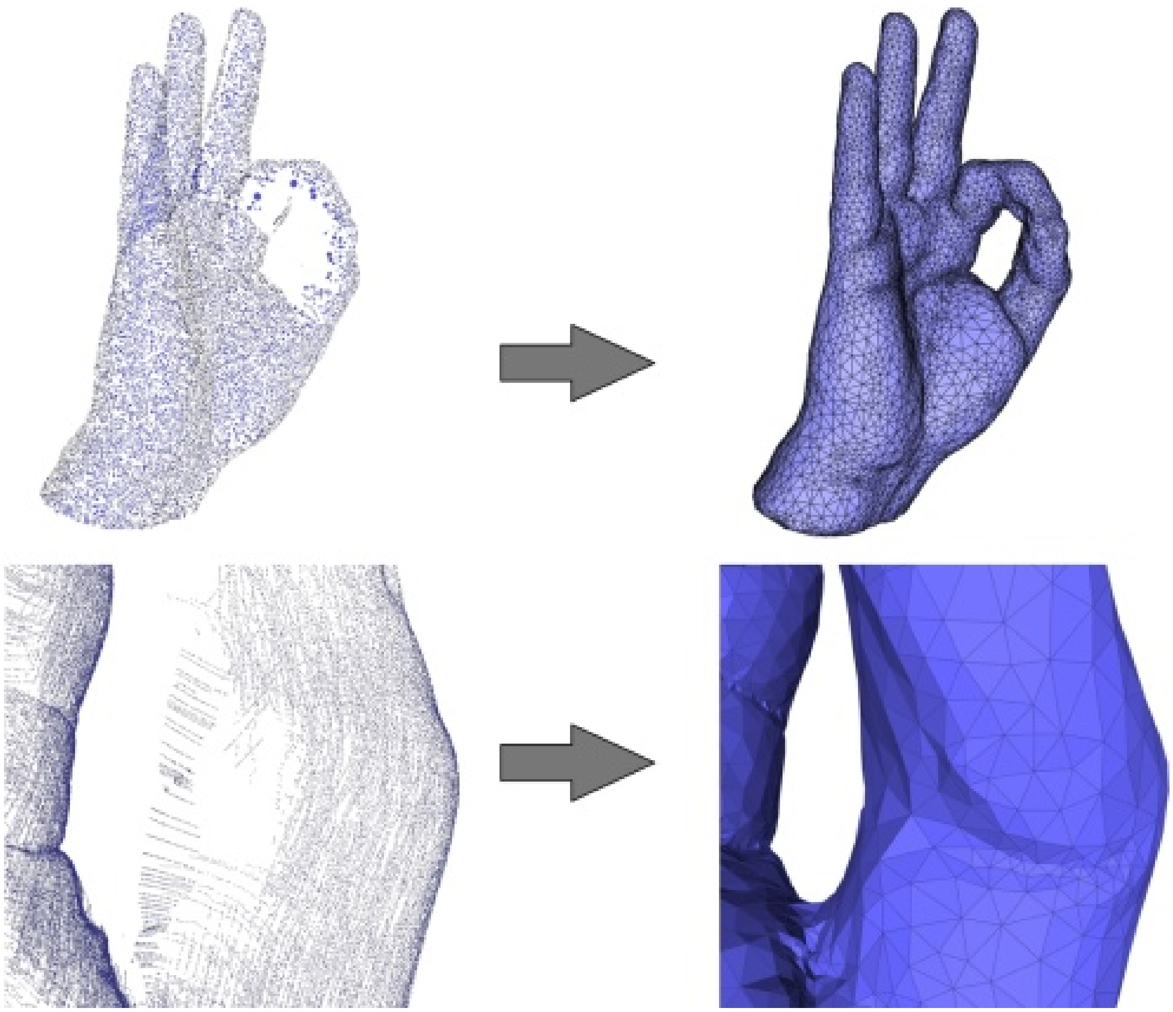

Figure 49.5: Top left: 65K points sampled on a hand (Kreon laser scanner). Bottom left: the point set is highly anisotropic due to the scanning technology. Right: reconstructed surface mesh and closeup. The holes are properly closed.

The algorithm is in general not robust to outliers, although a few outliers do not always create a failure, see Figure 49.6.

