Part I

General Introduction

Chapter 1

Introduction

CGAL Editorial Board

The goal of the CGAL Open Source Project is to provide *easy access to efficient and reliable geometric algorithms* in the form of a C++ library.

The Computational Geometry Algorithms Library offers data structures and algorithms like triangulations, Voronoi diagrams, Boolean operations on polygons and on polyhedra, arrangements of curves, mesh generation, geometry processing, convex hull algorithms, to name just a few.

All these data structures and algorithms operate on geometric objects like points and segments, and perform geometric tests on them. These objects and predicates are regrouped in CGAL *Kernels*.

Finally, the CGAL *Support Library* offers geometric object generators and spatial sorting functions, as well as a matrix search framework and a solver for linear and quadratic programs. It further offers interfaces to third party software such as the GUI libraries Qt, Geomview, and the Boost Graph Library.

1.1 Organization of the Manual

This manual is organized in several parts covering the many domains of computational geometry. Each part consists of several chapters, and each chapter is split into a *user manual* and a *reference manual*. The user manual gives the general idea and comes with examples. The reference manual presents the API of the various classes and functions.

The manual has a table of contents, and an index, as well as a package overview, which gives a short paragraph what the package is about, what license it has, and on which other packages it depends. It further provides links to precompiled demo programs for the Windows platform.

1.2 Demos and Examples

In the distribution of the library you find the two directories *demo* and *examples*. They contain subdirectories for the CGAL packages. The demos use third party libraries for the graphical user interface. The examples don't have this dependency and most examples are refered to in the user manual.

1.3 Hello World

In this section we will take a closer look at three CGAL example programs, all of them computing the 2D convex hull of a set of points.

1.3.1 Points in a built-in array

In the first example we have an array of five points. As the convex hull of these points is a subset of the input it is safe to provide an array for storing the result which has the same size.

```
#include <iostream>
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/convex_hull_2.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point_2;

int main()
{
  Point_2 points[5] = { Point_2(0,0), Point_2(10,0), Point_2(10,10),
   Point_2(6,5), Point_2(4,1) };
  Point_2 result[5];

  Point_2 *ptr = CGAL::convex_hull_2( points, points+5, result );
  std::cout <<  ptr - result << " points on the convex hull" <<
   std::endl;
  return 0;
}
```

File: `examples/Convex_hull_2/array_convex_hull_2.cpp`

All CGAL header files are in the subdirectory “include/CGAL”. All CGAL classes and functions are in the namespace “CGAL”. The geometric primitives, like the point type, are defined in a kernel. CGAL comes with several kernels, and as the convex hull algorithm only makes comparisons of coordinates and orientation tests of input points, we can choose a kernel that provides exact predicates, but no exact geometric construction.

The convex hull function takes three arguments, the start and past-the-end pointer for the input, and the start pointer of the array for the result. The function returns the pointer into the result array just behind the last convex hull point written, so the pointer difference tells us how many points are on the convex hull.

1.3.2 Points in a STL vector

In the second example we replace the built-in array by a *std::vector* of the Standard Template Library.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/convex_hull_2.h>

#include <vector>
```

```
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point_2;
typedef std::vector<Point_2> Points;

int main()
{
  Points points, result;
  points.push_back(Point_2(0,0));
  points.push_back(Point_2(10,0));
  points.push_back(Point_2(10,10));
  points.push_back(Point_2(6,5));
  points.push_back(Point_2(4,1));

  CGAL::convex_hull_2( points.begin(), points.end(),
   std::back_inserter(result) );
  std::cout << result.size() << " points on the convex hull" <<
   std::endl;
  return 0;
}
```

File: examples/Convex_hull_2/vector_convex_hull_2.cpp

We put some points in the vector calling the *push_back()* method of the *std::vector* class.

We then call the convex hull function. The first two arguments, *points.begin()* and *points.end()* are *iterators*, which are a generalization of pointers: they can be dereferenced and incremented. The convex hull function is *generic* in the sense that it takes as input whatever can be dereferenced and incremented.

The third argument is where the result gets written to. In the previous example we provided a pointer to allocated memory. The generalization of such a pointer is the *output iterator*, which allows to increment and assign a value to the dereferenced iterator. In this example we start with an empty vector which grows as needed. Therefore, we cannot simply pass it *result.begin()*, but an output iterator generated by the helper function *std::back_inserter(result)*. This output iterator does nothing when incremented, and calls *result.push_back(..)* on the assignment.

1.3.3 Points in Streams

The last example program reads a sequence of points from standard input *std::cin* and writes the points on the convex hull to standard output *std::cout*.

Instead of storing the points in a container such as an *std::vector*, and passing the begin/end iterator of the vector to the convex hull function, we use helper classes that turn file pointers into iterators.

```
#include <iostream>
#include <iterator>
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/convex_hull_2.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point_2;
```

```
int main()
{
  std::istream_iterator< Point_2 >  input_begin( std::cin );
  std::istream_iterator< Point_2 >  input_end;
  std::ostream_iterator< Point_2 >  output( std::cout, "\n" );
  CGAL::convex_hull_2( input_begin, input_end, output );
  return 0;
}
```

File: examples/Convex_hull_2/iostream_convex_hull_2.cpp

In the example code you see input and output stream iterators templated with the point type. A *std::istream_iterator<Point_2>* hence allows to traverse a sequence of objects of type *Point_2*, which come from standard input as we pass *std::cin* to the constructor of the iterator. The variable *input_end* denotes end-of-file.

A *std::ostream_iterator<Point_2>* is an output iterator, that is an iterator to which, when dereferenced, we can assign a value. When such an assignment to the output iterator happens somewhere inside the convex hull function, the iterator just writes the assigned point to standard output, because the iterator was constructed with *std::cout*.

The call to the convex hull function takes three arguments, the input iterator range, and the output iterator to which the result gets written.

If you know the STL, the Standard Template Library, the above makes perfect sense, as this is the way the STL decouples algorithms from containers. If you don't know the STL, you maybe better first familiarize yourself with its basic ideas.

1.4 Further Reading

We also recommend the standard text books by Josuttis [Jos99], or Austern [Aus98] for the STL and its notion of *concepts* and *models*.

Other resources for CGAL are the tutorials at http://www.cgal.org/Tutorials/ and the user support page at http://www.cgal.org/.

Introduction
Reference Manual

CGAL Editorial Board

This chapter contains no Reference Manual pages.

Chapter 2

Preliminaries

CGAL Editorial Board

This chapter lists the licenses under which the CGAL datastructures and algorithms are distributed. The chapter further explains how to control inlining, thread safety, code deprecation, checking of pre- and postconditions, and how to alter the failure behavior.

2.1 License Issues

CGAL is distributed under a dual license scheme, that is under the GPL/LGPL open source license, as well as under commercial licenses.

CGAL consists of different parts covered by different open source licenses. In this section we explain the essence of the different licenses, as well as the rationale why we have chosen them.

The fact that CGAL is Open Source software does not mean that users are free to do whatever they want with the software. Using the software means to accept the license, which has the status of a contract between the user and the owner of the CGAL software.

2.1.1 GPL

The GPL is an Open Source license that, if you distribute your software based on GPLed CGAL data structures,you are obliged to distribute the source code of your software under the GPL.

The exact license terms can be found at the Free Software Foundation web site: `http://www.gnu.org/copyleft/gpl.html`.

2.1.2 LGPL

The LGPL is an Open Source license that obliges you to distribute modifications you make on CGAL software accessible to the users. In contrast to the GPL , there is no obligation to make the source code of software you build on top of LGPLed CGAL data structures

The exact license terms can be found at the Free Software Foundation web site: `http://www.gnu.org/copyleft/lesser.html`.

2.1.3 Rationale of the License Choice

We have chosen the GPL and the LGPL as they are well known and well understood open source licenses. The former restricts commercial use, and the latter allows to promote software as de facto standard so that people can build new higher level data structures on top.

Therefore, the packages forming a foundation layer are distributed under the LGPL, and the higher level packages under the GPL. The package overview states for each package under which license it is distributed.

2.1.4 Commercial Licenses

Users who cannot comply to the Open Source license terms can buy individual data structures under various commercial licenses from GeometryFactory: `http://www.geometryfactory.com/`. License fees paid by commercial customers are reinvested in R&D performed by the CGAL project partners, as well as in evolutive maintenance.

2.2 Marking of Special Functionality

In this manual you will encounter sections marked as follows.

2.2.1 Advanced Features

Some functionality is considered more advanced, for example because it is relatively low-level, or requires special care to be properly used.

advanced

Such functionality is identified this way in the manual.

advanced

2.2.2 Debugging Support Features

Usually related to advanced features that for example may not guarantee class invariants, some functionality is provided that helps debugging, for example by performing invariants checks on demand.

debugging support

Such functionality is identified this way in the manual.

debugging support

2.2.3 Deprecated Code

Sometimes, the CGAL project decides that a feature is deprecated. This means that it still works in the current release, but it will be removed in the next, or a subsequent release. This can happen when we have found a better way to do something, and we would like to reduce the maintenance cost of CGAL at some point in the future. There is a trade-off between maintaining backward compatibility and implementing new features more easily.

In order to help users manage the changes to apply to their code, we attempt to make CGAL code emit warnings when deprecated code is used. This can be done using some compiler specific features. Those warnings can be disabled by defining the macro *CGAL_NO_DEPRECATION_WARNINGS*. On top of this, we also provide a macro, *CGAL_NO_DEPRECATED_CODE*, which, when defined, disables all deprecated features. This allows users to easily test if their code relies on deprecated features.

deprecated

Such functionality is identified this way in the manual.

deprecated

2.3 Namespace CGAL

All names introduced by CGAL, especially those documented in these manuals, are in a namespace called *CGAL*, which is in global scope. A user can either qualify names from CGAL by adding *CGAL::*, e.g., *CGAL::Point_2< CGAL::Exact_predicates_inexact_constructions_kernel >*, make a single name from CGAL visible in a scope via a *using* statement, e.g., *using CGAL::Point_2;*, and then use this name unqualified in this scope, or even make all names from namespace *CGAL* visible in a scope with *using namespace CGAL;*. The latter, however, is likely to give raise to name conflicts and is therefore not recommended.

2.4 Inclusion Order of Header Files

Not all compilers fully support standard header names. CGAL provides workarounds for these problems in *CGAL/basic.h*. Consequently, as a golden rule, you should always include *CGAL/basic.h* first in your programs (or *CGAL/Cartesian.h*, or *CGAL/Homogeneous.h*, since they include *CGAL/basic.h* first).

2.5 Thread Safety

CGAL is progressively being made thread-safe. The guidelines which are followed are:

- it should be possible to use different objects in different threads at the same time (of the same type or not),
- it is not safe to access the same object from different threads at the same time, unless otherwise specified in the class documentation.

If the macro *CGAL_HAS_THREADS* is not defined, then CGAL assumes it can use any thread-unsafe code (such as static variables). By default, this macro is not defined, unless *BOOST_HAS_THREADS* or *_OPENMP* is defined. It is possible to force its definition on the command line, and it is possible to prevent its default definition by setting *CGAL_HAS_NO_THREADS* from the command line.

2.6 C++11 Support

CGAL is based on the C++ standard released in 1998 (and later refined in 2003). A new major version of this standard has been released, and is refered to as C++11. Some compilers and standard library implementations already provide some of the functionality of this new standard. For example, g++ provides a command-line switch (*-std=c++0x* or *-std=c++11* depending on the compiler version) which enables some of those features.

CGAL attempts to support this mode progressively, and already makes use of some of these features if they are available, although no extensive support has been implemented yet.

2.7 Functor Return Types

CGAL functors support the result_of protocol. If a functor *F* has the same return type across all overloads of *operator()*, the nested type *F::result_type* is defined to be that type. Otherwise the return type of calling the functor with an argument of type *Arg* can be accessed through *boost::result_of<F(Arg)>::type*.

2.8 Checks

Much of the CGAL code contains checks. For example, all checks used in the kernel code are prefixed by *CGAL_KERNEL*. Other packages have their own prefixes, as documented in the corresponding chapters. Some are there to check if the kernel behaves correctly, others are there to check if the user calls kernel routines in an acceptable manner.

There are five types of checks. The first three are errors and lead to a halt of the program if they fail. The fourth only leads to a warning, and the last one is compile-time only.

Preconditions check if the caller of a routine has called it in a proper fashion. If such a check fails it is the responsibility of the caller (usually the user of the library).

Postconditions check if a routine does what it promises to do. If such a check fails it is the fault of this routine, so of the library.

Assertions are other checks that do not fit in the above two categories.

Warnings are checks for which it is not so severe if they fail.

Static assertions are compile-time assertions, used e.g. to verify the values of compile-time constants or compare types for (in)equality.

By default, all of these checks are performed. It is however possible to turn them off through the use of compile time switches. For example, for the checks in the kernel code, these switches are the following: *CGAL_KERNEL_NO_PRECONDITIONS*, *CGAL_KERNEL_NO_POSTCONDITIONS*, *CGAL_KERNEL_NO_ASSERTIONS* and *CGAL_KERNEL_NO_WARNINGS*. So, in order to compile the file `foo.cpp` with the postcondition checks off, you can do:

```
CC -DCGAL_KERNEL_NO_POSTCONDITIONS foo.cpp
```

This is also preferably done by modifying your makefile by adding *-DCGAL_KERNEL_NO_POSTCONDITIONS* to the *CXXFLAGS* variable.

The name *KERNEL* in the macro name can be replaced by a package specific name in order to control assertions done in a given package. This name is given in the documentation of the corresponding package, in case it exists.

Note that global macros can also be used to control the behavior over the whole CGAL library:

- *CGAL_NO_PRECONDITIONS*,
- *CGAL_NO_POSTCONDITIONS*,
- *CGAL_NO_ASSERTIONS*,
- *CGAL_NO_WARNINGS* and
- *CGAL_NDEBUG*.

Setting the macro *CGAL_NDEBUG* disables all checks. Note that the standard flag *NDEBUG* sets *CGAL_NDEBUG*, but it also affects the standard *assert* macro. This way, adding *-DCGAL_NDEBUG* to your compilation flags removes absolutely all checks. This is the default recommended setup for performing timing benchmarks for example.

Not all checks are on by default. The first four types of checks can be marked as expensive or exactness checks (or both). These checks need to be turned on explicitly by supplying one or both of the compile time switches *CGAL_KERNEL_CHECK_EXPENSIVE* and *CGAL_KERNEL_CHECK_EXACTNESS*.

Expensive checks are, as the word says, checks that take a considerable time to compute. Considerable is an imprecise phrase. Checks that add less than 10 percent to the execution time of the routine they are in are not expensive. Checks that can double the execution time are. Somewhere in between lies the border line. Checks that increase the asymptotic running time of an algorithm are always considered expensive. Exactness checks are checks that rely on exact arithmetic. For example, if the intersection of two lines is computed, the postcondition of this routine may state that the intersection point lies on both lines. However, if the computation is done with doubles as number type, this may not be the case, due to round off errors. So, exactness checks should only be turned on if the computation is done with some exact number type.

By definition, static assertions are both inexpensive and unaffected by precision management. Thus, the categories do not apply for static assertions.

2.8.1 Altering the Failure Behavior

As stated above, if a postcondition, precondition or assertion is violated, an exception is thrown, and if nothing is done to catch it, the program will abort. This behavior can be changed by means of the following function.

#include <CGAL/assertions_behaviour.h>

Failure_behaviour   *set_error_behaviour(Failure_behaviour eb)*

The parameter should have one of the following values.

enum Failure_behaviour { *ABORT, EXIT, EXIT_WITH_SUCCESS, CONTINUE, THROW_EXCEPTION*}*;*

The *THROW_EXCEPTION* value is the default, which throws an exception.

If the *EXIT* value is set, the program will stop and return a value indicating failure, but not dump the core. The *CONTINUE* value tells the checks to go on after diagnosing the error. Note that since CGAL 3.4, *CONTINUE* has the same effect as *THROW_EXCEPTION* for errors (but it keeps its meaning for warnings), it is not possible anymore to let assertion failures simply continue (except by totally disabling them).

advanced

If the *EXIT_WITH_SUCCESS* value is set, the program will stop and return a value corresponding to successful execution and not dump the core.

advanced

The value that is returned by *set_error_behaviour* is the value that was in use before.

For warnings there is a separate routine, which works in the same way. The only difference is that for warnings the default value is *CONTINUE*.

Failure_behaviour   *set_warning_behaviour(Failure_behaviour eb)*

2.8.2 Control at a Finer Granularity

The compile time flags as described up to now all operate on the whole library. Sometimes you may want to have a finer control. CGAL offers the possibility to turn checks on and off with a bit finer granularity, namely the module in which the routines are defined. The name of the module is to be appended directly after the CGAL prefix. So, the flag *CGAL_KERNEL_NO_ASSERTIONS* switches off assertions in the kernel only, the flag *CGAL_CH_CHECK_EXPENSIVE* turns on expensive checks in the convex hull module. The name of a particular module is documented with that module.

advanced

2.8.3 Customizing how Errors are Reported

Normally, error messages are written to the standard error output. It is possible to do something different with them. To that end you can register your own handler. This function should be declared as follows.

```
void        my_failure_function(
                const char *type,
                const char *expression,
                const char *file,
                int line,
                const char *explanation)
```

Your failure function will be called with the following parameters. *type* is a string that contains one of the words precondition, postcondition, assertion or warning. The parameter *expression* contains the expression that was violated. *file* and *line* contain the place where the check was made. The *explanation* parameter contains an explanation of what was checked. It can be *NULL*, in which case the *expression* is thought to be descriptive enough.

There are several things that you can do with your own handler. You can display a diagnostic message in a different way, for instance in a pop up window or to a log file (or a combination). You can also implement a different policy on what to do after an error. For instance, you can throw an exception or ask the user in a dialog whether to abort or to continue. If you do this, it is best to set the error behavior to *CONTINUE*, so that it does not interfere with your policy.

You can register two handlers, one for warnings and one for errors. Of course, you can use the same function for both if you want. When you set a handler, the previous handler is returned, so you can restore it if you want.

#include <CGAL/assertions.h>

Failure_function *set_error_handler(Failure_function handler)*

Failure_function *set_warning_handler(Failure_function handler)*

Example

```
#include <CGAL/assertions.h>

 void my_failure_handler(
     const char *type,
     const char *expr,
     const char* file,
     int line,
     const char* msg)
 {
     /* report the error in some way. */
 }

 void foo()
 {
     CGAL::Failure_function prev;
     prev = CGAL::set_error_handler(my_failure_handler);
     /* call some routines. */
     CGAL::set_error_handler(prev);
 }
```

advanced

2.9 Identifying the Version of CGAL

#include <CGAL/config.h>

Every release of CGAL defines the following preprocessor macros:

CGAL_VERSION – a textual description of the current release (e.g., or 3.3 or 3.2.1 or 3.2.1-I-15), and

CGAL_VERSION_STR – same as `CGAL_VERSION` but as a string constant token, and

CGAL_VERSION_NR – a numerical description of the current release such that more recent releases have higher number.

More precisely, it is defined as `1MMmmbiiii`, where `MM` is the major release number (e.g. 03), `mm` is the minor release number (e.g. 02), `b` is the bug-fix release number (e.g. 0), and `iiii` is the internal release number (e.g. 0001). For public releases, the latter is defined as 1000. Examples: for the public release 3.2.4 this number is 1030241000; for internal release 3.2-I-1, it is 1030200001. Note that this scheme was modified around 3.2-I-30.

CGAL_VERSION_NUMBER(M,m,b) – a function macro computing the version number macro from the M.m.b release version. Note that the internal release number is dropped here. Example: `CGAL_VERSION_NUMBER(3,2,4)` is equal to 1030241000.

advanced

2.10 Compile-time Flags to Control Inlining

Making functions inlined can, at times, improve the efficiency of your code. However this is not always the case and it can differ for a single function depending on the application in which it is used. Thus CGAL defines a set of compile-time macros that can be used to control whether certain functions are designated as inlined functions or not. The following table lists the macros and their default values, which are set in one of the CGAL include files.

macro name	default
CGAL_KERNEL_INLINE	inline
CGAL_KERNEL_MEDIUM_INLINE	
CGAL_KERNEL_LARGE_INLINE	
CGAL_MEDIUM_INLINE	inline
CGAL_LARGE_INLINE	
CGAL_HUGE_INLINE	

If you wish to change the value of one or more of these macros, you can simply give it a new value when compiling. For example, to make functions that use the macro *CGAL_KERNEL_MEDIUM_INLINE* inline functions, you should set the value of this macro to `inline` instead of the default blank.

Note that setting inline manually is very fragile, especially in a template context. It is usually better to let the compiler select by himself which functions should be inlined or not.

Chapter 3

Installation

Eric Berberich, Joachim Reichel, and Fernando Cacciola

Contents

3.1 Introduction

This document describes how to install CGAL on Windows, Unix-like systems, and MacOS X.

Ideally, setting up CGAL amounts to:

```
cd  CGAL-4.1                          # go to CGAL directory
cmake .                               # configure CGAL
make                                  # build the CGAL libraries
```

Compiling an example shipped with CGAL is similar simple:

```
cd examples/Straight_skeleton_2       # go to an example directory
cmake -DCGAL_DIR=$HOME/CGAL-4.1 .     # configure the examples
make                                  # build the examples
```

Compiling an own non-shipped program is also close:

```
cd /path/to/program
cgal_create_CMakeLists -s executable
cmake -DCGAL_DIR=$HOME/CGAL-4.1 .
make
```

where the second line creates a `CMakeLists.txt` file (check its options in Section 3.15.1 for various details).

In a less ideal world, you probably have to install CMake, a makefile generator, and third party libraries. That is what this manual is about.

3.2 Prerequisites

Installing CGAL requires a few components to be installed ahead: a supported compiler (see Section 3.5, CMake, BOOST, and at least GMP, and MPFR; see Section 3.8 for more details on essential third party software.

3.3 OS-shipped CGAL

Some operating systems with package managers offer CGAL and its essential third party software through the manager, for instance, Mac OS X, or some Linux distribution (e.g. Debian).

3.3.1 CGAL on MAC OS X

For instance, use macports in the following way:

```
sudo port install cgal
```

or if Qt4 demos are desired

```
sudo port install cgal +qt4 +universal +demos
```

The setup is similar for homebrew.

3.3.2 CGAL on Linux

For instance in debian/Ubuntu, use apt-get in the following way:

```
sudo apt-get install libcgal-dev
```

To get the demos use

```
sudo apt-get install libcgal-demo
```

Check the CGAL-FAQ for source repository of newest releases.

On other distributions, please consult your package manager documentation.

3.4 Downloading CGAL

You can obtain the CGAL library from `http://www.cgal.org/download.html` and install it yourself.

After you have downloaded the file `CGAL-4.1.tar.gz` containing the CGAL sources, you have to unpack it. Under a Unix-like shell, use the command:

```
tar xzf CGAL-4.1.tar.gz
```

When you are on Windows you may download and run `CGAL-4.1-Setup.exe`. It is a self extracting executable that installs the CGAL source, and that allows you to select and download some precompiled third party libraries.

In both cases the directory `CGAL-4.1` will be created. This directory contains the following subdirectories:

directory	**contents**
`auxiliary`	precompiled GMPand MPFR for Windows
`cmake/modules`	modules for finding and using libraries
`config`	configuration files for install script
`demo`	demo programs (most of them need QT, geomview or other third-party products)
`doc_html`	documentation (HTML)
`examples`	example programs
`include`	header files
`scripts`	some useful scripts (e.g. for creating CMakeLists.txt files)
`src`	source files

The directories `include/CGAL/CORE` and `src/CGALCore` contain a distribution of the CORE library[1] version 1.7 for dealing with algebraic numbers. CORE is not part of CGAL and has its own license.

The directory `include/CGAL/OpenNL` contains a distribution of the Open Numerical Library which provides solvers for sparse linear systems, especially designed for the Computer Graphics community. OPENNL is not part of CGAL and has its own license.

The only documentation shipped with CGAL sources is the present installation manual. The CGAL manual must be downloaded separately from `http://www.cgal.org/download.html`.

3.5 Supported Compilers

In order to build the CGAL libraries, you need a C++ compiler. CGAL 4.1 is supported for the following compilers/operating systems:

compiler	**operating system**
GNU `g++` 3.4 or later[1]	Linux / MacOS X MS Windows 95/98/2000/XP/NT4
INTEL `C++` 11.0 or later[2]	Linux
MS Visual `C++` 9.0, 10.0 (VISUAL STUDIO 2008 AND 2010)[3]	MS Windows 95/98/2000/XP/NT4/Vista/7

[1]`http://www.cs.nyu.edu/exact/`
[1]`http://gcc.gnu.org/`
[2]`http://software.intel.com/en-us/intel-compilers/`
[3]`http://msdn.microsoft.com/en-us/vstudio/`

3.6 Configuring CGAL with CMake

In order to configure, build, and install the CGAL libraries, examples and demos, you need CMake, a cross-platform "makefile generator". If CMake is not installed already you can obtain it from `http://www.cmake.org/`. CMake version 2.6.2 or higher is required. On Windows, CMake version 2.8.6 or higher is required, for a proper support of DLL's generation. This manual explains only those features of CMake which are needed in order to build CGAL. Please refer to the CMake documentation at `http://www.cmake.org/` for further details.

Before building CGAL you have to choose the compiler/linker, set compiler and linker flags, specify which third-party libraries you want to use and where they can be found, and which CGAL libraries you want to build. Gathering all this information is called *configuration*. The end of the process is marked by the generation of a makefile or a Visual C++ solution and project file that you can use to build CGAL.

3.6.1 Configuring CGAL with the CMake GUI

The simplest way to start the configuration is to run the graphical user interface of CMake. We recommend to use `cmake-gui`. It is available on many platforms as of CMake version 2.6. You must pass as argument the root directory of CGAL. For example:

```
cd  CGAL-4.1
cmake-gui . # Notice the dot to indicate the current directory.
```

After `cmake-gui` opens, press 'Configure'. A dialog will pop up and you will have to choose what shall gets generated. After you have made your choice and pressed 'Finish', you will see the output of configuration tests in the lower portion of the application. When these tests are done, you will see many red entries in the upper portion of the application. Just ignore them and press 'Configure'. By now CMake should have found many libraries and have initialized variables. If you still find red entries, you have to provide the necessary information. This typically happens if you have installed software at non-standard locations. Providing information and pressing 'Configure' goes on until all entries are grayed. You are now ready to press 'Generate'. Once this is done, you can quit `cmake-gui`.

3.6.2 Configuring CGAL with the cmake command-line tool

Alternatively, you can run the command-line tool called `cmake`. You pass as argument the root directory of CGAL. For example:

```
cd  CGAL-4.1
cmake . # Notice the dot to indicate the current directory.
```

The very first thing CMake does is to detect the compiler to use. This detection is performed by a special CMake module called a *generator*. A CMake generator understands the build requirements for a particular compiler/linker and generates the necessary files for that. For example, the *UNIX Makefiles* generator understands the GNU chain of tools (g++, ld etc.) and produces makefiles, which can be used to build a target by a simple call to `make`. Likewise, the *Visual Studio 2010* generator produces solution and project files and can be manually launched in the VS IDE to build the target.

Each platform has a default generator, so you only need to select one when the default is not what you want. For example, under Windows, it is possible to generate *NMakefiles* instead of Visual Studio project files in order to build the library with `nmake`. Running `cmake` with no parameters in a command-line prints the list of available generators supported by your platform and CMake version. If the generator you need is not listed there, you can try a newer CMake version, as generators are hardcoded into CMake, and additional generators are added with each release.

Since the choice of the generator determines the type of build files to generate, in some cases you choose a particular generator as a mean to choose a specific compiler (because they use different build files). For example, the following generates solution files for use in Visual C++ 11.0 on a 64bit machine:

```
cd CGAL-4.1
cmake -G"Visual Studio 11 Win64" .
```

In other cases, however, the generator doesn't directly identify a specific compiler but a chain of tools. For example, the `UNIX Makefiles` generator produces `makefiles` that call some auto-detected command-line compiler, like g++. If you need the makefiles to use a different compiler, you need to specify the desired compiler in the call to CMake, as in this example:

```
cd CGAL-4.1
cmake -DCMAKE_CXX_COMPILER:FILEPATH=g++-4.7 .
```

CMake maintains configuration parameters in so-called *cmake variables*, like the `CMAKE_CXX_COMPILER` in the example above. These variables *are not environment variables* but *CMake variables*. Some of the CMake variables represent user choices, such as `WITH_examples` or `CMAKE_BUILD_TYPE=Release`, while others indicate the details of a third-party library, such as `Boost_INCLUDE_DIR` or the compiler flags to use, such as `CMAKE_CXX_FLAGS`.

The command line tool `cmake` accepts CMake variables as arguments of the form `-D<VAR>:<TYPE>=<VALUE>`, as in the example above, but this is only useful if you already know which variables need to be explicitly defined.

advanced

CMake keeps the variables that a user can manipulate in a so-called *CMake cache*, a simple text file named `CMakeCache.txt`, whose entries are of the form VARIABLE:TYPE=VALUE. Advanced users can manually edit this file, instead of going through the interactive configuration session.

advanced

The configuration process not only determines the location of the required dependencies, it also dynamically generates a `compiler_config.h` file, which encodes the properties of your system and a special file named `CGALConfig.cmake`, which is used to build programs using CGAL. The purpose of this file is explained below.

3.7 CGAL Libraries

CGAL is split into five libraries. During configuration, you can select the libraries that you would like to build by setting a CMake variable of the form `WITH_<library>`. By default all are switched `ON`. All activated libraries are build after configuration; see 3.11

We next list the libraries and essential 3rd party software (see 3.8) for each library:

library	CMake variable	functionality	dependencies
`CGAL`	*none*	Main library	GMP, MPFR, BOOST (headers) and Boost.Thread (library)
`CGAL_Core`	`WITH_CGAL_Core`	The CORE library for algebraic numbers.[15]	GMP and MPFR
`CGAL_ImageIO`	`WITH_CGAL_ImageIO`	Utilities to read and write image files	OPENGL, ZLIB, VTK(optional)
`CGAL_Qt3`	`WITH_CGAL_Qt3`	*CGAL::Qt_widget* used by QT3-based demos	QT3 and OPENGL
`CGAL_Qt4`	`WITH_CGAL_Qt4`	*QGraphicsView* support for QT4-based demos	QT4 and OPENGL

3.7.1 Debug vs. Release

The CMake variable `CMAKE_BUILD_TYPE` indicates how to build the libraries. It accepts the values `Release` or `Debug`. The default is `Release` and should be kept, unless you want to debug your program.

This is not an issue for solution/project files, as there the user selects the build type from within the IDE.

3.7.2 Static vs. Shared Libraries

Shared libraries, also called *dynamic-link libraries*, are built by default (`.dll` on Windows, `.so` on Linux, `.dylib` on MacOS). You can choose to produce static libraries instead by setting the CMake variable `BUILD_SHARED_LIBS` to `FALSE`. If you use `cmake-gui`, a tick box for that variable is available to set it.

These setting affect the variants of third-party libraries (see next section) selected whenever the choice is available.

3.8 Essential Third Party Libraries

The focus of CGAL is on geometry, and we rely on other highly specialized libraries and software for non-geometric issues, for instance, for numeric solvers, or visualization. We first list software that is essential to build (all) libraries of CGAL, that is, this software must be found during the configuration of CGAL for an actived library of CGAL (i.e. `WITH_<library>=ON`); see 3.16.4 to specify the location of 3rd party software.

The libraries STL (shipped with any compiler) and BOOST are essential to all components (i.e. libCGAL, libCGAL_Core, libCGAL_imageIO, libCGAL_Qt3 and libCGAL_Qt4).

3.8.1 Standard Template Library (STL)

CGAL heavily uses the STL, and in particular adopted many of its design ideas. You can find online documentation for the STL at various web sites, for instance, `http://www.sgi.com/tech/stl/`, `http://www.cplusplus.com/reference/`, or `http://msdn.microsoft.com/en-us/library/1fe2x6kt(VS.100).aspx`.

[15] CGAL_Core is not part of CGAL, it is a custom version the CORE library distributed by CGAL for the user convenience and it has it's own license.

The STL comes with the compiler, so there is nothing to install.

3.8.2 BOOST

The BOOST libraries are a set of portable C++ source libraries. Most of BOOST libraries are header-only, but a few of them need to be compiled or installed as binaries.

CGAL requires the BOOST libraries. In particular the header files and the threading library (`Boost.Thread` and `Boost.System` binaries). Version 1.39 (or higher) are needed.

On Windows, as auto-linking is used, you also need the binaries of `Boost.Serialization` and `Boost.DateTime`, but the dependency is artificial and used only at link-time: the CGAL libraries do not depend on the DLL's of those two libraries.

In CGAL some demos and examples depend on `Boost.Program_options`.

In case the BOOST libraries are not installed on your system already, you can obtain them from `http://www.boost.org/`. For Windows you can download an installer from `http://www.boostpro.com/download/`. Since `Boost.Thread` is required, make sure to either install the precompiled libraries for your compiler or build `libboost-thread` and `libboost-system`.

As on Windows there is no canonical directory for where to find BOOST, we recommend that you define the environment variable *BOOST_ROOT* and set it to where you have installed BOOST, e.g., `C:\boost\boost_1_41_0`.

3.8.3 GMP and MPFR

The components libCGAL, libCGAL_Core, libCGAL_Qt3 and libCGAL_Qt4 require GMP and MPFR which are libraries for multi precision integers and rational numbers, and for multi precision floating point numbers.

CGAL combines floating point arithmetic with exact arithmetic, in order to be efficient and reliable. CGAL has a built-in number type for that, but GMP and MPFR provide a faster solution, and we recommend to use them.

Having GMP version 4.2 or higher and MPFR version 2.2.1 or higher installed is recommended. These libraries can be obtained from `http://gmplib.org/` and `http://www.mpfr.org/`, respectively.

As Visual C++ is not properly supported by the GMP and MPFR projects, we provide precompiled versions of GMP and MPFR, which can be downloaded with the installer `CGAL-4.1-Setup.exe`.

3.8.4 ZLIB

ZLIB is a data compression library, and is essential for the component libCGAL_ImageIO.

In CGAL this library is used in the examples of the Surface Mesh Generation (Page **??**) package.

If it is not already on your system, for instance, on Windows, you can download it from `http://www.zlib.net/`.

3.8.5 OPENGL

OPENGL (Open Graphics Library) provides an API for applications that produce 2D and 3D computer graphics.

In CGAL the library is essential for the components libCGAL_Qt3 and libCGAL_Qt4, as well as libCGAL_ImageIO and for various demos.

Typically, OPENGL is preinstalled on systems; if not, it can be downloaded from `http://www.opengl.org/`.

3.8.6 QT3 and QT4

Qt is a cross-platform application and UI framework.

The component libCGAL_Qt3 requires QT3 installed on your system, while the component libCGAL_Qt4 requires QT4 installed on your system. In case QT is not yet installed on your system, you can download it from `http://qt.nokia.com/`.

Older demos of CGALuse libCGAL_Qt3 and QT3, while newer and newly developed demos require libCGAL_Qt4 and QT4.

Having QT4 version 4.3.0 or higher is recommended.

3.9 CGAL Examples and Demos

CGAL is distributed with a large collection of examples and demos. By default, these are **not** configured along with the CGAL libraries, unless you set the variables `WITH_examples=ON` and/or `WITH_demos=ON`.

Nevertheless, even when configured with CGAL, they are not automatically built along with the libraries. You must build the `examples` or `demos` targets (or IDE projects) explicitly.

If you do not plan to compile any demos, you might skip some of the essential libraries (as QT or OPENGL), as the corresponding CGAL-libraries are not linked. But for your own demos you might need these CGAL-libraries.

3.10 Optional Third Party Libraries

Optional 3rd party software can be used by CGAL for various reasons: Usually certain optional libraries are required to build examples and demos shipped with CGAL or to build your own project using CGAL. Another reason is to speed up basic tasks. In order to support these goals, all optional libraries can be *prepared to be used with* CGAL while configuring CGAL, just in the same way as essential libraries are configured. Whenever building an example or a demo (or your own executable), these *preconfigured* libraries are available when using CGAL.

3.10.1 LEDA

LEDA is a library of efficient data structures and algorithms. Like CORE, LEDA offers a real number data type.

In CGAL this library is optional, and its number types can be used as an alternative to GMP, MPFR, and CORE.

Free and commercial editions of LEDA are available from http://www.algorithmic-solutions.com/leda/index.html.

3.10.2 MPFI

MPFI provide arbitrary precision interval arithmetic with intervals represented using MPFR reliable floating-point numbers. It is based on the GMP library and on the MPFR library. In the setting of CGAL it is mainly used in sync with Rs. The library is optional and needed in certain algebraic kernels.

MPFI can be downloaded from http://mpfi.gforge.inria.fr/. Version 1.4 or higher is recommended.

3.10.3 Rs and Rs3

Rs (Real Solutions) is devoted to the study of the real roots of polynomial systems with a finite number of complex roots (including univariate polynomials).

In CGAL, Rs is used by one model of the Algebraic Kernel (Page **??**).

Rs is freely distributable for non-commercial use. You can download it from http://vegas.loria.fr/rs/. The library Rs needs MPFI, which can be downloaded from http://mpfi.gforge.inria.fr/. Version 1.4 or higher is recommended.

The successor of Rs is called Rs3. It less restrictive when it comes to licencing and also contains improved and more efficient interfaces. Mainly parts in CGAL's algebraic kernel require Rs3.

3.10.4 NTL

NTL provides data structures and algorithms for signed, arbitrary length integers, and for vectors, matrices, and polynomials over the integers and over finite fields. The optional library NTL is used by CGAL to speed up operations of the Polynomial package, such as GCDs. It is recommended to install NTL with support from GMP.

NTL can be downloaded from http://www.shoup.net/ntl/. Version 5.1 or higher is recommended.

3.10.5 EIGEN

EIGEN is a C++ template library for linear algebra. EIGEN supports all matrix sizes, various matrix decomposition methods and sparse linear solvers.

In CGAL, EIGEN provides sparse linear solvers in the Surface Reconstruction from Point Sets (Page **??**) and the Planar Parameterization of Triangulated Surface Meshes (Page **??**) packages.

In addition, EIGEN also provides singular value decomposition for the Estimation of Local Differential Properties (Page **??**) and the Approximation of Ridges and Umbilics (Page **??**) packages.

The EIGEN web site is http://eigen.tuxfamily.org.

3.10.6 libQGLViewer

libQGLViewer is a 3D widget based on QT 4's *QGLWidget*.

In CGAL some 3D demos are based on libQGLViewer.

It can be downloaded from `http://www.libqglviewer.com/`.

3.10.7 COIN3D

COIN3D is an implementation of Open Inventor.

In CGAL, COIN3D is used in the demo of the Kinetic Data Structures (Page **??**) package.

You can download it from `http://www.coin3d.org/`.

3.10.8 ESTBL

The ESTBL (Easy Structural Biology Template Library) is a library that allows the handling of PDB data.

In CGAL the ESTBL is used in an example of the 3D Skin Surface Meshing (Page **??**) package.

It can be downloaded from `http://esbtl.sourceforge.net/`.

3.11 Building CGAL

The results of a successful configuration are build files that control the build step. The nature of the build files depends on the generator used during configuration, but in all cases they contain several *targets*, one per library, and a default global target corresponding to all the libraries.

For example, in a UNIX-like environment the default generator produces makefiles. You can use the `make` command-line tool for the succeeding build step as follows:

```
cd CGAL-4.1

# build all the selected libraries at once

make
```

The resulting libraries are placed in the subdirectory `lib` under <CMAKE_BINARY_DIR> (which is `CGAL-4.1` in case you run an in-source-configuration).

With generators other than `UNIX Makefiles` the resulting build files are solution and project files which should be launched in an IDE, such as Visual Studio or KDevelop3. They will contain the targets described above, which you can manually build as with any other solution/project within your IDE.

Alternatively, you can build it with the command line version of the VISUAL STUDIO IDE:

```
devenv CGAL.sln /Build Debug
```

The "Debug" argument is needed because CMake creates solution files for all four configurations, and you need to explicitly choose one when building (the other choices are Release, RelWithDebInfo and MinSizeRel).

advanced

The build files produced by CMake are autoconfigured. That is, if you change any of the dependencies, the build step automatically goes all the way back to the configuration step. This way, once the target has been configured the very first time by invoking cmake, you don't necessarily need to invoke `cmake` again. Rebuilding will call itself `cmake` and re-generate the build file whenever needed. Keep this in mind if you configure CGAL for the Visual Studio IDE since a build could then change the solution/project file in-place and VS will prompt you to reload it.

advanced

If you have turned on the configuration of examples (`-DWITH_examples=ON`) and/or demos (`-DWITH_demos=ON`), there will be additional targets named `examples` and `demos`, plus one target for each example and each demo in the build files. None of these targets are included by default, so you need to build them explicitly *after* the CGAL libraries have been successfully built. The targets `examples` and `demos` include themselves all the targets for examples and demos respectively.