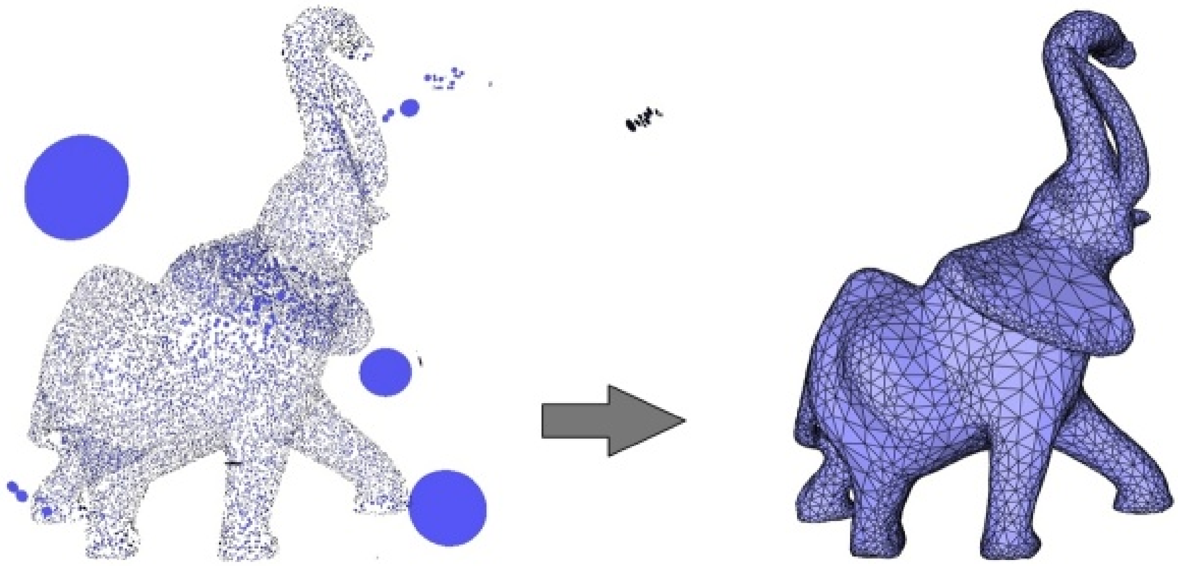

Figure 49.6: Left: 70K points sampled on an elephant with few outliers emphasized with disks. Right: reconstructed surface mesh.

The algorithm works well even when the inferred surface is composed of several connected components, provided that both all normals are properly estimated and oriented (the current CGAL normal orienter algorithm may fail in some cases, see *CGAL::mst_orient_normals()*), and that the final contouring algorithm is properly seeded for each component. When the inferred surface is composed of several nested connected components care should be taken to orient the normals of each component in alternation (inward/outward) so that the final contouring stage picks a proper contouring value.

Contouring Parameters

Our implementation of the Poisson surface reconstruction algorithm computes an implicit function represented as a piecewise linear function over the tetrahedra of a 3D Delaunay triangulation constructed from the input points then refined through Delaunay refinement. For this reason, any iso-surface is also piecewise linear and hence may contain sharp creases. As the contouring algorithm *CGAL::make_surface_mesh()* expects a smooth implicit function these sharp creases may create spurious clusters of vertices in the final reconstructed surface mesh when setting a small mesh sizing or surface approximation error parameter (see Figure 49.7).
One way to avoid these spurious clusters consists of adjusting the mesh sizing and surface approximation parameters large enough compared to the average sampling density (obtained through *CGAL::compute_average_spacing()*) so that the contouring algorithm "perceives" a smooth iso-surface. We recommend to use the following contouring parameters:

- Max triangle radius: at least 100 times the average spacing.
- Approximation distance: at least 0.25 times the average spacing.

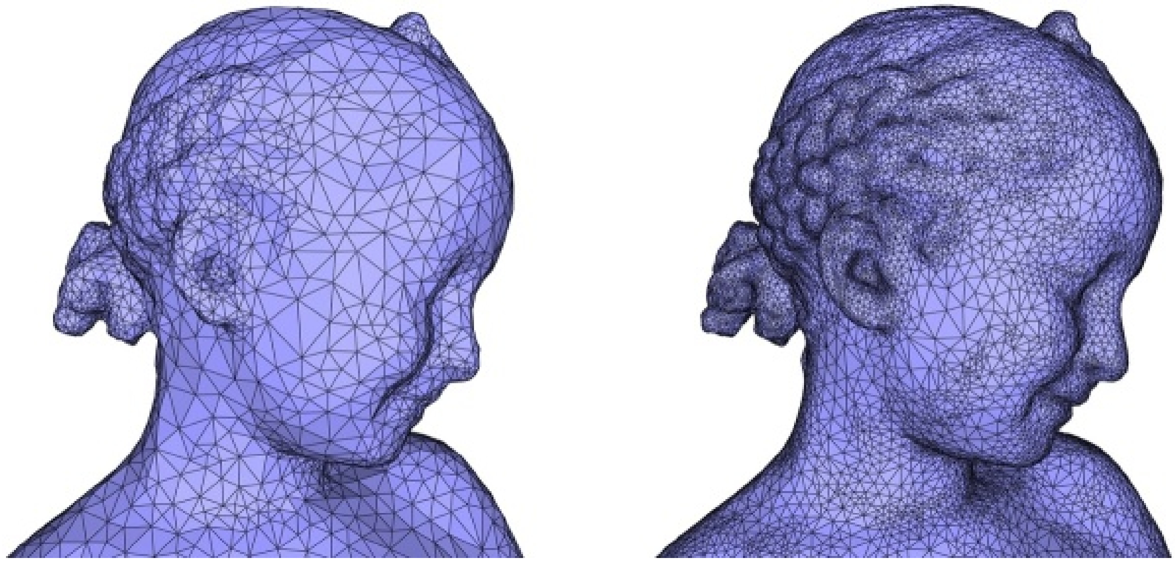

Figure 49.7: Left: surface reconstructed with approximation distance = 0.25 * average spacing. Right: surface reconstructed with approximation distance = 0.15 * average spacing. Notice the spurious cluster on the chick.

49.6.2 Degraded Conditions

The conditions listed above are rather restrictive and in practice not all of them are met in the applications. We now illustrates the behavior of the algorithm when the conditions are not met in terms of sampling, wrongly oriented normals, noise and sharp creases.

Sparse Sampling

The reconstruction algorithm expects a sufficiently dense point set. Although there is no formal proof of correctness of the algorithm under certain density conditions due to its variational nature, our experiments show that the algorithm reconstructs well all thin features when the local spacing is at most one tenth of the local feature size (the distance to the medial axis, which captures altogether curvature, thickness and separation). When this condition is not met the reconstruction does not reconstruct the thin undersampled features (see Figure 49.8).

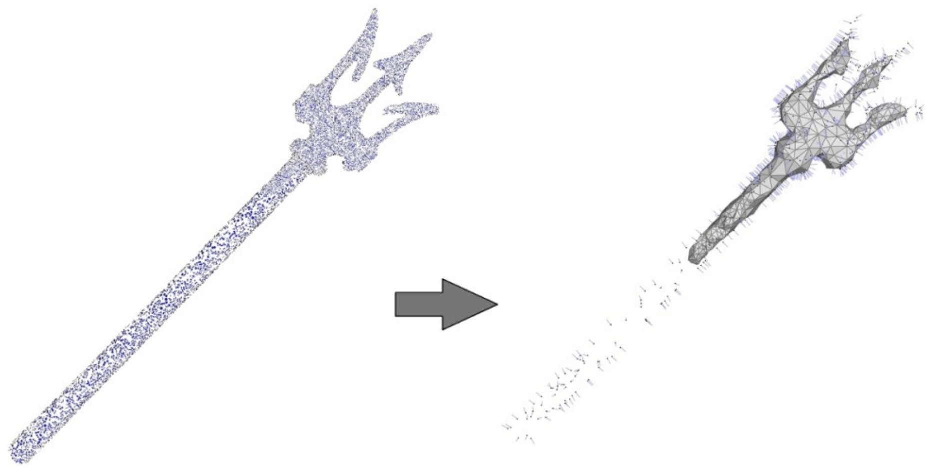

Figure 49.8: Left: 50K points sampled on the Neptune trident. The reconstruction (not shown) is successful in this case. Right: point set simplified to 1K points then reconstructed (all input points are depicted with normals). The thin feature is not reconstructed.

Large Holes

The reconstruction is devised to solve for an implicit function which is an approximate indicator function of an inferred solid. For this reason the contouring algorithm always extracts a closed surface mesh and hence is able to fill the small holes where data are missing due, e.g., to occlusions during acquisition. In case of large holes the algorithm still closes them all but sometimes in an unexpected manner. In addition the resulting piecewise linear implicit function may exhibit large triangle patches and sharp creases as the 3D Delaunay triangulation used for solving is very coarse where the holes are filled (see Figure 49.9).

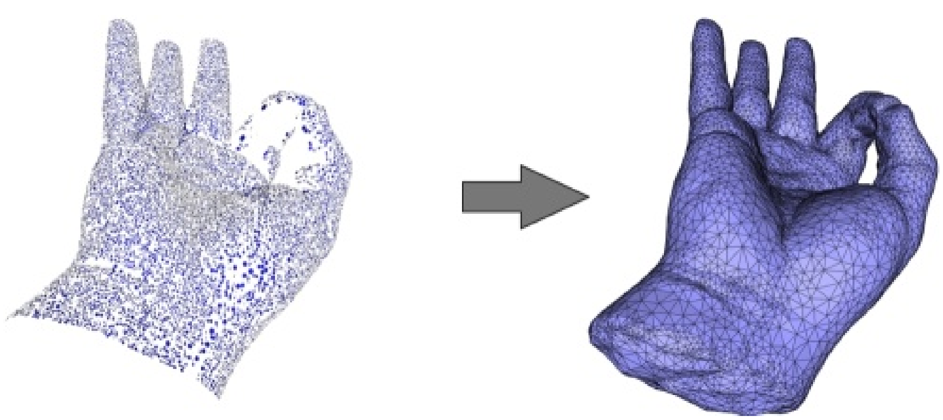

Figure 49.9: Left: 65K points sampled on a hand with no data captured at the wrist base. Right: reconstructed surface mesh. The surface is properly closed on the fingers and also closed at the wrist but in a less plausible manner.

Wrongly Oriented Normals

The Poisson surface reconstruction approaches solves for an implicit function whose gradient best matches a set of input normals. Because it solves this problem in the least squares sense, it is robust to few isolated wrongly oriented (flipped) normals. Nevertheless a cluster of wrongly oriented normals leads to an incorrect implicit function and hence to spurious geometric or even topological distortion (see Figure 49.10).

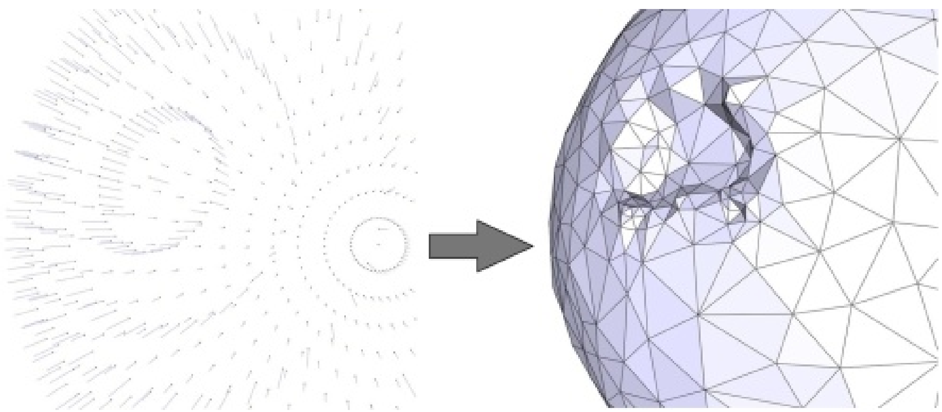

Figure 49.10: Left: points sampled on a sphere with a cluster of wrongly oriented normals. Right: reconstructed surface mesh with a spurious bump.