```
# build all examples at once
make examples

# build all demos at once
make demos

# build only the Straight Skeleton demo
make Straight_skeleton_2_demo
```

advanced

When using `UNIX Makefiles` you can find out the exact name of the example or demo target of a particular package by typing `make help | grep <package>`.

advanced

3.12 Installing CGAL

On many platforms, library pieces such as headers, docs and binaries are expected to be placed in specific locations. A typical example being `/usr/include` and `/usr/lib` on UNIX-like operating systems or `C:/Program Files/` on Windows. The process of placing or copying the library elements into its standard location is sometimes referred to as *Installation* and it is a postprocessing step after the build step.

CMake carries out the installation by producing a build target named *install*. The following example shows a typical session from configuration to installation in a UNIX-like environment:

```
cd CGAL-4.1

cmake .      # configure
make         # compile
make install # install
```

If you use a generator that produces IDE files (for Visual Studio for instance) there will be an optional `INSTALL` project, which you will be able to *"build"* to execute the installation step.

advanced

The files are copied into a directory tree relative to the *installation directory* determined by the CMake variable `CMAKE_INSTALL_PREFIX`. This variable defaults to `/usr/local` under UNIX-like operating systems and `C:\Program Files` under Windows. If you want to install to a different location, you must override that CMake variable explicitly *at the configuration time* and not when executing the install step.

advanced

The file `CGALConfig.cmake` is installed by default in `$CMAKE_INSTALLED_PREFIX/lib/CGAL-4.1`.

3.13 Example Configuration

Below is an example output on a linux machine with g++4.4 installed, using CMake 2.8.5, and the following command-line call to `cmake`:

```
cmake -DWITH_examples=OFF -DWITH_demos=OFF -DCMAKE_BUILD_TYPE=Release
  /path/to/unpacked/CGAL-tarball/
```

```

3.14 Multiple Variants of makefiles (out-of-source build)

While you can choose between release or debug builds, and shared or static libraries, it is not possible to generate different variants during a single configuration. You need to run CMake in a different directory for each variant you are interested in, each with its own selection of configuration parameters.

CMake stores the resulting makefiles and project files, along with several temporary and auxiliary files such as the variables cache, in the directory where it is executed, called `CMAKE_BINARY_DIR`, but it takes the source files and configuration scripts from `CMAKE_SOURCE_DIR`.

The binary and source directories do not need to be the same. Thus, you can configure multiple variants by creating a distinct directory for each configuration and by running CMake from there. This is known in CMake terminology as *out-of-source configuration*, as opposite to an *in-source configuration*, as showed in the previous sections.

You can, for example, generate subdirectories `CGAL-4.1/cmake/platforms/debug` and `CGAL-4.1/cmake/platforms/release` for two configurations, respectively:

```
mkdir CGAL-4.1/cmake/platforms/debug
cd CGAL-4.1/cmake/platforms/debug
cmake -DCMAKE_BUILD_TYPE=Debug ../../..

mkdir CGAL-4.1/cmake/platforms/release
cd CGAL-4.1/cmake/platforms/release
cmake -DCMAKE_BUILD_TYPE=Release ../../..
```

3.15 Configuring and Building Programs Using CGAL

Ideally, configuring and compiling a demo/example/program amounts to

```
cd CGAL-4.1/examples/Straight_skeleton_2
cmake -DCGAL_DIR=$HOME/CGAL-4.1 .
make
```

In this ideal world, as for all shipped examples and demos of CGAL, the required `CMakeLists.txt` is already provided.

CMake can also be used to configure and build user programs via such CMake-scripts. In this less ideal world, one has to provide the `CMakeLists.txt` script either manually, or with the help of a shell-script that is introduced below.

For a user program `executable.cpp`, the ideal world looks like this:

```
cd /path/to/program
cgal_create_CMakeLists -s executable
cmake -DCGAL_DIR=$HOME/CGAL-4.1 .
make
```

In both examples we specify the `CGAL_DIR`: During configuration of the CGAL libraries a file named `CGALConfig.cmake` is generated in CGAL's root directory (in contrast to CGAL's source directory that has been used for installation). This file contains the definitions of several CMake variable that summarize the configuration of CGAL. In order to configure a program, you need to indicate the location of that config file in the CMake variable `CGAL_DIR` (as indicated in the example above). `CGAL_DIR` can also be an environment variable. Setting `CGAL_DIR` makes particular sense if having multiple out-of-source builds of CGAL as in Section 3.14.

If you have installed CGAL, `CGAL_DIR` must afterwards be set to `$CMAKE_INSTALLED_PREFIX/lib/CGAL`. Note that CGAL is recommended to be installed in release mode when using it to build programs.

3.15.1 Creating a cmake script for a program using CGAL

For compiling a non-shipped program, it is recommended, to also rely on a CMake-supported configuration using a `CMakeLists.txt` used for configuration.

Use the following Bourne-shell script for programs that are relatively simple to configure:

cgal_create_CMakeLists

The Bourne-shell script `cgal_create_CMakeLists.txt` resides in the `CGAL-4.1/scripts` directory. It can be used to create `CMakeLists.txt` files for compiling CGAL applications. Executing `cgal_create_CMakeLists.txt` in an application directory creates a `CMakeLists.txt` containing rules to build the contained application(s). Three command line options determine details of the configuration.

-s source If this parameter is given the script will create **a single executable** for 'source' linked with compilations of all other source files (`*.cpp`). This behaviour is usually needed for (graphical) demos.
If the parameter is not given, the script creates **one executable for each given source file**.

-c com1:com2:... Lists components ("com1", "com2") of CGAL to which the executable(s) should be linked. Valid components are CGAL's libraries (i.e. "Core", "ImageIO", "Qt3" and "Qt4"; note that it only make sense to either pick "Qt3" or "Qt4") and all preconfigured 3rd party software, such as "MPFI" or "RS3"). An example is `-c Core:GMP:RS3:MPFI`

-b boost1:boost2:... Lists components ("boost1", "boost2") of BOOST to which the executable(s) should be linked. Valid options are, for instance, "filesystem" or "program_options".

This options should suffice to create `CMakeLists.txt` script for most directories containing programs. However, in some special cases, it might still be required to create the script manually, for instance, if some source files/executables need a different linking than other source files.

deprecated

cgal_create_cmake_script

For backward-compatibility we still provide the Bourne-shell script `cgal_create_cmake_script` that is contained in the `CGAL-4.1/scripts` directory. It can be used to create `CMakeLists.txt` files for compiling CGAL applications. Executing `cgal_create_cmake_script` in an application directory creates a `CMakeLists.txt` containing rules for every `*.cpp` file there. The script is deprecated, as it only works for applications with a single course file that only need libCGAL and libCGAL_Core.

deprecated

Such a shell-script simply creates a CMake script. Processing it with CMake, searches for CGAL using `find_package`. If found, the variable `CGAL_USE_FILE` is set to a compilation environment CMake file. Including this file within a CMake script sets up include paths and libraries to link with CGAL and essential third party libraries. Beyond, `find_package` can demand for `COMPONENTS` of CGAL, that is, all CGAL libraries libCGAL_Core ("Core"), libCGAL_imageIO ("ImageIO") , libCGAL_Qt3 ("Qt3") and libCGAL_Qt4 ("Qt4") or optional 3rd party software such as "MPFI" or "RS3". A user is free to create the `CMakeLists.txt` without calling the script (manual creation).

3.15.2 Custom flags in the programs using CGAL

Normally, programs linked with CGAL must be compiled with the same flags used by the compilation of CGAL libraries. For this reason, the *very first* time a program is configured, all the flags given by the CMake variables `CMAKE_*_FLAGS` are *locked* in the sense that the values recorded in `CGALConfig.cmake` are used to override any values given by CMake itself or yourself.

This does not apply to the additional flags that can be given via `CGAL_*_FLAGS`.

Such *inherited* values are then recorded in the current CMake cache for the program. The flags are then *unlocked* in the sense that at any subsequent configuration you can provide your own flags and this time they will not be overridden.

When using the interactive `cmake-gui` the first press on `Configure` unlocks the flags, so that you can edit them as needed.

advanced

The locking of flags is controlled by the variable `CGAL_DONT_OVERRIDE_CMAKE_FLAGS` which starts out FALSE and is toggled right after the flags have been loaded from `CGALConfig.cmake`.

If you use the command line tool you can specify flags *directly* by setting the controlling variable right up front:

```
cd CGAL-4.1

cmake -DCMAKE_BUILD_TYPE=Release -DCMAKE_CXX_FLAGS=-g .

cd CGAL-4.1/examples/Straight_skeleton_2

cmake -DCGAL_DIR=CGAL-4.1 -DCMAKE_BUILD_TYPE=Debug -DCMAKE_CXX_FLAGS=-O2 -DCGAL_DONT_OVERRIDE_CMAKE_FLAGS
```

3.16 Summary of CGAL's Configuration Variables

Most configuration variables are not environment variables but *CMake variables*. They are given in the command line to CMake via the `-D` option, or passed from the interactive interface of `cmake-gui`. Unless indicated differently, all the variables summarized below are CMake variables.

3.16.1 Component selection

The following boolean variables indicate which CGAL components to configure and build. Their values can be ON or OFF.

Variable	Default value
`WITH_examples`	OFF
`WITH_demos`	OFF
`WITH_CGAL_Core`	ON
`WITH_CGAL_Qt3`	ON
`WITH_CGAL_Qt4`	ON
`WITH_CGAL_ImageIO`	ON

3.16.2 Compiler and Linker Flags

The following variables specify compiler and linker flags. Each variable holds a space-separated list of command-line switches for the compiler and linker and their default values are automatically defined by CMake based on the target platform.

Have in mind that these variables specify a list of flags, not just one single flag. If you provide your own definition for a variable, you will *entirely* override the list of flags chosen by CMake for that particular variable.

The variables that correspond to both debug and release builds are always used in conjunction with those for the specific build type.

Program	Both Debug and Release	Release only	Debug Only
C++ Compiler	`CMAKE_CXX_FLAGS`	`CMAKE_CXX_FLAGS_RELEASE`	`CMAKE_CXX_FLAGS_DEBUG`
Linker (shared libs)	`CMAKE_SHARED_LINKER_FLAGS`	`CMAKE_SHARED_LINKER_FLAGS_RELEASE`	`CMAKE_SHARED_LINKER_FLAGS_DEBUG`
Linker (static libs)	`CMAKE_MODULE_LINKER_FLAGS`	`CMAKE_MODULE_LINKER_FLAGS_RELEASE`	`CMAKE_MODULE_LINKER_FLAGS_DEBUG`
Linker (programs)	`CMAKE_EXE_LINKER_FLAGS`	`CMAKE_EXE_LINKER_FLAGS_RELEASE`	`CMAKE_EXE_LINKER_FLAGS_DEBUG`

Additional Compiler and Linker Flags

The following variables can be used to *add* flags without overriding the ones defined by cmake.

Program	Both Debug and Release	Release only	Debug Only
C++ Compiler	`CGAL_CXX_FLAGS`	`CGAL_CXX_FLAGS_RELEASE`	`CGAL_CXX_FLAGS_DEBUG`
Linker (shared libs)	`CGAL_SHARED_LINKER_FLAGS`	`CGAL_SHARED_LINKER_FLAGS_RELEASE`	`CGAL_SHARED_LINKER_FLAGS_DEBUG`
Linker (static libs)	`CGAL_MODULE_LINKER_FLAGS`	`CGAL_MODULE_LINKER_FLAGS_RELEASE`	`CGAL_MODULE_LINKER_FLAGS_DEBUG`
Linker (programs)	`CGAL_EXE_LINKER_FLAGS`	`CGAL_EXE_LINKER_FLAGS_RELEASE`	`CGAL_EXE_LINKER_FLAGS_DEBUG`

3.16.3 Miscellaneous Variables

Variable	Description	Type	Default value
`CMAKE_BUILD_TYPE`	Indicates type of build. Possible values are 'Debug' or 'Release'	CMake	Release
`CMAKE_CXX_COMPILER`	Full-path to the executable corresponding to the C++ compiler to use.	CMake	platform-dependent
`CXX`	Idem	Environment	Idem

Variables used only when building programs (such as demos or examples)

Variable	Description	Type	Default value
`CGAL_DIR`	Full-path to the binary directory where CGAL was configured	Either CMake or Environment	*none*

3.16.4 Variables providing information about 3rd-party libraries

The following variables provide information about the availability and location of the 3rd party libraries used by CGAL. CMake automatically searches for dependencies so you need to specify these variables if CMake was unable to locate something. This is indicated by a value ending in `NOTFOUND`.

Since 3rd-party libraries are system wide, many of the CMake variables listed below can alternatively be given as similarly-named environment variables instead. Keep in mind that you must provide one or the other but never both.

BOOST libraries

In most cases, if BOOST is not automatically found, setting the `BOOST_ROOT` variable is enough. If it is not, you can specify the header and library directories individually. You can also provide the full pathname to a specific compiled library if it cannot be found in the library directory or its name is non-standard.

By default, when BOOST binary libraries are needed, the shared versions are used if present. You can set the variable `CGAL_Boost_USE_STATIC_LIBS` to `ON` if you want to link with static versions explicitly.

On Windows, if you link with BOOST shared libraries, you must ensure that the `.dll` files are found by the dynamic linker, at run time. For example, you can add the path to the BOOST `.dll` to the `PATH` environment variable.

Variable	Description	Type
`BOOST_ROOT`[16]	Root directory of your BOOST installation	Either CMake or Environment
`Boost_INCLUDE_DIR`	Directory containing the `boost/version.hpp` file	CMake
`BOOST_INCLUDEDIR`	Idem	Environment
`Boost_LIBRARY_DIRS`	Directory containing the compiled BOOST libraries	CMake
`BOOST_LIBRARYDIR`	Idem	Environment
`Boost_(xyz)_LIBRARY_RELEASE`	Full pathname to a release build of the compiled 'xyz' BOOST library	CMake
`Boost_(xyz)_LIBRARY_DEBUG`	Full pathname to a debug build of the compiled 'xyz' BOOST library	CMake

GMP and MPFR libraries

Under Windows, auto-linking is used, so only the *directory* containing the libraries is needed and you would specify `GMP|MPFR_LIBRARY_DIR` rather than `GMP|MPFR_LIBRARIES`. On the other hand, under Linux the actual library filename is needed. Thus you would specify `GMP|MPFR_LIBRARIES`. In no case you need to specify both.

CGAL uses both GMP and MPFR so both need to be supported. If either of them is unavailable the usage of GMP and of MPFR will be disabled.

Variable	Description	Type
`WITH_GMP`	Indicates whether to search and use GMPMPFR or not	CMake
`GMP_DIR`	Directory of GMP default installation	Environment
`GMP_INCLUDE_DIR`	Directory containing the `gmp.h` file	CMake
`GMP_INC_DIR`	Idem	Environment
`GMP_LIBRARIES_DIR`	Directory containing the compiled GMP library	CMake
`GMP_LIB_DIR`	Idem	Environment
`GMP_LIBRARIES`	Full pathname of the compiled GMP library	CMake
`MPFR_INCLUDE_DIR`	Directory containing the `mpfr.h` file	CMake
`MPFR_INC_DIR`	Idem	Environment
`MPFR_LIBRARIES_DIR`	Directory containing the compiled MPFR library	CMake
`MPFR_LIB_DIR`	Idem	Environment
`MPFR_LIBRARIES`	Full pathname of the compiled MPFR library	CMake

Under Linux, the GMPXX is also searched for, and you may specify the following variables:

Variable	Description	Type
`GMPXX_DIR`	Directory of GMPXX default installation	Environment
`GMPXX_INCLUDE_DIR`	Directory containing the `gmpxx.h` file	CMake
`GMPXX_LIBRARIES`	Full pathname of the compiled GMPXX library	CMake

QT3 library

In most cases, if QT3 is not automatically found, setting the `QTDIR` environment variable is sufficient. If it is not, you can specify the directory containing the header files and the full pathnames of the QT3 libraries.

[16] The environment variable can be spelled either `BOOST_ROOT` or `BOOSTROOT`

Variable	Description	Type
QTDIR	Root directory of the QT3 library	Environment
QT3_INCLUDE_DIR	Directory containing the qt.h file	CMake
QT3_QT_LIBRARY	Full pathname to the qt library of QT3	CMake
QT3_QTMAIN_LIBRARY	Full pathname to the qtmain library of QT3	CMake
QT3_QASSISTANTCLIENT_LIBRARY	Full pathname to the qassistantclient library of QT3	CMake
QT3_MOC_EXECUTABLE	Full pathname to the moc executable of QT3	CMake
QT3_UIC_EXECUTABLE	Full pathname to the uic executable of QT3	CMake

QT4 library

The CMake scripts that search for QT4 can use the introspection feature of the tool `qmake` included in QT4 distributions. If QT4 is not automatically found, it is sufficient to set the `PATH` environment variable, so that QT4 `qmake` tool is in the path, and before QT3 `qmake` if that one exists. One can alternatively set the CMake variable `QT_QMAKE_EXECUTABLE`. The following variables should be then assigned automatically by CMake.

Variable	Description	Type
QT_INCLUDE_DIR	Directory containing the QtCore/qglobal.h file	CMake
QT_LIBRARY_DIR	Directory containing the compiled QT4 libraries	CMake
QT_*(xyz)*_LIBRARY	Full pathname to the compiled 'xyz' QT4 library[17]	CMake
QT_QMAKE_EXECUTABLE	Full pathname to the qmake executable of QT4	CMake
QT_MOC_EXECUTABLE	Full pathname to the moc executable of QT4	CMake
QT_UIC_EXECUTABLE	Full pathname to the uic executable of QT4	CMake

LEDA library

When the LEDA libraries are not automatically found, yet they are installed on the system with base names 'leda' and 'ledaD' (for the release and debug versions resp.), it might be sufficient to just indicate the library directory via the `LEDA_LIBRARY_DIRS` variable. If that doesn't work because, for example, the names are different, you can provide the full pathnames of each variant via `LEDA_LIBRARY_RELEASE` and `LEDA_LIBRARY_DEBUG`.

The variables specifying definitions and flags can be left undefined if they are not needed by LEDA.

[17] If both release and debug versions are available, this variable contains a list of the following form: '`optimized;<fullpath-to-release-lib>;debug;<fullpath-to-debug-lib>`', where the '`optimized`' and '`debug`' tags should appear verbatim.

Variable	Description	Type
WITH_LEDA	Indicates whether to search and use LEDA or not	CMake
LEDA_DIR	Directory of LEDA default installation	Environment
LEDA_INCLUDE_DIR	Directory containing the file LEDA/system/basic.h	CMake
LEDA_LIBRARIES	Directory containing the compiled LEDA libraries	CMake
LEDA_INC_DIR	Directory containing the file LEDA/system/basic.h	Environment
LEDA_LIB_DIR	Directory containing the compiled LEDA libraries	Environment
LEDA_LIBRARY_RELEASE	Full pathname to a release build of the LEDA library	Either CMake
LEDA_LIBRARY_DEBUG	Full pathname to a debug build of the LEDA library	Either CMake
LEDA_DEFINITIONS	Preprocessor definitions	Either CMake
LEDA_CXX_FLAGS	Compiler flags	Either CMake
LEDA_LINKER_FLAGS	Linker flags	Either CMake

MPFI library

CGAL provides a number type based on this library, but the CGAL library itself does not depend on MPFI. This means that this library must be configured when compiling an application that uses the above number type.

When MPFI files are not on the standard path, the locations of the headers and library files must be specified by using environment variables.

Variable	Description	Type
MPFI_DIR	Directory of MPFI default installation	Environment
MPFI_INCLUDE_DIR	Directory containing the mpfi.h file	CMake
MPFI_INC_DIR	Idem	Environment
MPFI_LIBRARIES_DIR	Directory containing the compiled MPFI library	CMake
MPFI_LIB_DIR	Idem	Environment
MPFI_LIBRARIES	Full pathname of the compiled MPFI library	CMake

Rs and Rs3 library

As said before, only the CGAL univariate algebraic kernel depends on the library Rs. As the algebraic kernel is not compiled as a part of the CGAL library, this library is not detected nor configured at installation time.

CMake will try to find Rs in the standard header and library directories. When it is not automatically detected, the locations of the headers and library files must be specified using environment variables.

Rs needs GMP 4.2 or later and MPFI 1.3.4 or later. The variables related to the latter library may also need to be defined.

Variable	Description	Type
RS_DIR	Directory of Rs default installation	Environment
RS_INCLUDE_DIR	Directory containing the rs_exports.h file	CMake
RS_INC_DIR	Idem	Environment
RS_LIBRARIES_DIR	Directory containing the compiled Rs library	CMake
RS_LIB_DIR	Idem	Environment
RS_LIBRARIES	Full pathname of the compiled Rs library	CMake

Similar variables exist for Rs3.

Variable	Description	Type
RS3_DIR	Directory of Rs3 default installation	Environment
RS3_INCLUDE_DIR	Directory containing the rs_exports.h file	CMake
RS3_INC_DIR	Idem	Environment
RS3_LIBRARIES_DIR	Directory containing the compiled Rs library	CMake
RS3_LIB_DIR	Idem	Environment
RS3_LIBRARIES	Full pathname of the compiled Rs library	CMake

NTL library

Some polynomial computations in CGAL's algebraic kernel are speed up when NTL is available. As the algebraic kernel is not compiled as a part of the CGAL library, this library is not detected nor configured at installation time.

CMake will try to find NTL in the standard header and library directories. When it is not automatically detected, the locations of the headers and library files must be specified using environment variables.

Variable	Description	Type
NTL_DIR	Directory of NTL default installation	Environment
NTL_INCLUDE_DIR	Directory containing the NTL/ZZX.h file	CMake
NTL_INC_DIR	Idem	Environment
NTL_LIBRARIES_DIR	Directory containing the compiled NTL library	CMake
NTL_LIB_DIR	Idem	Environment
NTL_LIBRARIES	Full pathname of the compiled NTL library	CMake

EIGEN library

EIGEN is a header-only template library. Only the *directory* containing the header files of EIGEN 3.1 (or greater) is needed.

Variable	Description	Type
EIGEN3_DIR	Directory of EIGEN default installation	Environment
EIGEN3_INCLUDE_DIR	Directory containing the file signature_of_eigen3_matrix_library	CMake
EIGEN3_INC_DIR	Idem	Environment

QGLViewer library

Some demos require the GLViewer library.

In most cases, if QGLViewer is not automatically found, setting the `QGLVIEWERROOT` environment variable is sufficient. If it is not, you can specify the directory containing the header files and the full pathnames of the release and debug libraries

Variable	Description	Type
`QGLVIEWERROOT`	Root directory of the QGLViewer library	Environment
`QGLVIEWER_INCLUDE_DIR`	Directory containing the `QGLViewer/qglviewer.h` file	CMake
`QGLVIEWER_LIBRARY_RELEASE`	Full pathname to a release build of the QGLViewer library	CMake
`QGLVIEWER_LIBRARY_DEBUG`	Full pathname to a debug build of the QGLViewer library	CMake

ESBTL library

One skin surface example requires the ESBTL library in order to read PDB files.

If ESBTL is not automatically found, setting the `ESBTL_INC_DIR` environment variable is sufficient.

Variable	Description	Type
`ESBTL_DIR`	Directory of ESTBL default installation	Environment
`ESBTL_INC_DIR`	Directory containing the `ESBTL/default.h` file	Environment
`ESBTL_INCLUDE_DIR`	Directory containing the `ESBTL/default.h` file	CMake

3.17 Compiler Workarounds

A number of boolean flags are used to workaround compiler bugs and limitations. They all start with the prefix `CGAL_CFG`. These flags are used to work around compiler bugs and limitations. For example, the flag `CGAL_CFG_NO_CPP0X_LONG_LONG` denotes that the compiler does not know the type `long long`.

For each installation a file `<CGAL/compiler_config.h>` is defined, with the correct settings of all flags. This file is generated automatically by CMake, and it is located in the `include` directory of where you run CMake. For an in-source configuration this means `CGAL-x.y/include`.

The test programs used to generate the `compiler_config.h` file can be found in `config/testfiles`. Both `compiler_config.h` and the test programs contain a short description of the problem. In case of trouble with one of the `CGAL_CFG` flags, it is a good idea to take a look at it.

The file `CGAL/compiler_config.h` is included from `<CGAL/config.h>`. which is included by all CGAL header files.

3.18 Compiler Optimizations

By default CMake generates makefiles for Release mode, with optimization flags switched on, and vcproj files for Release and Debug modes.

Algebraic Foundations

Michael Hemmer

Contents

4.1 Introduction

CGAL is targeting towards exact computation with non-linear objects, in particular objects defined on algebraic curves and surfaces. As a consequence types representing polynomials, algebraic extensions and finite fields play a more important role in related implementations. This package has been introduced to stay abreast of these changes. Since in particular polynomials must be supported by the introduced framework the package avoids the term *number type*. Instead the package distinguishes between the *algebraic structure* of a type and whether a type is embeddable on the real axis, or *real embeddable* for short. Moreover, the package introduces the notion of *interoperable* types which allows an explicit handling of mixed operations.

4.2 Algebraic Structures

The algebraic structure concepts introduced within this section are motivated by their well known counterparts in traditional algebra, but we also had to pay tribute to existing types and their restrictions. To keep the interface minimal, it was not desirable to cover all known algebraic structures, e.g., we did not introduce concepts for such basic structures as *groups* or exceptional structures as *skew fields*.

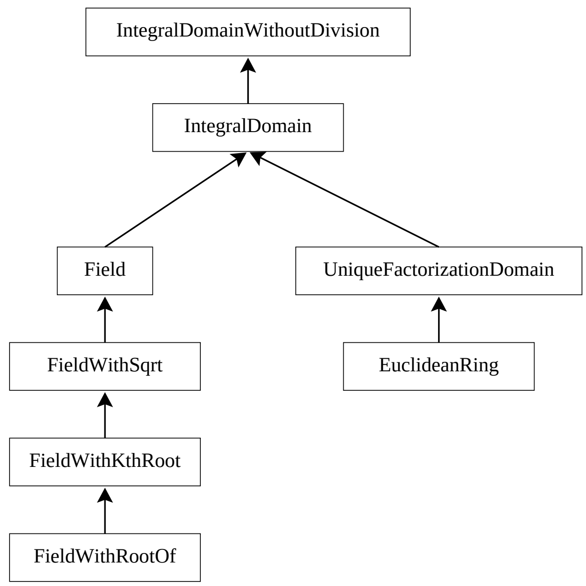

Figure 4.1: Concept Hierarchy of Algebraic Structures

Figure 4.1 shows the refinement relationship of the algebraic structure concepts. *IntegralDomain*, *UniqueFactorizationDomain*, *EuclideanRing* and *Field* correspond to the algebraic structures with the same name. *FieldWithSqrt*, *FieldWithKthRoot* and *FieldWithRootOf* are fields that in addition are closed under the operations 'sqrt', 'k-th root' and 'real root of a polynomial', respectively. The concept *IntegralDomainWithoutDivision* also corresponds to integral domains in the algebraic sense, the distinction results from the fact that some implementations of integral domains lack the (algebraically always well defined) integral division. Note that *Field* refines *IntegralDomain*. This is because most ring-theoretic notions like greatest common divisors become trivial for *Field*s. Hence we see *Field* as a refinement of *IntegralDomain* and not as a refinement of one of the more advanced ring concepts. If an algorithm wants to rely on gcd or remainder computation, it is trying to do things it should not do with a *Field* in the first place.

The main properties of an algebraic structure are collected in the class *Algebraic_structure_traits*. In particular the (most refined) concept each concrete model *AS* fulfills is encoded in the tag *Algebraic_structure_traits<AS> ::Algebraic_category*. An algebraic structure is at least *Assignable*, *CopyConstructible*, *DefaultConstructible* and *EqualityComparable*. Moreover, we require that it is constructible from *int*. For ease of use and since their semantic is sufficiently standard to presume their existence, the usual arithmetic and comparison operators are required to be realized via C++ operator overloading. The division operator is reserved for division in fields. All other unary (e.g., sqrt) and binary functions (e.g., gcd, div) must be models of the well known STL-concepts *AdaptableUnaryFunction* or *AdaptableBinaryFunction* concept and local to the traits class (e.g., *Algebraic_structure_traits<AS>::Sqrt()(x)*). This design allows us to profit from all parts in the STL and its programming style and avoids the name-lookup and two-pass template compilation problems experienced with the old design using overloaded functions. However, for ease of use and backward compatibility all functionality is also accessible through global functions defined within namespace *CGAL*, e.g., *CGAL::sqrt(x)*. This is realized via function templates using the according functor of the traits class. For an overview see Section 4.8 in the reference manual.

4.2.1 Tags in Algebraic Structure Traits

Algebraic Category

For a type *AS*, *Algebraic_structure_traits*<*AS*> provides several tags. The most important tag is the *Algebraic_category* tag, which indicates the most refined algebraic concept the type *AS* fulfills. The tag is one of; *Integral_domain_without_division_tag*, *Integral_domain_tag*, *Field_tag*, *Field_with_sqrt_tag*, *Field_with_kth_root_tag*, *Field_with_root_of_tag*, *Unique_factorization_domain_tag*, *Euclidean_ring_tag*, or even *Null_tag* in case the type is not a model of an algebraic structure concept. The tags are derived from each other such that they reflect the hierarchy of the algebraic structure concept, e.g., *Field_with_sqrt_tag* is derived from *Field_tag*.

Exact and Numerical Sensitive

Moreover, *Algebraic_structure_traits*<*AS*> provides the tags *Is_exact* and *Is_numerical_sensitive*, which are both *Boolean_tags*.
An algebraic structure is considered *exact*, if all operations required by its concept are computed such that a comparison of two algebraic expressions is always correct.
An algebraic structure is considered as *numerically sensitive*, if the performance of the type is sensitive to the condition number of an algorithm. Note that there is really a difference among these two notions, e.g., the fundamental type *int* is not numerical sensitive but considered inexact due to overflow. Conversely, types as *leda_real* or *CORE::Expr* are exact but sensitive to numerical issues due to the internal use of multi precision floating point arithmetic. We expect that *Is_numerical_sensitive* is used for dispatching of algorithms, while *Is_exact* is useful to enable assertions that can be check for exact types only.

Tags are very useful to dispatch between alternative implementations. The following example illustrates a dispatch for *Field*s using overloaded functions. The example only needs two overloads since the algebraic category tags reflect the algebraic structure hierarchy.

```
#include <CGAL/basic.h>
#include <CGAL/IO/io.h>
#include <CGAL/Algebraic_structure_traits.h>

template< typename NT > NT unit_part(const NT& x);
template< typename NT >
NT unit_part_(const NT& x, CGAL::Field_tag);
template< typename NT >
NT unit_part_(const NT& x, CGAL::Integral_domain_without_division_tag);

template< typename NT >
NT unit_part(const NT& x){
    // the unit part of 0 is defined as 1.
    if (x == 0 ) return NT(1);

    typedef CGAL::Algebraic_structure_traits<NT> AST;
    typedef typename AST::Algebraic_category Algebraic_category;
    return unit_part_(x,Algebraic_category());
}

template< typename NT >
NT unit_part_(const NT& x, CGAL::Integral_domain_without_division_tag){
    // For many other types the only units are just -1 and +1.
```

```
    return NT(int(CGAL::sign(x)));
}

template< typename NT >
NT unit_part_(const NT& x, CGAL::Field_tag){
    // For Fields every x != 0 is a unit.
    // Therefore, every x != 0 is its own unit part.
    return x;
}

int main(){
    // Function call for a model of EuclideanRing, i.e. int.
    std::cout<< "int:    unit_part(-3  ): " << unit_part(-3  ) <<
   std::endl;
    // Function call for a model of FieldWithSqrt, i.e. double
    std::cout<< "double: unit_part(-3.0): " << unit_part(-3.0) <<
   std::endl;
    return 0;
}

// Note that this is just an example
// This implementation for unit part won't work for some types, e.g.,
// types that are not RealEmbeddable or types representing structures
   that have
// more units than just -1 and +1. (e.g. MP_Float representing Z[1/2])
// From there Algebraic_structure_traits provides the functor Unit_part.
```

4.3 Real Embeddable

Most number types represent some subset of the real numbers. From those types we expect functionality to compute the sign, absolute value or double approximations. In particular we can expect an order on such a type that reflects the order along the real axis. All these properties are gathered in the concept *RealComparable*. The concept is orthogonal to the algebraic structure concepts, i.e., it is possible that a type is a model of *RealEmbeddable* only, since the type may just represent values on the real axis but does not provide any arithmetic operations.

As for algebraic structures this concept is also traits class oriented. The main functionality related to *RealEmbeddable* is gathered in the class *Real_embeddable_traits*. In particular, it porivdes the boolean tag *Is_real_embeddable* indicating whether a type is a model of *RealEmbeddable*. The comparison operators are required to be realized via C++ operator overloading. All unary functions (e.g. *sign*, *to_double*) and binary functions (e.g. *compare*) are models of the STL-concepts *AdaptableUnaryFunction* and *AdaptableBinaryFunction* and are local to *Real_embeddable_traits*.

In case a type is a model of *IntegralDomainWithoutDivision* and *RealEmbeddable* the number represented by an object of this type is the same for arithmetic and comparison. It follows that the ring represented by this type is a superset of the integers and a subset of the real numbers and hence has characteristic zero. In case the type is a model of *Field* and *RealEmbeddable* it is a superset of the rational numbers.

4.4 Real Number Types

Every CGAL *Kernel* comes with two *real number types* (number types embeddable into the real numbers). One of them is a *FieldNumberType*, and the other a *RingNumberType*. The coordinates of the basic kernel objects (points, vectors, etc.) come from one of these types (the *FieldNumberType* in case of Cartesian kernels, and the *RingNumberType* for Homogeneous kernels).

The concept *FieldNumberType* combines the requirements of the concepts *Field* and *RealEmbeddable*, while *RingNumberType* combines *IntegralDomainWithoutDivision* and *RealEmbeddable*. Algebraically, the real number types do not form distinct structures and are therefore not listed in the concept hierarchy of Figure 4.1.

4.5 Interoperability

This section introduces two concepts for interoperability of types, namely *ImplicitInteroperable* and *ExplicitInteroperable*. While *ExplicitInteroperable* is the base concept, we start with *ImplicitInteroperable* since it is the more intuitive one.

In general mixed operations are provided by overloaded operators and functions or just via implicit constructor calls. This level of interoperability is reflected by the concept *ImplicitInteroperable*. However, within template code the result type, or so called coercion type, of a mixed arithmetic operation may be unclear. Therefore, the package introduces *CGAL::Coercion_traits* giving access to the coercion type via *CGAL::Coercion_traits< A,B>::Type* for two interoperable types *A* and *B*.

Some trivial example are *int* and *double* with coercion type double or *CGAL::Gmpz* and *CGAL::Gmpq* with coercion type *CGAL::Gmpq*. However, the coercion type is not necessarily one of the input types, e.g. the coercion type of a polynomial with integer coefficients that is multiplied by a rational type is supposed to be a polynomial with rational coefficients.

CGAL::Coercion_traits is also required to provide a functor *CGAL::Coercion_traits<A,B>::Cast()*, that converts from an input type into the coercion type. This is in fact the core of the more basic concept *ExplicitInteroperable*. *ExplicitInteroperable* has been introduced to cover more complex cases for which it is hard or impossible to guarantee implicit interoperability. Note that this functor can be useful for *ImplicitInteroperable* types as well, since it can be used to void redundant type conversions.

In case two types *A* and *B* are *ExplicitInteroperable* with coercion type *C* they are valid argument types for all binary functors provided by *Algebraic_structure_traits* and *Real_embeddable_traits* of *C*. This is also true for the according global functions.

4.5.1 Examples

The following example illustrates how two write code for *ExplicitInteroperable* types.

```
#include <CGAL/basic.h>
#include <CGAL/Coercion_traits.h>
#include <CGAL/IO/io.h>

// this is an implementation for ExplicitInteroperable types
// the result type is determined via Coercion_traits<A,B>
template <typename A, typename B>
typename CGAL::Coercion_traits<A,B>::Type
```

```
binary_func(const A& a , const B& b){
    typedef CGAL::Coercion_traits<A,B> CT;

    // check for explicit interoperability
    CGAL_static_assertion((CT::Are_explicit_interoperable::value));

    // CT::Cast is used to to convert both types into the coercion type
    typename CT::Cast cast;
    // all operations are performed in the coercion type
    return cast(a)*cast(b);
}

int main(){
    // Function call for the interoperable types
    std::cout<< binary_func(double(3), int(5)) << std::endl;
    // Note that Coercion_traits is symmetric
    std::cout<< binary_func(int(3), double(5)) << std::endl;
    return 0;
}
```

File: examples/Algebraic_foundations/interoperable.cpp

The following example illustrates a dispatch for *ImplicitInteroperable* and *ExplicitInteroperable* types. The binary function (that just multiplies its two arguments) is supposed to take two *ExplicitInteroperable* arguments. For *ImplicitInteroperable* types a variant that avoids the explicit cast is selected.

```
#include <CGAL/basic.h>
#include <CGAL/Coercion_traits.h>
#include <CGAL/Quotient.h>
#include <CGAL/Sqrt_extension.h>
#include <CGAL/IO/io.h>

// this is the implementation for ExplicitInteroperable types
template <typename A, typename B>
typename CGAL::Coercion_traits<A,B>::Type
binary_function_(const A& a , const B& b, CGAL::Tag_false){
    std::cout << "Call for ExplicitInteroperable types: " << std::endl;
    typedef CGAL::Coercion_traits<A,B> CT;
    typename CT::Cast cast;
    return cast(a)*cast(b);
}

// this is the implementation for ImplicitInteroperable types
template <typename A, typename B>
typename CGAL::Coercion_traits<A,B>::Type
binary_function_(const A& a , const B& b, CGAL::Tag_true){
    std::cout << "Call for ImpicitInteroperable types: " << std::endl;
    return a*b;
}

// this function selects the correct implementation
template <typename A, typename B>
typename CGAL::Coercion_traits<A,B>::Type
```

```
binary_func(const A& a , const B& b){
    typedef CGAL::Coercion_traits<A,B> CT;
    typedef typename CT::Are_implicit_interoperable
   Are_implicit_interoperable;
    return binary_function_(a,b,Are_implicit_interoperable());
}

int main(){
    CGAL::set_pretty_mode(std::cout);

    // Function call for ImplicitInteroperable types
    std::cout<< binary_func(double(3), int(5)) << std::endl;

    // Function call for ExplicitInteroperable types
    CGAL::Quotient<int>           rational(1,3);    // == 1/3
    CGAL::Sqrt_extension<int,int> extension(1,2,3); // == 1+2*sqrt(3)
    CGAL::Sqrt_extension<CGAL::Quotient<int>,int> result =
   binary_func(rational, extension);
    std::cout<< result << std::endl;

    return 0;
}
```

File: examples/Algebraic_foundations/implicit_interoperable_dispatch.cpp

4.6 Fractions

Beyond the need for performing algebraic operations on objects as a whole, there are also number types which one would like to decompose into numerator and denominator. This does not only hold for rational numbers as *Quotient*, *Gmpq*, *mpq_class* or *leda_rational*, but also for compound objects as *Sqrt_extension* or *Polynomial* which may decompose into a (scalar) denominator and a compound numerator with a simpler coefficient type (e.g. integer instead of rational). Often operations can be performed faster on these denominator-free multiples. In case a type is a *Fraction* the relevant functionality as well as the numerator and denominator type are provided by *CGAL::Fraction_traits*. In particular *CGAL::Fraction_traits* provides a tag *Is_fraction* that can be used for dispatching.

A related class is *CGAL::Rational_traits* which has been kept for backward compatibility reasons. However, we recommend to use *Fraction_traits* since it is more general and offers dispatching functionality.

4.6.1 Examples

The following example show a simple use of *Fraction_traits*:

```
#include <CGAL/basic.h>
#include <CGAL/Fraction_traits.h>
#include <CGAL/IO/io.h>

#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
```

```
#include <CGAL/Gmpq.h>
int main(){
    typedef CGAL::Fraction_traits<CGAL::Gmpq> FT;
    typedef FT::Numerator_type Numerator_type;
    typedef FT::Denominator_type Denominator_type;

   CGAL_static_assertion((boost::is_same<Numerator_type,CGAL::Gmpz>::value));

   CGAL_static_assertion((boost::is_same<Denominator_type,CGAL::Gmpz>::value));

    Numerator_type numerator;
    Denominator_type denominator;
    CGAL::Gmpq fraction(4,5);
    FT::Decompose()(fraction,numerator,denominator);

    CGAL::set_pretty_mode(std::cout);
    std::cout << "decompose fraction: "<< std::endl;
    std::cout << "fraction   : " << fraction << std::endl;
    std::cout << "numerator  : " << numerator<< std::endl;
    std::cout << "denominator: " << denominator << std::endl;

    std::cout << "re-compose fraction: "<< std::endl;
    fraction = FT::Compose()(numerator,denominator);
    std::cout << "fraction   : " << fraction << std::endl;
}
#else
int main(){ std::cout << "This examples needs GMP" << std::endl; }
#endif
```

File: examples/Algebraic_foundations/fraction_traits.cpp

The following example illustrates the integralization of a vector, i.e., the coefficient vector of a polynomial. Note that for minimizing coefficient growth *Fraction_traits<Type>::Common_factor* is used to compute the 'least' common multiple of the denominators.

```
#include <CGAL/basic.h>
#include <CGAL/Fraction_traits.h>
#include <CGAL/IO/io.h>
#include <vector>

template <class Fraction>
std::vector<typename CGAL::Fraction_traits<Fraction>::Numerator_type >
integralize(
        const std::vector<Fraction>& vec,
        typename CGAL::Fraction_traits<Fraction>::Denominator_type& d
) {
    typedef CGAL::Fraction_traits<Fraction> FT;
    typedef typename FT::Numerator_type Numerator_type;
    typedef typename FT::Denominator_type Denominator_type;
    typename FT::Decompose decompose;

    std::vector<Numerator_type>   num(vec.size());
```

```
    std::vector<Denominator_type> den(vec.size());

    // decompose each coefficient into integral part and denominator
    for (unsigned int i = 0; i < vec.size(); i++) {
        decompose(vec[i], num[i], den[i]);
    }

    // compute 'least' common multiple of all denominator
    // We would like to use gcd, so let's think of Common_factor as gcd.
    typename FT::Common_factor        gcd;
    d = 1;
    for (unsigned int i = 0; i < vec.size(); i++) {
        d *= CGAL::integral_division(den[i], gcd(d, den[i]));
    }

    // expand each (numerator, denominator) pair to common denominator
    for (unsigned int i = 0; i < vec.size(); i++) {
        // For simplicity ImplicitInteroperability is expected in this
   example
        num[i] *= CGAL::integral_division(d, den[i]);
    }
    return num;
}

#ifdef CGAL_USE_GMP

#include <CGAL/Gmpz.h>
#include <CGAL/Gmpq.h>

int main(){
    std::vector<CGAL::Gmpq> vec(3);
    vec[0]=CGAL::Gmpq(1,4);
    vec[1]=CGAL::Gmpq(1,6);
    vec[2]=CGAL::Gmpq(1,10);
    std::cout<< "compute an integralized vector" << std::endl;
    std::cout<<"input vector:  ["
             << vec[0] << "," << vec[1] << "," << vec[2] << "]" <<
   std::endl;
    CGAL::Gmpz d;
    std::vector<CGAL::Gmpz> integral_vec = integralize(vec,d);
    std::cout<<"output vector:  ["
             << integral_vec[0] << ","
             << integral_vec[1] << ","
             << integral_vec[2] << "]" << std::endl;
    std::cout<<"denominator  : "<< d <<std::endl;
}
#else
int main(){ std::cout << "This examples needs GMP" << std::endl; }
#endif
```

File: examples/Algebraic_foundations/integralize.cpp

4.7 Design and Implementation History

The package is part of CGAL since release 3.3. Of course the package is based on the former Number type support of CGAL. This goes back to Stefan Schirra and Andreas Fabri. But on the other hand the package is to a large extend influenced by the experience with the number type support in EXACUS [BEH+05], which in the main goes back to Lutz Kettner, Susan Hert, Arno Eigenwillig and Michael Hemmer. However, the package abstracts from the pure support for number types that are embedded on the real axis which allows the support of polynomials, finite fields, and algebraic extensions as well. See also related subsequent chapters.