Noise and Outliers

A large amount of noise inevitably impacts on the reconstruction (see Figure 49.11, top) and the current implementation does not provide any mean to trade data fitting for smoothness. Nevertheless if the signal-to-noise ratio is sufficiently high and/or the surface approximation and sizing parameters set for contouring the iso-surface is large with respect to the noise level the output surface mesh will appear smooth (not shown). If the user wants to produce a smooth and detailed output surface mesh, we recommend to apply smoothing through *CGAL::jet_smooth_point_set()* ((see Figure 49.11, bottom).

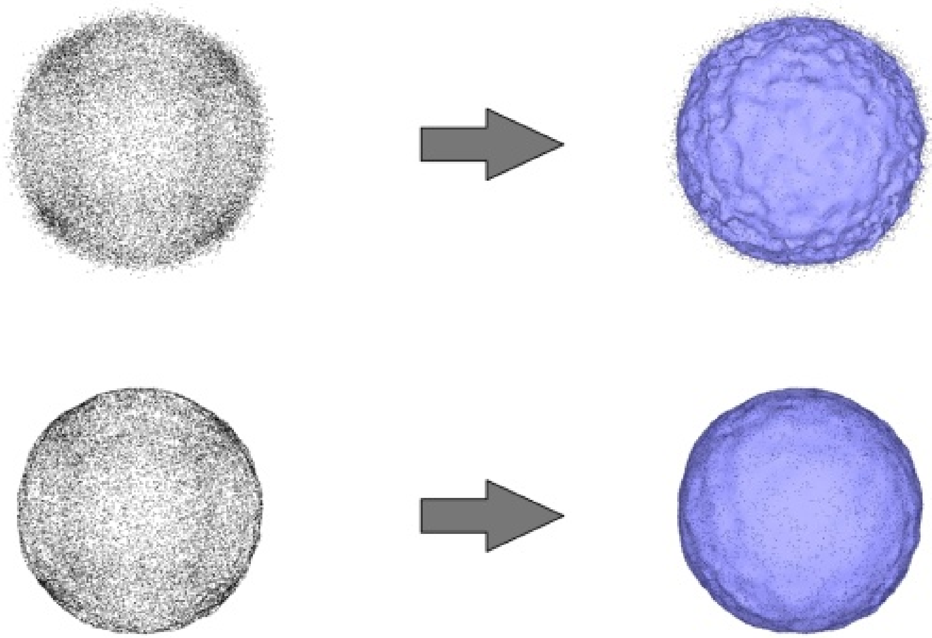

Figure 49.11: Top-left: points sampled on a sphere and corrupted with a lot of noise. Top-right: reconstructed surface mesh. Bottom-left: smoothed point set. Bottom-right: reconstructed surface mesh.

For a large number of outliers the failure cases (not shown) translate into spurious small connected components and massive distortion near the inferred surface. In this case the outliers must be removed through *CGAL::remove_outliers()*.

Sharp Creases

The current reconstruction algorithm is not able to recover the sharp creases and corners present in the inferred surface. This translates into smoothed sharp creases.

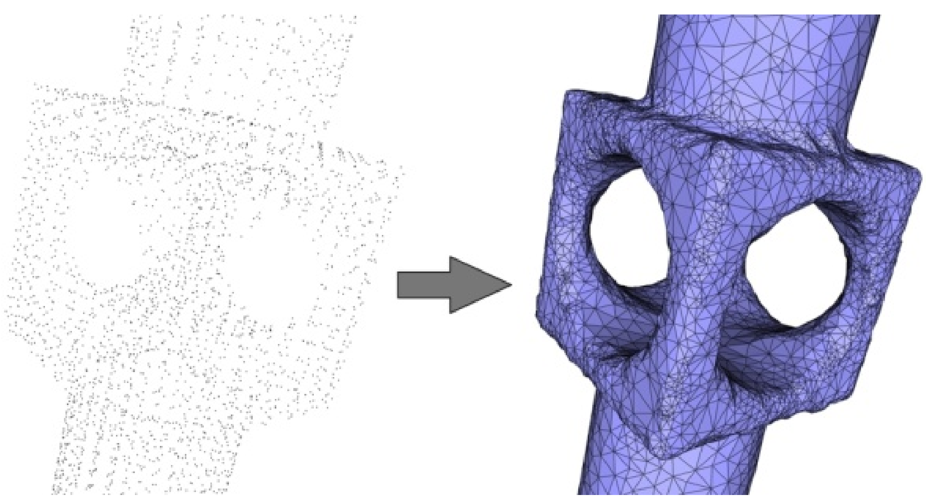

Figure 49.12: Left: 5K points sampled on a mechanical piece with sharp features (creases, darts and corners). Right: reconstructed surface mesh with smoothed creases.

Surface Reconstruction from Point Sets Reference Manual

Pierre Alliez, Laurent Saboret, Gael Guennebaud

This CGAL component implements a state-of-the-art surface reconstruction method: Poisson Surface Reconstruction. The input is an unorganized point set, possibly with attributes such as unoriented or oriented normals. The output is either an implicit function (ready for evaluation by any contouring algorithm), or a surface mesh generated by the CGAL surface mesh generator.

Note that since reconstruction methods often require pre-processing a point set (through reduction, smoothing, outlier removal, normal estimation, normal orientation), we provide components devoted to these tasks in the Point Set Processing component.

Class

CGAL::Poisson_reconstruction_function<GeomTraits>

Definition

Given a set of 3D points with oriented normals sampled on the boundary of a 3D solid, the Poisson Surface Reconstruction method [KBH06] solves for an approximate indicator function of the inferred solid, whose gradient best matches the input normals. The output scalar function, represented in an adaptive octree, is then iso-contoured using an adaptive marching cubes.

Poisson_reconstruction_function implements a variant of this algorithm which solves for a piecewise linear function on a 3D Delaunay triangulation instead of an adaptive octree.

#include <CGAL/Poisson_reconstruction_function.h>

Parameters

template<class Gt>
class *Poisson_reconstruction_function*;

Parameters:
Gt: Geometric traits class.

Is Model for the Concepts

Model of the *ImplicitFunction* concept.

Types

Poisson_reconstruction_function<GeomTraits>:: Geom_traits

Geometric traits class.

Poisson_reconstruction_function<GeomTraits>:: FT	typedef to *Geom_traits::FT*
Poisson_reconstruction_function<GeomTraits>:: Point	typedef to *Geom_traits::Point_3*
Poisson_reconstruction_function<GeomTraits>:: Vector	typedef to *Geom_traits::Vector_3*
Poisson_reconstruction_function<GeomTraits>:: Sphere	typedef to *Geom_traits::Sphere_3*

Creation

template<typename InputIterator, typename PointPMap, typename NormalPMap>
Poisson_reconstruction_function<GeomTraits> fct(InputIterator first,
InputIterator beyond,
PointPMap point_pmap,

NormalPMap normal_pmap)

Creates a Poisson implicit function from the [first, beyond) range of points.
Template Parameters:
InputIterator: iterator over input points. *PointPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type* = *Point_3*. It can be omitted if *InputIterator value_type* is convertible to *Point_3*. *NormalPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type* = *Vector_3*.
Parameters:
first: iterator over the first input point. *beyond*: past-the-end iterator over the input points. *point_pmap*: property map to access the position of an input point. *normal_pmap*: property map to access the oriented normal of an input point.

Operations

Sphere *fct.bounding_sphere() const* Returns a sphere bounding the inferred surface.

template<class SparseLinearAlgebraTraits_d>
bool *fct.compute_implicit_function(SparseLinearAlgebraTraits_d solver = SparseLinearAlgebraTraits_d())*

The function *compute_implicit_function*() must be called after the insertion of oriented points. It computes the piecewise linear scalar function operator() by: applying Delaunay refinement, solving for operator() at each vertex of the triangulation with a sparse linear solver, and shifting and orienting operator() such that it is 0 at all input points and negative inside the inferred surface.
Template parameters:
SparseLinearAlgebraTraits_d: Symmetric definite positive sparse linear solver. If EIGEN 3.1 (or greater) is available and *CGAL_EIGEN3_ENABLED* is defined, the default solver is *Eigen::ConjugateGradient*.
Returns: false if the linear solver fails.
Parameters:
solver: sparse linear solver.

FT *fct.operator()(const Point& p) const*

ImplicitFunction interface: evaluates the implicit function at a given 3D query point. The function *compute_implicit_function* must be called before the first call to *operator()*.

Point *fct.get_inner_point() const* Returns an arbitray point located inside the inferred surface.

Example

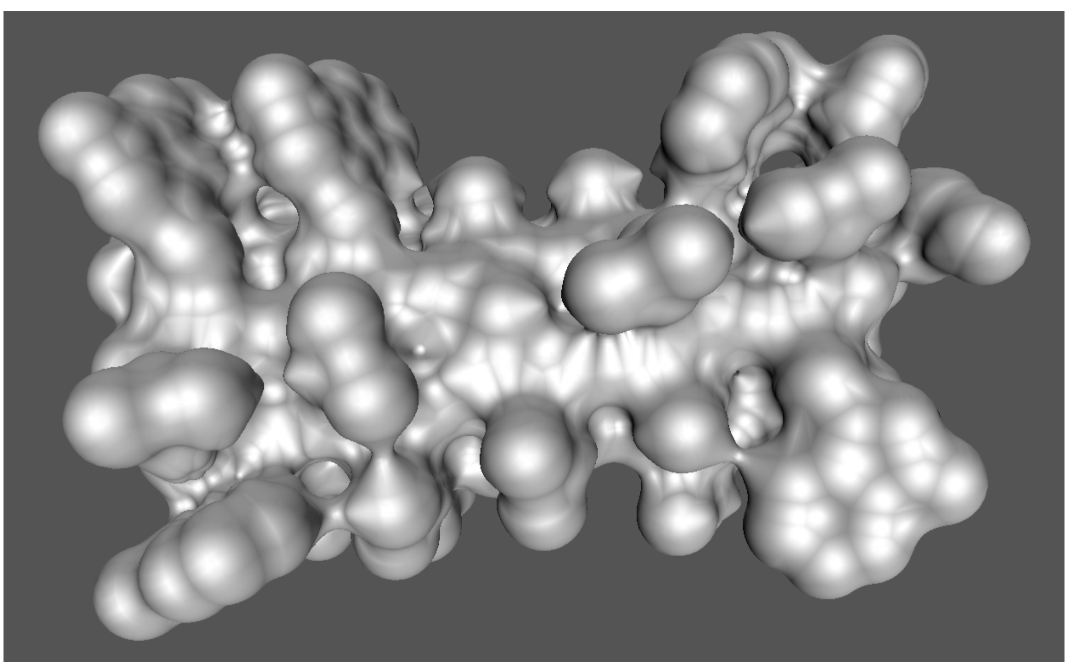
See *Surface_reconstruction_points_3/poisson_reconstruction_example.cpp*.