FromIntConstructible

Definition

A model of the concept *FromIntConstructible* is required to be constructible from int.

Creation

FromIntConstructible type(int& *i);*

Has Models

int
long
double

FromDoubleConstructible

Concept

Definition

A model of the concept *FromDoubleConstructible* is required to be constructible from the type *double*.

In case the type is a model of *RealEmbeddable* too, for any double d the identity: *d == CGAL::to_double(T(d))*, is guaranteed.

Creation

FromDoubleConstructible type(double d); conversion constructor from double.

Concept

ExplicitInteroperable

Definition

Two types *A* and *B* are a model of the *ExplicitInteroperable* concept, if it is possible to derive a superior type for *A* and *B*, such that both types are embeddable into this type. This type is *Coercion_traits<A,B>::Type*.

In this case *Coercion_traits<A,B>::Are_explicit_interoperable* is *Tag_true*.

A and *B* are valid argument types for all binary functors in *Algebraic_structure_traits<Type>* and *Real_embeddable_traits<Type>*. This is also the case for the respective global functions.

ImplicitInteroperable

Concept

Definition

Two types *A* and *B* are a model of the concept *ImplicitInteroperable*, if there is a superior type, such that binary arithmetic operations involving *A* and *B* result in this type. This type is *Coercion_traits<A,B>::Type*.

The type *Coercion_traits<A,B>::Type* is required to be implicit constructible from *A* and *B*.

In this case *Coercion_traits<A,B>::Are_implicit_interoperable* is *Tag_true*.

Class

CGAL::Coercion_traits<A,B>

Definition

An instance of *Coercion_traits<A,B>* reflects the type coercion of the types A and B, it is symmetric in the two template arguments.

#include <CGAL/Coercion_traits.h>

Types

Coercion_traits<A,B>:: Are_explicit_interoperable

Tag indicating whether the two types A and B are a model of *ExplicitInteroperable*
This is either *CGAL::Tag_true* or *CGAL::Tag_false*.

Coercion_traits<A,B>:: Are_implicit_interoperable

Tag indicating whether the two types A and B are a model of *ImplicitInteroperable*
This is either *CGAL::Tag_true* or *CGAL::Tag_false*.

Coercion_traits<A,B>:: Type

The coercion type of *A* and *B*.
In case A and B are not *ExplicitInteroperable* this is undefined.

Coercion_traits<A,B>:: Cast

A model of the *AdaptableFunctor* concept, providing the conversion of *A* or *B* to *Type*.
In case A and B are not *ExplicitInteroperable* this is undefined.

IntegralDomainWithoutDivision

Definition

This is the most basic concept for algebraic structures considered within CGAL.

A model *IntegralDomainWithoutDivision* represents an integral domain, i.e. commutative ring with 0, 1, +, * and unity free of zero divisors.
Note: A model is not required to offer the always well defined integral division.

It refines *Assignable*, *CopyConstructible*, *DefaultConstructible* and *FromIntConstructible*.
It refines *EqualityComparable*, where equality is defined w.r.t. the ring element being represented.
The operators unary and binary plus +, unary and binary minus -, multiplication * and their compound forms +=, -=, *= are required and implement the respective ring operations.

Moreover, *CGAL::Algebraic_structure_traits< IntegralDomainWithoutDivision >* is a model of *AlgebraicStructureTraits* providing:
- *CGAL::Algebraic_structure_traits< IntegralDomainWithoutDivision >::Algebraic_type* derived from *Integral_domain_without_division_tag*
- *CGAL::Algebraic_structure_traits< IntegralDomainWithoutDivision >::Is_zero*
- *CGAL::Algebraic_structure_traits< IntegralDomainWithoutDivision >::Is_one*
- *CGAL::Algebraic_structure_traits< IntegralDomainWithoutDivision >::Square*
- *CGAL::Algebraic_structure_traits< IntegralDomainWithoutDivision >::Simplify*
- *CGAL::Algebraic_structure_traits< IntegralDomainWithoutDivision >::Unit_part*

Refines

Assignable

Concept

UniqueFactorizationDomain

Definition

A model of *UniqueFactorizationDomain* is an *IntegralDomain* with the additional property that the ring it represents is a unique factorization domain (a.k.a. UFD or factorial ring), meaning that every non-zero non-unit element has a factorization into irreducible elements that is unique up to order and up to multiplication by invertible elements (units). (An irreducible element is a non-unit ring element that cannot be factored further into two non-unit elements. In a UFD, the irreducible elements are precisely the prime elements.)

In a UFD, any two elements, not both zero, possess a greatest common divisor (gcd).

Moreover, *CGAL::Algebraic_structure_traits*< *UniqueFactorizationDomain* > is a model of *AlgebraicStructureTraits* providing:
- *CGAL::Algebraic_structure_traits*< *UniqueFactorizationDomain* >*::Algebraic_type* derived from *Unique_factorization_domain_tag*
- *CGAL::Algebraic_structure_traits*< *UniqueFactorizationDomain* >*::Gcd*

Refines

IntegralDomain

See Also

EuclideanRing

Concept

Definition

A model of *EuclideanRing* represents an euclidean ring (or Euclidean domain). It is an *UniqueFactorizationDomain* that affords a suitable notion of minimality of remainders such that given x and $y \neq 0$ we obtain an (almost) unique solution to $x = qy + r$ by demanding that a solution (q, r) is chosen to minimize r. In particular, r is chosen to be 0 if possible.

Moreover, *CGAL::Algebraic_structure_traits< EuclideanRing >* is a model of *AlgebraicStructureTraits* providing:

- *CGAL::Algebraic_structure_traits< EuclideanRing >::Algebraic_type* derived from *Unique_factorization_domain_tag*
- *CGAL::Algebraic_structure_traits< EuclideanRing >::Mod*
- *CGAL::Algebraic_structure_traits< EuclideanRing >::Div*
- *CGAL::Algebraic_structure_traits< EuclideanRing >::Div_mod*

Remarks

The most prominent example of a Euclidean ring are the integers. Whenever both x and y are positive, then it is conventional to choose the smallest positive remainder r.

Concept

Field

Definition

A model of *Field* is an *IntegralDomain* in which every non-zero element has a multiplicative inverse. Thus, one can divide by any non-zero element. Hence division is defined for any divisor != 0. For a Field, we require this division operation to be available through operators / and /=.

Moreover, *CGAL::Algebraic_structure_traits*< *Field* > is a model of *AlgebraicStructureTraits* providing:
- *CGAL::Algebraic_structure_traits*< *Field* >*::Algebraic_type* derived from *Field_tag*

Concept

AlgebraicStructureTraits

Definition

A model of *AlgebraicStructureTraits* reflects the algebraic structure of an associated type *Type*.

Depending on the concepts that *Type* fulfills, it contains various functors and descriptive tags. Moreover it gives access to the several possible algebraic operations within that structure.

Types

A model of *AlgebraicStructureTraits* is supposed to provide:

AlgebraicStructureTraits:: Type

The associated type.

AlgebraicStructureTraits:: Algebraic_category

Tag indicating the algebraic structure of the associated type.

Tag is:	*Type* is model of:
CGAL::Null_tag	no algebraic concept
CGAL::Integral_domain_without_division_tag	*IntegralDomainWithoutDivision*
CGAL::Integral_domain_tag	*IntegralDomain*
CGAL::Unique_factorization_domain_tag	*UniqueFactorizationDomain*
CGAL::Euclidean_ring_tag	*EuclideanRing*
CGAL::Field_tag	*Field*
CGAL::Field_with_sqrt_tag	*FieldWithSqrt*
CGAL::Field_with_kth_root_tag	*FieldWithKthRoot*
CGAL::Field_with_root_of_tag	*FieldWithRootOf*

AlgebraicStructureTraits:: Is_exact

Tag indicating whether *Type* is exact.
This is either *CGAL::Tag_true* or *CGAL::Tag_false*.
An algebraic structure is considered exact, if all operations required by its concept are computed such that a comparison of two algebraic expressions is always correct. The exactness covers only those operations that are required by the algebraic structure concept.
e.g. an exact *Field* may have a *Sqrt* functor that is not exact.

AlgebraicStructureTraits:: Is_numerical_sensitive

Tag indicating whether *Type* is numerical sensitive.
This is either *CGAL::Tag_true* or *CGAL::Tag_false*.
An algebraic structure is considered as numerically sensitive, if the performance of the type is sensitive to the condition number of an algorithm.

AlgebraicStructureTraits:: Boolean

This type specifies the return type of the predicates provided by this traits. The type must be convertible to *bool* and typically the type indeed maps to *bool*. However, there are also cases such as interval arithmetic, in which it is *Uncertain<bool>* or some similar type.

Functors

In case a functor is not provided, it is set to *CGAL::Null_functor*.

AlgebraicStructureTraits:: Is_zero

A model of *AlgebraicStructureTraits::IsZero*.
Required by the concept *IntegralDomainWithoutDivision*. In case *Type* is also model of *RealEmbeddable* this is a model of *RealEmbeddableTraits::IsZero*.

AlgebraicStructureTraits:: Is_one

A model of *AlgebraicStructureTraits::IsOne*.
Required by the concept *IntegralDomainWithoutDivision*.

AlgebraicStructureTraits:: Square

A model of *AlgebraicStructureTraits::Square*.
Required by the concept *IntegralDomainWithoutDivision*.

AlgebraicStructureTraits:: Simplify

A model of *AlgebraicStructureTraits::Simplify*.
Required by the concept *IntegralDomainWithoutDivision*.

AlgebraicStructureTraits:: Unit_part

A model of *AlgebraicStructureTraits::UnitPart*.
Required by the concept *IntegralDomainWithoutDivision*.

AlgebraicStructureTraits:: Integral_division

A model of *AlgebraicStructureTraits::IntegralDivision*.
Required by the concept *IntegralDomain*.

AlgebraicStructureTraits:: Divides

A model of *AlgebraicStructureTraits::Divides*.
Required by the concept *IntegralDomain*.

AlgebraicStructureTraits:: Is_square

A model of *AlgebraicStructureTraits::IsSquare*.
Required by the concept *IntegralDomainWithoutDivision*.

AlgebraicStructureTraits:: Gcd

A model of *AlgebraicStructureTraits::Gcd*.
Required by the concept *UniqueFactorizationDomain*.

AlgebraicStructureTraits:: Mod

A model of *AlgebraicStructureTraits::Mod*.
Required by the concept *EuclideanRing*.

AlgebraicStructureTraits:: Div

AlgebraicStructureTraits . . . . page 78

AlgebraicStructureTraits::UnitPart

Definition

This *AdaptableUnaryFunction* computes the unit part of a given ring element.

The mathematical definition of unit part is as follows: Two ring elements a and b are said to be associate if there exists an invertible ring element (i.e. a unit) u such that $a = ub$. This defines an equivalence relation. We can distinguish exactly one element of every equivalence class as being unit normal. Then each element of a ring possesses a factorization into a unit (called its unit part) and a unit-normal ring element (called its unit normal associate).

For the integers, the non-negative numbers are by convention unit normal, hence the unit-part of a non-zero integer is its sign. For a *Field*, every non-zero element is a unit and is its own unit part, its unit normal associate being one. The unit part of zero is, by convention, one.

Refines

AdaptableUnaryFunction

AlgebraicStructureTraits . . . . page 78

AlgebraicStructureTraits::IntegralDivision

Definition

AdaptableBinaryFunction providing an integral division.

Integral division (a.k.a. exact division or division without remainder) maps ring elements (x,y) to ring element z such that $x = yz$ if such a z exists (i.e. if x is divisible by y). Otherwise the effect of invoking this operation is undefined. Since the ring represented is an integral domain, z is uniquely defined if it exists.

Functor
Concept

AlgebraicStructureTraits::Divides

Definition

AdaptableBinaryFunction, returns true if the first argument divides the second argument.

Integral division (a.k.a. exact division or division without remainder) maps ring elements (n,d) to ring element c such that $n = dc$ if such a c exists. In this case it is said that d divides n.

This functor is required to provide two operators. The first operator takes two arguments and returns true if the first argument divides the second argument. The second operator returns c via the additional third argument.

Refines

AdaptableBinaryFunction

Types

AlgebraicStructureTraits::Divides:: result_type

Is *AlgebraicStructureTraits::Boolean*.

AlgebraicStructureTraits::Divides:: first_argument

Is *AlgebraicStructureTraits::Type*.

AlgebraicStructureTraits::Divides:: second_argument

Is *AlgebraicStructureTraits::Type*.

Operations

result_type *divides(first_argument_type d, second_argument_type n)*

Computes whether d divides n.

result_type *divides(first_argument_type d, second_argument_type n, AlgebraicStructureTraits::Type& c)*

Computes whether d divides n. Moreover it computes c if d divides n, otherwise the value of c is undefined.

See Also

AlgebraicStructureTraits .... page 78
AlgebraicStructureTraits::IntegralDivision .... page 87

AlgebraicStructureTraits::IsSquare

Definition

AdaptableBinaryFunction that computes whether the first argument is a square. If the first argument is a square the second argument, which is taken by reference, contains the square root. Otherwise, the content of the second argument is undefined.

A ring element x is said to be a square iff there exists a ring element y such that $x = y * y$. In case the ring is a *UniqueFactorizationDomain*, y is uniquely defined up to multiplication by units.

Refines

Types

AlgebraicStructureTraits::IsSquare:: result_type

Is *AlgebraicStructureTraits::Boolean*.

AlgebraicStructureTraits::IsSquare:: first_argument

Is *AlgebraicStructureTraits::Type*.

AlgebraicStructureTraits::IsSquare:: second_argument

Is *AlgebraicStructureTraits::Type*`&`.

Operations

result_type *is_square(first_argument_type x, second_argument_type y)*

returns `true` in case x is a square, i.e. $x = y * y$.
Postcondition: $unit\_part(y) == 1$.

result_type *is_square(first_argument_type x)*

returns `true` in case x is a square.

See Also

AlgebraicStructureTraits . . . . page 78

AlgebraicStructureTraits::Gcd

Definition

AdaptableBinaryFunction providing the gcd.

The greatest common divisor (*gcd*) of ring elements x and y is the unique ring element d (up to a unit) with the property that any common divisor of x and y also divides d. (In other words: d is the greatest lower bound of x and y in the partial order of divisibility.) We demand the *gcd* to be unit-normal (i.e. have unit part 1).

$gcd(0,0)$ is defined as 0, since 0 is the greatest element with respect to the partial order of divisibility. This is because an element $a \in R$ is said to divide $b \in R$, iff $\exists r \in R$ such that $a \cdot r = b$. Thus, 0 is divided by every element of the Ring, in particular by itself.

Refines

AdaptableBinaryFunction

AlgebraicStructureTraits::Gcd:: first_argument — Is *AlgebraicStructureTraits::Type*.

AlgebraicStructureTraits::Gcd:: second_argument — Is *AlgebraicStructureTraits::Type*.

Operations

result_type gcd(first_argument_type x, second_argument_type y)

returns $gcd(x,y)$.

template <class NT1, class NT2>
result_type gcd(NT1 x, NT2 y)

This operator is defined if *NT1* and *NT2* are *ExplicitInteroperable* with coercion type *AlgebraicStructureTraits::Type*.

See Also

AlgebraicStructureTraits . . . . page 78

AlgebraicStructureTraits::DivMod

Definition

AdaptableFunctor computes both integral quotient and remainder of division with remainder. The quotient q and remainder r are computed such that $x = q * y + r$ and $|r| < |y|$ with respect to the proper integer norm of the represented ring. [1] In particular, r is chosen to be 0 if possible. Moreover, we require q to be minimized with respect to the proper integer norm.

Note that the last condition is needed to ensure a unique computation of the pair (q, r). However, an other option is to require minimality for $|r|$, with the advantage that a *mod(x,y)* operation would return the unique representative of the residue class of x with respect to y, e.g. $mod(2,3)$ should return -1. But this conflicts with nearly all current implementation of integer types. From there, we decided to stay conform with common implementations and require q to be computed as x/y rounded towards zero.

The following table illustrates the behavior for integers:

x	y	q	r
3	3	1	0
2	3	0	2
1	3	0	1
0	3	0	0
-1	3	0	-1
-2	3	0	-2
-3	3	-1	0

-

x	y	q	r
3	-3	-1	0
2	-3	0	2
1	-3	0	1
0	-3	0	0
-1	-3	0	-1
-2	-3	0	-2
-3	-3	1	0

RealEmbeddable

Definition

A model of this concepts represents numbers that are embeddable on the real axis. The type obeys the algebraic structure and compares two values according to the total order of the real numbers.

Moreover, *CGAL::Real_embeddable_traits< RealEmbeddable >* is a model of *RealEmbeddableTraits*
with:
- *CGAL::Real_embeddable_traits< RealEmbeddable >::Is_real_embeddable* set to *Tag_true*
and functors :
- *CGAL::Real_embeddable_traits< RealEmbeddable >::Is_zero*
- *CGAL::Real_embeddable_traits< RealEmbeddable >::Abs*
- *CGAL::Real_embeddable_traits< RealEmbeddable >::Sgn*
- *CGAL::Real_embeddable_traits< RealEmbeddable >::Is_positive*
- *CGAL::Real_embeddable_traits< RealEmbeddable >::Is_negative*
- *CGAL::Real_embeddable_traits< RealEmbeddable >::Compare*
- *CGAL::Real_embeddable_traits< RealEmbeddable >::To_double*
- *CGAL::Real_embeddable_traits< RealEmbeddable >::To_interval*

Remark:
If a number type is a model of both *IntegralDomainWithoutDivision* and *RealEmbeddable*, it follows that the ring represented by such a number type is a sub-ring of the real numbers and hence has characteristic zero.

Concept

RealEmbeddableTraits

Definition

A model of *RealEmbeddableTraits* is associated to a number type *Type* and reflects the properties of this type with respect to the concept *RealEmbeddable*.

Types

A model of *RealEmbeddableTraits* is supposed to provide:

RealEmbeddableTraits:: Type	The associated number type.
RealEmbeddableTraits:: Is_real_embeddable	Tag indicating whether the associated type is real embeddable. This is either *CGAL::Tag_true* or *CGAL::Tag_false*.
RealEmbeddableTraits:: Boolean	This type specifies the return type of the predicates provided by this traits. The type must be convertible to *bool* and typically the type indeed maps to *bool*. However, there are also cases such as interval arithmetic, in which it is *Uncertain< bool>* or some similar type.
RealEmbeddableTraits:: Sign	This type specifies the return type of the *Sgn* functor. The type must be convertible to *CGAL::Sign* and typically the type indeed maps to *CGAL::Sign*. However, there are also cases such as interval arithmetic, in which it is *Uncertain< CGAL::Sign>* or some similar type.
RealEmbeddableTraits:: Comparison_result	This type specifies the return type of the *Compare* functor. The type must be convertible to *CGAL::Comparison_result* and typically the type indeed maps to *CGAL::Comparison_result*. However, there are also cases such as interval arithmetic, in which it is *Uncertain<CGAL::Comparison_result>* or some similar type.

Functors

In case the associated type is *RealEmbeddable* all functors are provided.
In case a functor is not provided, it is set to *CGAL::Null_functor*.

RealEmbeddableTraits:: Is_zero	A model of *RealEmbeddableTraits::IsZero* In case *Type* is also model of *IntegralDomainWithoutDivision* this is a model of *AlgebraicStructureTraits::IsZero*.
RealEmbeddableTraits:: Abs	A model of *RealEmbeddableTraits::Abs*

RealEmbeddableTraits:: Sgn	A model of *RealEmbeddableTraits::Sgn*
RealEmbeddableTraits:: Is_positive	A model of *RealEmbeddableTraits::IsPositive*
RealEmbeddableTraits:: Is_negative	A model of *RealEmbeddableTraits::IsNegative*
RealEmbeddableTraits:: Compare	A model of *RealEmbeddableTraits::Compare*
RealEmbeddableTraits:: To_double	A model of *RealEmbeddableTraits::ToDouble*
RealEmbeddableTraits:: To_interval	A model of *RealEmbeddableTraits::ToInterval*

Chapter 5

Number Types

Michael Hemmer, Susan Hert, Sylvain Pion, and Stefan Schirra

Contents

5.1 Introduction

This chapter gives an overview of the number types supported by CGAL. Number types must fulfill certain syntactical and semantic requirements, such that they can be successfully used in CGAL code. In general they are expected to be a model of an algebraic structure concepts and in case they model a subring of the real numbers they are also a model of *RealEmbeddable*. For an overview of the algebraic structure concepts see Section 4.8.

5.2 Built-in Number Types

The built-in number types *float*, *double* and *long double* have the required arithmetic and comparison operators. They lack some required routines though which are automatically included by CGAL. [1]

[1] The functions can be found in the header files `CGAL/int.h`, `CGAL/float.h`, `CGAL/double.h` and `CGAL/long_long.h`.

All built-in number types of C++ can represent a discrete (bounded) subset of the rational numbers only. We assume that the floating-point arithmetic of your machine follows IEEE floating-point standard. Since the floating-point culture has much more infrastructural support (hardware, language definition and compiler) than exact computation, it is very efficient. Like with all number types with finite precision representation which are used as approximations to the infinite ranges of integers or real numbers, the built-in number types are inherently potentially inexact. Be aware of this if you decide to use the efficient built-in number types: you have to cope with numerical problems. For example, you can compute the intersection point of two lines and then check whether this point lies on the two lines. With floating point arithmetic, roundoff errors may cause the answer of the check to be *false*. With the built-in integer types overflow might occur.

5.3 Number Types Provided by CGAL

CGAL provides several number types that can be used for exact computation. These include the *Quotient* class that can be used to create, for example, a number type that behaves like a rational number when parameterized with a number type which can represent integers.

The number type *MP_Float* is able to represent multi-precision floating point values, a generalization of integers scaled by a (potentially negative) power of 2. It allows to deal with ring operations over floating-point values with requiring rational numbers. By plugging it in *Quotient*, one obtains rational numbers. Note that *MP_Float* may not be as efficient as the integer types provided by GMP or LEDA, but it has the advantage to make more parts of CGAL independent on these external libraries for handling robustness issues.

The templated number type *Lazy_exact_nt<NT>* is able to represent any number that *NT* is able to represent, but because it first tries to use an approximate value to perform computations it can be faster than *NT*.

A number type for doing interval arithmetic, *Interval_nt*, is provided. This number type helps in doing arithmetic filtering in many places such as *Filtered_predicate*.

CGAL::Sqrt_extension is a number type that allows to represent algebraic numbers of degree 2 as well as nested forms. A generic function *CGAL::make_root_of_2* allows to build this type generically.

A debugging helper *Number_type_checker<NT1,NT2,Comparator>* is also provided which allows to compare the behavior of operations over two number types.

5.4 Number Types Provided by GMP

CGAL provides wrapper classes for number types defined in the GNU Multiple Precision arithmetic library [Gra]. The file `CGAL/Gmpz.h` provides the class *Gmpz*, a wrapper class for the arbitrary-precision integer type *mpz_t*, which is compliant with the CGAL number type requirements. The file `CGAL/Gmpq.h` provides the class *Gmpq*, a wrapper class for the arbitrary-precision rational type *mpq_t*, which is compliant with the CGAL number type requirements.

The file `CGAL/Gmpzf.h` provides the class *Gmpzf*, an exact arbitrary-precision floating-point type. Hence, It does not support operators like `/` to guarantee exactness of the operations. The arithmetic operations on this type are restricted to `+`, `-`, `*` and *CGAL::integral_division*.

The file `CGAL/Gmpfr.h` provides the class *Gmpfr*, a fixed-precision floating-point number type. Since the precision (number of bits used to represent the mantissa of the number) is fixed for each object, the result of each operation is rounded when necessary. Though not necessary at first, the user will take full advantage of this number type by understanding the ideas behind floating-point arithmetic, such as precision and rounding, and understanding the flags set by this library after each operation. For more details, the reader should refer to [MPFb] and the *Gmpfr* reference manual.

In addition, it is possible to directly use the C++ number types provided by GMP : *mpz_class*, *mpq_class* (note that support for *mpf_class* is incomplete). The file `CGAL/gmpxx.h` provides the necessary functions to make these classes compliant to the CGAL number type requirements.

To use these classes, GMP and MPFR must be installed.

5.5 Number Types Provided by LEDA

LEDA provides number types that can be used for exact computation with both Cartesian and homogeneous representations. If you are using homogeneous representation with the built-in integer types *short*, *int*, and *long* as ring type, exactness of computations can be guaranteed only if your input data come from a sufficiently small integral range and the depth of the computations is sufficiently small. LEDA provides the number type *leda_integer* for integers of arbitrary length. (Of course the length is somehow bounded by the resources of your computer.) It can be used as ring type in homogeneous kernels and leads to exact computation as long as all intermediate results are rational. For the same kind of problems, Cartesian representation with number type *leda_rational* leads to exact computation as well. The number type *leda_bigfloat* in LEDA is a variable precision floating-point type. Rounding mode and precision (i.e. mantissa length) of *leda_bigfloat* can be set.

The most sophisticated number type in LEDA is the number type called *leda_real*. Like in Pascal, where the name *real* is used for floating-point numbers, the name *leda_real* does not describe the number type precisely, but intentionally. *leda_real*s are a subset of real algebraic numbers. Any integer is *leda_real* and *leda_real*s are closed under the operations $+,-,*,/$ and k-th root computation. For LEDA version 5.0 and or later *leda_real* is also able to represent real roots of polynomials. *leda_real*s guarantee that all comparisons between expressions involving *leda_real*s produce the exact result.

The files `CGAL/leda_integer.h`, `CGAL/leda_rational.h`, `CGAL/leda_bigfloat.h` and `CGAL/leda_real.h` provide the necessary functions to make these classes compliant to the CGAL number type requirements.

5.6 Number Types Provided by CORE

In principle CORE [KLPY99] provides the same set of number types as LEDA. The type *CORE::BigInt* represent integers and *CORE::BigRat* represent rationals of arbitrary length. The number type *CORE::BigFloat* is a variable precision floating-point type. It is also possible to interpret it as an interval type, since it also carries the error of a computed value. As for LEDA, the most sophisticated number type in CORE is *CORE::Expr*, which is in its functionality equivalent to *leda_real*.

The files `CGAL/CORE_BigInt.h`, `CGAL/CORE_BigRat.h`, `CGAL/CORE_BigFloat.h` and `CGAL/CORE_Expr.h` provide the necessary functions to make these classes compliant to the CGAL number type requirements.

CORE version 1.7 or later is required.

5.7 Interval arithmetic

Interval arithmetic is very important for geometric programming. It is a fundamental tool for filtering predicates. For many problems, intervals of machine double-precision numbers are sufficient, but it is not always enough. For example, one approach for determining the sign of an expression is to evaluate its sign using interval arithmetic and to repeatedly increase the precision of the bounds of the intervals until either the interval does not contain zero or its width is less than the separation bound of the polynomial.

For intervals of machine double-precision numbers, CGAL provides the class *Interval_nt*. For intervals of floating-point arbitrary-precision numbers, the class *Gmpfi* is provided in the file `CGAL/Gmpfi.h`.

Endpoints of *Gmpfi* intervals are represented as *Gmpfr* numbers. Each interval has an associated *precision*, which is the maximum precision (number of bits used to represent the mantissa) of its endpoints. The result of the operations is guaranteed to be always contained in the returned interval. Since the interval arithmetic is implemented on top of *Gmpfr*, the global flags and the default precision are inherited from the *Gmpfr* interface. See [MPFa] and the *Gmpfi* reference manual for details.

To use the *Gmpfi* class, MPFI must be installed.

5.8 User-supplied Number Types

In order to use your own number type it must be a model of the according algebraic structure concept, in particular you must provide a specialization of *CGAL::Algebraic_structure_traits* and also of *Real_embeddable_traits* in case it is a sub ring of the real numbers. If you even want to provide a related ensemble of number types you should also provide specializations for *CGAL::Coercion_traits* in order to reflect their interoperability.

5.9 Design and Implementation History

This package was naturally one of the first packages implemented in CGAL. It initially contained the *Quotient*, *Gmpz* and *Gmpq* classes, together with the interfaces to the number types provided by LEDA, which were implemented by Stefan Schirra and Andreas Fabri.

Later, around 1998-2002, Sylvain Pion implemented *Interval_nt MP_Float* and *Lazy_exact_nt*, together with the interfaces to the *mpz_class* and *mpq_class* types from GMP.

Number type concepts were then refined, notably by Lutz Kettner and Susan Hert, who also contributed utility algorithms.

The work on concepts was further extended within the EXACUS project, and was finally contributed to CGAL by Michael Hemmer in 2006, as what is now the separate Algebraic Foundations package 4, together with a rewritten interface to operations on number types.

The class *Sqrt_extension* was contributed by Michael Hemmer and Ron Wein around 2006. In 2010 it went through a considerable reinvestigation by Sébastien Loriot, Michael Hemmer, and Monique Teillaud. As a result it got further improved and now replaces several similar types such as *Root_of_2*, which had been contributed by Pedro M. M. de Castro, Sylvain Pion and Monique Teillaud, and is deprecated since CGAL-3.8.

In 2008-2010, Bernd Gärtner added the *Gmpzf* class, while Luis Peñaranda and Sylvain Lazard contributed the *Gmpfi* and *Gmpfr* classes.

CGAL::Gmpz

Class

Definition

An object of the class *Gmpz* is an arbitrary precision integer based on the GNU Multiple Precision Arithmetic Library.

#include <CGAL/Gmpz.h>

Is Model for the Concepts

EuclideanRing
RealEmbeddable

Creation

Gmpz z;	creates an uninitialized multiple precision integer z.
Gmpz z(int i);	creates a multiple-precision integer initialized with i.
Gmpz z(double d);	creates a multiple-precision integer initialized with the integral part of d.

Operations

Gmpz &	$++z$	prefix increment.
Gmpz	$z++$	postfix increment.
Gmpz &	$--z$	prefix decrement.
Gmpz	$z--$	postfix decrement.
Gmpz	$a >>$ *unsigned long i*	rightshift by i.
Gmpz	$a <<$ *unsigned long i*	leftshift by i.
Gmpz &	$z >>=$ *long i*	rightshift by i, where $i >= 0$.
Gmpz &	$z <<=$ *long i*	leftshift by i, where $i >= 0$.
Gmpz	$a \,\&\, b$	bitwise AND.
Gmpz	$a \mid b$	bitwise IOR.
Gmpz	$a\,\hat{}\,b$	bitwise XOR.
Gmpz &	$z \,\&= b$	bitwise AND.
Gmpz &	$z \mid= b$	bitwise IOR.
Gmpz &	$z\,\hat{}= b$	bitwise XOR.
Sign	*z.sign() const*	Returns the sign of z.
size_t	*z.bit_size() const*	Returns the bit-size (that is, the number of bits needed to represent the mantissa) of z.
size_t	*z.size() const*	Returns the size in limbs of z. A limb is the type used by GMP to represent the integer (usually *long*).

size_t	*z.approximate_decimal_length() const*	
		Returns the approximate number of decimal digits needed to represent *z*. Approximate means either a correct result, either the correct result plus one.
double	*z.to_double() const*	Returns a double approximation of *z*. The integer is truncated if needed. If the exponent of the conversion is too big, the result is system dependent (returning infinity where it is supported).
std::ostream&	*std::ostream& out* << *z*	writes *z* to the ostream *out*.
std::istream&	*std::istream& in* >> & *z*	reads an integer from *in*, then converts it to a *Gmpz*.

Implementation

*Gmpz*s are reference counted.

CGAL::Gmpq

Class

Definition

An object of the class *Gmpq* is an arbitrary precision rational number based on the GNU Multiple Precision Arithmetic Library.

#include <CGAL/Gmpq.h>

Is Model for the Concepts

Field
RealEmbeddable
Fraction

Creation

Gmpq q;	creates an uninitialized *Gmpq* q.
Gmpq q(int i);	creates a *Gmpq* initialized with i.
Gmpq q(Gmpz n);	creates a *Gmpq* initialized with n.
Gmpq q(Gmpfr f);	creates a *Gmpq* initialized with f.
Gmpq q(int n, int d);	creates a *Gmpq* initialized with *n/d*.
Gmpq q(signed long n, unsigned long d);	creates a *Gmpq* initialized with *n/d*.
Gmpq q(unsigned long n, unsigned long d);	creates a *Gmpq* initialized with *n/d*.
Gmpq q(Gmpz n, Gmpz d);	creates a *Gmpq* initialized with *n/d*.
Gmpq q(double d);	creates a *Gmpq* initialized with d.
Gmpq q(std::string str);	creates a *Gmpq* initialized with *str*, which can be an integer like "41" or a fraction like "41/152". White space is allowed in the string, and ignored.
Gmpq q(std::string str, int base);	creates a *Gmpq* initialized with *str* in base *base*, which is an integer between 2 and 62. White space in the string is ignored.

Operations

std::ostream&	*std::ostream& out << q*	writes q to the ostream *out*, in the form n/d.
std::istream&	*std::istream& in >> & q*	reads a number from *in*, then converts it to a *Gmpq*. The number may be an integer, a rational number in the form n/d, or a floating-point number.

There are two access functions, namely to the numerator and the denominator of a rational. Note that these values are not uniquely defined. It is guaranteed that *q.numerator()* and *q.denominator()* return values *nt_num* and *nt_den* such that q = *nt_num/nt_den*, only if *q.numerator()* and *q.denominator()* are called consecutively wrt. q, i.e. q is not involved in any other operation between these calls.

Gmpz	*q.numerator() const*	returns the numerator of q.

Gmpz	*q.denominator() const*	returns the denominator of q.

Implementation

*Gmpq*s are reference counted.

CGAL::Gmpzf

Class

Definition

This is an multiple-precision floating-point type; it can represent numbers of the form $m * 2^e$, where m is an arbitrary precision integer based on the GNU Multiple Precision Arithmetic Library, and e is of type *long*. This type can be considered exact, even if the exponent is not a multiple-precision number. This number type offers functionality very similar to *MP_Float* but is generally faster.

#include <CGAL/Gmpzf.h>

Is Model for the Concepts

EuclideanRing

RealEmbeddable

Creation

Gmpzf f;	creates a *Gmpzf* initialized with 0.
Gmpzf f(int i);	creates a *Gmpzf* initialized with *i*.
Gmpzf f(long int l);	creates a *Gmpzf* initialized with *l*.
Gmpzf f(Gmpz i);	creates a *Gmpzf* initialized with *i*.
Gmpzf f(Gmpfr f);	creates a *Gmpzf* initialized with *f*.
Gmpzf f(double d);	creates a *Gmpzf* initialized with *d*.

Operations

std::ostream&	*std::ostream& out << f*	
		writes a double approximation of *f* to the ostream *out*.
std::ostream&	*print(std::ostream& out, f)*	
		writes an exact representation of *f* to the ostream *out*.
std::istream&	*std::istream& in >> & f*	
		reads a *double* from *in*, then converts it to a *Gmpzf*.

Implementation

The significand m of a *Gmpzf* is a *Gmpz* and is reference counted. The exponent e of a *Gmpzf* is a `long`.

CGAL::Gmpfr

Class

Definition

An object of the class *Gmpfr* is a fixed precision floating-point number, based on the MPFR library. This type is inexact, due to the fact that the mantissa of each number is represented by a fixed amount of bits (this amount is called *precision*). If an operation needs more bits than the precision of the result number, the results are rounded following different possible criteria (called *rounding modes*).

Currently, MPFR supports four rounding modes: round to nearest, round toward zero, round down (or toward $-\infty$) and round up (or toward $+\infty$). When not specified explicitly, the operations use the default rounding mode, which is in practice a variable local to each execution thread. The default rounding mode can be set to any of the four rounding modes (initially, it is set to nearest). To specify rounding modes for operations, the type used is *std::float_round_style*.

This type is *ImplicitInteroperable* with *Gmpz*, `long`, `unsigned long`, `int`, `double` and `long double`.

#include <CGAL/Gmpfr.h>

Is Model for the Concepts

FieldWithKthRoot
RealEmbeddable

Types

Gmpfr:: Precision_type	Type representing the precision (number of bits used to represent the mantissa) of a number.

Creation

Gmpfr f;	Creates an uninitialized *Gmpfr f*.
Gmpfr f(n);	Copy constructor. The copied object inherits the precision of *n*, and thus it is not rounded.
Gmpfr f(long si);	Creates *Gmpfr*, initialized with the value of *si*.
Gmpfr f(unsigned long ui);	Creates a *Gmpfr*, initialized with the value of *ui*.
Gmpfr f(int i);	Creates a *Gmpfr*, initialized with the value of *i*.
Gmpfr f(double d);	Creates a *Gmpfr*, initialized with the value of *d*.
Gmpfr f(long double ld);	Creates a *Gmpfr*, initialized with the value of *ld*.
Gmpfr f(Gmpz z);	Creates a *Gmpfr*, initialized with the value of *z*.

Gmpfr f(Gmpzf zf); — Creates a *Gmpfr*, initialized with the value of zf.

Gmpfr f(std::pair<Gmpz,long> ie); — Creates a *Gmpfr*, initialized with the value of $ie.first \times 2^{ie.second}$.

Note that all constructors can be called with two optional parameters. One can specify as second parameter the rounding mode desired for the conversion from the source number and as a third parameter the precision with which this *Gmpfr* will be created. If only one optional parameter is specified, it can be either the rounding mode or the precision. If no optional parameters are specified, the precision of the created object is chosen in such a way that the conversion is exact (i.e., no rounding is performed).

These optional parameters, along with other functions which will be explained below, allow users to control the rounding and precision. For example, being `z` a *Gmpz*, `Gmpfr g(z,53,std::round_toward_neg_infinity)` will construct a *Gmpfr* `g` having as value the biggest 53-bit floating-point number that is equal or smaller than to `z`.

Operations

Each Gmpfr object has a precision associated to it. The precision is the amount of bits needed to represent the mantissa. MPFR has a default precision value, which can be controlled by static functions of the Gmpfr class (in practice, this default value is a variable local to each execution thread). There are also functions to get and set the precision of each Gmpfr object.

static Precision_type *get_default_precision()* — This returns the current precision used in *Gmpfr* creation by default.

static Precision_type *set_default_precision(Precision_type p)*

This function sets the default MPFR precision to p, and returns the old one.

Precision_type *f.get_precision() const* — Returns the precision of f.

Gmpfr *f.round(Precision_type p, std::float_round_style r) const*

Returns the value of f, rounded with precision p in the direction r.

static std::float_round_style

get_default_rndmode() — This function returns the current rounding mode used by MPFR.

static std::float_round_style

set_default_rndmode(std::float_round_style r)

This function sets the MPFR rounding mode to r and returns the old one.

MPFR provides some flags to know whether performed operations were exact or not, or they incurred in overflow or underflow, if the exponent is out of range, or the result was *NaN* (not-a-number). One can clear the flags before a set of operations and inspect them afterward, in order to see if something unexpected happened during the operations. The static functions used to handle flags are:

static void	*clear_flags()*	Clears all the flags set by MPFR(they are not cleared automatically).
static bool	*underflow_flag()*	Shows whether an operation incurred in underflow.
static bool	*overflow_flag()*	Shows whether an operation incurred in overflow.
static bool	*nan_flag()*	Shows whether the result of an operation was *NaN*.
static bool	*inex_flag()*	Shows whether an operation was inexact.
static bool	*erange_flag()*	Returns *true* iff a range error occurred. Such an exception occurs when some function which does not return a *Gmpfr* has an invalid result. For example, this flag will be set if one of the operands of a comparison is *NaN*.