Chapter 50

3D Skin Surface Meshing

Nico Kruithof

Contents



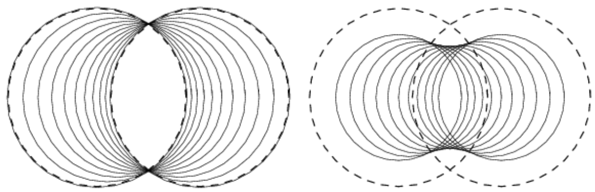


Figure 50.1: Left: Convex combinations of two weighted points (the two dashed circles). Right: The skin curve of the weighted points. The smaller circles form a subset of the weighted points whose boundary is the skin curve.

50.1 Introduction

Skin surfaces, introduced by Edelsbrunner in [Ede99], have a rich and simple combinatorial and geometric structure that makes them suitable for modeling large molecules in biological computing. Meshing such surfaces is often required for further processing of their geometry, like in numerical simulation and visualization.

A skin surface is defined by a set of weighted points (input balls) and a scalar called the shrink factor. If the shrink factor is equal to one, the surface is just the boundary of the union of the input balls. For a shrink factor smaller than one, the skin surface becomes tangent continuous, due to the appearance of patches of spheres and hyperboloids connecting the balls.

This package constructs a mesh isotopic to the skin surface defined by a set of balls and a shrink factor using the algorithm described in [KV05].

An optimized algorithm is implemented for meshing the union of a set of balls.

50.2 Definition of a Skin Surface

This section first briefly reviews skin surfaces. For a more thorough introduction to skin surfaces, we refer to [Ede99] where they were originally introduced.

A skin surface is defined in terms of a finite set of weighted points $\mathbf{P}$ and a shrink factor s, with $0 \leq s \leq 1$. A weighted point $\mathbf{p} = (p, w_p) \in \mathbb{R}^3 \times \mathbb{R}$ corresponds to a ball with center p and radius $\sqrt{w_p}$. A weighted point with zero weight is called an unweighted point.

A pseudo distance between a weighted point $\mathbf{p} = (p, w_P)$ and an unweighted point x is defined as

$$\pi(\mathbf{p}, x) = \| p - x \|^2 - w_p,$$

where $\| p - x \|$ is the Euclidean distance between p and x. The ball corresponding to a weighted point $\mathbf{p}$ is the zero set of $\pi(\mathbf{p}, \cdot)$. Note that if $w_p < 0$ the radius of the ball is imaginary and the zero-set is empty.

We can take convex combinations of weighted points by taking convex combinations of their distance functions. Figure 50.1 (left) shows weighted points that are obtained as convex combinations of the dashed circles. For further reading on the space of circles and spheres we refer to [Ped70].

Starting from a weighted point $\mathbf{p} = (p, w_P)$, the shrunk weighted point $\mathbf{p}^s$ is obtained by taking a convex combination with the unweighted point centered at p, formally $\mathbf{p}^s = s\mathbf{p} + (1-s)\mathbf{p}'$, with $\mathbf{p}' = (p, 0)$. A simple calculation shows that, $\mathbf{p}^s = (p, s \cdot w_p)$. The set $\mathbf{P}^s$ is the set obtained by shrinking every weighted point of $\mathbf{P}$ by a factor s: $\mathbf{P}^s = \{\mathbf{p}^s \mid \mathbf{p} \in \mathbf{P}\}$. The shrunk weighted points of Figure 50.1 (left) are shown in Figure 50.1 (right).

We now define the skin surface $\mathrm{skn}^s(\mathbf{P})$ associated with a set of weighted points $\mathbf{P}$. Consider the set of weighted points obtained by taking the convex hull of the input weighted points. A calculation shows that every weighted point lies within the union of the input balls. Next, we shrink each weighted point in the convex hull with the shrink factor s. Hence, we multiply the radius of the corresponding (real) input circles with a factor $\sqrt{s}$. The skin surface is the boundary of the union of this set of weighted points:

$$\mathrm{skn}^s(\mathbf{P}) \quad = \quad \partial \bigcup \{\mathbf{p}^s \mid \mathbf{p} \in \mathrm{conv}(\mathbf{P})\}. \tag{50.1}$$

Here $\mathrm{conv}(\mathbf{P}) \subset \mathbb{R}^3 \times \mathbb{R}$ is the convex hull of a set of weighted points $\mathbf{P}$, whereas ∂ denotes the boundary – in $\mathbb{R}^3$ – of the union of the corresponding set of balls.

Recall that each weighted point in the convex hull of the input weighted points is contained in the union of the input weighted points. Hence, for a shrink factor equal to one, the skin surface is the boundary of the union of the input weighted points.

By definition of a skin surface, the weights of the input balls (their radius-squared) are shrunk with a factor of s and the skin surface wraps around the shrunk input balls. In order to make the skin surface wrap around the (unshrunk) input balls, we can first increase the weights of the input balls by multiplying them with a factor $1/s$ and then compute the skin surface.

50.3 The Interface

The interface to the skin surface package consists of one main function, taking a set of weighted points and a shrink factor and outputting the meshed surface. Further, it defines classes and functions and classed used to perform the main steps of the algorithm. There are two global classes *Skin_surface_3* and *Union_of_balls_3* both of which are models of the concept *SkinSurface_3* and there are two functions to extract a mesh of the skin surface (union of balls) from the objects of the aforementioned classes. A final function takes a mesh and the *Skin_surface_3* (*Union_of_balls_3*) object it is constructed from and refines the mesh. This section describes these classes and functions in more detail.

The main function of the skin surface package takes an iterator range of weighted points, a shrink factor and the number of subdivision steps and outputs a mesh in a *CGAL::Polyhedron_3*:

```
template <class WP_iterator, class Polyhedron_3>
void    make_skin_surface_mesh_3( Polyhedron_3 &p,
                                  WP_iterator begin,
                                  WP_iterator end,
                                  FT shrink_factor=.5,
                                  int nSubdiv=0,
                                  bool grow_balls = true)
```

Where, *FT* is the number type used by the *Weighted_points*.

To obtain more control over the algorithm, the different steps can also be performed separately. First, a *Skin_surface_3* object is created from an iterator range of weighted points and a shrink factor. Optional arguments are a boolean telling whether the input weighted points should be grown in such a way that the skin surface wraps around the input balls instead of the shrunk input balls.

```
template <class SkinSurfaceTraits_3>
        Skin_surface_3( WP_iterator begin, WP_iterator end, FT shrink_factor, bool grow_balls = true)
```

The template parameter should implement the *SkinSurfaceTraits_3* concept. The type *WP_iterator*, is an iterator over weighted points as defined by *SkinSurfaceTraits_3* and *FT* is the number type used by the weighted points.

For a shrink factor equal to one the skin surface is the boundary of the union of the input balls. In this case the algorithm used for meshing the skin surface greatly simplifies. These optimizations are implemented in the class *Union_of_balls_3*. The constructor for the union of balls class is similar, except for the missing shrink factor:

template <class SkinSurfaceTraits_3>
Union_of_balls_3(WP_iterator begin, WP_iterator end, bool grow_balls = true)

With a model of the concept *SkinSurface_3* it is possible to generate a coarse mesh isotopic to the skin surface. Using the function *mesh_skin_surface_3* with signature:

template <class SkinSurface_3, class Polyhedron>
void mesh_skin_surface_3(SkinSurface_3 skin_surface, Polyhedron &p)

The last function takes the (coarse) mesh and subdivides it in-situ by applying a given number of 1-4 split operations (each triangle is split into four sub-triangles) and moving the new vertices towards the skin surface. If the number of iterations is not specified, one subdivision step is done. The object of the *SkinSurface_3* concept used to construct the coarse mesh is needed to move new points on the skin surface.

template <class SkinSurface_3, class Polyhedron >
void subdivide_skin_surface_mesh_3(SkinSurface_3 skinsurface, Polyhedron &p, int iterations=1)

50.4 Timings

The timings of the construction of the coarse mesh and the first subdivision are given in seconds and were done on a Pentium 4, 3.5 GHz, with 1 Gb of memory.

Data set	Number of weighted points	Coarse mesh	first subdivision step
Caffeine	23	0.2 sec.	0.05 sec.
Gramicidin A	318	5 sec.	2 sec.

50.5 Example Programs

50.5.1 Meshing a Skin Surface

The following example shows the construction of a coarse mesh of the skin surface using the function *make_skin_surface_mesh_3*. The output is a *CGAL::Polyhedron*.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/make_skin_surface_mesh_3.h>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_3                                          Bare_point;
```

```
typedef CGAL::Weighted_point<Bare_point,K::RT>
    Weighted_point;
typedef CGAL::Polyhedron_3<K>                               Polyhedron;

int main() {
  std::list<Weighted_point> l;
  double                    shrinkfactor = 0.5;

  l.push_front(Weighted_point(Bare_point( 1,-1,-1), 1.25));
  l.push_front(Weighted_point(Bare_point( 1, 1, 1), 1.25));
  l.push_front(Weighted_point(Bare_point(-1, 1,-1), 1.25));
  l.push_front(Weighted_point(Bare_point(-1,-1, 1), 1.25));

  Polyhedron p;

  CGAL::make_skin_surface_mesh_3(p, l.begin(), l.end(), shrinkfactor);

  return 0;
}
```

File: examples/Skin_surface_3/skin_surface_simple.cpp

50.5.2 Meshing and Subdividing a Skin Surface

The following example shows the construction of mesh of the skin surface by explicitly performing different steps of the algorithm. It first constructs a *Skin_surface_3* object from an iterator range of weighted points and a shrink factor. From this object, the coarse mesh isotopic to the skin surface is extracted using the function *CGAL::mesh_skin_surface_3*

Next, the coarse mesh is refined to obtain a better approximation. The use of *CGAL::Skin_surface_polyhedral_items_3<Skin_surface_3>* in the *CGAL::Polyhedron* is not necessary, but gives the subdivision a significant speedup.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Skin_surface_3.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/mesh_skin_surface_3.h>
#include <CGAL/subdivide_skin_surface_mesh_3.h>
#include "skin_surface_writer.h"
#include <list>
#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Skin_surface_traits_3<K>                      Traits;
typedef CGAL::Skin_surface_3<Traits>
    Skin_surface_3;
typedef Skin_surface_3::FT                                  FT;
typedef Skin_surface_3::Weighted_point
    Weighted_point;
typedef Weighted_point::Point                               Bare_point;
typedef CGAL::Polyhedron_3<K,
  CGAL::Skin_surface_polyhedral_items_3<Skin_surface_3> >   Polyhedron;
```

```
int main() {
  std::list<Weighted_point> l;
  FT                        shrinkfactor = 0.5;

  l.push_front(Weighted_point(Bare_point( 1,-1,-1), 1.25));
  l.push_front(Weighted_point(Bare_point( 1, 1, 1), 1.25));
  l.push_front(Weighted_point(Bare_point(-1, 1,-1), 1.25));
  l.push_front(Weighted_point(Bare_point(-1,-1, 1), 1.25));

  Polyhedron p;

  Skin_surface_3 skin_surface(l.begin(), l.end(), shrinkfactor);
  CGAL::mesh_skin_surface_3(skin_surface, p);

  CGAL::subdivide_skin_surface_mesh_3(skin_surface, p);

  std::ofstream out("mesh.off");
  out << p;

  return 0;
}
```