Arithmetic operators `+`, `-`, `*` and `/` are overloaded, but special care must be taken when applying them. The precision of an operation between two *Gmpfr*s is defined as the maximum of the operands precision and the default precision.

The second operand of the former operations can be a `Gmpfr`, `int`, `long`, `unsigned`, `unsigned long`, or `Gmpz`. The precision of an operation between a *Gmpfr* and a number of another type is defined as the maximum between the number's precision and the default precision.

To specify the rounding mode and/or the precision to perform an operation, this class provides the four static functions `add`, `sub`, `mul` and `div`. Only one of them is shown here, since their interfaces are similar:

static Gmpfr	*add(a, b)*
static Gmpfr	*add(a, b, std::float_round_style r)*
static Gmpfr	*add(a, b, Precision_type p)*
static Gmpfr	*add(a, b, Precision_type p, std::float_round_style r)*

When the precision is not specified in this family of functions, it is defined as in the overloaded operators. When the rounding mode is not specified, the default is used.

Other arithmetic functions provided by the class are:

Gmpfr *f.abs(Precision_type p, std::float_round_style r=get_default_rndmode())*

Returns the absolute value of f, rounded with precision p in the direction r. If p is not specified, the precision used is the maximum between f's precision and the default.

Gmpfr *f.sqrt(Precision_type p, std::float_round_style r=get_default_rndmode())*

Returns the square root of f, rounded with precision p in the direction r. If p is not specified, the precision used is the maximum between f's precision and the default.

Gmpfr *f.kthroot(int k, Precision_type p, std::float_round_style r=get_default_rndmode())*

Returns the k-th root of f, rounded with precision p in the direction r. If p is not specified, the precision used is the maximum between f's precision and the default.

Gmpfr *f.square(Precision_type p, std::float_round_style r=get_default_rndmode())*

Returns the square of f, rounded with precision p in the direction r. If p is not specified, the precision used is the maximum between f's precision and the default.

double *f.to_double(std::float_round_style r=get_default_rndmode())*

Returns a double precision approximation of f using the rounding mode r.

std::pair<double,double>

f.to_interval() Returns an interval of doubles which contains f. If a rounded endpoint does not fit in a double, the double is set to plus or minus infinity and the *overflow* or *underflow* flag.

std::pair<double,long>

f.to_double_exp(std::float_round_style r=get_default_rndmode())

Returns the pair (d,e) such that $0.5 \leq |d| < 1$ and $d \times 2^e$ equals f rounded to double precision, using the rounding mode r. If f is *NaN* or infinity, then the corresponding double is returned, leaving the exponent undefined and setting the appropriate error flag.

std::pair<std::pair<double,double>,long>

f.to_interval_exp() Returns $((m,M),e)$ such that $m \times 2^e \leq f \leq M \times 2^e$. If f is *NaN* or infinity, then the corresponding doubles are returned, leaving the exponent undefined and setting the appropriate error flag.

std::pair<Gmpz,long>

	f.to_integer_exp()	Returns a pair of integers (m,e), such that $f = m \times 2^e$. Note that the returned value of m is not necessarily the smallest possible value of m (that is, it might be that $2|m$).

Comparisons

Comparison operators `==`, `!=`, `>`, `<`, `>=` and `<=` are also overloaded. A *Gmpfr* can be compared with other *Gmpfr*, as well as with a *Gmpz*, `long`, `unsigned long`, `int`, `double` or `long double`. It is worth noting that the numbers are never converted nor rounded before comparison. In the case where one of the compared numbers is *NaN*, the *erange* flag is set.

Query Functions

Sign	*f.sign()*	Returns the sign of f.
bool	*f.is_zero()*	Returns *true* iff f is zero.
bool	*f.is_one()*	Returns *true* iff f is one.
bool	*f.is_nan()*	Returns *true* iff f is NaN (not-a-number).
bool	*f.is_inf()*	Returns *true* iff f is plus or minus infinity.
bool	*f.is_number()*	Returns *true* iff f is a valid number.
bool	*f.is_square()*	Returns *true* iff f is the square of a number representable by an object of this type.
bool	*f.is_square(y)*	Returns *true* iff f is the square of a number representable by an object of this type, computing and storing it in y.

Input/Output

std::istream&	*std::istream& in >> & f*	Reads a floating-point number from *in*. The number $M \times 2^E$ must be in the form MeE, where the mantissa M and the exponent E are integers in base 10.
std::ostream&	*std::ostream& out << f*	If the ostream *out* is in pretty-print mode, writes a decimal approximation of f to *out*. Otherwise, writes f to *out* in the form MeE, where M is its mantissa and E is its exponent, both in base 10.

Implementation

Since the MPFR library can be compiled to be thread-safe, this interface is designed to keep the thread-safety.

*Gmpfr*s are reference counted. This behavior may be changed, by setting the flag `CGAL_GMPFR_NO_REFCOUNT`. A non-reference-counted class is slightly more efficient in case the implementation does not need to copy numbers (this is not usually the case). Nevertheless, setting this flag may be useful for debugging purposes.

CGAL::Gmpfi

Class

Definition

An object of the class *Gmpfi* is a closed interval, with endpoints represented as *Gmpfr* floating-point numbers. An interval can have finite or infinite endpoints and its meaning is straightforward. It can also have one (or both) *NaN* endpoint(s): this indicates that an invalid operation has been performed and that the resulting interval has no mathematical meaning.

All the operations of *Gmpfi* were designed in such a way that the mathematical correct result is always contained in the resulting interval.

This type is *ImplicitInteroperable* with *Gmpfr*, *Gmpz*, *Gmpq*, `long`, `unsigned long`, `int`, `double` and `long double`.

#include <CGAL/Gmpfi.h>

Is Model for the Concepts

FieldWithKthRoot
RealEmbeddable

Types

Gmpfi:: Precision_type — Type representing the precision (number of bits used to represent the mantissa) of a number.

Creation

All the constructors accept an optional last argument: a precision (a *Precision_type*, which can be used to specify the precision of the *Gmpfr* endpoints. If none is specified, the default precision will be used. As the endpoints are represented with a fixed number of bits, they may need to be rounded. In this case, the number from which the *Gmpfi* was constructed is guaranteed to be included in the constructed interval.

Gmpfi i(Precision_type p=get_default_precision());

creates an uninitialized *Gmpfi* interval *i*.

template <class T>
Gmpfi i(T t, Precision_type p=get_default_precision());

creates a *Gmpfi* initialized with the value of *t*. *T* is *Gmpfr*, *Gmpq*, or any type from which *Gmpfr* can be constructed from. The rounding of the endpoints will guarantee that *t* is included in *i*.

Gmpfi i(Gmpfr left, Gmpfr right, Precision_type p=get_default_precision());

creates a *Gmpfi* initialized with endpoints *left* and *right*. The rounding of the endpoints will guarantee that $[left, right]$ is included in *i*.

template<class L, class R>
Gmpfi i(std::pair<L,R> endpoints, Precision_type p=get_default_precision());

creates a *Gmpfi* initialized with endpoints *endpoints.first* and *endpoints.second*. *L* and *R* are types from which *Gmpfr* can be constructed from. The rounding of the endpoints will guarantee that [*endpoints.first*, *endpoints.second*] is included in *i*.

Operations

Gmpfr *i.inf() const* Returns the smallest (or *inferior*) *Gmpfr* endpoint of *i*.

Gmpfr *i.sup() const* Returns the largest (or *superior*) *Gmpfr* endpoint of *i*.

static Precision_type *i.get_default_precision()*

Returns the default precision.

static Precision_type *i.set_default_precision(Precision_type prec)*

Sets the default precision to *prec* and returns the old value.

Precision_type *i.get_precision() const*

Returns the precision of *i*.

Gmpfi *i.round(Precision_type p) const*

Returns the value of the number, rounded with precision *p*.

Arithmetic operators `+`, `-`, `*` and `/` are overloaded, but special care must be taken when applying them. The precision of an operation between two *Gmpfi*s is defined as the maximum of the operands precision and the default precision.

The second operand of the former operations can be a `Gmpfi`, `Gmpfr`, `int`, `long`, `unsigned`, `unsigned long`, `Gmpz` or `Gmpq`. The precision of an operation between a *Gmpfi* and a number of another type is defined as the *Gmpfi*'s precision (even when operating with a `Gmpfr`).

To specify the rounding mode and/or the precision to perform an operation, this class provides the four static functions `add`, `sub`, `mul` and `div`. Only one of them is shown here, since their interfaces are similar:

static Gmpfi *add(a, b, Precision_type p=0)*

When the precision is not specified in this family of functions, it is defined as in the overloaded operators.

Other arithmetic functions provided by the class are:

Gmpfi *i.abs(Precision_type p) const*

Returns the absolute value of i, with precision p. If p is not specified, the precision used is the maximum between i's precision and the default.

Gmpfi *i.sqrt(Precision_type p) const*

Returns the square root of i, with precision p. If p is not specified, the precision used is the maximum between i's precision and the default.

Gmpfi *i.kthroot(int k, Precision_type p) const*

Returns the k-th root of i, with precision p. If p is not specified, the precision used is the maximum between i's precision and the default.

Gmpfi *i.square(Precision_type p) const*

Returns the square of i, with precision p. If p is not specified, the precision used is the maximum between i's precision and the default.

std::pair<double,double>

i.to_interval() const Returns an interval of doubles which contains i. If a rounded endpoint does not fit in a double, sets its value to plus or minus infinity and the *overflow* or *underflow* flag.

std::pair<double,long>

i.to_double_exp() const

Returns (m,e) such that $m \times 2^e$ is the center of i, rounded to nearest. If one of the endpoints of i is *NaN* or infinity, then the corresponding double is returned, leaving the exponent undefined and setting the appropriate error flag.

std::pair<std::pair<double,double>,long>

i.to_interval_exp() const

Returns $((m_1,m_2),e)$, such that $[m_1 \times 2^e, m_2 \times 2^e]$ contains i. If one of the endpoints of i is *NaN* or infinity, then the corresponding doubles are returned, leaving the exponent undefined and setting the appropriate error flag.

Comparisons

The semantics of the comparison operators is the same than on *Interval_nt<Protected>*. The result of the comparison is always an *Uncertain<bool>* (this type is convertible to *bool*, but may throw an exception). If compared intervals have no common points, the result is *true* or *false*; otherwise, *Uncertain<bool>::indeterminate()* will be returned.

In the same way, we can explain the semantics of *Uncertain<Comparison_result>* and *Uncertain<Sign>*.

With the semantics described above, this class provides comparisons between *Gmpfi* and *Gmpfi*, *Gmpfr*, *long*, *unsigned long*, *int*, *double*, *Gmpz* and *Gmpq*. Comparison operators ==, !=, >, <, >= and <= are overloaded.

The class provides also functions to test efficiently some special kinds of comparisons:

bool	*i.is_same(j) const*	Returns *true* iff left endpoints of *i* and *j* are equal and right endpoints of them are also equal. Note that this does not mean equality between *i* and *j*.
bool	*i.do_overlap(j) const*	Returns *true* iff *i* and *j* overlap, i.e., iff they have points in common.
Uncertain<Comparison_result>		
	i.compare(j) const	If *i* and *j* do not overlap, this function returns the result of the comparison. Otherwise, it returns *indeterminate*.

Query Functions

bool	*i.is_point() const*	Returns *true* iff both endpoints are equal.
bool	*i.is_nan() const*	Returns *true* iff at least one of the endpoints is *NaN*.
bool	*i.is_inf() const*	Returns *true* iff at least one of the endpoints is plus or minus infinity.
bool	*i.is_number() const*	Returns *true* iff *i* is a bounded interval, i.e. its endpoints are neither invalid nor infinite.
Uncertain<bool>	*i.is_zero() const*	Returns *true* if both endpoints are zero, *false* if the interval does not contain zero and *indeterminate* otherwise.
Uncertain<bool>	*i.is_one() const*	Returns *true* if both endpoints are one, *false* if the interval does not contain one and *indeterminate* otherwise.
Uncertain<Sign>	*i.sign() const*	If all numbers contained in the interval have the same sign, this function returns it. Otherwise it returns *indeterminate*.
Uncertain<bool>	*i.is_positive() const*	Returns *true* if all numbers contained in the interval are positive, false if all of them are negative or zero and *indeterminate* otherwise.
Uncertain<bool>	*i.is_negative() const*	Returns *true* if all numbers contained in the interval are negative, false if all of them are positive or zero and *indeterminate* otherwise.

Input/Output

std::istream&	*std::istream &is >> i*	Reads *i* from *is*. *is* must have the form *[inf,sup]*, where *inf* and *sup* have valid *Gmpfr* input formats.
std::ostream&	*std::ostream &os << i*	Writes *i* to *os*, in the form *[i.inf(),i.sup()]*. The endpoints are written according to the *Gmpfr* formatting.

Implementation

All interval operations are performed by the MPFI library. The class *Gmpfi* is not reference counted, but its members are.

Class

CGAL::MP_Float

Definition

An object of the class *MP_Float* is able to represent a floating point value with arbitrary precision. This number type has the property that additions, subtractions and multiplications are computed exactly, as well as the construction from *float*, *double* and *long double*.

Division and square root are not enabled by default since CGAL release 3.2, since they are computed approximately. We suggest that you use rationals like *Quotient<MP_Float>* when you need exact divisions.

Note on the implementation : although the mantissa length is basically only limited by the available memory, the exponent is currently represented by a (integral valued) *double*, which can overflow in some circumstances. We plan to also have a multiprecision exponent to fix this issue.

#include <CGAL/MP_Float.h>

Is Model for the Concepts

EuclideanRing.

RealEmbeddable

Creation

MP_Float m;	introduces an uninitialized variable *m*.
MP_Float m(MP_Float);	copy constructor.
MP_Float m(int i);	introduces the integral value i.
MP_Float m(float d);	introduces the floating point value d (exact conversion).
MP_Float m(double d);	introduces the floating point value d (exact conversion).
MP_Float m(long double d);	introduces the floating point value d (exact conversion).

Operations

std::ostream& *std::ostream& out << m*

writes a double approximation of *m* to the ostream *out*.

std::istream& *std::istream& in >> & m*

reads a *double* from *in*, then converts it to an *MP_Float*.

MP_Float *approximate_division(a, b)*

computes an approximation of the division by converting the operands to *double*, performing the division on *double*, and converting back to *MP_Float*.

MP_Float	*approximate_sqrt(a)*	computes an approximation of the square root by converting the operand to *double*, performing the square root on *double*, and converting back to *MP_Float*.

Implementation

The implementation of *MP_Float* is simple but provides a quadratic complexity for multiplications. This can be a problem for large operands. For faster implementations of the same functionality with large integral values, you may want to consider using *GMP* or *LEDA* instead.

Class

CGAL::Interval_nt<Protected>

Definition

This section describes briefly what interval arithmetic is, its implementation in CGAL, and its possible use by geometric programs. The main reason for having interval arithmetic in CGAL is its integration into the filtered robust and fast predicates scheme, but we also provide a number type so that you can use it separately if you find any use for it, such as interval analysis, or to represent data with tolerance...

The purpose of interval arithmetic is to provide an efficient way to bound the roundoff errors made by floating point computations. You can choose the behavior of your program depending on these errors. You can find more theoretical information on this topic in [BBP01].

Interval arithmetic is a large concept and we will only consider here a simple arithmetic based on intervals whose bounds are *double*s. So each variable is an interval representing any value inside the interval. All arithmetic operations (+, -, $*$, $/$, $\sqrt{}$, *square()*, *min()*, *max()* and *abs()*) on intervals preserve the inclusion. This property can be expressed by the following formula (x and y are real, X and Y are intervals, $\mathcal{OP}$ is an arithmetic operation):

$$\forall\, x \in X, \forall\, y \in Y, (x\ \mathcal{OP}\ y) \in (X\ \mathcal{OP}\ Y)$$

For example, if the final result of a sequence of arithmetic operations is an interval that does not contain zero, then you can safely determine its sign.

#include <CGAL/Interval_nt.h>

Parameters

The template parameter *Protected* is a Boolean parameter, which defaults to *true*. It provides a way to select faster computations by avoiding rounding mode switches, at the expense of more care to be taken by the user (see below). The default value, *true*, is the safe way, and takes care of proper rounding mode changes. When specifying *false*, the user has to take care about setting the rounding mode towards plus infinity before doing any computations with the interval class. He can do so using the *Protect_FPU_rounding* class for example.

Is Model for the Concepts

FieldWithSqrt

RealEmbeddable

Types

The class *Interval_nt* defines the following types: *typedef double* *value_type;* The type of the bounds of the in

typedef Uncertain_conversion_exception

unsafe_comparison; The type of the exceptions raised when uncertain comparisons are performed.

Interval_nt<Protected>:: Protector — A type whose default constructor and destructor allow to protect a block of code from FPU rounding modes necessary for the computations with *Interval_nt<false>*. It does nothing for *Interval_nt<true>*. It is implemented as *Protect_FPU_rounding<!Protected>*.

Creation

Interval_nt<Protected> I(int i); — introduces the interval [i;i].

Interval_nt<Protected> I(double d); — introduces the interval [d;d].

Interval_nt<Protected> I(double i, double s); — introduces the interval [i;s].

Interval_nt<Protected> I(std::pair<double, double> p);

introduces the interval [*p.first*;*p.second*].

Operations

All functions required by a class to be considered as a CGAL number type (see 5) are present, as well as the utility functions, sometimes with a particular semantic which is described below. There are also a few additional functions.

Interval_nt	*I / Interval_nt J*	returns $[-\infty;+\infty]$ when the denominator contains 0.
Interval_nt	*sqrt(Interval_nt I)*	returns $[0;\sqrt{upper\_bound(I)}]$ when only the lower bound is negative (expectable case with roundoff errors), and is unspecified when the upper bound also is negative (unexpected case).
double	*to_double(Interval_nt I)*	returns the middle of the interval, as a double approximation of the interval.
double	*I.inf()*	returns the lower bound of the interval.
double	*I.sup()*	returns the upper bound of the interval.
bool	*I.is_point()*	returns whether both bounds are equal.
bool	*I.is_same(Interval_nt J)*	returns whether both intervals have the same bounds.
bool	*I.do_overlap(Interval_nt J)*	returns whether both intervals have a non empty intersection.

The comparison operators ($<$, $>$, $<=$, $>=$, $==$, $!=$, *sign()* and *compare()*) have the following semantic: it is the intuitive one when for all couples of values in both intervals, the comparison is identical (case of non-overlapping intervals). This can be expressed by the following formula (x and y are real, X and Y are intervals, $\mathcal{OP}$ is a comparison operator):

$$(\forall x \in X, \forall y \in Y, (x\ \mathcal{OP}\ y) = true) \Rightarrow (X\ \mathcal{OP}\ Y) = true$$

and

$$(\forall x \in X, \forall y \in Y, (x\ \mathcal{OP}\ y) = false) \Rightarrow (X\ \mathcal{OP}\ Y) = false$$

Otherwise, the comparison is not safe, and we specify this by returning a type encoding this uncertainty, namely using *Uncertain<bool>* or *Uncertain<Sign>*, which can be probed for uncertainty explicitly, and which has a conversion to the normal type (e.g. *bool*) which throws an exception when the conversion is not certain. Note that each failed conversion increments a profiling counter (see *CGAL_PROFILE*), and then throws the exception of type *unsafe_comparison*.

Uncertain<bool>	*Interval_nt i* $<$ *Interval_nt j*
Uncertain<bool>	*Interval_nt i* $>$ *Interval_nt j*
Uncertain<bool>	*Interval_nt i* $<=$ *Interval_nt j*
Uncertain<bool>	*Interval_nt i* $>=$ *Interval_nt j*
Uncertain<bool>	*Interval_nt i* $==$ *Interval_nt j*
Uncertain<bool>	*Interval_nt i* $!=$ *Interval_nt j*
Uncertain<Comparison_result>	*compare(Interval_nt i, Interval_nt j)*
Uncertain<Sign>	*sign(Interval_nt i)*

typedef Interval_nt<false>

Interval_nt_advanced;

This typedef (at namespace CGAL scope) exists for backward compatibility, as well as removing the need to remember the Boolean value for the template parameter.

advanced

Implementation

The operations on *Interval_nt* with the default parameter *true*, are automatically protected against rounding modes, and are thus slower than those on *Interval_nt_advanced*, but easier to use. Users that need performance are encouraged to use *Interval_nt_advanced* instead.

Changing the rounding mode affects all floating point computations, and might cause problems with parts of your code, or external libraries (even CGAL), that expect the rounding mode to be the default (round to the nearest).

We provide two interfaces to change the rounding mode. The first one is to use a protector object whose default constructor and destructor will take care of changing the rounding mode. The protector is implemented using *Protect_FPU_rounding*.

The second one is the following detailed set of functions :

typedef int	*FPU_CW_t;*	The type used by the following functions to deal with rounding modes. This is usually an *int*.
void	*FPU_set_cw(FPU_CW_t R)*	
		sets the rounding mode to *R*.
FPU_CW_t	*FPU_get_cw(void)*	returns the current rounding mode.
FPU_CW_t	*FPU_get_and_set_cw(FPU_CW_t R)*	
		sets the rounding mode to *R* and returns the old one.

The macros *CGAL_FE_TONEAREST*, *CGAL_FE_TOWARDZERO*, *CGAL_FE_UPWARD* and *CGAL_FE_DOWNWARD* are the values corresponding to the rounding modes.

Example

Protecting an area of code that uses operations on the class *Interval_nt_advanced* can be done in the following way:

```
{
  Interval_nt_advanced::Protector P;
  ... // The code to be protected.
}
```

The basic idea is to use the directed rounding modes specified by the *IEEE 754* standard, which are implemented by almost all processors nowadays. It states that you have the possibility, concerning the basic floating point operations $(+,-,*,/,\sqrt{})$ to specify the rounding mode of each operation instead of using the default, which is set to 'round to the nearest'. This feature allows us to compute easily on intervals. For example, to add the two intervals [a.i;a.s] and [b.i;b.s], compute $c.i = a.i + b.i$ rounded towards minus infinity, and $c.s = a.s + b.s$ rounded towards plus infinity, and the result is the interval [c.i;c.s]. This method can be extended easily to the other operations.

The problem is that we have to change the rounding mode very often, and the functions of the C library doing this operation are slow and not portable. That's why assembly versions are used as often as possible. Another trick is to store the opposite of the lower bound, instead of the lower bound itself, which allows us to never change the rounding mode inside simple operations. Therefore, all basic operations, which are in the class *Interval_nt_advanced* assume that the rounding mode is set to 'round to infinity', and everything works with this correctly set.

So, if the user needs the speed of *Interval_nt_advanced*, he must take care of setting the rounding mode to 'round to infinity' before each block of operations on this number type. And if other operations might be affected by this, he must take care to reset it to 'round to the nearest' before they are executed.

Notes:

- On Intel platforms (with any operating system and compiler), due to a misfeature of the floating point unit, which does not handle exactly IEEE compliant operations on doubles, we are forced to use a workaround which slows down the code, but is only useful when the intervals can overflow or underflow. If you know that the intervals will never overflow nor underflow for your code, then you can disable this workaround with the flag *CGAL_IA_NO_X86_OVER_UNDER_FLOW_PROTECT*. Other platforms are not affected by this flag.

- When optimizing, compilers usually propagate the value of variables when they know it's a constant. This can break the interval routines because the compiler then does some floating point operations on these constants with the default rounding mode, which is wrong. This kind of problem is avoided by stopping constant propagation in the interval routines. However, this solution slows down the code and is rarely useful, so you can disable it by setting the flag *CGAL_IA_DONT_STOP_CONSTANT_PROPAGATION*.

advanced

CGAL::Lazy_exact_nt<NT>

Class

Definition

An object of the class *Lazy_exact_nt<NT>* is able to represent any real embeddable number which *NT* is able to represent. The idea is that *Lazy_exact_nt<NT>* works exactly like *NT*, except that it is expected to be faster because it tries to only compute an approximation of the value, and only refers to *NT* when needed. The goal is to speed up exact computations done by any exact but slow number type *NT*.

NT must be a model of concept *RealEmbeddable*.
NT must be at least model of concept *IntegralDomainWithoutDivision*.

Note that some filtering mechanism is available at the predicate level using *Filtered_predicate* and *Filtered_kernel*.

#include <CGAL/Lazy_exact_nt.h>

Is Model for the Concepts

IntegralDomainWithoutDivision	same as *NT*
RealEmbeddable	
Fraction	if *NT* is a *Fraction*

Creation

Lazy_exact_nt<NT> m;	introduces an uninitialized variable *m*.
Lazy_exact_nt<NT> m(int i);	introduces the integral value *i*.
Lazy_exact_nt<NT> m(double d);	introduces the floating point value *d* (works only if *NT* has a constructor from a double too).
Lazy_exact_nt<NT> m(NT n);	introduces the value *n*.
template <class NT1> *Lazy_exact_nt<NT> m(Lazy_exact_nt<NT1> n);*	introduces the value *n*. *NT1* needs to be convertible to *NT* (and this conversion will only be done if necessary).

Operations

NT	*m.exact()*	returns the corresponding NT value.
Interval_nt<true>	*m.approx()*	returns an interval containing the exact value.
Interval_nt<false>	*m.interval()*	returns an interval containing the exact value.

static void *m.set_relative_precision_of_to_double(double d)*

specifies the relative precision that *to_double()* has to fulfill. The default value is 10^{-5}.
Precondition: d¿0 and d¡1.

static double *m.get_relative_precision_of_to_double()*

returns the relative precision that *to_double()* currently fulfills.

std::ostream& *std::ostream& out << m*

writes *m* to ostream *out* in an interval format.

std::istream& *std::istream& in >> & m*

reads a *NT* from *in*, then converts it to a *Lazy_exact_nt<NT>*.

Example

```
#include <CGAL/Cartesian.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Lazy_exact_nt.h>
#include <CGAL/Quotient.h>

typedef CGAL::Lazy_exact_nt<CGAL::Quotient<CGAL::MP_Float> > NT;
typedef CGAL::Cartesian<NT> K;
```

CGAL::Quotient<NT>

Class

Definition

An object of the class *Quotient<NT>* is an element of the field of quotients of the integral domain type *NT*. If *NT* behaves like an integer, *Quotient<NT>* behaves like a rational number. LEDA's class *rational* (see Section 5.5) has been the basis for *Quotient<NT>*. A *Quotient<NT> q* is represented as a pair of *NT*s, representing numerator and denominator.

NT must be at least model of concept *IntegralDomainWithoutDivision*.
NT must be a model of concept *RealEmbeddable*.

#include <CGAL/Quotient.h>

Is Model for the Concepts

Field
RealEmbeddable
Fraction

Creation

Quotient<NT> q;	introduces an uninitialized variable *q*.
template <class T> *Quotient<NT> q(T t);*	introduces the quotient *t/1*. NT needs to have a constructor from T.
template <class T> *Quotient<NT> q(Quotient<T> t);*	introduces the quotient *NT(t.numerator())/NT(t.denominator())*. NT needs to have a constructor from T.
Quotient<NT> q(NT n, NT d);	introduces the quotient *n/d*. *Precondition*: $d \neq 0$.

Operations

There are two access functions, namely to the numerator and the denominator of a quotient. Note that these values are not uniquely defined. It is guaranteed that *q.numerator()* and *q.denominator()* return values *nt_num* and *nt_den* such that *q* = *nt_num/nt_den*, only if *q.numerator()* and *q.denominator()* are called consecutively wrt *q*, i.e. *q* is not involved in any other operation between these calls.

NT	*q.numerator() const*	returns a numerator of *q*.
NT	*q.denominator() const*	returns a denominator of *q*.

The stream operations are available as well. They assume that corresponding stream operators for type *NT* exist.

std::ostream&	*std::ostream& out* << *q*	
		writes *q* to ostream *out* in format "`n/d`", where `n`==*q.numerator()* and `d`==*q.denominator()*.
std::istream&	*std::istream& in* >> & *q*	
		reads *q* from istream *in*. Expected format is "`n/d`", where `n` and `d` are of type *NT*. A single `n` which is not followed by a `/` is also accepted and interpreted as `n/1`.

The following functions are added to fulfill the CGAL requirements on number types.

double	*to_double(q)*	returns some double approximation to *q*.
bool	*is_valid(q)*	returns true, if numerator and denominator are valid.
bool	*is_finite(q)*	returns true, if numerator and denominator are finite.
Quotient<NT>	*sqrt(q)*	returns the square root of *q*. This is supported if and only if *NT* supports the square root as well.

CGAL::Number_type_checker<NT1,NT2,Comparator>

Definition

Number_type_checker is a number type whose instances store two numbers of types *NT1* and *NT2*. It forwards all arithmetic operations to them, and calls the binary predicate *Comparator* to check the equality of the instances after each modification, as well as for each comparison.

This is a debugging tool which is useful when dealing with number types.

Parameters

NT1 must be a model of some algebraic structure concept. *NT2* must be a model of the same algebraic structure concept. *NT1* and *NT2* must be *FromDoubleConstructible*. *Comparator* has to be a model of a binary predicate taking *NT1* as first argument, and *NT2* as second. The *Comparator* parameter has a default value which is a functor calling *operator==* between the two arguments.

#include <CGAL/Number_type_checker.h>

Is Model for the Concepts

IntegralDomainWithoutDivision (same as *NT1*)
RealEmbeddable **Creation**

Number_type_checker<NT1,NT2,Comparator> c;

introduces an uninitialized variable *c*.

Number_type_checker<NT1,NT2,Comparator> c(int i);

introduces the integral value i.

Number_type_checker<NT1,NT2,Comparator> c(double d);

introduces the floating point value d.

Number_type_checker<NT1,NT2,Comparator> c(NT1 n1, NT2 n2);

introduces a variable storing the pair *n1, n2*.

Operations

Some operations have a particular behavior documented here.

NT1	*c.n1() const*	returns a const reference to the object of type *NT1*.
NT2	*c.n2() const*	returns a const reference to the object of type *NT2*.
NT1&	*c.n1()*	returns a reference to the object of type *NT1*.
NT2&	*c.n2()*	returns a reference to the object of type *NT2*.

bool	*c.is_valid() const*	calls the *Comparator* binary predicate on the two stored objects and returns its result.
std::ostream&	*std::ostream& out << Number_type_checker c*	
		writes *c.n1()* to the ostream *out*.
std::istream&	*std::istream& in >> Number_type_checker& c*	
		reads an *NT1* from *in*, then converts it to an *NT2*, so a conversion from *NT1* to *NT2* is required here.

CGAL::Max<T,Less>

Functor
Class

Definition

The function object class *Max<T,Less>* returns the larger of two values. The order is induced by the second template argument `Less`. The default value for *Less* is *std::less*.

Note that *T* must be a model of *LessThanComparable* in case *std::less* is used.

#include <CGAL/utils_classes.h>

Is Model for the Concepts

AdaptableFunctor . . . . page **??**

Creation

Max<T,Less> max;	default constructor.
Max<T,Less> max(Less c);	The constructed object will use *c* to compare the arguments.

Operations

T	*operator()(T x, T y)*	returns the larger of *x* and *y*, with respect to the order induced by *Less*.

Functor
Class

CGAL::Min<T,Less>

Definition

The function object class *Min<T,Less>* returns the smaller of two values. The order is induced by the second template argument `Less`. The default value for *Less* is *std::less*.

Note that *T* must be a model of *LessThanComparable* in case *std::less* is used.

#include <CGAL/utils_classes.h>

Is Model for the Concepts

AdaptableFunctor . . . . page **??**

Creation

Min<T,Less> min;	default constructor.
Min<T,Less> min(Less c);	The constructed object will use *c* to compare the arguments.

Operations

T	*operator()(T x, T y)*	returns the larger of *x* and *y*, with respect to the order induced by *Less*.

CGAL::Is_valid<T>

Functor
Class

Definition

Not all values of a type need to be valid. The function object class *Is_valid<T>* checks this.

For example, an expression like *NT(0)/NT(0)* can result in an invalid number. Routines may have as a precondition that all values are valid.

#include <CGAL/utils_classes.h>

Is Model for the Concepts

AdaptableFunctor . . . . page **??**

bool	*operator()(T x)*	returns if the argument is valid.

Function

CGAL::max

Definition

The function *max* returns the larger of two values.

#include <CGAL/utils.h>

T	*max(T x, T y)*

Max . . . . page **??**

CGAL::min

Function

Is_valid . . . . page **??**

CGAL::Rational_traits<NT>

Class

Definition

The class *Rational_traits<NT>* can be used to determine the type of the numerator and denominator of a rational number type as *Quotient*, *Gmpq*, *mpq_class* or *leda_rational*.

#include <CGAL/Rational_traits.h>

Types

Rational_traits<NT>:: RT — the type of the numerator and denominator.

Operations

RT *t.numerator(NT r) const*

returns the numerator of r.

RT *t.denominator(NT r) const*

returns the denominator of r.

NT *t.make_rational(RT n, RT d) const*

constructs a rational number.

NT *t.make_rational(NT n, NT d) const*

constructs a rational number.

CGAL::simplest_rational_in_interval

Function

Definition

The function *simplest_rational_in_interval* computes the simplest rational number in an interval of two *double* values.

#include <CGAL/simplest_rational_in_interval.h>

Rational	*simplest_rational_in_interval(double d1, double d2)*	
		computes the rational number with the smallest denominator in the interval *[d1,d2]*.

Implementation

See Knuth, "Seminumerical algorithms", page 654, answer to exercise 4.53-39.

See Also

CGAL::simplest_rational_in_interval<Rational>(double d1, double d2).

Concept

RootOf_2

Definition

Concept to represent algebraic numbers of degree up to 2 over a *RealEmbeddable IntegralDomain* *RT*.

A model of this concept is associated to this *RT* via *CGAL::Root_of_traits*<*RT*>, which provides *Root_of_2* as a public type. Moreover, *CGAL::Root_of_traits*<*RT*> provides the public type *Root_of_1*, which is the quotient field of *RT*. We refer to *Root_of_1* as FT (for field type).

The model of *RootOf_2* is a *RealEmbeddable IntegralDomain*, which is *ImplicitInteroperable* with *RT*, *FT*. In particular, it provides the comparison operators ==, *!*=, <, >, <=, >= as well as the *sign* and *compare* functions needed to compare elements of types *RootOf_2, RT* and *FT*. It also provides all arithmetic operators +,-,*,/ among elements of type *RootOf_2* as well as mixed forms with *RT* and *FT*.

However, it is important to note that arithmetic operations among elements of *RootOf_2* are only allowed in the special case when they have been constructed from equations having the same discriminant, that is, if they are defined in the same algebraic extension of degree 2.

Besides construction from *int, RT* and *FT* the following functions provide special construction for extensions of degree 2:
- *make_root_of_2*
- *make_sqrt*

Refines

DefaultConstructible
CopyConstructible
FromIntConstructible
ImplicitInteroperable with RT
ImplicitInteroperable with FT

Operations

RootOf_2 &	$+= a$	*Precondition*: **this* and *a* are defined in the same extension.
RootOf_2	$a+b$	*Precondition*: *a* and *b* are defined in the same extension.

bool	$a == b$
bool	$a < b$

Same for operator `-`, `*`, `/`, `!=`, `<=`, `>`, `>=` as well as mixed forms with *RT* and *FT*.

Class

CGAL::Sqrt_extension<NT,ROOT>

In addition, *Sqrt_extension* has another two default template arguments:
· *DifferentExtensionComparable = ::CGAL::Tag_false*
· *FilterPredicates = ::CGAL::Tag_false*
See below for more details.

Definition

An instance of this class represents an extension of the type *NT* by **one** square root of the type *ROOT*.
NT is required to be constructible from *ROOT*.
NT is required to be an *IntegralDomainWithoutDivision*.
Sqrt_extension<NT,ROOT> is *RealEmbeddable* if NT is *RealEmbeddable*.

For example, let *Integer* be some type representing $\mathbb{Z}$, then *Sqrt_extension<Integer,Integer>* is able to represent $\mathbb{Z}[\sqrt{root}]$ for some arbitrary Integer *root*.[2] The value of *root* is set at construction time, or set to zero if it is not specified.

Arithmetic operations among different extensions, say $\mathbb{Z}[\sqrt{a}]$ and $\mathbb{Z}[\sqrt{b}]$, are not supported. The result would be in $\mathbb{Z}[\sqrt{a},\sqrt{b}]$, which is not representable by *Sqrt_extension<Integer,Integer>*. **The user is responsible to check that arithmetic operations are carried out for elements from the same extensions only.** This is not tested by *Sqrt_extension<NT,ROOT>* for efficiency reasons. A violation of the precondition leads to undefined behavior. Be aware that for efficiency reasons the given *root* is stored as it is given to the constructor. In particular, an extension by a square root of a square is considered as an extension.

Since elements of *Sqrt_extension<NT,ROOT>* that lie in different extensions are not interoperable with respect to any arithmetic operations, the full value range of *Sqrt_extension<NT,ROOT>* does not represent an algebraic structure. However, each subset of the value range that represents the extension of NT by a particular square root is a valid algebraic structure, since this subset is closed under all provided arithmetic operations. From there, *Sqrt_extension<NT,ROOT>* can be used as if it were a model of an algebraic structure concept, with the following correspondence:

NT	*Sqrt_extension<NT,ROOT>*
IntegralDomainWithoutDivision	*IntegralDomainWithoutDivision*
IntegralDomain	*IntegralDomain*
UniqueFactorizationDomain	*IntegralDomain*
EuclideanRing	*IntegralDomain*
Field	*Field*

The extension of a *UniqueFactorizationDomain* or *EuclideanRing* is just an *IntegralDomain*, since the extension in general destroys the unique factorization property. For instance consider $\mathbb{Z}[\sqrt{10}]$, the extension of $\mathbb{Z}$ by $\sqrt{10}$: in $\mathbb{Z}[\sqrt{10}]$ the element 10 has two different factorizations $\sqrt{10}\cdot\sqrt{10}$ and $2\cdot 5$. In particular, the factorization is not unique.

If *NT* is a model of *RealEmbeddable* the type *Sqrt_extension* is also considered as *RealEmbeddable*. However, by default it is not allowed to compare values from different extensions for efficiency reasons. In case such a comparison becomes necessary, use the member function compare with the according Boolean flag. If such a comparison is a very frequent case, override the default of *DifferentExtensionComparable* by giving *::CGAL::Tag_true* as third template parameter. This effects the behavior of compare functions as well as the compare operators.

[2] $R[a]$ denotes the extension of a ring R by an element a. See also: http://mathworld.wolfram.com/ExtensionRing.html

The fourth template argument, *FilterPredicates*, triggers an internal filter that may speed up comparisons and sign computations. In case *FilterPredicates* is set to *CGAL::Tag_true* the type first computes a double interval containing the represented number and tries to perform the comparison or sign computation using this interval. Once computed, this interval is stored by the corresponding *Sqrt_extension* object for further usage. Note that this internal filter is switched off by default, since it may conflict with other filtering methods, such as *CGAL::Lazy_exact_nt<Sqrt_extension>*.

In case *NT* is not *RealEmbeddable*, *DifferentExtensionComparable* as well as *FilterPredicates* have no effect.

Is Model for the Concepts

Assignable	
CopyConstructible	
DefaultConstructible	
EqualityComparable	
ImplicitInteroperable	with int
ImplicitInteroperable	with NT
Fraction	if NT is a *Fraction*
RootOf_2	

Creation

Sqrt_extension<NT,ROOT>	*ext*;	Introduces an variable initialized with 0.
Sqrt_extension<NT,ROOT>	*ext(Sqrt_extension x);*	Copy constructor.
Sqrt_extension<NT,ROOT>	*ext(int i);*	Introduces an variable initialized with *i*.
Sqrt_extension<NT,ROOT>	*ext(NT x);*	Introduces an variable initialized with *x*.
Sqrt_extension<NT,ROOT>	*ext(int a0, int a1, int r);*	Constructor from int: *ext*$= a0 + a1 \cdot sqrt(r)$. *Precondition*: $r \neq 0$
Sqrt_extension<NT,ROOT>	*ext(NT a0, NT a1, ROOT r);*	General constructor: *ext*$= a0 + a1 \cdot sqrt(r)$. *Precondition*: $r \neq 0$

Operations

An object of type *Sqrt_extension* represent an expression of the form: $a0 + a1 * sqrt(root)$.

NT	*ext.a0() const*	Const access operator for a0
NT	*ext.a1() const*	Const access operator for a1
ROOT	*ext.root() const*	Const access operator for root
bool	*ext.is_extended() const*	Returns true in case root of *ext* is not zero. Note that $a1 == 0$ does not imply $root == 0$.
void	*ext.simplify()*	Simplifies the representation, in particular *root* is set to zero if $a1$ is zero, that is, *ext* becomes not extended. Moreover, it propagates the simplify command to members of *ext*. see also: *AlgebraicStructureTraits::Simplify*.
bool	*ext.is_zero() const*	returns true if *ext* represents the value zero.

CGAL::Sign	*ext.sign() const*	Determines the sign of *ext* by (repeated) squaring. *Precondition*: *Sqrt_extension* is *RealEmbeddable*.
Sqrt_extension	*ext.abs() const*	returns the absolute value of *ext*. *Precondition*: *Sqrt_extension* is *RealEmbeddable*.

CGAL::Comparison_result

ext.compare(Sqrt_extension y, bool in_same_extension = !DifferentExtensionComparable::value) const

Compares *ext* with y.
The optional bool *in_same_extension* indicates whether *ext* and *y* are in the same extension of NT.

Sqrt_extension *operator+(Sqrt_extension a, Sqrt_extension b)*

Precondition: *(a.root()==0 or b.root()==0 or a.root() == b.root())*

Sqrt_extension *operator-(Sqrt_extension a, Sqrt_extension b)*

Precondition: *(a.root()==0 or b.root()==0 or a.root() == b.root())*

Sqrt_extension *operator*(Sqrt_extension a, Sqrt_extension b)*

Precondition: *(a.root()==0 or b.root()==0 or a.root() == b.root())*

Sqrt_extension& *ext.operator+=(Sqrt_extension a)*

Precondition: *(this->root()==0 or a.root()==0 or this->root() == a.root())*

Sqrt_extension& *ext.operator-=(Sqrt_extension a)*

Precondition: *(this->root()==0 or a.root()==0 or this->root() == a.root())*

Sqrt_extension& *ext.operator*=(Sqrt_extension a)*

Precondition: *(this->root()==0 or a.root()==0 or this->root() == a.root())*

In case *NT* is only an *IntegralDomain* operator/ implements integral division. In case *NT* is a *Field* operator/ implements the field division.

Sqrt_extension *operator/(Sqrt_extension a, Sqrt_extension b)*

Precondition: *(a.root()==0 or b.root()==0 or a.root() == b.root())*

Sqrt_extension& *ext.operator/=(Sqrt_extension a)*

Precondition: *(this->root()==0 or a.root()==0 or this->root() == a.root())*

bool *operator==(Sqrt_extension a, Sqrt_extension b)*

Precondition: *(a.root()==0 or b.root()==0 or a.root() == b.root())*

bool *operator!=(Sqrt_extension a, Sqrt_extension b)*

Precondition: *(a.root()==0 or b.root()==0 or a.root() == b.root())*

In case *Sqrt_extension* is *RealEmbeddable*:

bool *operator<(Sqrt_extension a, Sqrt_extension b)*

Precondition: *(a.root()==0 or b.root()==0 or a.root() == b.root())*

bool *operator<=(Sqrt_extension a, Sqrt_extension b)*

Precondition: *(a.root()==0 or b.root()==0 or a.root() == b.root())*

bool *operator>(Sqrt_extension a, Sqrt_extension b)*

Precondition: *(a.root()==0 or b.root()==0 or a.root() == b.root())*

bool *operator>=(Sqrt_extension a, Sqrt_extension b)*

Precondition: *(a.root()==0 or b.root()==0 or a.root() == b.root())*

The stream operations are available as well. They assume that corresponding stream operators for type *NT* and *ROOT* exist.

std::ostream& *operator<<(std::ostream& os, ext)*

writes *ext* to ostream *os*. The format depends on the *CGAL::IO::MODE* of *os*.
In case the mode is *CGAL::IO::ASCII* the format is `EXT[a0,a1,root]`.
In case the mode is *CGAL::IO::PRETTY* the format is human readable.

std::istream& *operator>>(std::istream& is, ext)*

reads *ext* from istream *is* in format `EXT[a0,a1,root]`, the output format in mode *CGAL::IO::ASCII*

CGAL::Set_ieee_double_precision

Definition

The IEEE754 standard specifies that the precision of double precision floating-point numbers should be 53 bits, with 11 bits for the exponent range.

Some processors violate this rule by providing excess precision during some computations (when values are in registers). This is the case of the x86 Intel processor and compatible processors (note that the SSE2 more recent alternative FPU is fortunately not affected by this issue). The effect of such excess precision can be a problem for some computations, since it can produce so-called double rounding effects, where actually *less* precision is actually provided! It can also be the root of non-deterministic computations depending on compiler optimizations or not (since this affects how long variables are kept in registers), for example numerical floating-point values get computed with slightly different results. Finally, it affects code that carefully makes use of cancellation properties, like *Residue*.

The class *Set_ieee_double_precision* provides a mechanism to set the correct 53 bits precision for a block of code. It does so by having a default constructor that sets a particular mode on the FPU which corrects the problem, and have its destructor reset the mode to its previous state.

Note that nothing can be done for the excess range of the exponent, which affects underflow and overflow cases, fortunately less frequent.

Note also that in the process of setting the correct precision, the rounding mode is also set to the nearest.

Moreover, some compilers provide a flag that performs this setting at the time of program startup. For example, GCC provides the option `-mpc64` since release 4.3 which does exactly this. Other compilers may have similar options.

Similarly, some third-party libraries may do the same thing as part of their startup process, and this is notably the case of LEDA (at least some versions of it). CGAL does not enforce this at startup as it would impact computations with long double performed by other codes in the same program.

Note that this property is notably required for proper functionning of the *Residue* class that performs modular arithmetic using efficient floating-point operations.

Note concerning Visual C++ 64-bit: due to a compiler bug, the stack unwinding process happenning when an exception is thrown does not correctly execute the restoring operation when the *Set_ieee_double_precision* object is destroyed. Therefore, for this configuration, some explicit code has to be added if you care about the state being restored.

#include <CGAL/FPU.h>

Creation

If the platform is not affected by the excess precision problem, this class becomes an empty class doing nothing.

Set_ieee_double_precision P;	Sets the precision of operations on double to 53bits. Note that the rounding mode is set to the nearest in the same process.

void *˜Set_ieee_double_precision()*

The precision and rounding modes are reset to the values they held before the constructor was called.

Also note that the following free function is also provided that does the same thing as the default constructor of *Set_ieee_double_precision* except that it does not perform the save and restore of the previous state.

void *force_ieee_double_precision()*

Sets the precision of operations on double to 53bits. Note that the rounding mode is set to the nearest in the same process.

CGAL::Protect_FPU_rounding<Protected>

Class

Definition

Floating-point arithmetic, as specified by the IEEE-754 standard, allows to use so-called directed rounding for the following arithmetic operations: addition, subtraction, multiplication, division and square root. The default behavior is that the result of such an arithmetic operation is the closest floating-point number to the exact real result of the operation (rounding to the nearest). The other rounding modes are: round towards plus infinity, round towards minus infinity, and round towards zero.

Interval arithmetic uses such directed rounding modes to offer guaranteed enclosures for the evaluation of real functions, such as with CGAL's *Interval_nt* class.

In order to efficiently evaluate sequences of interval arithmetic operations, such as a geometric predicate computing for example a determinant, it is advised to reduce the number of rounding mode changes, which otherwise are performed for each arithmetic operation. CGAL exploits the fact that it is possible to compute a sequence of interval arithmetic operations by doing only one rounding mode change around the whole function evaluation in order to benefit from this optimization.

The class *Protect_FPU_rounding* allows to easily benefit from this. Its constructor saves the current rounding mode in the object, and then sets the current rounding mode to the value provided as argument to the constructor. The destructor sets the rounding mode back to the saved value. This allows to protect a block of code determined by a C++ scope, and have the destructor take care of restoring the value automatically.

The related class *Set_ieee_double_precision* allows to similarly protect a block of code from excess precision on some machines (x86 typically with the traditional FPU, not the more recent SSE2). Note that *Protect_FPU_rounding_mode*, when changing rounding modes, also sets the precision to the correct 64 bit precision, hence providing a similar effect to *Set_ieee_double_precision*. This notably affects the *Residue* class.

Note for Visual C++ 64-bit users: due to a compiler bug, the stack unwinding process happenning when an exception is thrown does not correctly execute the rounding mode restoration when the *Protect_FPU_rounding* object is destroyed. Therefore, for this configuration, some explicit code has to be added.

#include <CGAL/FPU.h>

Parameters

The template parameter *Protected* is a Boolean parameter, which defaults to *true*. It follows the same parameter of the *Interval_nt* class. When it is *false*, the constructor and the destructor of the class do nothing (this is meant to be used in a context where you know that the rounding mode change has been taken care of at a higher level in the call stack.

What follows describes the behavior when the parameter has its default value, *true*.

Creation

Protect_FPU_rounding<Protected> P(FPU_CW_t r = CGAL_FE_UPWARD);

The current rounding mode is saved in the object, and rounding mode is set to *r* which can be any of *CGAL_FE_TONEAREST*, *CGAL_FE_TOWARDZERO*, *CGAL_FE_UPWARD* (the default) and *CGAL_FE_DOWNWARD*.

void ~*Protect_FPU_rounding()*

The rounding mode is restored to the saved value.

Chapter 6

Modular Arithmetic

Michael Hemmer and Sylvain Pion

6.1 Introduction

Modular arithmetic is a fundamental tool in modern algebra systems. In conjunction with the Chinese remainder theorem it serves as the workhorse in several algorithms computing the gcd, resultant etc. Moreover, it can serve as a very efficient filter, since it is often possible to exclude that some value is zero by computing its modular correspondent with respect to one prime only.

First of all, this package introduces a type *CGAL::Residue*. It represents $\mathbb{Z}_{/p\mathbb{Z}}$ for some prime p. The prime number p is stored in a static member variable. The class provides static member functions to change this value. **Note that changing the prime invalidates already existing objects of this type.** However, already existing objects do not lose their value with respect to the old prime and can be reused after restoring the old prime. Since the type is based on double arithmetic the prime is restricted to values less than 2^{26}. The initial value of p is 67111067.

Please note that the implementation of class *CGAL::Residue* requires a mantissa precision according to the IEEE Standard for Floating-Point Arithmetic (IEEE 754). However, on some processors the traditional FPU uses an extended precision. Hence, it is indispensable that the proper mantissa length is enforced before performing any arithmetic operations. Moreover, it is required that numbers are rounded to the next nearest value. This can be ensured using *CGAL::Protect_FPU_rounding* with *CGAL_FE_TONEAREST*, which also enforces the required precision as a side effect.

advanced

In case the flag *CGAL_HAS_THREADS* is undefined the prime is just stored in a static member of the class, that is, *CGAL::Residue* is not thread-safe in this case. In case *CGAL_HAS_THREADS* the implementation of the class is thread safe using *boost::thread_specific_ptr*. However, this may cause some performance penalty. Hence, it may be advisable to configure CGAL with *CGAL_HAS_NO_THREADS*.

advanced

Moreover, the package introduces the concept *Modularizable*. An algebraic structure *T* is considered as *Modularizable* if there is a mapping from *T* into an algebraic structure that is based on the type *CGAL::Residue*. For scalar types, e.g. Integers, this mapping is just the canonical homomorphism into $\mathbb{Z}_{/p\mathbb{Z}}$ represented by *CGAL::Residue*. For compound types, e.g. Polynomials, the mapping is applied to the coefficients of the compound type. The mapping is provided by the class *CGAL::Modular_traits<T>*. The class *CGAL::Modular_* *traits<T>* is designed such that the concept *Modularizable* can be considered as optional, i.e., *CGAL::Modular_traits<T>* provides a tag that can be used for dispatching.

6.1.1 Example

In the following example modular arithmetic is used as a filter.

```
/* Modular arithmetic can be used as a filter, in this example modular
   arithmetic is used to avoid unnecessary gcd computations of
   polynomials.
   A gcd computation can be very costly due to coefficient growth within
   the
   Euclidean algorithm.

   The general idea is that firstly the gcd is computed with respect
   to one prime only. If this modular gcd is constant we can (in most
   cases)
   conclude that the actual gcd is constant as well.

   For this purpose the example introduces the function
   may_have_common_factor.
   Note that there are two versions of this function, namely for the case
   that the coefficient type is Modularizable and that it is not.
   If the type is not Modularizable the filter is just not applied and
   the
   function returns true.
*/

#include <CGAL/basic.h>

#ifdef CGAL_USE_GMP

#include <CGAL/Gmpz.h>
#include <CGAL/Polynomial.h>

// Function in case  Polynomial is Modularizable
template< typename Polynomial >

6.2 Design and Implementation History

The class *CGAL::Residue* is based on the C-code of Sylvain Pion et. al. as it was presented in [BEPP99].

The remaining part of the package is the result of the integration process of the NumeriX library of EXACUS [BEH+05] into CGAL.

Modular Arithmetic Reference Manual

Class

CGAL::Residue

Definition

The class *Residue* represents a finite field $\mathbb{Z}/p\mathbb{Z}$, for some prime number p.

The prime number p is stored in a static member variable. The class provides static member functions to change this value. **Note that changing the prime invalidates already existing objects of this type.** However, already existing objects do not lose their value with respect to the old prime and can be reused after restoring the old prime. Since the type is based on double arithmetic the prime is restricted to values less than 2^{26}. The initial value of p is 67111067.

Please note that the implementation of class *CGAL::Residue* requires a mantissa precision according to the IEEE Standard for Floating-Point Arithmetic (IEEE 754). However, on some processors the traditional FPU uses an extended precision. Hence, it is indispensable that the proper mantissa length is enforced before performing any arithmetic operations. Moreover, it is required that numbers are rounded to the next nearest value. This can be ensured using *CGAL::Protect_FPU_rounding* with *CGAL_FE_TONEAREST*, which also enforces the required precision as a side effect.

In case the flag *CGAL_HAS_THREADS* is undefined the prime is just stored in a static member of the class, that is, *Residue* is not thread-safe in this case. In case *CGAL_HAS_THREADS* the implementation of the class is thread safe using *boost::thread_specific_ptr*. However, this may cause some performance penalty. Hence, it may be advisable to configure *CGAL* with *CGAL_HAS_NO_THREADS*.

#include <CGAL/Residue.h>

Modularizable

Definition

An algebraic structure is called Modularizable, if there is a suitable mapping into an algebraic structure which is based on the type *CGAL::Residue*. For scalar types, e.g. Integers, this mapping is just the canonical homomorphism into the type *CGAL::Residue* with respect to the current prime. For compound types, e.g. Polynomials, the mapping is applied to the coefficients of the compound type.

The mapping is provided via *CGAL::Modular_traits<Modularizable>*, being a model of *ModularTraits*.

Note that types representing rationals, or types which do have some notion of denominator, are not *Modularizable*. This is due to the fact that the denominator may be zero modulo the prime, which can not be represented.

ModularTraits

Concept

Definition

A model of *ModularTraits* is associated to a specific *Type*. In case this associated type is *Modularizable*, this is indicated by the boolean tag *Is_modularizable*. The mapping into the *Residue_type* is provided by the functor *Modular_image*.

Types

A model of *ModularTraits* is supposed to provide:

ModularTraits:: Type	The associated type.
ModularTraits:: Is_modularizable	Tag indicating whether the associated type is modularizable. This is either *CGAL::Tag_true* or *CGAL::Tag_false*.
ModularTraits:: Residue_type	The type of the modular image. In case the type is not *Modularizable* this is undefined.

Functors

In case the associated type is *Modularizable* all functors are provided.
In case a functor is not provided, it is set to *CGAL::Null_functor*.

ModularTraits:: Modular_image	A model of *ModularTraits::ModularImage*
ModularTraits:: Modular_image_representative	A model of *ModularTraits::ModularImageRepresentative*

ModularTraits::ModularImage

Definition

This *AdaptableUnaryFunction* computes the modular image of the given value with respect to a homomorphism φ from the *ModularTraits::Type* into the *ModularTraits::Residue_type*.

The homomorphism preserves the mapping of *int* into both types , i.e., $\varphi(Type(i)) == Residue\_type(i)$.

Types

typedef ModularTraits::Residue_type

result_type;

typedef ModularTraits::Type

argument_type;

result_type	*fo(argument_type x)*	computes $\varphi(x)$.

ModularTraits::ModularImageRepresentative

Definition

This *AdaptableUnaryFunction* returns a representative in the original type of a given modular image. More precisely, it implements the *rightinverse* of a proper restriction of the homomorphism φ, which is implemented by *ModularTraits::ModularImage*.

Types

typedef ModularTraits::Type

result_type;

typedef ModularTraits::Residue_type

argument_type;

result_type *fo(argument_type x)* computes $\varphi^{-1}(x)$.

Chapter 7

Polynomial

Michael Hemmer

7.1 Fundamentals

Note that this is just a very brief introduction to polynomials. For a quick reference we refer to the Wikipedia or for a more elaborate introduction to any class book on elementary algebra.

A *polynomial* is either zero, or can be written as the sum of one or more non-zero *terms*. The number of terms is finite. A term consist of a constant *coefficient* and a *monomial*, that is, the product of zero or more variables. Each variable may have an exponent that is a non-negative integer. The exponent on a variable in a term is equal to the *degree* of that variable in that term. A term with no variables is called a constant term. The degree of a constant term is 0.

For example, $-7x^3y$ is a term. The coefficient is -7, the monomial is x^3y, comprised of the variables x and y, the degree of x is three, and the degree of y is one. The *total degree* of the entire term is the sum of the degrees in each variable. In the example above, the degree is $3+1=4$.

A one-variable (univariate) polynomial f of degree n has the following form:

$$f = a_n x^n + a_{n-1} x^{n-1} + \ldots + a_2 x^2 + a_1 x + a_0$$

The coefficient a_0 is called the *constant coefficient*, a_n is called the *leading coefficient*. If f is not the zero polynomial the leading coefficient is not zero. The polynomial is called monic if $a_n = 1$. In case the coefficient domain of f possess a greatest common divisor (gcd) the *content* of f is the gcd of all coefficients of f. For instance, the content of $12x^3 + 6$ is 6.

A multivariate polynomial is a polynomial in more than one variable. According to the number of variables it is possible to further classify multivariate polynomials as bivariate, trivariate etc. In contrast to univariate polynomials the terms of a multivariate polynomial are not completely ordered by their total degree. However, given a certain order on the variables it is possible to define a lexicographic order on the terms. Given this order the leading coefficient of a multivariate polynomial is defined as the coefficient of the highest term. For instance the leading coefficient of the multivariate polynomial $p = 5x^3y + 7xy^2$ is 7, given that y has an higher order than x.

However, it is also possible to interpret a multivariate polynomial as a univariate polynomial in that variable.

For instance the trivariate polynomial

$$q = x^5 + 7x^2y^1z^2 + 13x^1y^2z^2 \in \mathbb{Z}[x,y,z]$$

may be interpreted as a univariate polynomial in z, that is, q is interpreted as an element of $R[z]$, with $R = \mathbb{Z}[x,y]$.

$$q = (13x^1y^2 + 7x^2y^1)z^2 + x^5z^0 \in R[z]$$

In this case the leading coefficient of q with respect to z is $13x^1y^2 + 7x^2y^1$ and x^5 becomes the 'constant' term.

A *homogeneous polynomial* is a polynomial whose terms do all have the same total degree. For example, $h = x^5 + 7x^2y^1z^2 + 13x^1y^2z^2$ is a homogeneous polynomial of degree 5, in three variables.

7.2 General Design

The package introduces a concept *Polynomial_d*, a concept for multivariate polynomials in d variables. Though the concept is written for an arbitrary number of variables, the number of variables is considered as fixed for a particular model of *Polynomial_d*. The concept also allows univariate polynomials.

First of all a model of *Polynomial_d* is considered as an algebraic structure, that is, the ring operations $\{+,-,\cdot\}$ are provided due to the fact that *Polynomial_d* refines at least the concept *IntegralDomainWithoutDivision*. However, a model of *Polynomial_d* has to be accompanied by a traits class *CGAL::Polynomial_traits_d< Polynomial_d>* being a model of *PolynomialTraits_d*. In principal the traits class provides all further functionalities on polynomials.

Given a d-variate polynomial over some base ring R there are at least two different possible views on such a polynomial.

- The recursive or univariate view: In this view, a polynomial is considered as an element of $R[x_0,\ldots,x_{d-2}][x_{d-1}]$. That is, the polynomial is treated as a univariate polynomial over the ring $R[x_0,\ldots,x_{d-2}]$.
- The symmetric or multivariate view: This view is almost symmetric with respect to all variables. It considers the polynomial as an element of $R[x_0,\ldots,x_{d-1}]$.

According to these two different views the traits class is required to provide two different coefficient types:

- *CGAL::Polynomial_traits_d<Polynomial_d>::Coefficient_type* representing $R[x_0,\ldots,x_{d-2}]$.
- *CGAL::Polynomial_traits_d<Polynomial_d>::Innermost_coefficient_type* representing the base ring R.

Another important type which is introduced by this package is *CGAL::Exponent_vector*. It is derived from *std::vector<int>* and used to identify multivariate monomials. For instance the exponent vector containing the sequence $[3,2,4]$ corresponds to the trivariate monomial $x_0^3x_1^2x_2^4$. Note that a vector with negative exponents is considered as invalid. However, we decided to in principal allow negative exponents as they may appear as intermediate results, in particular we did **not** derive from *std::vector<unsigned int>*.

7.3 Constructing a multivariate polynomial

First of all the concept *Polynomial_d* requires that the model is constructible from int. This is due to the fact that *Polynomial_d* refines *IntegralDomainWithoutDivision* which in turn refines *FromIntConstructible*. Of course this allows only the construction of constant polynomials.

In general a polynomial is constructed using the functor *CGAL::Polynomial_traits_d<Polynomial_d> ::Construct_polynomial* a model of *PolynomialTraits_d::ConstructPolynomial*. Basically there are two options:

- The polynomial is constructed from an iterator range with value type *CGAL::Polynomial_traits_d< Polynomial_d>::Coefficient_type*, where the *begin* iterator refers to the constant term (constant with respect to the outermost variable).
- The polynomial is constructed from an iterator range with value type *std::pair< CGAL::Exponent_vector, CGAL::Polynomial_traits_d<Polynomial_d>::Innermost_coefficient_type>*, where each pair defines the coefficient for the monomial defined by the exponent vector.

However, in some cases it might be more convenient to just construct the polynomials representing the different variables and to obtain the final polynomial using algebraic expressions. The most elegant way to construct a certain variable is *CGAL::Polynomial_traits_d<Polynomial_d>::Shift* being a model of *PolynomialTraits_d::Shift*.

7.3.1 Examples

The following example illustrates different ways to construct a bivariate polynomial:

```
#include <CGAL/config.h>
#include <CGAL/Polynomial.h>
#include <CGAL/Polynomial_traits_d.h>
#include <CGAL/Polynomial_type_generator.h>

int main(){
  CGAL::set_pretty_mode(std::cout);

  typedef CGAL::Polynomial_type_generator<int,2>::Type Poly_2;
  typedef CGAL::Polynomial_traits_d<Poly_2>            PT_2;
  typedef PT_2::Coefficient_type                       Poly_1;
  typedef PT_2::Innermost_coefficient_type             Integer;

  PT_2::Construct_polynomial construct_polynomial;

  // constructing a constant polynomial from int
  Poly_2 two(2); // = 2
  std::cout << "A constant polynomial: " << two << std::endl;

  // construction from an iterator range of univariate polynomials

  std::list<Poly_1> univariate_coeffs;
  univariate_coeffs.push_back(Poly_1(3));
  univariate_coeffs.push_back(Poly_1(0));
  univariate_coeffs.push_back(Poly_1(5));
  Poly_2 F = // 5*y^2 + 3

   construct_polynomial(univariate_coeffs.begin(),univariate_coeffs.end());
  std::cout << "The bivariate polynomial F: " << F << std::endl;
```

```
  // construction from an iterator range over monomials

  std::list<std::pair<CGAL::Exponent_vector, Integer> > innermost_coeffs;

   innermost_coeffs.push_back(std::make_pair(CGAL::Exponent_vector(0,0),-2));

   innermost_coeffs.push_back(std::make_pair(CGAL::Exponent_vector(3,5),2));
  Poly_2 G = // (2*x^3)*y^5 + (-2)

   construct_polynomial(innermost_coeffs.begin(),innermost_coeffs.end());
  std::cout << "The bivariate polynomial G: " << G << std::endl;

  //construction using shift
  PT_2::Shift shift;
  Poly_2 x = shift(Poly_2(1),1,0); // 'multiply' 1 by x_0^1
  Poly_2 y = shift(Poly_2(1),1,1); // 'multiply' 1 by x_1^1

  Poly_2 H = 5 * x * y + 3 * y * y; // = 3*y^2 + (5*x)*y
  std::cout << "The bivariate polynomial H: " << H << std::endl;
}
```

File: examples/Polynomial/construction.cpp

7.4 Coefficient Access

In order to obtain a certain coefficient the traits class provides several functors. Note that the functors do not allow a write access to the coefficients.

- *PolynomialTraits_d::GetCoefficient*: a model of this concept provides access to a coefficient in the univariate view, that is, it returns elements of $R[x_0,...,x_{d-2}]$.
- *PolynomialTraits_d::GetInnermostCoefficient*: a model of this concept provides access to a coefficient in the multivariate view, that is, it returns elements of R.
- *PolynomialTraits_d::LeadingCoefficient*: a model of this concept provides access to the leading coefficient in the univariate view.
- *PolynomialTraits_d::InnermostLeadingCoefficient*: a model of this concept provides access to the leading coefficient in the multivariate view, that is, it returns the (innermost) coefficient of the leading multivariate monomial. See also *PolynomialTraits_d::DegreeVector*.

7.4.1 Examples

The following example illustrates the application of the functors discussed above:

```
#include <CGAL/config.h>
#include <CGAL/Polynomial.h>
#include <CGAL/Polynomial_traits_d.h>
#include <CGAL/Polynomial_type_generator.h>
```

```
int main(){
  CGAL::set_pretty_mode(std::cout);
  typedef CGAL::Polynomial_type_generator<int,2>::Type Poly_2;
  typedef CGAL::Polynomial_traits_d<Poly_2>            PT_2;

  //construction using shift
  Poly_2 x = PT_2::Shift()(Poly_2(1),1,0); // = x^1
  Poly_2 y = PT_2::Shift()(Poly_2(1),1,1); // = y^1

  Poly_2 F // = (11*x^2 + 5*x)*y^4 + (7*x^2)*y^3
    = 11 * CGAL::ipower(y,4) * CGAL::ipower(x,2)
    + 5 * CGAL::ipower(y,4)  * CGAL::ipower(x,1)
    + 7 * CGAL::ipower(y,3)  * CGAL::ipower(x,2);
  std::cout << "The bivariate polynomial F: " << F <<"\n"<< std::endl;

  PT_2::Get_coefficient get_coefficient;
  std::cout << "Coefficient of y^0: "<< get_coefficient(F,0) <<
   std::endl;
  std::cout << "Coefficient of y^1: "<< get_coefficient(F,1) <<
   std::endl;
  std::cout << "Coefficient of y^2: "<< get_coefficient(F,2) <<
   std::endl;
  std::cout << "Coefficient of y^3: "<< get_coefficient(F,3) <<
   std::endl;
  std::cout << "Coefficient of y^4: "<< get_coefficient(F,4) <<
   std::endl;
  std::cout << "Coefficient of y^5: "<< get_coefficient(F,5) <<
   std::endl;
  std::cout << std::endl;

  PT_2::Leading_coefficient lcoeff;
  std::cout << "Leading coefficient with respect to y:           "
            << lcoeff(F)   // = 11*x^2 + 5*x
            << std::endl;

  PT_2::Get_innermost_coefficient get_icoeff;
  std::cout << "Innermost coefficient of monomial x^1y^4:        "
            << get_icoeff(F,CGAL::Exponent_vector(1,4)) // = 5
            << std::endl;

  PT_2::Innermost_leading_coefficient ilcoeff;
  std::cout << "Innermost leading coefficient with respect to y: "
            << ilcoeff(F) // = 11
            << std::endl;
}
```

File: examples/Polynomial/coefficient_access.cpp

7.5 Degree, total degree and degree vector

There are three functors in *PolynomialTraits_d* related to the degree of a polynomial.

- *PolynomialTraits_d::Degree*: a model of this concept returns the degree of the polynomial in the univariate view. By default this is the degree with respect to the outermost variable, but it is also possible to select another variable.
- *PolynomialTraits_d::TotalDegree*: a model of this concept returns the *total degree* of a polynomial. The polynomial is considered as a multivariate polynomial. The total degree is the maximum over the sums of the exponents of each multivariate monomial.
- *PolynomialTraits_d::DegreeVector*: a model of this concept returns the exponent vector of the leading monomial, where the monomial order is lexicographic and starts with the outermost variable. See also *PolynomialTraits_d::InnermostLeadingCoefficient*.

7.5.1 Examples

The following example illustrates the application of the functors discussed above:

```
#include <CGAL/config.h>
#include <CGAL/Polynomial.h>
#include <CGAL/Polynomial_traits_d.h>
#include <CGAL/Polynomial_type_generator.h>

int main(){
  CGAL::set_pretty_mode(std::cout);
  typedef CGAL::Polynomial_type_generator<int,2>::Type Poly_2;
  typedef CGAL::Polynomial_traits_d<Poly_2>            PT_2;

  //construction using shift
  Poly_2 x = PT_2::Shift()(Poly_2(1),1,0); // x_0^1
  Poly_2 y = PT_2::Shift()(Poly_2(1),1,1); // x_1^1

  Poly_2 F // = (11*x^2 + 5*x)*y^4 + (7*x^2)*y^3
    = 11 * CGAL::ipower(y,4) * CGAL::ipower(x,2)
    + 5 * CGAL::ipower(y,4)  * CGAL::ipower(x,1)
    + 7 * CGAL::ipower(y,3)  * CGAL::ipower(x,2);
  std::cout << "The bivariate polynomial F: " << F <<"\n"<< std::endl;

  PT_2::Degree degree;
  PT_2::Total_degree total_degree;
  PT_2::Degree_vector degree_vector;

  std::cout << "The degree of F with respect to y: "<< degree(F)
   // = 4
          << std::endl;
  std::cout << "The degree of F with respect to x: "<< degree(F,0)
   // = 2
          << std::endl;
  std::cout << "The total degree of F            : "<< total_degree(F)
   // = 6
          << std::endl;
  std::cout << "The degree vector of F           : "<<
   degree_vector(F)// = (2,4)
          << std::endl;
```

```
}
```

File: examples/Polynomial/degree.cpp

7.6 Changing the order of variables

Given for instance a bivariate polynomial it is conceivable that one wants to interchange the role of x and y. That is one wants to interpret the x as y and vice versa. For such a case the polynomial traits provides *PolynomialTraits_d::Swap*:
Given a polynomial p and to two indices i and j, the functor returns the polynomial in which x_i is substituted by x_j and vice versa, that is, the variables swap their positions. The order of the other variables remains untouched.

Another scenario is, that a particular variable should be moved to another position, for instance, it should become the outermost variable while the relative order of the other variables remains unchanged. For such a case the polynomial traits provides *PolynomialTraits_d::Move*.

Of course there is also a general method to interchange the order of variables, namely *PolynomialTraits_d::Permute*.

7.6.1 Examples

The following example illustrates the application of the functors discussed above:

```
#include <CGAL/config.h>
#include <CGAL/Polynomial.h>
#include <CGAL/Polynomial_traits_d.h>
#include <CGAL/Polynomial_type_generator.h>

int main(){
  CGAL::set_pretty_mode(std::cout);
  typedef CGAL::Polynomial_type_generator<int,3>::Type Poly_3;
  typedef CGAL::Polynomial_traits_d<Poly_3>            PT_3;

  //construction using shift
  Poly_3 x = PT_3::Shift()(Poly_3(1),1,0); // x_0^1
  Poly_3 y = PT_3::Shift()(Poly_3(1),1,1); // x_1^1
  Poly_3 z = PT_3::Shift()(Poly_3(1),1,2); // x_2^1

  Poly_3 F = x*y*y*z*z*z;
  std::cout << "The trivariate polynomial F: " << F << std::endl;
  std::cout << std::endl;

  PT_3::Swap swap;
  PT_3::Move move;
  PT_3::Permute permute;

  std::cout << "x and z swapped: "<< swap(F,0,2) // = x^3*y^2*z
```

```
                << std::endl;
  std::cout << "x and y swapped: "<< swap(F,0,1) // = x^2*y*z^3
            << std::endl << std::endl;

  std::cout << "x moved to outermost position            : "
            << move(F,0,2)                      // = x^2*y^3*z
            << std::endl;
  std::cout << "Same as swap(swap(F,0,1),1,2)           : "
            << swap(swap(F,0,1),1,2)            // = x^2*y^3*z
            << std::endl;

  std::cout << "Same as the permutation (0,1,2)->(2,0,1): ";
  std::vector<int> perm;
  perm.push_back(2);perm.push_back(0);perm.push_back(1);
  std::cout << permute(F,perm.begin(),perm.end())// = x^2*y^3*z
            << std::endl;

}
```

File: examples/Polynomial/swap_move.cpp

7.7 GCD and More

Since the concept *PolynomialTraits_d* refines the concept *AlgebraicStructureTraits* the polynomial traits provides functors for integral division, division with remainder, greatest common divisor, etc. But note that the algebraic structure of a polynomial depends on the algebraic structure of the innermost coefficient, for instance, a gcd is available if and only if the innermost coefficient is a *Field* or a *UniqueFactorizationDomain*. Hence, we can not provide a *gcd* if the innermost coefficient is just an *IntegralDomain* since it is simply not well defined[1]. However, if we would consider the polynomial over the quotient field of the integral domain the *gcd* would be well defined. The only problem is that the result can not be represented over the ring since it contains denominators. Therefore, the *PolynomialTraits_d* requires functors such as *PolynomialTraits_d::GcdUpToConstantFactor*. This functor computes the gcd of two polynomials up to a constant factor (utcf). That is, it returns the correct gcd for polynomials over the quotient field, but multiplied by some constant such that the result is representable with coefficients in the ring.

However, note that these 'utcf' functions are usually a bit faster than their strict counterparts. This is due to the fact that the 'utcf' functions are allowed to skip the computation of the correct constant factor. Note that in many cases the constant factor is in fact not needed. In particular if the polynomials are supposed to represent some zero set, that is, an algebraic curve or surface.

The concepts for the related functors are:

- *AlgebraicStructureTraits::Gcd*
  PolynomialTraits_d::GcdUpToConstantFactor
- *AlgebraicStructureTraits::IntegralDivision*
  PolynomialTraits_d::IntegralDivisionUpToConstantFactor

[1] An example for such a number type is the template *CGAL::Sqrt_extension<NT,ROOT>* representing an algebraic extension of degree two. This is just an *IntegralDomain* if NT is not a *Field*.

- *PolynomialTraits_d::UnivariateContent*
  PolynomialTraits_d::UnivariateContentUpToConstantFactor
- *PolynomialTraits_d::SquareFreeFactorize*
  PolynomialTraits_d::SquareFreeFactorizeUpToConstantFactor

Another analog functionality is the pseudo division. The related functors replace the usual division with remainder in case the Polynomial is not a *EuclideanRing*.
The concepts for the related functors are:

- *AlgebraicStructureTraits::Div_mod*
  PolynomialTraits_d::PseudoDivision
- *AlgebraicStructureTraits::Div*
  PolynomialTraits_d::PseudoDivisionQuotient
- *AlgebraicStructureTraits::Mod*
  PolynomialTraits_d::PseudoDivisionRemainder

7.7.1 Examples

The following example illustrates the application of some functors discussed above:

```
#include <CGAL/config.h>
#include <CGAL/Polynomial.h>
#include <CGAL/Polynomial_traits_d.h>
#include <CGAL/Polynomial_type_generator.h>

int main(){
  CGAL::set_pretty_mode(std::cout);
  typedef CGAL::Polynomial_type_generator<int,1>::Type Poly_1;
  typedef CGAL::Polynomial_traits_d<Poly_1>            PT_1;

  PT_1::Shift                         shift;
  PT_1::Gcd                           gcd;
  PT_1::Gcd_up_to_constant_factor gcd_utcf;
  PT_1::Multivariate_content          mcontent;
  PT_1::Canonicalize                  canonicalize;

  //construction using shift
  Poly_1 x = shift(Poly_1(1),1,0); // x^1

  // common factor 7 * (x^2-2)
  Poly_1 F = 21*(x-5)*(x*x-2); // = 21*x^3 + (-105)*x^2 + (-42)*x + 210
  Poly_1 G = 14*(x-3)*(x*x-2); // = 14*x^3 + (-42)*x^2 + (-28)*x + 84

  std::cout << "The univariate polynomial F: " << F << std::endl;
  std::cout << "The univariate polynomial G: " << G << std::endl;
  std::cout << "Common multivariate content:                  "
            << CGAL::gcd(mcontent(F),mcontent(G)) // = 7
            << std::endl;
  std::cout << "The gcd of F and G:                           "
            << gcd(F,G)                       // = 7*x^2 + (-14)
```

```
            << std::endl;
  std::cout << "The gcd up to constant factor of F and G: "
            << gcd_utcf(F,G)                    // = x^2 + (-2)
            << std::endl;
  std::cout << "Same as canonicalized gcd of F and G:     "
            << canonicalize(gcd_utcf(F,G))      // = x^2 + (-2)
            << std::endl;

}
```

File: examples/Polynomial/gcd_up_to_constant_factor.cpp

7.8 Evaluation and Substitution

Of course, it should also be possible to evaluate a polynomial or substitute its variables. We also require a special functor to determine whether a polynomial is zero at a given point. In case the inner most coefficient is *RealEmbeddable* the traits also must provide a function to compute the sign at a given point.
The concepts for the related functors are:

- *PolynomialTraits_d::Substitute*
- *PolynomialTraits_d::Evaluate*
- *PolynomialTraits_d::IsZeroAt*
- *PolynomialTraits_d::SignAt*

The traits is also required to provide variants of these functors that interpret the polynomial as a homogeneous polynomial by adding a virtual homogeneous variable such that each term has the same degree, namely the degree of the polynomial. Of course there is a difference between the univariate and multivariate view. For instance the polynomial

$$5x^3 + 7x - 3$$

has degree 3, hence it is interpreted as the homogeneous polynomial

$$5x^3 + 7xw^2 - 3w^3$$

by adding the homogeneous variable w. In case of the multivariate view each term is filled up by the homogeneous variable such that the degree of each term is equal to the total degree of the polynomial. Note that these functors may significantly improve efficiency. For instance, it is possible to determine the sign of a polynomial over integer coefficients at a rational point without changing the coefficient domain of the polynomial. For more details have a look at the following concepts:

- *PolynomialTraits_d::SubstituteHomogeneous*
- *PolynomialTraits_d::EvaluateHomogeneous*
- *PolynomialTraits_d::IsZeroAtHomogeneous*
- *PolynomialTraits_d::SignAtHomogeneous*

Note that substitute allows the substitution of the variables by any type that is *ExplicitInteroperable* with the innermost coefficient type. This is a very powerful tool since it allows the substitution of the variables by polynomials. However, for some standard manipulations such as translation or scaling we require special functors since they are expected to be faster than their equivalent implementation using substitution:

- *PolynomialTraits_d::Shift*

- *PolynomialTraits_d::Negate*
- *PolynomialTraits_d::Invert*
- *PolynomialTraits_d::Translate*
- *PolynomialTraits_d::TranslateHomogeneous*
- *PolynomialTraits_d::Scale*
- *PolynomialTraits_d::ScaleHomogeneous*

7.8.1 Examples

The following example illustrates the application of some functors discussed above:

```
#include <CGAL/config.h>
#include <CGAL/Polynomial.h>
#include <CGAL/Polynomial_traits_d.h>
#include <CGAL/Polynomial_type_generator.h>

int main(){
  CGAL::set_pretty_mode(std::cout);
  typedef CGAL::Polynomial_type_generator<int,2>::Type Poly_2;
  typedef CGAL::Polynomial_traits_d<Poly_2>            PT_2;

  //construction using shift
  Poly_2 x = PT_2::Shift()(Poly_2(1),1,0); // x^1
  Poly_2 y = PT_2::Shift()(Poly_2(1),1,1); // y^1

  Poly_2 F = 2*x*y + 3*CGAL::ipower(y,3);
  std::cout << "The bivariate polynomial F: " << F // = 3*y^3 + (2*x)*y
            << std::endl << std::endl;

  PT_2::Evaluate evaluate;
  PT_2::Evaluate_homogeneous hevaluate;

  // Evaluation considers a polynomials as univariate:

7.9 Resultants, Subresultants and Sturm-Habicht sequences

The *PolynomialTraits_d* concept also provides more sophisticated functors for computations with polynomials – computing the resultant of two polynomials, their polynomial subresultant sequence, with or without cofactors, and their principal subresultant coefficients.

- PolynomialTraits_d::Resultant . . . . . . page 312
- PolynomialTraits_d::PolynomialSubresultants . . . . . . page 314
- PolynomialTraits_d::PolynomialSubresultantsWithCofactors . . . . . . page 316
- PolynomialTraits_d::PrincipalSubresultants . . . . . . page 318

Moreover, functors to compute the Sturm-Habicht sequence, with or without cofactors, and for the principal Sturm-Habicht coefficients exist.

- PolynomialTraits_d::SturmHabichtSequence . . . . . . page 319
- PolynomialTraits_d::SturmHabichtSequenceWithCofactors . . . . . . page 321
- PolynomialTraits_d::PrincipalSturmHabichtSequence . . . . . . page 323

For a formal definition of all used terms, we refer to the corresponding reference pages.

The principal Sturm-Habicht sequence allows to count the number of real roots of a polynomial using the function

- *CGAL::number_of_real_roots* . . . . . . page 377.

As input, this function requires an iterator range that represents the principal Sturm-Habicht coefficients. This might look complicated at a first sight, as one has to store the principal Sturm-Habicht sequence temporarily. However, we remark an important property of the (principal) Sturm-Habicht sequence. Having a polynomial $f_t(x)$ that depends on a parameter t, and its (principal) Sturm-Habicht coefficients $\mathrm{stha}_0(f_t), \ldots, \mathrm{stha}_n(f_t)$, evaluating $\mathrm{stha}_0(f_t)$ for $t = t_0$ yields a valid (principal) Sturm-Habicht sequence for f_{t_0}. The same holds for (principal) subresultants. Thus, it is enough in such situations to compute the sequence once for the parameter t, and call *CGAL::number_of_real_roots* for each specialized parameter value.