File: examples/Skin_surface_3/skin_surface_subdiv.cpp

3D Skin Surface Meshing Reference Manual

Nico Kruithof

Skin surfaces form a class of tangent continuous surfaces defined by a set of balls and a scalar called the shrink factor. The skin surface package constructs an triangular mesh isotopic to the skin surface, using the algorithm described in [KV05]. The mesh is stored in a *CGAL::Polyhedron_3*.

SkinSurface_3

Definition

The concept SkinSurface_3 defines a skin surface and provides an interface for the dedicated skin surface mesher. The concept requires a constructor from an iterator range of weighted points and a shrink factor. By default the input balls are grown in such that the skin surface wraps around the input balls.

Has Models

CGAL::Skin_surface_3<SkinSurfaceTraits_3>
CGAL::Union_of_balls_3<SkinSurfaceTraits_3>

Types

SkinSurface_3:: Geometric_traits	The geometric traits used for the construction of the regular triangulation.
SkinSurface_3:: Weighted_point	The *Weighted_point* type defined by the *Geometric_traits*.
SkinSurface_3:: Bare_point	The *Bare_point* type defined by the *Geometric_traits*.
SkinSurface_3:: FT	The *FT* type defined by the *Geometric_traits*. This is the number type used by the weighted points.

Creation

SkinSurface_3 skin(WP_iterator begin, WP_iterator end, RT shrink_factor);

The mandatory arguments to the constructor are an iterator range *[begin,end)* of weighted points and a shrink factor between 0 and 1.

Operations

template <class Polyhedron_3>
void skin.mesh_skin_surface_3(Polyhedron_3 &p)

Constructs a coarse mesh in *p*.
Precondition: *Polyhedron_3::HDS* can be used as the template argument of the *Polyhedron_incremental_builder_3< HDS>*.

template <class Polyhedron_3>
void skin.subdivide_skin_surface_mesh_3(Polyhedron_3 &p, int nSubdiv = 1)

Subdivides the skin surface using *nSubdiv* 1-4 split operations (each triangle is split into four sub-triangles) and the new vertices are moved towards the skin surface.

Concept

SkinSurfaceTraits_3

Required types and member functions for the SkinSurfaceTraits_3 concept. This geometric traits concept is used for the construction of a polyhedral mesh approximating a skin surface *CGAL::skin_surface_3<Traits>*.

Refines

RegularTriangulationTraits_3

Types

SkinSurfaceTraits_3:: RT The number type.

SkinSurfaceTraits_3:: Construct_anchor_point_3

A constructor object which provides the following function operator:
Point operator()(const Point &center_del, const Point &center_vor);
Constructs the anchor point in between the Delaunay and Voronoi centers, i.e., the point $(1-s)\cdot center\_del + s\cdot center\_vor$, where s is the shrink factor.

Creation

SkinSurfaceTraits_3 traits(RT s=.5);

constructor that takes the shrink factor as argument. For meshing the boundary of the union of a set of balls, the shrink factor is discarded.

Has Models

CGAL::Skin_surface_traits_3<K> . . . . page 3123

Operations

The following functions give access to the constructor objects:

Regular_RT *traits.shrink_factor() const*

Returns the shrink factor.

Construct_anchor_point_3 *traits.construct_anchor_point_3_object() const*

returns a *Construct_anchor_point_3* object.

CGAL::Skin_surface_3<SkinSurfaceTraits_3>

Class

Definition

The *Skin_surface_3<SkinSurfaceTraits_3>* is the main class in the *Skin_surface_3* package. It is a model of the concept *SkinSurface_3*.

The template argument is required to be a model of the concept *SkinSurfaceTraits_3*, which means that it provides predicates to construct a regular triangulation of the weighted points and for point location in the mixed complex.

#include <CGAL/Skin_surface_3.h>

Is Model for the Concepts

SkinSurface_3

Class

CGAL::Union_of_balls_3<SkinSurfaceTraits_3>

Definition

The *Union_of_balls_3<SkinSurfaceTraits_3>* is used to represent a skin surface with shrink factor equal to one, which is the boundary of the union of the input balls. This case is handled separately since the mixed complex is equal to the power diagram, which has a much simpler structure.

The template argument must be a model of the concept *SkinSurfaceTraits_3*, which means that it provides the predicates to construct a regular triangulation of the weighted points.

#include <CGAL/Union_of_balls_3.h>

Is Model for the Concepts

SkinSurface_3

CGAL::Skin_surface_traits_3<K>

Class

Definition

The class *Skin_surface_traits_3<K>* is designed as a default traits class for the class *Skin_surface_3< SkinSurfaceTraits_3>*. It is a model of the *SkinSurfaceTraits_3*.

The template argument *K* must be a model of the *Kernel* concept.

#include <CGAL/Skin_surface_traits_3.h>