We finally remark that computing subresultants and Sturm-Habicht sequences introduces an enormous coefficient blow-up. An application of the functors therefore does not make sense for built-in integers except for toy examples. To avoid overflows, one should use arbitrary size integer types in real applications.

7.9.1 Examples

The following example illustrates how two compute resultants of two polynomials, and how to count the number of distinct real roots of a polynomial using its principal Sturm-Habicht coefficients.

```
#include <CGAL/config.h>
#include <CGAL/Polynomial.h>
#include <CGAL/Polynomial_traits_d.h>
#include <CGAL/Polynomial_type_generator.h>

#include <CGAL/Gmpz.h>

int main(){
  CGAL::set_pretty_mode(std::cout);

  typedef CGAL::Gmpz Int;

  typedef CGAL::Polynomial_type_generator<Int,1>::Type Poly_1;
  typedef CGAL::Polynomial_traits_d<Poly_1>            PT_1;

  //construction using shift
  Poly_1 x = PT_1::Shift()(Poly_1(1),1); // x^1

  Poly_1 F // = (x+1)^2*(x-1)*(2x-1)=2x^4+x^3-3x^2-x+1
    =   2 * CGAL::ipower(x,4) + 1 * CGAL::ipower(x,3)
      - 3 * CGAL::ipower(x,2) - 1 * CGAL::ipower(x,1)
      + 1 * CGAL::ipower(x,0);
  std::cout << "F=" << F << std::endl;

  Poly_1 G // = (x+1)*(x+3)=x^2+4*x+3
    =   1 * CGAL::ipower(x,2) + 4 * CGAL::ipower(x,1) + 3 *
   CGAL::ipower(x,0);
  std::cout << "G=" << G << std::endl;

  // Resultant computation:
  PT_1::Resultant resultant;

  std::cout << "The resultant of F and G is: " << resultant(F,G) <<
   std::endl;
  // It is zero, because F and G have a common factor

  // Real root counting:
  PT_1::Principal_sturm_habicht_sequence stha;
  std::vector<Int> psc;

  stha(F,std::back_inserter(psc));
```

```
  int roots = CGAL::number_of_real_roots(psc.begin(),psc.end());

  std::cout << "The number of real roots of F is: " << roots <<
    std::endl; // 3

  roots =  CGAL::number_of_real_roots(G);

  std::cout << "The number of real roots of G is: " << roots <<
    std::endl; // 2

  return 0;

}
```

7.10 Design and Implementation History

This package is the result of the integration process of the NumeriX library of EXACUS [BEH+05] into CGAL.

The class *CGAL::Polynomial<Coeff>* had been started by Michael Seel within CGAL as part of the Nef_2 package. As part of the EXACUS project it got significantly improved by Arno Eigenwillig and Michael Hemmer.

However, due to the recursive definition the class was rather restricted to the univariate view. Moreover, it is clear that depending on the context other classes that are symmetric in all variables or dedicated for sparse polynomials may be more efficient. As a consequence this package introduced the *CGAL::Polynomial_traits_d<Polynomial_d>* giving also the symmetric view on polynomials and the opportunity to introduce and use other classes representing polynomials within CGAL.

Polynomial_d

Definition

A model of Polynomial_d is representing a multivariate polynomial in $d \geq 1$ variables over some basic ring R. This type is denoted as the innermost coefficient. A model of Polynomial_d accompanied by a traits class *CGAL::Polynomial_traits_d<Polynomial_d>*, which is a model of *PolynomialTraits_d*. Please have a look at the concept *PolynomialTraits_d*, since nearly all functionality related to polynomials is provided by the traits.

Refines

IntegralDomainWithoutDivision

The algebraic structure of *Polynomial_d* depends on the algebraic structure of *Innermost_coefficient_type*:

Innermost_coefficient_type	*Polynomial_d*
IntegralDomainWithoutDivision	*IntegralDomainWithoutDivision*
IntegralDomain	*IntegralDomain*
UniqueFactorizationDomain	*UniqueFactorizationDomain*
EuclideanRing	*UniqueFactorizationDomain*
Field	*UniqueFactorizationDomain*

Note: In case the polynomial is univariate and the innermost coefficient is a *Field* the polynomial is model of *EuclideanRing*.

Concept

PolynomialTraits_d

Definition

A model of *PolynomialTraits_d* is associated with a type *Polynomial_d*. The type *Polynomial_d* represents a multivariate polynomial. The number of variables is denoted as the dimension d of the polynomial, it is arbitrary but fixed for a certain model of this concept. Note that univariate polynomials are not excluded by this concept. In this case d is just set to one.

PolynomialTraits_d provides two different views on the multivariate polynomial.

- The recursive view: In this view, the polynomial is considered as an element of $R[x_0,\ldots,x_{d-2}][x_{d-1}]$. That is, the polynomial is treated as a univariate polynomial over the ring $R[x_0,\ldots,x_{d-2}]$.
- The symmetric or multivariate view: This view is symmetric with respect to all variables, considering the polynomial as an element of $R[x_0,\ldots,x_{d-1}]$.

Many functors consider the polynomial as a univariate polynomial in one variable. By default this is the outermost variable x_{d-1}. However, in general it is possible to select a certain variable.

AlgebraicStructureTraits

Constants

static const int *d;* The dimension and the number of variables respectively.

Types

PolynomialTraits_d:: Polynomial_d Type representing $R[x_0,\ldots,x_{d-1}]$.

PolynomialTraits_d:: Coefficient_type Type representing $R[x_0,\ldots,x_{d-2}]$.

PolynomialTraits_d:: Innermost_coefficient_type

Type representing the base ring R.

PolynomialTraits_d:: Coefficient_const_iterator

Const iterator used to iterate through all coefficients of the polynomial.

PolynomialTraits_d:: Innermost_coefficient_const_iterator

Const iterator used to iterate through all innermost coefficients of the polynomial.

PolynomialTraits_d:: template <typename T, int d> struct Rebind

This nested template class has to define a type *Other* which is a model of the concept *PolynomialTraits_d*, where *d* is the number of variables and *T* the *Innermost_coefficient_type*.

Functors

In case a functor is not provided it is set to *CGAL::Null_functor*.

PolynomialTraits_d:: Construct_polynomial A model of *PolynomialTraits_d::ConstructPolynomial*.

PolynomialTraits_d:: Get_coefficient A model of *PolynomialTraits_d::GetCoefficient*.

PolynomialTraits_d:: Get_innermost_coefficient A model of *PolynomialTraits_d::GetInnermostCoefficient*.

PolynomialTraits_d:: Construct_coefficient_const_iterator_range

A model of *PolynomialTraits_d::ConstructCoefficientConstIteratorRange*.

PolynomialTraits_d:: Construct_innermost_coefficient_const_iterator_range

A model of *PolynomialTraits_d::ConstructInnermostCoefficientConstIteratorRange*.

PolynomialTraits_d:: Swap A model of *PolynomialTraits_d::Swap*.

PolynomialTraits_d:: Move A model of *PolynomialTraits_d::Move*.

PolynomialTraits_d:: Degree A model of *PolynomialTraits_d::Degree*.

PolynomialTraits_d:: Total_degree A model of *PolynomialTraits_d::TotalDegree*.

PolynomialTraits_d:: Degree_vector A model of *PolynomialTraits_d::DegreeVector*.

PolynomialTraits_d:: Leading_coefficient A model of *PolynomialTraits_d::LeadingCoefficient*.

PolynomialTraits_d:: Innermost_leading_coefficient

A model of *PolynomialTraits_d::InnermostLeadingCoefficient*.

PolynomialTraits_d:: Canonicalize A model of *PolynomialTraits_d::Canonicalize*.

PolynomialTraits_d:: Differentiate A model of *PolynomialTraits_d::Differentiate*.

PolynomialTraits_d:: Evaluate	A model of *PolynomialTraits_d::Evaluate*.
PolynomialTraits_d:: Evaluate_homogeneous	A model of *PolynomialTraits_d::EvaluateHomogeneous*.
PolynomialTraits_d:: Substitute	A model of *PolynomialTraits_d::Substitute*.
PolynomialTraits_d:: Substitute_homogeneous	A model of *PolynomialTraits_d::SubstituteHomogeneous*.
PolynomialTraits_d:: Is_zero_at	A model of *PolynomialTraits_d::IsZeroAt*.
PolynomialTraits_d:: Is_zero_at_homogeneous	A model of *PolynomialTraits_d::IsZeroAtHomogeneous*.
PolynomialTraits_d:: Sign_at	A model of *PolynomialTraits_d::SignAt*. In case *Innermost_coefficient_type* is not *RealEmbeddable* this is *CGAL::Null_functor*.
PolynomialTraits_d:: Sign_at_homogeneous	A model of *PolynomialTraits_d::SignAtHomogeneous*. In case *Innermost_coefficient_type* is not *RealEmbeddable* this is *CGAL::Null_functor*.
PolynomialTraits_d:: Compare	A model of *PolynomialTraits_d::Compare*. In case *Innermost_coefficient_type* is not *RealEmbeddable* this is *CGAL::Null_functor*.
PolynomialTraits_d:: Univariate_content	In case *PolynomialTraits_d::Coefficient_type* is **not** a model of *UniqueFactorizationDomain*, this is *CGAL::Null_functor*, otherwise this is a model of *PolynomialTraits_d::UnivariateContent*.
PolynomialTraits_d:: Multivariate_content	In case *PolynomialTraits_d::Innermost_coefficient_type* is **not** a model of *UniqueFactorizationDomain*, this is *CGAL::Null_functor*, otherwise this is a model of *PolynomialTraits_d::MultivariateContent*.
PolynomialTraits_d:: Shift	A model of *PolynomialTraits_d::Shift*.
PolynomialTraits_d:: Negate	A model of *PolynomialTraits_d::Negate*.
PolynomialTraits_d:: Invert	A model of *PolynomialTraits_d::Invert*.

PolynomialTraits_d::ConstructPolynomial

Definition

This *AdaptableFunctor* provides several operators to construct objects of type *PolynomialTraits_d::Polynomial_d*.

Refines

AdaptableFunctor
CopyConstructible
DefaultConstructible

Types

typedef PolynomialTraits_d::Polynomial_d

result_type;

Operations

result_type *fo()* Construct the zero polynomial.

result_type *fo(int i)* Construct the constant polynomial equal to *i*.

result_type *fo(PolynomialTraits_d::Innermost_coefficient_type a)*

Construct the constant polynomial equal to *a*.

result_type *fo(PolynomialTraits_d::Coefficient_type a)*

Construct the polynomial equal to *a*.

template < class InputIterator >
result_type *fo(InputIterator begin, InputIterator end)*

Precondition: The value type of *InputIterator* is *PolynomialTraits_d::Coefficient_type*.

The operator constructs the a polynomial from the iterator range, with respect to the outermost variable, x_{d-1}.
The range starts with the coefficient for x_{d-1}^0.
In case the range is empty, the zero polynomial is constructed.

template < class InputIterator >

result_type *fo(InputIterator begin, InputIterator end, bool is_sorted= false)*

Constructs a *Polynomial_d* from a given iterator range of *std::pair< Exponent_vector, PolynomialTraits_d::Innermost_coefficient_type>*.
The optional parameter *is_sorted* indicates whether the given iterator range is already sorted.
Precondition: The value type of *InputIterator* is *std::pair<Exponent_vector, PolynomialTraits_d::Innermost_coefficient_type>*.
Precondition: Each *Exponent_vector* must have size d.
Precondition: All appearing *Exponent_vector*s are different.

Concept

PolynomialTraits_d::Permute

Definition

This *AdaptableFunctor* permutes the variables of the given polynomial with respect to a permutation σ, that is, each monomial $\prod x_i^{e_i}$ will be mapped to the monomial $\prod x_{\sigma(i)}^{e_i}$. The permutation σ is given by the iterator range of length *PolynomialTraits_d::d*, which is supposed to contain the second row of the permutation.

For instance, let p be a polynomial in 4 variables and it is intended to change the order of the variables such that $x_0 \mapsto x_2$, $x_1 \mapsto x_0$, $x_2 \mapsto x_1$ and $x_3 \mapsto x_3$. In this case the iterator range should contain the sequence $[2,0,1,3]$.

Refines

AdaptableFunctor

PolynomialTraits_d::Degree

Concept

Definition

This *AdaptableUnaryFunction* computes the degree of a *PolynomialTraits_d::Polynomial_d* with respect to a certain variable.

The degree of p with respect to a certain variable x_i, is the highest power e of x_i such that the coefficient of x_i^e in p is not zero.
For instance the degree of $p = x_0^2 x_1^3 + x_1^4$ with respect to x_1 is 4.

The degree of the zero polynomial is set to 0. From the mathematical point of view this should be $-infinity$, but this would imply an inconvenient return type.

Refines

PolynomialTraits_d::Canonicalize

Definition

For a given polynomial p this *AdaptableUnaryFunction* computes the unique representative of the set

$$\mathcal{P} := \{q \mid \lambda * q = p \ for \ some \ \lambda \in R\},$$

where R is the base of the polynomial ring.

In case *PolynomialTraits::Innermost_coefficient_type* is a model of *Field*, the computed polynomial is the *monic* polynomial in $\mathcal{P}$, that is, the innermost leading coefficient equals one.
In case *PolynomialTraits::Innermost_coefficient_type* is a model of *UniqueFactorizationDomain*, the computed polynomial is the one with a multivariate content of one.
For all other cases the notion of uniqueness is up to the concrete model.

Note that the computed polynomial has the same zero set as the given one.

Concept

PolynomialTraits_d::PseudoDivision

Definition

This *AdaptableFunctor* computes the *pseudo division* of two polynomials f and g.

Given f and $g \neq 0$ this functor computes quotient q and remainder r such that $D \cdot f = g \cdot q + r$ and $degree(r) < degree(g)$, where $D = leading\_coefficient(g)^{max(0,degree(f)-degree(g)+1)}$

This functor is useful if the regular division is not available, which is the case if *PolynomialTraits_d::Coefficient_type* is not a *Field*. Hence in general it is not possible to invert the leading coefficient of g. Instead f is extended by D allowing integral divisions in the internal computation.

PolynomialTraits_d::GcdUpToConstantFactor

Concept

Definition

This *AdaptableBinaryFunction* computes the *gcd up to a constant factor (utcf)* of two polynomials of type *PolynomialTraits_d::Polynomial_d*.

In case the base ring R (*PolynomialTraits_d::Innermost_coefficient_type*) is not a *UniqueFactorizationDomain* or not a *Field* the polynomial ring $R[x_0,\ldots,x_{d-1}]$ (*PolynomialTraits_d::Polynomial_d*) may not possesses greatest common divisors. However, since R is an integral domain one can consider its quotient field $Q(R)$ for which *gcd*s of polynomials exist.

This functor computes $gcd\_utcf(f,g) = D * gcd(f,g)$, for some $D \in R$ such that $gcd\_utcf(f,g) \in R[x_0,\ldots,x_{d-1}]$. Hence, $gcd\_utcf(f,g)$ may not be a divisor of f and g in $R[x_0,\ldots,x_{d-1}]$.

PolynomialTraits_d::TranslateHomogeneous

Definition

Given numerator a and denominator b this *AdaptableFunctor* translates a *PolynomialTraits_d::Polynomial_d* p with respect to one variable by a/b, that is, it computes $b^{degree(p)} \cdot p(x+a/b)$.

Note that this functor operates on the polynomial in the univariate view, that is, the polynomial is considered as a univariate homogeneous polynomial in one specific variable.

Concept

PolynomialTraits_d::Resultant

Definition

This *AdaptableBinaryFunction* computes the *resultant* of two polynomials f and g of type *PolynomialTraits_d::Polynomial_d* with respect to a certain variable.

Note that this functor operates on the polynomial in the univariate view, that is, the polynomial is considered as a univariate polynomial in one specific variable.

Let f and g be two univariate polynomials over some commutative ring A, where

$$f = f_m x^m + \ldots + f_0$$

and

$$g = g_n x^n + \ldots + g_0.$$

The resultant of f and g is defined as the determinant of the *Sylvester matrix*:

$$\begin{pmatrix} f_m & \cdots & f_0 & & & \\ & f_m & \cdots & f_0 & & \\ & & \ddots & & \ddots & \\ & & & f_m & \cdots & f_0 \\ g_n & \cdots & g_0 & & & \\ & g_n & \cdots & g_0 & & \\ & & \ddots & & \ddots & \\ & & & g_n & \cdots & g_0 \end{pmatrix}$$

Note that this is a $(n+m)\times(n+m)$ matrix as there are n rows for f and m rows that are used for g. The blank spaces are supposed to be filled with zeros.

advanced

Let L be the algebraic closure of A, and write f and g as

$$f := f_m \prod_{i=1}^{m}(x-\alpha_i),\ \alpha_i \in L$$

and

$$g := g_n \prod_{j=1}^{n}(x-\beta_j),\ \beta_i \in L,$$

then the resultant of f and g is (up to leading coefficients) the product of all pairwise differences of the roots of f and g, namely

$$res(f,g) = f_m^n g_n^m \prod_{i=1}^{m}\prod_{j=1}^{n}(\alpha_i - \beta_j).$$

In particular, $res(f,g) \neq 0$ iff f and g have a common factor with a positive degree in X.

advanced

There are various ways to compute the resultant. Naive options are the computation of the resultant as the determinant of the Sylvester Matrix or the Bezout Matrix as well as the so called subresultant algorithm, which is a variant of the Euclidean Algorithm. More sophisticated methods may use modular arithmetic and interpolation. For more information we refer to, e.g., [vzGG99].

PolynomialTraits_d::PrincipalSubresultants .... page 318

Concept

PolynomialTraits_d::PolynomialSubresultants

Note: This functor is optional!

Definition

Computes the polynomial subresultant of two polynomials p and q of type *PolynomialTraits_d::Polynomial_d* with respect to outermost variable. Let $p = \sum_{i=0,\ldots,n} p_i x^i$ and $q = \sum_{i=0,\ldots,m} q_i x^i$, where x is the outermost variable. The i-th subresultant (with $i = 0,\ldots,\min\{n,m\}$) is defined by

$$\mathrm{Sres}_i(p,q) \quad = \quad \det \begin{pmatrix} p_n & \cdots & & \cdots & p_{2i-m+2} & x^{m-i-1}p \\ & \ddots & & & \vdots & \vdots \\ & & p_n & \cdots & p_{i+1} & p \\ q_m & \cdots & & \cdots & q_{2i-n+2} & x^{n-i-1}q \\ & \ddots & & & \vdots & \vdots \\ & & q_m & \cdots & q_{i+1} & q \end{pmatrix}$$

where p_i and q_i are set to zero if $i < 0$. In the case that $n = m$, $\mathrm{Sres_n}$ is set to q.

The result is written in an output range, starting with the 0-th subresultant $\mathrm{Sres}_0(p,q)$ (aka as the resultant of p and q).

PolynomialTraits_d::SturmHabichtSequenceWithCofactors . . . . page 321

Concept

PolynomialTraits_d::PrincipalSubresultants

Note: This functor is optional!

Definition

Computes the principal subresultant of two polynomials p and q of type *PolynomialTraits_d::Coefficient_type* with respect to the outermost variable. The i-th principal subresultant, $\mathrm{sres}_i(p,q)$, is defined as the coefficient at t^i of the i-th polynomial subresultant $\mathrm{Sres}_i(p,q)$. Thus, it is either the leading coefficient of Sres_i, or zero in the case where its degree is below i.

The result is written in an output range, starting with the 0-th principal subresultant $\mathrm{sres}_0(p,q)$,aka as the resultant of p and q. (Note that $\mathrm{sres}_0(p,q) = \mathrm{Sres}_0(p,q)$ by definition)

PolynomialTraits_d::SturmHabichtSequence

Note: This functor is optional!

Definition

Computes the Sturm-Habicht sequence (aka the signed subresultant sequence) of a polynomial f of type *PolynomialTraits_d::Polynomial_d* with respect to a certain variable x_i. The Sturm-Habicht sequence is similar to the polynomial subresultant sequence of f and its derivative $f' := \frac{\partial f}{\partial x_i}$ with respect to x_i. The implementation is based on the following definition:

Let $n := \deg f$ and $\delta_k := (-1)^{k(k+1)/2}$. For $k \in \{0,\ldots,n\}$, the *k-th Sturm-Habicht polynomial* of f is defined as:

$$\mathrm{Stha}_k(f) = \begin{cases} f & \text{if } k = n \\ f' & \text{if } k = n-1 \\ \delta_{n-k-1}\mathrm{Sres}_k(f,f') & \text{if } 0 \le k \le n-2 \end{cases}$$

where $\mathrm{Sres}_k(f,f')$ is defined as in the concept *PolynomialTraits_d::PolynomialSubresultants*.

The result is written in an output range, starting with the 0-th Sturm-Habicht polynomial (which is equal to the discriminant of f up to a multiple of the leading coefficient).

Refines

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262

PolynomialTraits_d::PrincipalSturmHabichtSequence

Concept

Note: This functor is optional!

Definition

Computes the principal leading coefficients of the Sturm-Habicht sequence of a polynomials f of type *PolynomialTraits_d::Polynomial_d* with respect a certain variable x_i. This means that for the j-th Sturm-Habicht polynomial, this methods returns the coefficient of x_i^j.

Note that the degree of the j-th Sturm-Habicht polynomial is at most j, but the principal coefficient might be zero, thus, this functor does not necessarily give the leading coefficient of the Sturm-Habicht polynomials.

In case that *PolynomialTraits_d::Coefficient_type* is *RealEmbeddable*, the function *CGAL::number_of_real_roots* can be used on the resulting sequence to count the number of distinct real roots of the polynomial f.

Refines

Class

CGAL::Polynomial<Coeff>

Definition

An instance of the data type *Polynomial* represents a polynomial $p = a_0 + a_1 * x + ...a_i * x^i$ from the ring $Coeff[x]$. *Coeff* can itself be an instance of *Polynomial*, yielding a form of multivariate polynomials.

The template argument *Coeff* must be at least a model of *IntegralDomainWithoutDivision*. For all operations naturally involving division, an *IntegralDomain* is required. *Polynomial* offers a full set of algebraic operators, i.e. binary +, −, *, / as well as +=, −=, *=, /=; not only for polynomials but also for a polynomial and a number of the coefficient type. (The / operator must only be used for integral divisions, i.e. those with remainder zero.) The operations are implemented naively: + and − need a number of *Coeff* operations which is linear in the degree while * is quadratic. Unary + and − and (in)equality ==, != are provided as well.

Polynomial is a model of *LessThanComparable* if *Coeff* is a model of *LessThanComparable*. In this case *Polynomial* provides comparison operators <, >, <=, >=, where the comparison amounts to lexicographic comparison of the coefficient sequence, with the coefficient of the highest power taking precedence over those of lower powers.

Polynomial is a model of *Fraction* if *Coeff* is a model of *Fraction*. In this case Polynomial may be decomposed into a (scalar) denominator and a compound numerator with a simpler coefficient type. Often operations can be performed faster on these denominator-free multiples.

Polynomial is a model of *Modularizable* if *Coeff* is a model of *Modularizable*, where the homomorphic map on the polynomials is simply defined as the canonical extension of the homomorphic map which is defined on the coefficient type.

Implementation

Inexact and limited-precision types can be used as coefficients, but at the user's risk. The algorithms implemented were written with exact number types in mind.

This data type is implemented as a handle type with value semantics using *CGAL::Handle_with_policy*, where *HandlePolicy* is *Handle_policy_no_union*. An important invariant to be preserved by all methods is that the coefficient sequence does not contain leading zero coefficients (where leading means at the high-degree end), with the exception that the zero polynomial is represented by a single zero coefficient.

CGAL::Exponent_vector

Class

Definition

For a given (multivariate) monomial the vector of its exponents is called the exponent vector. The class is meant to represent such a vector.

A vector is considered as valid, in case it represents a valid monomial. that is, it should not contain negative exponents. We decided to use int as the value type, since negative exponents may appear in intermediate results. The set of exponent vectors with elementwise addition forms an *Abelian Group*.

Beside the constructors has almost the same interface as an *std::vector<int>*. Moreover the comparison is changed such that the lexicographic order starts the comparison at the last entry. This reflects the fact that the last entry corresponds to the outermost variable of a multivariate polynomial.

Polynomial_traits_d<Polynomial_d>::Total_degree::result_type

total_degree(Polynomial_d p)

Adapts *Polynomial_traits_d<Polynomial_d>::Total_degree*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::TotalDegree . . . . page 278

CGAL::degree_vector

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *degree_vector* adapts the according functor in *Polynomial_traits_d< Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::DegreeVector*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Degree_vector::result_type

degree_vector(Polynomial_d p)

Adapts *Polynomial_traits_d<Polynomial_d> ::DegreeVector*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::Degree_vector . . . . page **??**

Function

Function

CGAL::leading_coefficient

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *leading_coefficient* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::LeadingCoefficient*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Leading_coefficient::result_type

leading_coefficient(Polynomial_d p)

Adapts *Polynomial_traits_d<Polynomial_d>::Leading_coefficient*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::LeadingCoefficient . . . . page 280

CGAL::innermost_leading_coefficient

Function

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *innermost_leading_coefficient* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::InnermostLeadingCoefficient*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Innermost_leading_coefficient::result_type

innermost_leading_coefficient(Polynomial_d p)

Adapts *Polynomial_traits_d<Polynomial_d> ::InnermostLeadingCoefficient*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::InnermostLeadingCoefficient . . . . page 281

Function

CGAL::canonicalize

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *canonicalize* adapts the according functor in *Polynomial_traits_d< Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::Canonicalize*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Canonicalize::result_type

canonicalize(Polynomial_d p)

Adapts *Polynomial_traits_d<Polynomial_d>::Canonicalize*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::Canonicalize . . . . page 282

CGAL::differentiate

#include <CGAL/polynomial_utils.h>

Function

Definition

For a given *Polynomial_d* the function *differentiate* adapts the according functor in *Polynomial_traits_d< Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::Differentiate*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Differentiate::result_type

differentiate(Polynomial_d p, index = Polynomial_traits_d<Polynomial_d>::d-1)

Adapts *Polynomial_traits_d<Polynomial_d>::Differentiate*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::Differentiate . . . . page 283

Function

CGAL::evaluate

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *evaluate* adapts the according functor in *Polynomial_traits_d< Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::Evaluate*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Evaluate::result_type

evaluate(Polynomial_d p, Polynomial_traits_d<Polynomial_d>::Coefficient_type x)

Adapts *Polynomial_traits_d<Polynomial_d>::Evaluate*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::Evaluate . . . . page 284

CGAL::evaluate_homogeneous

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *evaluate_homogeneous* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::EvaluateHomogeneous*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Evaluate_homogeneous::result_type

evaluate_homogeneous(Polynomial_d p,
Polynomial_traits_d<Polynomial_d>::Coefficient_type u,
Polynomial_traits_d<Polynomial_d>::Coefficient_type v)

Adapts *Polynomial_traits_d<Polynomial_d>::Evaluate_homogeneous*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::EvaluateHomogeneous . . . . page 285

Function

Function

CGAL::substitute

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *substitute* adapts the according functor in *Polynomial_traits_d< Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::Substitute*.

template < class Polynomial_d, class InputIterator >
CGAL::Coercion_traits< Polynomial_traits_d<Polynomial_d>::Innermost_coefficient, std::iterator_traits< Input_iterator>::value_type >::Type

substitute(Polynomial_d p, InputIterator begin, InputIterator end)

Adapts *Polynomial_traits_d<Polynomial_d>::Substitute*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::Substitute . . . . page 286

CGAL::is_zero_at

Function

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *is_zero_at* adapts the according functor in *Polynomial_traits_d< Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::IsZeroAt*.

template < class Polynomial_d, class InputIterator >
Polynomial_traits_d<Polynomial_d>::Is_zero_at::result_type

is_zero_at(Polynomial_d p, InputIterator begin, InputIterator end)

Adapts *Polynomial_traits_d<Polynomial_d>::Is_zero_at*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::IsZeroAt . . . . page 288

Function

CGAL::sign_at

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *sign_at* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::SignAt*.

template < class Polynomial_d, class InputIterator >
Polynomial_traits_d<Polynomial_d>::Sign_at::result_type

sign_at(Polynomial_d p, InputIterator begin, InputIterator end)

Adapts *Polynomial_traits_d<Polynomial_d>::Sign_at*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::SignAt . . . . page 290

CGAL::substitute_homogeneous

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *substitute_homogeneous* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::SubstituteHomogeneous*.

template < class Polynomial_d, class InputIterator >
CGAL::Coercion_traits< Polynomial_traits_d<Polynomial_d>::Innermost_coefficient, std::iterator_traits< Input_iterator>::value_type >::Type

substitute_homogeneous(Polynomial_d p, InputIterator begin, InputIterator end)

Adapts *Polynomial_traits_d<Polynomial_d>::Substitute_homogeneous*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::SubstituteHomogeneous . . . . page 287

Function

CGAL::is_zero_at_homogeneous

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *is_zero_at_homogeneous* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::IsZeroAtHomogeneous*.

template < class Polynomial_d, class InputIterator >
Polynomial_traits_d<Polynomial_d>::Is_zero_at_homogeneous::result_type

is_zero_at_homogeneous(Polynomial_d p, InputIterator begin, InputIterator end)

Adapts *Polynomial_traits_d<Polynomial_d>::Is_zero_at_homogeneous*.

See Also

Polynomial_d . . . page 261
PolynomialTraits_d . . . page 262
PolynomialTraits_d::IsZeroAtHomogeneous . . . page 289

CGAL::sign_at_homogeneous

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *sign_at_homogeneous* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::SignAtHomogeneous*.

template < class Polynomial_d, class InputIterator >
Polynomial_traits_d<Polynomial_d>::Sign_at_homogeneous::result_type

sign_at_homogeneous(Polynomial_d p, InputIterator begin, InputIterator end)

Adapts *Polynomial_traits_d<Polynomial_d>::Sign_at_homogeneous*.

See Also

CGAL::compare

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *compare* adapts the according functor in *Polynomial_traits_d< Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::Compare*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Compare::result_type

compare(Polynomial_d p, Polynomial_d q)

Adapts *Polynomial_traits_d<Polynomial_d>::Compare*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::Compare . . . . page 292

CGAL::univariate_content

#include <CGAL/polynomial_utils.h>

Function

Definition

For a given *Polynomial_d* the function *univariate_content* adapts the according functor in *Polynomial_traits_d< Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::UnivariateContent*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Univariate_content::result_type

univariate_content(Polynomial_d p)

Adapts *Polynomial_traits_d<Polynomial_d> ::UnivariateContent*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::Univariate_Content . . . . page **??**

Function

CGAL::multivariate_content

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *multivariate_content* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::MultivariateContent*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Multivariate_content::result_type

multivariate_content(Polynomial_d p)

Adapts *Polynomial_traits_d<Polynomial_d>::Multivariate_content*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::MultivariateContent . . . . page 294

CGAL::square_free_factorize

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *square_free_factorize* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::SquareFreeFactorize*.

template <class Polynomial_d, class OutputIterator >
OutputIterator square_free_factorize(Polynomial_d p, OutputIterator it, Polynomial_traits_d<Polynomial>::Innermost_coefficient& a)

Adapts *Polynomial_traits_d<Polynomial_d>::Square_free_factorize*.

template <class Polynomial_d, class OutputIterator >
OutputIterator square_free_factorize(Polynomial_d p, OutputIterator it)

Adapts *Polynomial_traits_d<Polynomial_d>::Square_free_factorize*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::SquareFreeFactorize . . . . page 295

Function

Function

CGAL::make_square_free

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *make_square_free* adapts the according functor in *Polynomial_traits_d< Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::MakeSquareFree*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Make_square_free::result_type

make_square_free(Polynomial_d p)

Adapts *Polynomial_traits_d<Polynomial_d>::Make_square_free*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::MakeSquareFree . . . . page 296

CGAL::is_square_free

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *is_square_free* adapts the according functor in *Polynomial_traits_d< Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::IsSquareFree*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Is_square_free::result_type

is_square_free(Polynomial_d p)

Adapts *Polynomial_traits_d<Polynomial_d>::Is_square_free*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::IsSquareFree . . . . page 297

Function

Function

CGAL::pseudo_division

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *pseudo_division* adapts the according functor in *Polynomial_traits_d< Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::PseudoDivision*.

template <class Polynomial_d>
void *pseudo_division(Polynomial_d f, Polynomial_d g, Polynomial_d& q, Polynomial_d& r, Polynomial_traits_d<Polynomial_d>::Coefficient_type& D)*

Adapts *Polynomial_traits_d<Polynomial_d>::Pseudo_division*.

See Also

CGAL::pseudo_division_quotient

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *pseudo_division_quotient* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::PseudoDivisionQuotient*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Pseudo_division_quotient::result_type

pseudo_division_quotient(Polynomial_d p, Polynomial_d q)

Adapts *Polynomial_traits_d<Polynomial_d>::Pseudo_division_quotient*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::PseudoDivisionQuotient . . . . page 299

Function

Function

CGAL::pseudo_division_remainder

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *pseudo_division_remainder* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::PseudoDivisionRemainder*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Pseudo_division_remainder::result_type

pseudo_division_remainder(Polynomial_d p, Polynomial_d q)

Adapts *Polynomial_traits_d<Polynomial_d>::Pseudo_division_remainder*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::PseudoDivisionRemainder . . . . page 300

CGAL::gcd_up_to_constant_factor

Function

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *gcd_up_to_constant_factor* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::GcdUpToConstantFactor*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Gcd_up_to_constant_factor::result_type

gcd_up_to_constant_factor(Polynomial_d p, Polynomial_d q)

Adapts *Polynomial_traits_d<Polynomial_d>::Gcd_up_to_constant_factor*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::GcdUpToConstantFactor . . . . page 301

Function

CGAL::integral_division_up_to_constant_factor

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *integral_division_up_to_constant_factor* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::IntegralDivisionUpToConstantFactor*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Integral_division_up_to_constant_factor::result_type

integral_division_up_to_constant_factor(Polynomial_d p, Polynomial_d q)

Adapts *Polynomial_traits_d<Polynomial_d>::Integral_division_up_to_constant_factor*.

See Also

CGAL::univariate_content_up_to_constant_factor

Function

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *univariate_content_up_to_constant_factor* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::UnivariateContentUpToConstantFactor*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Univariate_content_up_to_constant_factor::result_type

univariate_content_up_to_constant_factor(Polynomial_d p)

Adapts *Polynomial_traits_d<Polynomial_d>::Univariate_content_up_to_constant_factor*.

See Also

CGAL::shift

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *shift* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::Shift*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Shift::result_type

shift(Polynomial_d p, int i, int index = Polynomial_traits_d<Polynomial_d>::d-1)

Adapts *Polynomial_traits_d<Polynomial_d>::Shift*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::Shift . . . . page 305

Function

CGAL::negate

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *negate* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::Negate*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Negate::result_type

negate(Polynomial_d p, int index = Polynomial_traits_d<Polynomial_d>::d-1)

Adapts *Polynomial_traits_d<Polynomial_d>::Negate*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::Negate . . . . page 306

CGAL::invert

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *invert* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::Invert*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Invert::result_type

invert(Polynomial_d p, int index = Polynomial_traits_d<Polynomial_d>::d-1)

Adapts *Polynomial_traits_d<Polynomial_d>::Invert*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::Invert . . . . page 307

Function

Function

CGAL::translate

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *translate* adapts the according functor in *Polynomial_traits_d< Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::Translate*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Translate::result_type

translate(Polynomial_d p,
Polynomial_traits_d<Polynomial_d>::Innermost_coefficient_type a,
int index = Polynomial_traits_d<Polynomial_d>::d-1)

Adapts *Polynomial_traits_d<Polynomial_d>::Translate*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::Translate . . . . page 308

CGAL::translate_homogeneous

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *translate_homogeneous* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::TranslateHomogeneous*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Translate_homogeneous::result_type

translate_homogeneous(Polynomial_d p,
Polynomial_traits_d<Polynomial_d>::Innermost_coefficient_type u,
Polynomial_traits_d<Polynomial_d>::Innermost_coefficient_type v,
int index = Polynomial_traits_d<Polynomial_d>::d-1)

Adapts *Polynomial_traits_d<Polynomial_d>::Translate_homogeneous*.

See Also

Polynomial_d . . . . . page 261
PolynomialTraits_d . . . . . page 262
PolynomialTraits_d::TranslateHomogeneous . . . . . page 309

Function

CGAL::scale

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *scale* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::Scale*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Scale::result_type

scale(Polynomial_d p,
Polynomial_traits_d<Polynomial_d>::Innermost_coefficient_type a,
int index = Polynomial_traits_d<Polynomial_d>::d-1)

Adapts *Polynomial_traits_d<Polynomial_d>::Scale*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::Scale . . . . page 310

CGAL::scale_homogeneous

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *scale_homogeneous* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::ScaleHomogeneous*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Scale_homogeneous::result_type

scale_homogeneous(Polynomial_d p,
Polynomial_traits_d<Polynomial_d>::Innermost_coefficient_type u,
Polynomial_traits_d<Polynomial_d>::Innermost_coefficient_type v,
int index = Polynomial_traits_d<Polynomial_d>::d-1)

Adapts *Polynomial_traits_d<Polynomial_d>::Scale_homogeneous*.

See Also

Polynomial_d . . . . . . page 261

Function

CGAL::resultant

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *resultant* adapts the according functor in *Polynomial_traits_d< Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::Resultant*.

template <class Polynomial_d>
Polynomial_traits_d<Polynomial_d>::Resultant::result_type

resultant(Polynomial_d p, Polynomial_d q)

Adapts *Polynomial_traits_d<Polynomial_d>::Resultant*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::Resultant . . . . page 312

CGAL::polynomial_subresultants

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *polynomial_subresultants* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::PolynomialSubresultants*.

template<typename Polynomial_d,typename OutputIterator>
OutputIterator *polynomial_subresultants(Polynomial_d p, Polynomial_d q, OutputIterator out)*

computes the polynomial subresultants of p and q, with respect to the outermost variable. Each element is of type *Polynomial_d*.

See Also

Polynomial_d . . . . page 261
PolynomialTraits_d . . . . page 262
PolynomialTraits_d::PolynomialSubresultants . . . . page 314

Function

Function

CGAL::polynomial_subresultants_with_cofactors

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *polynomial_subresultants_with_cofactors* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::PolynomialSubresultantsWithCofactors*.

template<typename Polynomial_d, typename OutputIterator1, typename OutputIterator2, typename OutputIterator3>
OutputIterator1 polynomial_subresultants_with_cofactors(Polynomial_d p, Polynomial_d q, OutputIterator1 sres_out, OutputIterator2 coP_out, OutputIterator3 coQ_out)

computes the polynomial subresultants of p and q, *sres_out*, with respect to the outermost variable, and the cofactors for P, *coP_out* and Q, *coQ_out*. The elements of each output range are of type *Polynomial_d*.

See Also

Polynomial_d . . . page 261
PolynomialTraits_d . . . page 262

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *sturm_habicht_sequence_with_cofactors* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::SturmHabichtSequenceWithCofactors*.

template<typename Polynomial_d, typename OutputIterator1, typename OutputIterator2, typename OutputIterator3>
OutputIterator1 sturm_habicht_sequence_with_cofactors(Polynomial_d f, OutputIterator1 stha_out, OutputIterator2 cof_out, OutputIterator3 cofx_out)

computes the Sturm-Habicht sequence of f *stha_out*, with respect to the outermost variable, and the cofactors for f, *cof_out* and f', *cofx_out*. The elements of each output range are of type *Polynomial_d*.

Function

CGAL::principal_sturm_habicht_sequence

#include <CGAL/polynomial_utils.h>

Definition

For a given *Polynomial_d* the function *principal_sturm_habicht_sequence* adapts the according functor in *Polynomial_traits_d<Polynomial_d>*.

For more details see the concept *PolynomialTraits_d::PrincipalSturmHabichtSequence*.

template <typename Polynomial_d,typename OutputIterator>
inline OutputIterator *principal_sturm_habicht_sequence(typename Polynomial_d f, OutputIterator out)*

computes the principal Sturm-Habicht coefficients of f with respect to the outermost variable. Each element is of type *Polynomial_traits_d<Polynomial_d>::Coefficient_type*.

CGAL::number_of_real_roots

#include <CGAL/polynomial_utils.h>

Definition

Given a polynomial f, or a range of values that is interpreted as the principal Sturm-Habicht coefficients of f, the function computes

$$m := \#\{\alpha \in \mathbb{R} \mid f(\alpha) = 0\}$$

that is, the number of distinct real roots of f.

The coefficient type of the polynomial, or the value type of the iterator range, respectively must be a model of *RealEmbeddable*. In the second version, it is not required to pass the exact principal Sturm-Habicht coefficients to the functions; it is only required that the sign of each element corresponds to the sign of the actual principal Sturm-Habicht coefficient.

advanced

We explain the internals of this function. For a sequence $I := (a_0, \ldots, a_n)$ of real numbers with $a_0 \neq 0$, define

$$C(I) = \sum_{i=1}^{s} \varepsilon_i$$

where s is the number of subsequences of I of the form

$$(a, \underbrace{0, \ldots, 0}_{k}, b)$$

with $a \neq 0, b \neq 0, k \geq 0$.
For the i-th subsequence of I, define

$$\varepsilon_i := \begin{array}{cl} 0 & \text{if } k \text{ is odd,} \\ (-1)^{k/2}\operatorname{sign}(ab) & \text{if } k \text{ is even.} \end{array}$$

For $f \in \mathbb{R}[x]$ with $\deg f = n$, we have:

$$C(\mathrm{stha}_n(f), \ldots, \mathrm{stha}_0(f)) = \#\{\alpha \in \mathbb{R} \mid f(\alpha) = 0\}$$

In other words, the signs of the principal Sturm-Habicht coefficients determine the number of distinct real roots of f.

advanced

Operations

template<typename Polynomial_d>
int *number_of_real_roots(Polynomial_d f)*

computes the number of distinct real roots of f

template<typename InputIterator>

int *number_of_real_roots(InputIterator start, InputIterator end)*

computes the number of distinct real roots of f whose principal Sturm-Habicht coefficients are passed by the iterator range.

Chapter 8

Algebraic Kernel

Eric Berberich, Michael Hemmer, Michael Kerber, Sylvain Lazard, Luis Peñaranda, and Monique Teillaud

Contents

8.1 Introduction

Real solving of polynomials is a fundamental problem with a wide application range. This package is targeted at providing black-box implementations of state-of-the-art algorithms to determine, compare, and approximate real roots of univariate polynomials and bivariate polynomial systems. Such a black-box is called an **Algebraic Kernel**. Since this package is aimed at providing more than one implementation, the interface of the algebraic kernels is expressed in concepts. The main concepts provided by this package are the *AlgebraicKernel_d_1* for univariate polynomial systems and *AlgebraicKernel_d_2* for bivariate polynomial systems, the latter being a refinement of the first.

8.2 Algebraic Kernel Concepts

8.2.1 Univariate Algebraic Kernel

Major types

First of all, the univariate algebraic kernel provides construction, comparison and approximation of real roots of univariate polynomials. Thus, the major public types the *AlgebraicKernel_d_1* provides are:
AlgebraicKernel_d_1::Polynomial_1 – the type representing univariate polynomials,
AlgebraicKernel_d_1::Coefficient – the coefficient type of these polynomials,
AlgebraicKernel_d_1::Algebraic_real_1 – the type representing real roots,
AlgebraicKernel_d_1::Bound – the type which is used to approximate these algebraic reals, in particular, it is used to represent the boundaries of isolating intervals.

Construction of Algebraic Real Numbers

The kernel provides two different function objects to construct an *AlgebraicKernel_d_1::Algebraic_real_1*. The most general way is to use *AlgebraicKernel_d_1::Isolate_1*; The function object takes a univariate polynomial and writes all real roots into a given output iterator. It is also possible to retrieve the multiplicity of each root. The second option is to construct one particular algebraic real using *AlgebraicKernel_d_1::Construct_algebraic_real_1*. This function object provides construction from the native int type, the coefficient type as well as the bound type. Moreover, it is possible to construct an algebraic real by giving a polynomial and either an isolating interval or the index of the root. A related function object is *AlgebraicKernel_d_1::Number_of_solutions_1* computing the number of real roots of a polynomial.

Comparison and Approximation of Algebraic Real Numbers

An *AlgebraicKernel_d_1::Algebraic_real_1* is model of *RealEmbeddable*, for instance, it is possible to compare two algebraic reals, to determine the sign of an algebraic real or to ask for its double approximation, see also section 4.3. Moreover, *AlgebraicKernel_d_1::Compare_1* provides comparison with int, the coefficient type and the bound type.

There are several ways to approximate an *AlgebraicKernel_d_1::Algebraic_real_1*:
AlgebraicKernel_d_1::Approximate_absolute_1 – provides an approximation that is better than the passed absolute error bound,
AlgebraicKernel_d_1::Approximate_relative_1 – provides an approximation that is better than the passed relative error bound,
AlgebraicKernel_d_1::Isolate_1 – returns an isolating interval with respect to a given univariate polynomial,
A related function object is *AlgebraicKernel_d_1::Bound_between_1*, which computes a number that isolates two algebraic real numbers.

Interplay with Polynomials

It is also possible to retrieve a representing polynomial from an algebraic real using *AlgebraicKernel_d_1::Compute_polynomial_1*, which guarantees that the algebraic real is a root of the returned polynomial. As the name already indicates, this operation may be very costly since the polynomial may not be computed yet. Moreover, it is not guaranteed that the returned polynomial is the minimal polynomial of the number. Together with *AlgebraicKernel_d_1::Isolate_1*, it is possible to retrieve the traditional representation of an algebraic real as a square free polynomial and an isolating interval.

Though the *AlgebraicKernel_d_1* does not provide arithmetic operations on *AlgebraicKernel_d_1::Algebraic_real_1*, it is possible to compute the sign of a polynomial at a given algebraic real using *AlgebraicKernel_d_1::Sign_at_1*. Or alternatively, just compute whether the polynomial is zero at an algebraic real number using *AlgebraicKernel_d_1::Is_zero_at_1*. Note that this operation can be significantly less expensive, in particular if the polynomial is not zero at the given algebraic real.

Auxiliary Functionality for Polynomials

First of all the type *AlgebraicKernel_d_1::Polynomial_1* is required to be a model of the concept *Polynomial_1*, which is defined in the Polynomial package (see chapter 7). This implies that all essential functionality is provided via *CGAL::Polynomial_traits_d*. However, the algebraic kernel also provides several function objects to handle polynomials:
AlgebraicKernel_d_1::Is_square_free_1 – determines whether a polynomial is square free,
AlgebraicKernel_d_1::Make_square_free_1 – computes the square free part of a polynomial,
AlgebraicKernel_d_1::Square_free_factorize_1 – computes a square free factorization of a polynomial,
AlgebraicKernel_d_1::Is_coprime_1 – computes whether a pair of polynomials is square free,
AlgebraicKernel_d_1::Make_coprime_1 – decomposes two polynomials into the coprime factors and their common factor.

Though the polynomial package provides similar functionality we suggest to use the function objects provided by the kernel, since the design of the algebraic kernel allows for instance internal caching by the kernel.

Also note that *AlgebraicKernel_d_1::Square_free_factorize_1* only computes the square free factorization up to a constant factor. This is a slight modification with respect to its counterpart in *CGAL::Polynomial_traits_d*. In this way it was possible that the concepts just require the coefficient type to be a model of *IntegralDomain*, instead of *Field* or *UniqueFactorizationDomain*. For more details see also:
PolynomialTraits_d::SquareFreeFactorize .... page 295
PolynomialTraits_d::SquareFreeFactorizeUpToConstantFactor .... page 304

Design Rationale

Most implementations of an *AlgebraicKernel_d_1* will represent an algebraic real number by the root of a square free polynomial and an isolating interval, that is, the number is defined as the only root of the polynomial within the interval. Usually, one will refrain from computing the minimal polynomial since the computation of the minimal polynomial is much more expensive and does not pay of. However, besides the representation by a polynomial and an isolating interval one can also imagine the representation by a polynomial and the index of the root, e.g., as the ith real root when enumerated from minus to plus infinity. Moreover, it may very well be that the kernel just computes an approximation of the number, whereas the representing polynomial is not computed yet. This is in particular relevant in relation to the *AlgebraicKernel_d_2*, where *AlgebraicKernel_d_1::Algebraic_real_1* is used to represent coordinates of solutions of bivariate systems. Hence, the design does not allow a direct access to any, seemingly obvious, members of an *AlgebraicKernel_d_1::Algebraic_real_1*. Instead there is, e.g., *AlgebraicKernel_d_1::Compute_polynomial_1* which emphasizes that the requested polynomial may not be computed yet. Similarly, there is no way to directly ask for the refinement of the current isolating interval since this would impose a state to every object of an *AlgebraicKernel_d_1::Algebraic_real_1*.

8.2.2 Bivariate Algebraic Kernel

The concept *AlgebraicKernel_d_2* is a refinement of *AlgebraicKernel_d_1*, that is, a model of *AlgebraicKernel_d_2* is also a model of *AlgebraicKernel_d_1*. Hence, the *AlgebraicKernel_d_2* concept is designed such that occurring names and functionalities are as similar as possible to those in the *AlgebraicKernel_d_1* concept. The following are a direct generalization of their univariate counterparts:

AlgebraicKernel_d_2::Polynomial_2,
AlgebraicKernel_d_2::Algebraic_real_2,
AlgebraicKernel_d_2::Construct_algebraic_real_2,
AlgebraicKernel_d_2::Isolate_2,
AlgebraicKernel_d_2::Is_square_free_2,
AlgebraicKernel_d_2::Make_square_free_2,
AlgebraicKernel_d_2::Square_free_factorize_2,
AlgebraicKernel_d_2::Is_coprime_2,
AlgebraicKernel_d_2::Make_coprime_2,
AlgebraicKernel_d_2::Solve_2,
AlgebraicKernel_d_2::Number_of_solutions_2,
AlgebraicKernel_d_2::Compare_xy_2,
AlgebraicKernel_d_2::Sign_at_2,
AlgebraicKernel_d_2::Is_zero_at_2.

For instance, *AlgebraicKernel_d_2::Solve_2* provides the solution for a bivariate polynomial system. However, it is also possible to obtain the coordinates of these solutions with the additional functors:

AlgebraicKernel_d_2::Compute_x_2,
AlgebraicKernel_d_2::Compute_y_2.

In principal this would be sufficient generalization, since functions such as isolating, approximating algebraic real numbers could be implemented using these access functions ant the corresponding functionalities in the univariate algebraic kernel. However, one should be aware that an *AlgebraicKernel_d_2::Algebraic_real_2* is not necessarily represented as a pair of univariate solutions, that is, using *AlgebraicKernel_d_2::Compute_y_2* may entail considerable computations. Therefore, the concept also requires the following additional functors that may allow a model to bypass this issue:

AlgebraicKernel_d_2::Compute_polynomial_x_2,
AlgebraicKernel_d_2::Compute_polynomial_y_2,
AlgebraicKernel_d_2::Isolate_x_2,
AlgebraicKernel_d_2::Isolate_y_2,
AlgebraicKernel_d_2::Compare_x_2,
AlgebraicKernel_d_2::Compare_y_2,
AlgebraicKernel_d_2::Approximate_absolute_x_2,
AlgebraicKernel_d_2::Approximate_relative_x_2,
AlgebraicKernel_d_2::Approximate_absolute_y_2,
AlgebraicKernel_d_2::Approximate_relative_y_2,
AlgebraicKernel_d_2::Bound_between_x_2,
AlgebraicKernel_d_2::Bound_between_y_2.

8.3 Models

8.3.1 Generic Algebraic Kernels

The package provides generic models of the univariate and bivariate algebraic kernel, namely *CGAL::Algebraic_kernel_d_1<Coeff>* and *CGAL::Algebraic_kernel_d_2<Coeff>*, respectively. Both kernels support a large set of number types as their template argument, which defines the supported coefficient type. The supported types are, for instance, *Gmpz* and *Gmpq* as well as the corresponding types of LEDA and CORE.

The *CGAL::Algebraic_kernel_d_1<Coeff>* represents an algebraic real root by a square free polynomial and an isolating interval that uniquely defines the root. The current method to isolate roots is the Bitstream Descartes method [Eig08]. The used method to refine the approximation of an algebraic real root is a slightly modified (filtered) version of the one presented in [Abb]. The method has quadratic convergence.

CGAL::Algebraic_kernel_d_2<Coeff> is based on an algorithm computing a geometric-topological analysis of a single curve [EKW07] and of a pair of curves [EK08]. The main idea behind both analyses is to compute the critical x-coordinates of curves and curve pairs by projection (resultants), and compute additional information about the critical fibers using subresultants and Sturm-Habicht sequences [GVRLR98]. With that information, the fiber at critical x-coordinates is computed by a variant of the Bitstream Descartes method. See also [Ker09] for a comprehensive description of these techniques. Almost all functors in the class that take a *Polynomial_2* object as argument trigger such an analysis as a main computation step. For efficiency, these analyses (of single curves and curve pairs) are therefore cached internally for efficiency. For instance, computing the pairwise solutions of 10 *Polynomial_2* objects requires 10 curve analyses and 45 curve pair analyses to be computed internally.

A point p of type *Algebraic_real_2* is represented by its x-coordinate x_0 (as described in the *Algebraic_kernel_d_1* paragraph above), an algebraic curve where p lies on, and an integer i, denoting that p is the ith point in the fiber at x_0, counted from the bottom (ignoring a possible vertical line at x_0). Note that this determines the point uniquely, but the y-coordinate is not stored internally in terms of an *Algebraic_real_1* object. Querying such a representation by calling *Compute_y_2* is a time-consuming step, and should be avoided for efficiency reasons if possible.

8.3.2 Algebraic Kernels Based on RS

The package offers two univariate algebraic kernels that are based on the library Rs [RS], namely *CGAL::Algebraic_kernel_rs_gmpz_d_1* and *CGAL::Algebraic_kernel_rs_gmpq_d_1*. As the names indicate, the kernels are based on the library Rs [RS] and support univariate polynomials over *CGAL::Gmpz* or *CGAL::Gmpq*, respectively.

In general we encourage to use *CGAL::Algebraic_kernel_rs_gmpz_d_1* instead of *CGAL::Algebraic_kernel_rs_gmpq_d_1*. This is caused by the fact that the most efficient way to compute operations (such as gcd) on polynomials with rational coefficients is to use the corresponding implementation for polynomials with integer coefficients. That is, the *CGAL::Algebraic_kernel_rs_gmpq_d_1* is slightly slower due to overhead caused by the necessary conversions. However, since this may not always be a major issue, the *CGAL::Algebraic_kernel_rs_gmpq_d_1* is provided for convenience.

The core of both kernels is the implementation of the interval Descartes algorithm [RZ04] of the library Rs [RS], which is used to isolate the roots of the polynomial. The Rs library restricts its attention to univariate integer polynomials and some substantial gain of efficiency can be made by using a kernel that does not follow the generic programming paradigm, by avoiding interfaces between layers. Specifically, working with only one number type allows to optimize some polynomial operations as well as memory handling. The implementation of these kernels make heavy use of the MPFR [MPFb] and MPFI [MPFa] libraries, and of their CGAL interfaces, *Gmpfr* and *Gmpfi*. The algebraic numbers (roots of the polynomials) are represented in the two Rs kernels by a *Gmpfi* interval and a pointer to the polynomial of which they are roots. See [LPT09] for more details on the implementation, tests of these kernels, comparisons with other algebraic kernels and discussions about the efficiency.

8.4 Examples

Construction of Algebraic Real Numbers

The following example illustrates the construction of *AlgebraicKernel_d_1::Algebraic_real_1* using *AlgebraicKernel_d_1::Construct_algebraic_real_1*:

```
#include <CGAL/basic.h>
#ifdef CGAL_USE_MPFI
#include <CGAL/Algebraic_kernel_d_1.h>
#include <CGAL/Gmpz.h>
#include <vector>
#include <iostream>

typedef CGAL::Algebraic_kernel_d_1<CGAL::Gmpz>          AK;
typedef AK::Polynomial_1                                Polynomial_1;
typedef AK::Algebraic_real_1                            Algebraic_real_1;
typedef AK::Coefficient                                 Coefficient;
typedef AK::Bound                                       Bound;
typedef AK::Multiplicity_type                           Multiplicity_type;

int main(){
  AK ak; // an object of
  AK::Construct_algebraic_real_1 construct_algreal_1 =
    ak.construct_algebraic_real_1_object();

  std::cout << "Construct from int         : " << construct_algreal_1(int(2)) <<
    "\n";
  std::cout << "Construct from Coefficient : " <<
    construct_algreal_1(Coefficient(2)) << "\n";
  std::cout << "Construct from Bound       : " << construct_algreal_1(Bound(2)) <<
     "\n\n";

  Polynomial_1 x = CGAL::shift(AK::Polynomial_1(1),1); // the monomial x
  std::cout << "Construct by index              : "
            << construct_algreal_1(x*x-2,1) << "\n"
            << to_double(construct_algreal_1(x*x-2,1)) << "\n";
  std::cout << "Construct by isolating interval : "
            << construct_algreal_1(x*x-2,Bound(0),Bound(2)) << "\n"
            << to_double(construct_algreal_1(x*x-2,Bound(0),Bound(2))) << "\n\n";

  return 0;
}
#else
int main(){
  std::cout << "This example requires CGAL to be configured with library MPFI." <<
     std::endl;
return 0;
}
#endif
```

File: examples/Algebraic_kernel_d/Construct_algebraic_real_1.cpp

Solving Univariate Polynomials

The following example illustrates the construction of *AlgebraicKernel_d_1::Algebraic_real_1* using *AlgebraicKernel_d_1::Solve_1*:

```
#include <CGAL/basic.h>
#ifdef CGAL_USE_MPFI
#include <CGAL/Algebraic_kernel_d_1.h>
#include <CGAL/Gmpz.h>
#include <vector>

typedef CGAL::Algebraic_kernel_d_1<CGAL::Gmpz>          AK;
typedef AK::Polynomial_1                                 Polynomial_1;
typedef AK::Algebraic_real_1                             Algebraic_real_1;
typedef AK::Bound                                        Bound;
typedef AK::Multiplicity_type                            Multiplicity_type;

int main(){
  AK ak; // an object of
  AK::Solve_1 solve_1 = ak.solve_1_object();
  Polynomial_1 x = CGAL::shift(AK::Polynomial_1(1),1); // the monomial x

  // variant using a bool indicating a square free polynomial
  // multiplicities are not computed
  std::vector<Algebraic_real_1> roots;
  solve_1(x*x-2,true, std::back_inserter(roots));
  std::cout << "Number of roots is           : " << roots.size() << "\n";
  std::cout << "First root should be -sqrt(2): " << CGAL::to_double(roots[0]) <<
    "\n";
  std::cout << "Second root should be sqrt(2): " << CGAL::to_double(roots[1]) <<
    "\n\n";
  roots.clear();

  // variant for roots in a given range of a square free polynomial
  solve_1((x*x-2)*(x*x-3),true, Bound(0),Bound(10),std::back_inserter(roots));
  std::cout << "Number of roots is           : " << roots.size() << "\n";
  std::cout << "First root should be  sqrt(2): " << CGAL::to_double(roots[0]) <<
    "\n";
  std::cout << "Second root should be sqrt(3): " << CGAL::to_double(roots[1]) <<
    "\n\n";
  roots.clear();

  // variant computing all roots with multiplicities
  std::vector<std::pair<Algebraic_real_1,Multiplicity_type> > mroots;
  solve_1((x*x-2), std::back_inserter(mroots));
  std::cout << "Number of roots is           : " << mroots.size() << "\n";
  std::cout << "First root should be -sqrt(2): " <<
    CGAL::to_double(mroots[0].first) << ""
            << " with multiplicity "           << mroots[0].second << "\n";
  std::cout << "Second root should be sqrt(2): " <<
    CGAL::to_double(mroots[1].first) << ""
            << " with multiplicity "           << mroots[1].second << "\n\n";
  mroots.clear();

  // variant computing roots with multiplicities for a range
  solve_1((x*x-2)*(x*x-3),Bound(0),Bound(10),std::back_inserter(mroots));
  std::cout << "Number of roots is           : " << mroots.size() << "\n";
```

```
  std::cout << "First root should be  sqrt(2): " <<
    CGAL::to_double(mroots[0].first) << ""
            << " with multiplicity "              << mroots[0].second << "\n";
  std::cout << "Second root should be sqrt(3): " <<
    CGAL::to_double(mroots[1].first) << ""
            << " with multiplicity "              << mroots[1].second << "\n\n";
  return 0;
}
#else
int main(){
  std::cout << "This example requires CGAL to be configured with library MPFI." <<
     std::endl;
return 0;
}
#endif
```

Comparison and Approximation of Algebraic Real Numbers

The following example illustrates the comparison of *AlgebraicKernel_d_1::Algebraic_real_1* numbers:

```
#include <CGAL/basic.h>
#ifdef CGAL_USE_MPFI
#include <CGAL/Algebraic_kernel_d_1.h>
#include <CGAL/Gmpz.h>
#include <vector>

typedef CGAL::Algebraic_kernel_d_1<CGAL::Gmpz>          AK;
typedef AK::Coefficient                                 Coefficient;
typedef AK::Polynomial_1                                Polynomial_1;
typedef AK::Algebraic_real_1                            Algebraic_real_1;
typedef AK::Bound                                       Bound;
typedef std::pair<Bound,Bound>                          Interval;

int main(){
  AK ak;

  AK::Construct_algebraic_real_1 construct_algebraic_real_1 =
    ak.construct_algebraic_real_1_object();
  Polynomial_1 x = CGAL::shift(AK::Polynomial_1(1),1); // the monomial x
  Algebraic_real_1 a = construct_algebraic_real_1(x*x-2,1); //  sqrt(2)
  Algebraic_real_1 b = construct_algebraic_real_1(x*x-3,1); //  sqrt(3)

  // Algebraic_real_1 is RealEmbeddable (just some functions:)
  std::cout << "sign of a is                 : " << CGAL::sign(a)      << "\n";
  std::cout << "double approximation of a is : " << CGAL::to_double(a) << "\n";
  std::cout << "double approximation of b is : " << CGAL::to_double(b) << "\n";
  std::cout << "double lower bound of a      : " << CGAL::to_interval(a).first  <<
     "\n";
  std::cout << "double upper bound of a      : " << CGAL::to_interval(a).second <<
     "\n";
  std::cout << "LessThanComparable (a<b)     : " << (a<b) << "\n\n";

  // use compare_1 with int, Bound, Coefficient, Algebraic_real_1
  AK::Compare_1 compare_1 = ak.compare_1_object();
  std::cout << " compare with an int                  : " << compare_1(a ,int(2))
    << "\n";
  std::cout << " compare with an Coefficient          : " << compare_1(a
    ,Coefficient(2)) << "\n";
  std::cout << " compare with an Bound                : " << compare_1(a
    ,Bound(2)) << "\n";
  std::cout << " compare with another Algebraic_real_1: " << compare_1(a ,b) <<
    "\n\n";

  // get a value between two roots
  AK::Bound_between_1 bound_between_1 = ak.bound_between_1_object();
  std::cout << " value between sqrt(2) and sqrt(3) " << bound_between_1(a,b) <<
    "\n";
  std::cout << " is larger than sqrt(2)             " <<
    compare_1(bound_between_1(a,b),a) << "\n";
  std::cout << " is less   than sqrt(3)             " <<
    compare_1(bound_between_1(a,b),b) << "\n\n";

  // approximate with relative precision
  AK::Approximate_relative_1 approx_r = ak.approximate_relative_1_object();
```

```
  std::cout << " lower bound of a with at least 100 bits:    "<<
    approx_r(a,100).first  << "\n";
  std::cout << " upper bound of a with at least 100 bits:    "<<
    approx_r(a,100).second << "\n\n";

  // approximate with absolute error
  AK::Approximate_absolute_1 approx_a = ak.approximate_absolute_1_object();

Isolation of Algebraic Real Numbers with respect to roots of other polynomials

The following example illustrates the isolation of *AlgebraicKernel_d_1::Algebraic_real_1* numbers:

```
#include <CGAL/basic.h>
#ifdef CGAL_USE_MPFI
#include <CGAL/Algebraic_kernel_d_1.h>
#include <CGAL/Gmpz.h>
#include <vector>

typedef CGAL::Algebraic_kernel_d_1<CGAL::Gmpz>          AK;
typedef AK::Polynomial_1                                Polynomial_1;
typedef AK::Algebraic_real_1                            Algebraic_real_1;
typedef AK::Coefficient                                 Coefficient;
typedef AK::Bound                                       Bound;
typedef AK::Multiplicity_type                           Multiplicity_type;

int main(){
  AK ak; // an object of
  AK::Construct_algebraic_real_1 construct_algreal_1 =
    ak.construct_algebraic_real_1_object();
  AK::Isolate_1 isolate_1 = ak.isolate_1_object();
  AK::Compute_polynomial_1 compute_polynomial_1 =
    ak.compute_polynomial_1_object();

  // construct an algebraic number from an integer
  Algebraic_real_1 frominteger=construct_algreal_1(int(2));
  std::cout << "Construct from int: " << frominteger << "\n";

  // the constructed algebraic number is root of a polynomial
  Polynomial_1 pol=compute_polynomial_1(frominteger);
  std::cout << "The constructed number is root of: " << pol << "\n";

  // construct an algebraic number from a polynomial and an isolating interval
  Polynomial_1 x = CGAL::shift(AK::Polynomial_1(1),1); // the monomial x
  Algebraic_real_1 frominterval=construct_algreal_1(x*x-2,Bound(0),Bound(2));
  std::cout << "Construct from isolating interval: " << frominterval << "\n";

  // isolate the second algebraic number from the first: this is to say,
  // isolating the second algebraic number with respect to the polynomial
  // of which the first constructed number is root
  std::pair<Bound,Bound> isolation1 = isolate_1(frominterval,pol);
  std::cout << "Isolating the second algebraic number gives: ["
            << isolation1.first << "," << isolation1.second << "]\n";

  // isolate again the same algebraic number, this time with respect to
  // the polynomial 10*x-14 (which has root 1.4, close to this algebraic
  // number)
  std::pair<Bound,Bound> isolation2 = isolate_1(frominterval,10*x-14);
  std::cout << "Isolating again the second algebraic number gives: ["
            << isolation2.first << "," << isolation2.second << "]\n";

  return 0;
}
#else
int main(){
  std::cout << "This example requires CGAL to be configured with library MPFI." <<
     std::endl;
```

```
return 0;
}
#endif
```

File: examples/Algebraic_kernel_d/Isolate_1.cpp

Interplay with Polynomials

The following example illustrates the sign evaluation of *AlgebraicKernel_d_1::Algebraic_real_1* numbers in polynomials:

```
#include <CGAL/basic.h>
#ifdef CGAL_USE_MPFI
#include <CGAL/Algebraic_kernel_d_1.h>
#include <CGAL/Gmpz.h>
#include <vector>

typedef CGAL::Algebraic_kernel_d_1<CGAL::Gmpz>          AK;
typedef AK::Polynomial_1                                Polynomial_1;
typedef AK::Algebraic_real_1                            Algebraic_real_1;
typedef AK::Coefficient                                 Coefficient;
typedef AK::Bound                                       Bound;
typedef AK::Multiplicity_type                           Multiplicity_type;

int main(){
  AK ak;
  AK::Construct_algebraic_real_1 construct_algreal_1 =
    ak.construct_algebraic_real_1_object();
  AK::Solve_1 solve_1 = ak.solve_1_object();
  AK::Sign_at_1 sign_at_1 = ak.sign_at_1_object();
  AK::Is_zero_at_1 is_zero_at_1 = ak.is_zero_at_1_object();

  // construct the polynomials p=x^2-5 and q=x-2
  Polynomial_1 x = CGAL::shift(AK::Polynomial_1(1),1); // the monomial x
  Polynomial_1 p = x*x-5;
  std::cout << "Polynomial p: " << p << "\n";
  Polynomial_1 q = x-2;
  std::cout << "Polynomial q: " << q << "\n";

  // find the roots of p (it has two roots) and q (one root)
  std::vector<Algebraic_real_1> roots_p,roots_q;
  solve_1(p,true, std::back_inserter(roots_p));
  solve_1(q,true, std::back_inserter(roots_q));

  // evaluate the second root of p in q
  std::cout << "Sign of the evaluation of root 2 of p in q: "
            << sign_at_1(q,roots_p[1]) << "\n";

  // evaluate the root of q in p
  std::cout << "Sign of the evaluation of root 1 of q in p: "
            << sign_at_1(p,roots_q[0]) << "\n";

  // check whether the evaluation of the first root of p in p is zero
  std::cout << "Is zero the evaluation of root 1 of p in p? "
            << is_zero_at_1(p,roots_p[0]) << "\n";

  return 0;
}

#else

8.5 Design and Implementation History

This package is clearly split into a univariate and bivariate kernel. However, with respect to its history the package splits into a design part and an implementation part.

The concepts, which make up the design part, were written by Eric Berberich, Michael Hemmer, and Monique Teillaud. The design history of the package is fairly old and several ideas that influenced this package can already be found in [BHKT07]. Since then, the initial design underwent considerable changes. For instance, it was decided that the algebraic numbers should be under the control of the algebraic kernel. On the other hand the initial support for polynomials was extended to a separate and independent package that is not restricted to a certain number of variables. Thus, the authors want to thank for all the useful feedback and ideas that was brought to them throughout the last years. In particular, they want to thank Menelaos Karavelas and Elias Tsigaridas for their initial contributions.

The two generic models where initially developed as part of the EXACUS [BEH+05] project. However, the models are now fully integrated into the CGAL library, since also the relevant layers of EXACUS are now part of CGAL. The main authors for *CGAL::Algebraic_kernel_d_1<Coeff>* and *CGAL::Algebraic_kernel_d_2<Coeff>* are Michael Hemmer and Michael Kerber, respectively. Notwithstanding, the authors also want to emphasize the contribution of all authors of the EXACUS project, particularly the contribution of Arno Eigenwillig, Sebastian Limbach and Pavel Emeliyanenko.

The two univariate kernels that interface the library Rs [RS] were written by Luis Peñaranda and Sylvain Lazard. Both models interface the library Rs [RS] by Fabrice Rouillier. The authors want to thank Fabrice Rouillier and Elias Tsigaridas for strong support and many useful discussions that lead to the integration of Rs.

Concept

AlgebraicKernel_d_1

Definition

A model of the *AlgebraicKernel_d_1* concept is meant to provide the algebraic functionalities on univariate polynomials of general degree d.

Refines

CopyConstructible
Assignable

A model of *AlgebraicKernel_d_1* must provide:

Types

AlgebraicKernel_d_1:: Coefficient	A model of *IntegralDomain* and *RealEmbeddable*. *ExplicitInteroperable* with *AlgebraicKernel_d_1::Bound*.
AlgebraicKernel_d_1:: Polynomial_1	A univariate polynomial that is a model of *Polynomial_d*, where *CGAL::Polynomial_traits_d<Polynomial_1> ::Innermost_coefficient* is *AlgebraicKernel_d_1::Coefficient*.
AlgebraicKernel_d_1:: Algebraic_real_1	A type that is used to represent real roots of univariate polynomials. The type must be a model of *DefaultConstructible*, *CopyConstructible*, *Assignable* and *RealEmbeddable*.
AlgebraicKernel_d_1:: Bound	A type to represent upper and lower bounds of *AlgebraicKernel_d_1::Algebraic_real_1*. The type is *ExplicitInteroperable* with *AlgebraicKernel_d_1::Coefficient* and must be a model *IntegralDomain*, *RealEmbeddable* and dense in $\mathbb{R}$.
AlgebraicKernel_d_1:: size_type	Size type (unsigned integral type).
AlgebraicKernel_d_1:: Multiplicity_type	Multiplicity type (unsigned integral type).

Functors

AlgebraicKernel_d_1:: Construct_algebraic_real_1

A model of *AlgebraicKernel_d_1::ConstructAlgebraicReal_1*.

AlgebraicKernel_d_1:: Compute_polynomial_1	A model of *AlgebraicKernel_d_1::ComputePolynomial_1*.
AlgebraicKernel_d_1:: Isolate_1	A model of *AlgebraicKernel_d_1::Isolate_1*.

AlgebraicKernel_d_1:: Is_square_free_1	A model of *AlgebraicKernel_d_1::IsSquareFree_1*.
AlgebraicKernel_d_1:: Make_square_free_1	A model of *AlgebraicKernel_d_1::MakeSquareFree_1*.

AlgebraicKernel_d_1:: Square_free_factorize_1

A model of *AlgebraicKernel_d_1::SquareFreeFactorize_1*.

AlgebraicKernel_d_1:: Is_coprime_1	A model of *AlgebraicKernel_d_1::IsCoprime_1*.
AlgebraicKernel_d_1:: Make_coprime_1	A model of *AlgebraicKernel_d_1::MakeCoprime_1*.
AlgebraicKernel_d_1:: Solve_1	A model of *AlgebraicKernel_d_1::Solve_1*.
AlgebraicKernel_d_1:: Number_of_solutions_1	A model of *AlgebraicKernel_d_1::NumberOfSolutions_1*.
AlgebraicKernel_d_1:: Sign_at_1	A model of *AlgebraicKernel_d_1::SignAt_1*.
AlgebraicKernel_d_1:: Compare_1	A model of *AlgebraicKernel_d_1::Compare_1*.
AlgebraicKernel_d_1:: Bound_between_1	A model of *AlgebraicKernel_d_1::BoundBetween_1*.

AlgebraicKernel_d_1:: Approximate_absolute_1

A model of *AlgebraicKernel_d_1::ApproximateAbsolute_1*.

AlgebraicKernel_d_1:: Approximate_relative_1

A model of *AlgebraicKernel_d_1::ApproximateRelative_1*.

Operations

For each of the function objects above, there must exist a member function that requires no arguments and returns an instance of that function object. The name of the member function is the uncapitalized name of the type returned with the suffix *_object* appended. For example, for the function object *AlgebraicKernel_d_1::Bound_between_1* the following member function must exist:

AlgebraicKernel_d_1::Bound_between_1

ak_1.bound_between_1_object() const

Functor Concept

AlgebraicKernel_d_1::ConstructAlgebraicReal_1

Definition

Constructs *AlgebraicKernel_d_1::Algebraic_real_1*.

Refines

AdaptableFunctor

Types

typedef AlgebraicKernel_d_1::Algebraic_real_1 *result_type;*

Operations

result_type *fo(int a)* introduces an *AlgebraicKernel_d_1::Algebraic_real_1* initialized to a.

result_type *fo(AlgebraicKernel_d_1::Bound a)*

introduces an *AlgebraicKernel_d_1::Algebraic_real_1* initialized to a.

result_type *fo(AlgebraicKernel_d_1::Coefficient a)*

introduces an *AlgebraicKernel_d_1::Algebraic_real_1* initialized to a.

result_type *fo(AlgebraicKernel_d_1::Polynomial_1 p, AlgebraicKernel_d_1::size_type i)*

introduces an *AlgebraicKernel_d_1::Algebraic_real_1* initialized to the i-th real root of p. The index starts at 0, that is, p must have at least $i+1$ real roots.
Precondition: p is square free.
Precondition: p has at least $i+1$ real roots.

result_type *fo.operator()(AlgebraicKernel_d_1::Polynomial_1 p,
AlgebraicKernel_d_1::Bound l,
AlgebraicKernel_d_1::Bound u)*

introduces an *AlgebraicKernel_d_1::Algebraic_real_1* initialized to the only real root of p in the open interval $I = (l, u)$.
Precondition: $l < u$
Precondition: p is square free.
Precondition: p has exactly one real root in I
Precondition: p has no real root on ∂I

Functor
Concept

AlgebraicKernel_d_1::ComputePolynomial_1

Definition

Computes a square free univariate polynomial p, such that the given *AlgebraicKernel_d_1::Algebraic_real_1* is a root of p.

Refines

AdaptableUnaryFunction

Types

typedef AlgebraicKernel_d_1::Polynomial_1	*result_type;*
typedef AlgebraicKernel_d_1::Algebraic_real_1	*argument_type;*

Operations

result_type *fo(argument_type x)*

Computes a square free polynomial p, such that x is a real root of p.

See Also

AlgebraicKernel_d_1::Isolate_1 . . . . page 403

AlgebraicKernel_d_1::Isolate_1

Functor
Concept

Definition

Computes an open isolating interval for an *AlgebraicKernel_d_1::Algebraic_real_1* with respect to the real roots of a given univariate polynomial.

Refines

AdaptableBinaryFunction

Types

typedef std::pair<AlgebraicKernel_d_1::Bound,AlgebraicKernel_d_1::Bound> *result_type;*

typedef AlgebraicKernel_d_1::Algebraic_real_1 *first_argument_type;*

typedef AlgebraicKernel_d_1::Polynomial_1 *second_argument_type;*

Operations

result_type *fo(first_argument_type a, second_argument_type p)*

Computes an open isolating interval $I = (l, u)$ for a with respect to the real roots of p. It is not required that a is a root of p.
Postcondition: $a \in I$.
Postcondition: $p(x) \neq 0 | \forall x \in \bar{I} \backslash a$.

Functor
Concept

AlgebraicKernel_d_1::IsSquareFree_1

Definition

Computes whether the given univariate polynomial is square free.

Refines

AdaptableUnaryFunction

Types

typedef bool	*result_type;*
typedef AlgebraicKernel_d_1::Polynomial_1	*argument_type;*

A model of this type must provide:

Operations

result_type *fo(argument_type p)*

Returns true if p is square free.

See Also

AlgebraicKernel_d_1::MakeSquareFree_1 .... page 405

AlgebraicKernel_d_1::MakeSquareFree_1

Functor
Concept

Definition

Returns a square free part of a univariate polynomial.

Refines

AdaptableUnaryFunction

Types

typedef AlgebraicKernel_d_1::Polynomial_1	*result_type;*
typedef AlgebraicKernel_d_1::Polynomial_1	*argument_type;*

Operations

result_type *fo(argument_type p)*

Returns a square free part of p

See Also

AlgebraicKernel_d_1::IsSquareFree_1 . . . . page 404
AlgebraicKernel_d_1::SquareFreeFactorize_1 . . . . page 406

Functor
Concept

AlgebraicKernel_d_1::SquareFreeFactorize_1

Definition

Computes a square free factorization of an *AlgebraicKernel_d_1::Polynomial_1*.

A polynomial p is factored into square free and pairwise coprime non-constant factors q_i with multiplicities m_i and a constant factor c, such that $p = c \cdot q_1^{m_1} \cdot \ldots \cdot q_n^{m_n}$.

The factor multiplicity pairs $< q_i, m_i >$ are written to the given output iterator. The constant factor c is not computed.

Refines

Assignable
CopyConstructible

Operations

template < class OutputIterator >
OutputIterator *fo(AlgebraicKernel_d_1::Polynomial_1 p, OutputIterator res)*

Copies in the output iterator the factors of a square free factorization of p, with their multiplicity, as objects of type *std::pair<AlgebraicKernel_d_1::Polynomial_1, AlgebraicKernel_d_1::Multiplicity_type>*.

See Also

AlgebraicKernel_d_1::IsSquareFree_1 . . . . page 404
AlgebraicKernel_d_1::MakeSquareFree_1 . . . . page 405

AlgebraicKernel_d_1::IsCoprime_1

Functor
Concept

Definition

Determines whether a given pair of univariate polynomials p_1, p_2 is coprime, namely if $\deg(\gcd(p_1, p_2)) = 0$.

Refines

AdaptableBinaryFunction

Types

typedef bool	*result_type;*
typedef AlgebraicKernel_d_1::Polynomial_1	*first_argument_type;*
typedef AlgebraicKernel_d_1::Polynomial_1	*second_argument_type;*

Operations

result_type *fo(first_argument_type p1, second_argument_type p2)*

Returns true if *p1* and *p2* are coprime.

See Also

AlgebraicKernel_d_1::MakeCoprime_1 . . . . page 408

Functor Concept

AlgebraicKernel_d_1::MakeCoprime_1

Definition

Computes for a given pair of univariate polynomials p_1, p_2 their common part g up to a constant factor and coprime parts q_1, q_2 respectively.

That is, it computes g, q_1, q_2 such that:
$c_1 \cdot p_1 = g \cdot q_1$ for some constant c_1 and
$c_2 \cdot p_2 = g \cdot q_2$ for some constant c_2, such that q_1 and q_2 are coprime.

It returns true if p_1 and p_2 are already coprime.

Refines

AdaptableFunctor with five arguments

Types

typedef bool *result_type;*

Operations

result_type *fo.operator()(AlgebraicKernel_d_1::Polynomial_1 p1,*
AlgebraicKernel_d_1::Polynomial_1 p2,
AlgebraicKernel_d_1::Polynomial_1 & g,
AlgebraicKernel_d_1::Polynomial_1 & q1,
AlgebraicKernel_d_1::Polynomial_1 & q2)

Computes g, q_1, q_2 as described above.
Returns whether p_1 and p_2 where already coprime.

See Also

AlgebraicKernel_d_1::IsCoprime_1 . . . . page 407

AlgebraicKernel_d_1::Solve_1

Definition

Computes the real roots of a univariate polynomial.

Refines

Assignable
CopyConstructible

Operations

A model of this type must provide:

template < class OutputIterator >
OutputIterator *fo(AlgebraicKernel_d_1::Polynomial_1 p, OutputIterator res)*

Computes all real solutions of p with multiplicity, and copies them as objects of type *std::pair<AlgebraicKernel_d_1::Algebraic_real_1, AlgebraicKernel_d_1::Multiplicity_type>* in *res*.

template < class OutputIterator >
OutputIterator *fo.operator()(AlgebraicKernel_d_1::Polynomial_1 p,*
bool known_to_be_square_free,
OutputIterator res)

Computes all real solutions of p, and copies them as objects of type *AlgebraicKernel_d_1::Algebraic_real_1* in *res*. The bool *known_to_be_square_free* indicates whether p is known to be square free. Each root, though it might be a multiple root, is reported only once.

template < class OutputIterator >
OutputIterator *fo.operator()(AlgebraicKernel_d_1::Polynomial_1 p,*
AlgebraicKernel_d_1::Bound l,
AlgebraicKernel_d_1::Bound u,
OutputIterator res)

Computes all real solutions of p in the closed interval $[l,u]$ with multiplicity, and copies them as objects of type *std::pair<AlgebraicKernel_d_1::Algebraic_real_1, AlgebraicKernel_d_1::Multiplicity_type>* in *res*.

template < class OutputIterator >
OutputIterator *fo.operator()(AlgebraicKernel_d_1::Polynomial_1 p,*
bool known_to_be_square_free,
AlgebraicKernel_d_1::Bound l,
AlgebraicKernel_d_1::Bound u,

OutputIterator res)

Computes all real solutions of p in the closed interval $[l,u]$, and copies them as objects of type *AlgebraicKernel_d_1::Algebraic_real_1* in *res*. The *bool known_to_be_square_free* indicates whether p is known to be square free. Each root, though it might be a multiple root, is reported only once.

See Also

AlgebraicKernel_d_1::NumberOfSolutions_1

Functor
Concept

Definition

Computes the number of real solutions of the given univariate polynomial.

Refines

AdaptableUnaryFunction

Types

typedef AlgebraicKernel_d_1::size_type	*result_type;*
typedef AlgebraicKernel_d_1::Polynomial_1	*argument_type;*

A model of this type must provide:

Operations

result_type   *fo(argument_type p)*

Returns the number of real solutions of p.
Precondition: p is square free.

See Also

Functor Concept

AlgebraicKernel_d_1::SignAt_1

Definition

Computes the sign of a univariate polynomial *AlgebraicKernel_d_1::Polynomial_1* at a real value of type *AlgebraicKernel_d_1::Algebraic_real_1*.

Refines

AdaptableBinaryFunction

Types

AlgebraicKernel_d_1::SignAt_1:: result_type	Type convertible to *CGAL::Sign*
typedef AlgebraicKernel_d_1::Polynomial_1	*first_argument_type;*
typedef AlgebraicKernel_d_1::Algebraic_real_1	*second_argument_type;*

Operations

result_type *fo(first_argument_type p, second_argument_type x)*

Computes the sign of p at x.

See Also

AlgebraicKernel_d_1::IsZeroAt_1 . . . . page 413

AlgebraicKernel_d_1::IsZeroAt_1

Functor Concept

Definition

Computes whether an *AlgebraicKernel_d_1::Polynomial_1* is zero at a given *AlgebraicKernel_d_1::Algebraic_real_1*.

Refines

AdaptableBinaryFunction

Types

AlgebraicKernel_d_1::IsZeroAt_1:: result_type

Type convertible to *bool*

typedef AlgebraicKernel_d_1::Polynomial_1	*first_argument_type;*
typedef AlgebraicKernel_d_1::Algebraic_real_1	*second_argument_type;*

Operations

result_type *fo(first_argument_type p, second_argument_type x)*

Computes whether p is zero at x.

See Also

AlgebraicKernel_d_1::SignAt_1 . . . . page 412

Functor
Concept

AlgebraicKernel_d_1::Compare_1

Definition

Compares *AlgebraicKernel_d_1::Algebraic_real_1* values.

Refines

AdaptableBinaryFunction

Types

AlgebraicKernel_d_1::Compare_1:: result_type

Type convertible to *CGAL::Comparison_result*

typedef AlgebraicKernel_d_1::Algebraic_real_1 *first_argument_type;*
typedef AlgebraicKernel_d_1::Algebraic_real_1 *second_argument_type;*

Operations

The following operators and their symmetric counterparts are required:

result_type *fo(AlgebraicKernel_d_1::Algebraic_real_1 a, AlgebraicKernel_d_1::Algebraic_real_1 b)*

Compares *a* and *b*.

result_type *fo(AlgebraicKernel_d_1::Algebraic_real_1 a, int b)*

Compares *a* and *b*.

result_type *fo(AlgebraicKernel_d_1::Algebraic_real_1 a, AlgebraicKernel_d_1::Bound b)*

Compares *a* and *b*.

result_type *fo(AlgebraicKernel_d_1::Algebraic_real_1 a, AlgebraicKernel_d_1::Coefficient b)*

Compares *a* and *b*.

AlgebraicKernel_d_1::BoundBetween_1

Functor
Concept

Definition

Computes a number of type *AlgebraicKernel_d_1::Bound* in-between two *AlgebraicKernel_d_1::Algebraic_real_1* values.

Refines

AdaptableBinaryFunction

Types

typedef AlgebraicKernel_d_1::Bound	*result_type;*
typedef AlgebraicKernel_d_1::Algebraic_real_1	*first_argument_type;*
typedef AlgebraicKernel_d_1::Algebraic_real_1	*second_argument_type;*

Operations

result_type *fo(first_argument_type a, second_argument_type b)*

Computes a value r, which is between a and b.

Precondition: $a \neq b$
Postcondition: $r > min(a,b)$
Postcondition: $r < max(a,b)$

Functor
Concept

AlgebraicKernel_d_1::ApproximateAbsolute_1

Definition

A model of AlgebraicKernel_d_1::ApproximateAbsolute_1 is an *AdaptableBinaryFunction* that computes an approximation of an *AlgebraicKernel_d_1::Algebraic_real_1* value with respect to a given absolute precision.

Refines

AdaptableBinaryFunction

Types

typedef std::pair<AlgebraicKernel_d_1::Bound, AlgebraicKernel_d_1::Bound>

result_type;

typedef AlgebraicKernel_d_1::Algebraic_real_1 *first_argument_type;*
typedef int *second_argument_type;*

Operations

result_type *fo(first_argument_type x, second_argument_type a)*

The function computes a pair p of *AlgebraicKernel_d_1::Bound*, where $p.first$ represents the lower approximation and $p.second$ represents the upper approximation. The pair p approximates the given value x with respect to the given absolute precision a.
Postcondition: $p.first <= x$
Postcondition: $x <= p.second$
Postcondition: $(x - p.first) <= 2^{-a}$
Postcondition: $(p.second - x) <= 2^{-a}$

#include <CGAL/Algebraic_kernel_d_1.h>

Definition

The class represents an algebraic real root by a square free polynomial and an isolating interval that uniquely defines the root. The template argument *Coeff* determines the coefficient type of the kernel, which is also the coefficient type of the supported polynomials.

Currently, the following coefficient types are supported:
– *Gmpz*, *Gmpq*, (requires configuration with external libraries GMP, MPFR and MPFI)
– *CORE::BigInt*, *CORE::BigRat*, (requires configuration with external library GMP)
– *leda_integer*, *leda_rational*. (requires configuration with external library LEDA)

advanced

The template argument type can also be set to *Sqrt_extension<NT,ROOT>*, where *NT* is one of the types listed above. *ROOT* should be one of the integer types. See also the documentation of *Sqrt_extension<NT,ROOT>*.

advanced

The current method to isolate roots is the bitstream Descartes method presented in [Eig08]. The used method to refine the approximation of an algebraic real root is a slightly modified (filtered) version of the one presented in [Abb]. The method has quadratic convergence.

Is Model for the Concepts

AlgebraicKernel_d_1.

Types

Algebraic_kernel_d_1<Coeff>:: Coefficient — Same type as the template argument *Coeff*.

Algebraic_kernel_d_1<Coeff>:: Polynomial_1 — A model of *AlgebraicKernel_d_1::Polynomial_1*.

Algebraic_kernel_d_1<Coeff>:: Algebraic_real_1

A model of *AlgebraicKernel_d_1::AlgebraicReal_1*.

Algebraic_kernel_d_1<Coeff>:: Bound — The choice of *Coeff* also determines the provided bound, type. In case of *Coeff* is:
– *Gmpz* or *Gmpq* this is *Gmpq*,
– *CORE::BigInt* or *CORE::BigInt* this is *CORE::BigRat*,
– *leda_integer* or *leda_integer* this is *leda_rational*.

Algebraic_kernel_d_1<Coeff>:: Multiplicity_type

The multiplicity type is *int*.

Class

CGAL::Algebraic_kernel_rs_gmpz_d_1

#include <CGAL/Algebraic_kernel_rs_gmpz_d_1.h>

Definition

This univariate algebraic kernel uses the Rs library to perform integer univariate polynomial root isolation. It is a model of the *AlgebraicKernel_d_1* concept.

Types

Algebraic_kernel_rs_gmpz_d_1:: Coefficient — It is a typedef to *CGAL::Gmpz*.

Algebraic_kernel_rs_gmpz_d_1:: Polynomial_1

It is defined as *CGAL::Polynomial<CGAL::Gmpz>*.

Algebraic_kernel_rs_gmpz_d_1:: Algebraic_real_1

Type that represents the real roots of integer univariate polynomials, containing a pointer to the polynomial of which the represented algebraic number is root and and a *CGAL::Gmpfi* isolating interval.

Algebraic_kernel_rs_gmpz_d_1:: Bound — Since the isolating intervals of the roots have type *CGAL::Gmpfi*, the bounds have type *CGAL::Gmpfr*.

Algebraic_kernel_rs_gmpz_d_1:: Multiplicity_type

The multiplicity is an *int*.

Is Model for the Concepts

AlgebraicKernel_d_1.

Algebraic_kernel_rs_gmpz_d_1

CGAL::Algebraic_kernel_rs_gmpq_d_1

#include <CGAL/Algebraic_kernel_rs_gmpq_d_1.h>

Class

Definition

This univariate algebraic kernel uses the Rs library to perform rational univariate polynomial root isolation. It is a model of the *AlgebraicKernel_d_1* concept. Due to the fact that RS can only isolate integer polynomials, the operations of this kernel have the overhead of converting the polynomials to integer.

Types

Algebraic_kernel_rs_gmpq_d_1:: Coefficient It is a typedef to *CGAL::Gmpq*.

Algebraic_kernel_rs_gmpq_d_1:: Polynomial_1

It is defined as *CGAL::Polynomial<CGAL::Gmpq>*.

Algebraic_kernel_rs_gmpq_d_1:: Algebraic_real_1

Type that represents the real roots of integer univariate polynomials, containing a pointer to the polynomial of which the represented algebraic number is root and and a *CGAL::Gmpfi* isolating interval.

Algebraic_kernel_rs_gmpq_d_1:: Bound Since the isolating intervals of the roots have type *CGAL::Gmpfi*, the bounds have type *CGAL::Gmpfr*.

Algebraic_kernel_rs_gmpq_d_1:: Multiplicity_type

The multiplicity is an *int*.

A model of *AlgebraicKernel_d_2::ApproximateRelativeX_2*.

AlgebraicKernel_d_2:: Approximate_relative_y_2

A model of *AlgebraicKernel_d_2::ApproximateRelativeY_2*.

Operations

For each of the function objects above, there must exist a member function that requires no arguments and returns an instance of that function object. The name of the member function is the uncapitalized name of the type returned with the suffix *_object* appended. For example, for the function object *AlgebraicKernel_d_2::Bound_betweenX_2* the following member function must exist:

AlgebraicKernel_d_2::Bound_between_x_2

ak_2.bound_between_x_2_object() const

Concept

AlgebraicKernel_d_2::ConstructAlgebraicReal_2

Definition

Constructs an *AlgebraicKernel_d_2::Algebraic_real_2*.

Refines

AdaptableFunctor

Types

typedef AlgebraicKernel_d_2::Algebraic_real_2 *result_type;*

Operations

result_type *fo(int x, int y)* introduces an *AlgebraicKernel_d_2::Algebraic_real_2* initialized to (x, y).

result_type *fo(AlgebraicKernel_d_2::Bound x, AlgebraicKernel_d_2::Bound y)*

introduces an *AlgebraicKernel_d_2::Algebraic_real_2* initialized to (x, y).

result_type *fo(AlgebraicKernel_d_2::Coefficient x, AlgebraicKernel_d_2::Coefficient y)*

introduces an *AlgebraicKernel_d_2::Algebraic_real_2* initialized to (x, y).

result_type *fo(AlgebraicKernel_d_2::Algebraic_real_1 x, AlgebraicKernel_d_2::Algebraic_real_1 y)*

introduces an *AlgebraicKernel_d_2::Algebraic_real_2* initialized to (x, y).

result_type *fo.operator()(AlgebraicKernel_d_2::Polynomial_2 f,*
AlgebraicKernel_d_2::Polynomial_2 g,
AlgebraicKernel_d_2::size_type i)

introduces an *AlgebraicKernel_d_2::Algebraic_real_2* initialized to the i-th real common solution of f and g, with respect to xy-lexicographic order. The index starts at 0, that is, the system must have at least $i+1$ real solutions.
Precondition: f is square free.
Precondition: g is square free.
Precondition: f and g are coprime.

result_type *fo.operator()(AlgebraicKernel_d_2::Polynomial_2 f,*
AlgebraicKernel_d_2::Polynomial_2 g,
AlgebraicKernel_d_2::Bound x_l,
AlgebraicKernel_d_2::Bound x_u,
AlgebraicKernel_d_2::Bound y_l,
AlgebraicKernel_d_2::Bound y_u)

introduces an *AlgebraicKernel_d_2::Algebraic_real_2* initialized to the only real intersection of f and g in the open box $B = (x_l, x_u) \times (y_l, y_u)$.
Precondition: $x_l < x_u$
Precondition: $y_l < y_u$
Precondition: f is square free.
Precondition: g is square free.
Precondition: f and g are coprime.
Precondition: f and g have exactly one common solution in B
Precondition: f and g have no common solution on ∂B

AlgebraicKernel_d_2::ApproximateAbsoluteX_2

Functor
Concept

Definition

A model of AlgebraicKernel_d_2::ApproximateAbsoluteX_2 is an *AdaptableBinaryFunction* that computes an approximation of the x-coordinate of an *AlgebraicKernel_d_2::Algebraic_real_2* value with respect to a given absolute precision.

Refines

AdaptableBinaryFunction

Types

typedef std::pair<AlgebraicKernel_d_1::Bound, AlgebraicKernel_d_1::Bound>

	result_type;
typedef AlgebraicKernel_d_2::Algebraic_real_2	*first_argument_type;*
typedef int	*second_argument_type;*

Operations

result_type *fo(first_argument_type v, second_argument_type a)*

The function computes a pair p of *AlgebraicKernel_d_1::Bound*, where $p.first$ represents the lower approximation and $p.second$ represents the upper approximation. The pair p approximates the x-coordinate x of the *AlgebraicKernel_d_2::Algebraic_real_2* value v with respect to the absolute precision a.
Postcondition: $p.first <= x$
Postcondition: $x <= p.second$
Postcondition: $(x - p.first) <= 2^{-a}$
Postcondition: $(p.second - x) <= 2^{-a}$

CGAL::Algebraic_kernel_d_2<Coeff>

#include <CGAL/Algebraic_kernel_d_2.h>

Definition

This class is based on an algorithm computing a geometric-topological analysis of a single curve [EKW07] and of a pair of curves [EK08]. The main idea behind both analyses is to compute the critical x-coordinates of curves and curve pairs by projection (resultants), and compute additional information about the critical fibers using subresultants and Sturm-Habicht sequences [GVRLR98]. With that information, the fiber at critical x-coordinates is computed by a variant of the Bitstream Descartes method. See also [Ker09] for a comprehensive description of these techniques.

A point p of type *Algebraic_real_2* is represented by its x-coordinate x_0 (as described in the *Algebraic_kernel_d_1* paragraph above), an algebraic curve where p lies on, and an integer i, denoting that p is the ith point in the fiber at x_0, counted from the bottom (ignoring a possible vertical line at x_0). This determines the point uniquely, but the y-coordinate is not stored internally in terms of an *Algebraic_real_1* object. Querying such a representation by calling *Compute_y_2* is a time-consuming step, and should be avoided for efficiency reasons if possible. Note that this representation is not exposed in the interface.

The template argument *Coeff* determines the coefficient type of the kernel, which is also the innermost coefficient type of the supported polynomials.

Currently, the following coefficient types are supported:
– *Gmpz*, *Gmpq*, (requires configuration with external libraries GMP, MPFR and MPFI)
– *CORE::BigInt*, *CORE::BigRat*, (requires configuration with external library GMP)
– *leda_integer*, *leda_rational*. (requires configuration with external library LEDA)

advanced

The template argument type can also be set to *Sqrt_extension<NT,ROOT>*, where *NT* is one of the types listed above. *ROOT* should be one of the integer types. See also the documentation of *Sqrt_extension<NT,ROOT>*.

Monotone and Sorted Matrix Search

Michael Hoffmann

CGAL::monotone_matrix_search and *CGAL::sorted_matrix_search* are techniques that deal with the problem of efficiently finding largest entries in matrices with certain structural properties. Many concrete problems can be modelled as matrix search problems, and for some of them we provide explicit solutions that allow you to solve them without knowing about the matrix search technique. Examples are, the computation of all furthest neighbors for the vertices of a convex polygon, maximal k-gons inscribed into a planar point set, and computing rectangular p-centers.

Monotone and Sorted Matrix Search Reference Manual

Michael Hoffmann

This chapter describes concepts, classes, and functions for monotone and sorted matrix search.

Assertions

The optimization code uses infix *OPTIMISATION* in the assertions, e.g. defining the compiler flag *CGAL_OPTIMISATION_NO_PRECONDITIONS* switches precondition checking off, cf. Section 2.8.

Function

CGAL::monotone_matrix_search

advanced

Definition

The function *monotone_matrix_search* computes the maxima for all rows of a totally monotone matrix.

More precisely, monotony for matrices is defined as follows.

Let K be a totally ordered set, $M \in K^{(n,m)}$ a matrix over K and for $0 \leq i < n$:

$$rmax_M(i) :\in \left\{ \min_{0 \leq j < m} j \;\middle|\; M[i,j] = \max_{0 \leq k < m} M[i,k] \right\}$$

the (leftmost) column containing the maximum entry in row i. M is called monotone, iff

$$\forall 0 \leq i_1 < i_2 < n \,:\, rmax_M(i_1) \leq rmax_M(i_2)\,.$$

M is totally monotone, iff all of its submatrices are monotone (or equivalently: iff all 2×2 submatrices are monotone).

#include <CGAL/monotone_matrix_search.h>

```
template < class Matrix, class RandomAccessIC, class Compare_strictly >
void    monotone_matrix_search(
            Matrix m,
            RandomAccessIC t,
            Compare_strictly compare_strictly = less< Matrix::Value >())
```

computes the maximum (as specified by *compare_strictly*) entry for each row of m and writes the corresponding column to t, i.e. *t[i]* is set to the index of the column containing the maximum element in row i. The maximum m_r of a row r is the leftmost element for which $compare\_strictly(m_r, x)$ is false for all elements x in r.

Precondition: t points to a structure of size at least *m.number_of_rows()*

Requirement:

1. *Matrix* is a model for *MonotoneMatrixSearchTraits*.
2. Value type of *RandomAccessIC* is *int*.
3. If *compare_strictly* is defined, it is an adaptable binary function: *Matrix::Value* $\times$ *Matrix::Value* $\rightarrow$ *bool* describing a strict (non-reflexive) total ordering on *Matrix::Value*.

Implementation

The implementation uses an algorithm by Aggarwal et al.[AKM+87]. The runtime is linear in the number of rows and columns of the matrix.

advanced

Class

CGAL::Dynamic_matrix<M>

advanced

Definition

The class *Dynamic_matrix<M>* is an adaptor for an arbitrary matrix class *M* to provide the dynamic operations needed for monotone matrix search.

Requirements

M is a model for *BasicMatrix*.

#include <CGAL/Dynamic_matrix.h>

Is Model for the Concepts

MonotoneMatrixSearchTraits . . . . page 462
BasicMatrix . . . . page 464

Creation

Dynamic_matrix<M> d(M m);

initializes *d* to *m*. *m* is *not* copied, we only store a reference.

Operations

int *d.number_of_columns() const*

returns the number of columns.

int *d.number_of_rows() const*

returns the number of rows.

Entry *d(int row, int column)*

returns the entry at position (*row*, *column*).
Precondition:
$0 \leq row < number\_of\_rows()$ and
$0 \leq column < number\_of\_columns()$.

void *d.replace_column(int old, int new)*

replace column *old* with column number *new*.
Precondition:
$0 \leq old, new < number\_of\_columns()$.

*Matrix** *d.extract_all_even_rows() const*

returns a new Matrix consisting of all rows of d with even index, (i.e. first row is row 0 of d, second row is row 2 of d etc.).
Precondition: *number_of_rows()* > 0.

void *d.shrink_to_quadratic_size()*

deletes the rightmost columns, such that d becomes quadratic.
Precondition:
number_of_columns() $\geq$ *number_of_rows()*.
Postcondition:
number_of_rows() $==$ *number_of_columns()*.

See Also

CGAL::monotone_matrix_search . . . . page 458
MonotoneMatrixSearchTraits . . . . page 462
BasicMatrix . . . . page 464

Implementation

All operations take constant time except for *extract_all_even_rows* which needs time linear in the number of rows.

advanced

MonotoneMatrixSearchTraits

advanced

Definition

The concept MonotoneMatrixSearchTraits is a refinement of *BasicMatrix* and defines types and operations needed to compute the maxima for all rows of a totally monotone matrix using the function *monotone_matrix_search*.

Types

MonotoneMatrixSearchTraits:: Value The type of a matrix entry.

Operations

int *m.number_of_columns() const*

returns the number of columns.

int *m.number_of_rows() const*

returns the number of rows.

Entry *m.operator()(int row, int column) const*

returns the entry at position (*row*, *column*).
Precondition:
$0 \leq row < number\_of\_rows()$ and
$0 \leq column < number\_of\_columns()$.

void *m.replace_column(int old, int new)*

replace column *old* with column number *new*.
Precondition:
$0 \leq old, new < number\_of\_columns()$.

*Matrix** *m.extract_all_even_rows() const*

returns a new Matrix consisting of all rows of *m* with even index, (i.e. first row is row 0 of *m*, second row is row 2 of *m* etc.).
Precondition: $number\_of\_rows() > 0$.

void *m.shrink_to_quadratic_size()*

deletes the rightmost columns, such that *m* becomes quadratic.
Precondition:
number_of_columns() $\geq$ *number_of_rows()*.
Postcondition:
number_of_rows() == *number_of_columns()*.

Notes

- For the sake of efficiency (and in order to achieve the time bounds claimed for *monotone_matrix_search*), all these operations have to be realized in constant time – except for *extract_all_even_rows* which may take linear time.
- There is an adaptor *Dynamic_matrix* that can be used to add most of the functionality described above to arbitrary matrix classes.

advanced

CGAL::sorted_matrix_search

advanced

Definition

The function *sorted_matrix_search* selects the smallest entry in a set of sorted matrices that fulfills a certain feasibility criterion.

More exactly, a matrix $M = (m_{ij}) \in S^{r \times l}$ (over a totally ordered set S) is sorted, iff

$$\forall 1 \leq i \leq r,\ 1 \leq j < l\ :\ m_{ij} \leq m_{i(j+1)}\ \ \mathit{and}$$
$$\forall 1 \leq i < r,\ 1 \leq j \leq l\ :\ m_{ij} \leq m_{(i+1)j}\ \ .$$

Now let $\mathcal{M}$ be a set of n sorted matrices over S and f be a monotone predicate on S, i.e.

$$f\ :\ S \longrightarrow \mathit{bool} \quad \text{with} \quad f(r) \implies \forall t \in S, t > r\ :\ f(t)\ .$$

If we assume there is any feasible element in one of the matrices in $\mathcal{M}$, there certainly is a smallest such element. This is the one we are searching for.

The feasibility test as well as some other parameters can (and have to) be customized through a traits class.

#include <CGAL/sorted_matrix_search.h>

template < class RandomAccessIterator, class Traits >
Traits::Value *sorted_matrix_search(RandomAccessIterator f, RandomAccessIterator l, Traits t)*

returns the element x in one of the sorted matrices from the range $[f, l)$, for which *t.is_feasible(x)* is true and *t.compare(x, y)* is true for all other y values from any matrix for which *t.is_feasible(y)* is true.

Precondition:

1. All matrices in $[f, l)$ are sorted according to *Traits::compare_non_strictly*.
2. There is at least one entry x in a matrix $M \in [f, l)$ for which *Traits::is_feasible(x)* is true.

Requirement:

1. *Traits* is a model for *SortedMatrixSearchTraits*.
2. Value type of *RandomAccessIterator* is *Traits::Matrix*.

See Also

SortedMatrixSearchTraits . . . . page 470

Function

Implementation

The implementation uses an algorithm by Frederickson and Johnson[FJ83, FJ84] and runs in $O(n \cdot k + f \cdot \log(n \cdot k))$, where n is the number of input matrices, k denotes the maximal dimension of any input matrix and f the time needed for one feasibility test.

Example

In the following program we build a random vector $a = (a_i)_{i=1,\ldots,5}$ (elements drawn uniformly from $\{0,\ldots,99\}$) and construct a Cartesian matrix M containing as elements all sums $a_i + a_j$, $i, j \in \{1,\ldots,5\}$. If a is sorted, M is sorted as well. So we can apply *sorted_matrix_search* to compute the upper bound for the maximal entry of a in M.

```
#include <CGAL/Random.h>
#include <CGAL/Cartesian_matrix.h>
#include <CGAL/sorted_matrix_search.h>
#include <vector>
#include <algorithm>
#include <iterator>
#include <functional>

typedef int                                           Value;
typedef std::vector<Value>                            Vector;
typedef Vector::iterator                              Value_iterator;
typedef std::vector<Vector>                           Vector_cont;
typedef CGAL::Cartesian_matrix<std::plus<int>,
                               Value_iterator,
                               Value_iterator>  Matrix;

int main()
{
  // set of vectors the matrices are build from:
  Vector_cont vectors;

  // generate a random vector and sort it:
  Vector a;
  const int n = 5;
  for (int i = 0; i < n; ++i)
    a.push_back(CGAL::default_random(100));
  std::sort(a.begin(), a.end());
  std::cout << "a = ( ";
  std::copy(a.begin(), a.end(), std::ostream_iterator<int>(std::cout,"
   "));
  std::cout << ")\n";

  // build a Cartesian matrix from a:
  Matrix M(a.begin(), a.end(), a.begin(), a.end());

  // search for an upper bound for max(a):
  Value bound = a[n-1];
  Value upper_bound =
  CGAL::sorted_matrix_search(
    &M, &M + 1,
    CGAL::sorted_matrix_search_traits_adaptor(
```

```
      std::bind2nd(std::greater_equal<Value>(), bound), M));
  std::cout << "Upper bound for " << bound << " is "
            << upper_bound << "." << std::endl;

  return 0;
}
```

Class

CGAL::Sorted_matrix_search_traits_adaptor<F,M>

advanced

#include <CGAL/Sorted_matrix_search_traits_adaptor.h>

Definition

The class *Sorted_matrix_search_traits_adaptor<F,M>* can be used as an adaptor to create sorted matrix search traits classes for arbitrary feasibility test and matrix classes F resp. M.

Is Model for the Concepts

SortedMatrixSearchTraits . . . . page 470

Requirements

1. M is a model for *BasicMatrix and*
2. F defines a copy constructor and a monotone *bool operator()(const Value&)*.

Creation

Sorted_matrix_search_traits_adaptor<F,M> t(const F& m);

initializes t to use m for feasibility testing.

Types

Sorted_matrix_search_traits_adaptor<F,M>:: Matrix

typedef to M.

Sorted_matrix_search_traits_adaptor<F,M>:: Value

typedef to *Matrix::Value*.

Sorted_matrix_search_traits_adaptor<F,M>:: Compare_strictly

typedef to *std::less<Value>*.

Sorted_matrix_search_traits_adaptor<F,M>:: Compare_non_strictly

typedef to *std::less_equal<Value>*.

Operations

Compare_strictly *t.compare_strictly() const*

returns the *Compare_strictly* object to be used for the search.

Compare_non_strictly

t.compare_non_strictly() const

returns the *Compare_non_strictly* object to be used for the search.

bool *t.is_feasible(const Value& a)*

uses the feasibility test given during creation.

advanced

Concept

SortedMatrixSearchTraits

advanced

Definition

The concept SortedMatrixSearchTraits defines types and operations needed to compute the smallest entry in a set of sorted matrices that fulfills a certain feasibility criterion using the function *sorted_matrix_search*.

Types

SortedMatrixSearchTraits:: Matrix — The class used for representing matrices. It has to be a model for *BasicMatrix*.

typedef Matrix::Value

Value; — The class used for representing the matrix elements.

SortedMatrixSearchTraits:: Compare_strictly — An adaptable binary function class: $Value \times Value \rightarrow bool$ defining a non-reflexive total order on *Value*. This determines the direction of the search.

SortedMatrixSearchTraits:: Compare_non_strictly

An adaptable binary function class: $Value \times Value \rightarrow bool$ defining the reflexive total order on *Value* corresponding to *Compare_strictly*.

Operations

Compare_strictly *t.compare_strictly() const*

returns the *Compare_strictly* object to be used for the search.

Compare_non_strictly

t.compare_non_strictly() const

returns the *Compare_non_strictly* object to be used for the search.

bool *t.is_feasible(const Value& a)*

The predicate to determine whether an element *a* is feasible. It has to be monotone in the sense that *compare(a, b)* and *is_feasible(a)* imply *is_feasible(b)*.

Chapter 10

Linear and Quadratic Programming Solver

Kaspar Fischer, Bernd Gärtner, Sven Schönherr, and Frans Wessendorp

Contents

10.1 Which Programs can be Solved?

This package lets you solve *convex quadratic programs* of the general form

$$\begin{array}{lll} \text{(QP)} & \text{minimize} & \mathbf{x}^T D\mathbf{x}+\mathbf{c}^T\mathbf{x}+c_0 \\ & \text{subject to} & A\mathbf{x} \gtreqless \mathbf{b}, \\ & & \mathbf{l}\leq \mathbf{x}\leq \mathbf{u} \end{array}$$

in n real variables $\mathbf{x}=(x_0,\ldots,x_{n-1})$. Here,

- A is an $m\times n$ matrix (the constraint matrix),
- $\mathbf{b}$ is an m-dimensional vector (the right-hand side),
- $\gtreqless$ is an m-dimensional vector of relations from $\{\leq,=,\geq\}$,
- $\mathbf{l}$ is an n-dimensional vector of lower bounds for $\mathbf{x}$, where $l_j\in\mathbb{R}\cup\{-\infty\}$ for all j
- $\mathbf{u}$ is an n-dimensional vector of upper bounds for $\mathbf{x}$, where $u_j\in\mathbb{R}\cup\{\infty\}$ for all j
- D is a symmetric positive-semidefinite $n\times n$ matrix (the quadratic objective function),
- $\mathbf{c}$ is an n-dimensional vector (the linear objective function), and
- c_0 is a constant.

If $D=0$, the program (QP) is actually a *linear program*. Section 10.2.2 on robustness briefly discusses the case of D not being positive-semidefinite and therefore not defining a convex program.

Solving the program means to find an n-vector $\mathbf{x}^*$ such that $A\mathbf{x}^* \gtreqless \mathbf{b}, \mathbf{l}\leq\mathbf{x}^*\leq\mathbf{u}$ (a *feasible solution*), and with the smallest objective function value ${\mathbf{x}^*}^T D\mathbf{x}^*+\mathbf{c}^T\mathbf{x}^*+c_0$ among all feasible solutions.

There might be no feasible solution at all, in which case the quadratic program is *infeasible*, or there might be feasible solutions of arbitrarily small objective function value, in which case the program is *unbounded*.

10.2 Design, Efficiency, and Robustness

The design of the package is quite simple. The linear or quadratic program to be solved is supplied in form of an object of a class that is a model of the concept *QuadraticProgram* (or some specialized other concepts, e.g. for linear programs). CGAL provides a number of easy-to-use and flexible models, see Section 10.3 below. The input data may be of any given number type, such as *double*, *int*, or any exact type.

Then the program is solved using the function *solve_quadratic_program* (or some specialized other functions, e.g. for linear programs). For this, you also have to provide a suitable *exact* number type *ET* used in the solution process. In case of input type *double*, solution methods that use floating-point-filtering are chosen by default for certain programs (in some cases, this is not appropriate, and the default should be changed; see Section 10.8 for details).

The output of this is an object of *Quadratic_program_solution<ET>* which you can in turn query for various things: what is the status of the program (optimally solved, infeasible, or unbounded?), what are the values of the optimal solution $\mathbf{x}^*$, what is the associated objective function value, etc.

You can in particular get *certificates* for the solution. In short, these are proofs that the output is correct. Thus, if you don't believe in the solution (whether it says "optimally solved", "infeasible", or "unbounded"), you can verify it yourself by using the certificates. Section 10.7 says more about this.

10.2.1 Efficiency

The concept *QuadraticProgram* (as well as the other specialized ones) require a *dense interface* of the program, in terms of *random-access iterators* over the matrices and vectors of (QP). Zero entries therefore play no special role and are treated like all other entries by the interface.

This has mainly historical reasons: the original motivation behind this package was low-dimensional geometric optimization where a dense representation is appropriate and efficient. In fact, the CGAL packages *Min_annulus_d<Traits>* and *Polytope_distance_d<Traits>* internally use the linear and quadratic programming solver.

As a user, however, you don't necessarily have to provide a dense *representation* of your program. You do not pass vectors or matrices to the solution functions, but rather specify the vectors and matrices through iterators. The iterator abstraction easily allows to build models that convert a sparse representation into a dense interface. The predefined models *Quadratic_program<NT>* and *Quadratic_program_from_mps<NT>* do exactly this; in using them, you can forget about the dense interface.

Nevertheless, if you care about efficiency, you cannot completely ignore the issue. If you think about a quadratic program in n variables and m constraints, its dense interface has $\Theta(n^2+mn)$ entries, even if actually very few of them are nonzero. This has consequences for the complexity of the internal computations. In fact, a single iteration of the solution process has complexity at least $\Omega(mn)$, since usually, all entries of the matrix A are accessed. This implies that problems where $\min(n,m)$ is large cannot be solved efficiently, even if the number of nonzero entries in the problem description is very small.

We can actually be quite precise about performance, in terms of the following parameters.

n	:	the number of variables (or columns of A),
m	:	the number of constraints (or rows of A),
e	:	the number of equality constraints,
r	:	the rank of the quadratic objective function matrix D.

The time required to solve the problems is in most cases linear in $\max(n,m)$, but with a factor heavily depending on $\min(n,e)+r$. Therefore, the solver will be efficient only if $\min(n,e)+r$ is small.

Here are the scenarios in which this applies:

- Quadratic programs with a small number of variables, but possibly a large number of inequality constraints,

- Linear programs with a small number of equality constraints but possibly a large number of variables,

- Quadratic programs with a small number of equality constraints and D of small rank, but possibly with a large number of variables.

How small is small? If $\min(n,e)+r$ is up to 10, the solver will probably be very fast, even if $\max(n,m)$ goes into the millions. If $\min(n,m)+r$ is up to a few hundreds, you may still get a solution within reasonable time, depending on the problem characteristics.

If you have a problem where both n and e are well above $1,000$, say, then chances are high that CGAL cannot solve it within reasonable time.

10.2.2 Robustness

Given that you use an *exact number type* in the function *solve_quadratic_program* (or in the other, specialized solution functions), the solver will give you *exact rational output*, for *every* convex quadratic program. It may fail to compute a solution only if

1. The quadratic program is too large (see the previous subsection on efficiency).
2. The quadratic objective function matrix D is not positive-semidefinite (see the discussion below).
3. The floating-point filter used by default for certain programs and input type *double* fails due to a *double* exponent overflow. This happens in rare cases only, and it does not pay off to sacrifice the efficiency of the filtered approach in order to cope with these rare cases. There are means, however, to avoid such problems by switching to a slower non-filtered variant, see Section 10.8.1.
4. The solver internally cycles. This also happens in rare cases only. However, if you have a hunch that the solver cycles on your problem, there are means to switch to a slower variant that is guaranteed not to cycle, see Section 10.8.2.

The second item merits special attention. First, you may ask why the solver does not check that D is positive semidefinite. But recall that D is given by a dense interface, and it would therefore cost $\Omega(n^2)$ time already to access all entries of the matrix D. The solver itself gets away with accessing much less entries of D in the relevant case where r, the rank of D, is small.

Nevertheless, the solver contains some runtime checks that may detect that the matrix D is not positive-semidefinite. But you may as well get an "optimal solution" in this case, even with valid certificates. The validity of these certificates, however, depends on D being positive-semidefinite; if this is not the case, the certificates only prove that the solver has found a "critical point" of your (nonconvex) program, but there are no guarantees whatsoever that this is a global optimum, or even a local optimum.

10.3 How to Enter and Solve a Program

In this section, we describe how you can supply and solve your problem, using the CGAL program models and solution functions. There are two essentially different ways to proceed, and we will discuss them in turn. In short,

- you can let the model take care of your program data; you start from an empty program and then simply insert the non-zero entries, or read them from a file (more generally, any input stream) in *MPSFormat*. You can also change program entries at any time. This is usually the most convenient way if you don't want to care about representation issues;
- you can maintain the data yourself and only supply suitable random-access iterators over the matrices and vectors. This is advantageous if you already have the data (explicitly, or implicitly encoded, for example through iterators) and want to avoid copying of data. Typically, this happens if you write generic iterator-based code.

Our running example is the following quadratic program in two variables:

$$\begin{array}{llcl} \text{minimize} & x^2+4(y-4)^2 & (= & x^2+4y^2-32y+64) \\ \text{subject to} & x+y & \leq & 7 \\ & -x+2y & \leq & 4 \\ & x & \geq & 0 \\ & y & \geq & 0 \\ & y & \leq & 4 \end{array}$$

Figure 10.1 shows a picture. It depicts the five inequalities of the program, along with the *feasible region* (green), the set of points that satisfy all the five constraints. The dashed elliptic curves represent *contour lines* of the objective function, i.e., along each dashed curve, the objective function value is constant.

The global minimum of the objective function is attained at the point $(0,4)$, and the minimum within the feasible region appears at the point $(2,3)$ marked with a black dot. The value of the objective function at this optimal solution is $2^2+4(3-4)^2=8$.

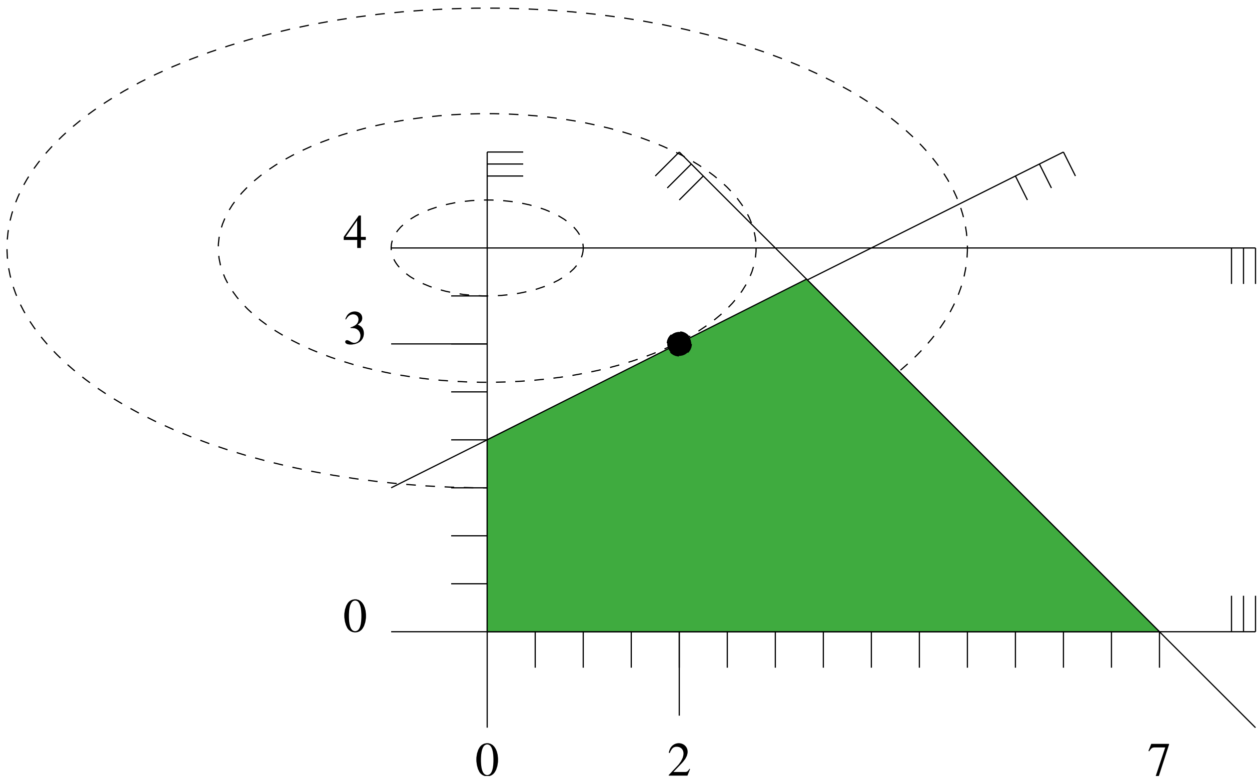

Figure 10.1: A quadratic program in two variables

10.3.1 Constructing a Program from Data

Here is how this quadratic program can be solved in CGAL according to the first way (letting the model take care of the data). We use *int* as the input type, and *MP_Float* or *Gmpz* (which is faster and preferable if GMP is installed) as the exact type for the internal computations. In larger examples, it pays off to use *double* as input type in order to profit from the automatic floating-point filtering that takes place then.

For examples how to work with the input type *double*, we refer to Sections 10.5 and 10.8.

Note: For the quadratic objective function, the entries of the matrix $2D$ have to be provided, rather than D. Although this is common to almost all quadratic programming solvers, it can easily be overlooked by a novice.

```
#include <iostream>
#include <cassert>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// choose exact integral type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

// program and solution types
typedef CGAL::Quadratic_program<int> Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

int main() {
  // by default, we have a nonnegative QP with Ax <= b
  Program qp (CGAL::SMALLER, true, 0, false, 0);

  // now set the non-default entries:
  const int X = 0;
  const int Y = 1;
  qp.set_a(X, 0,  1); qp.set_a(Y, 0, 1); qp.set_b(0, 7);  //  x + y  <= 7
  qp.set_a(X, 1, -1); qp.set_a(Y, 1, 2); qp.set_b(1, 4);  // -x + 2y <= 4
  qp.set_u(Y, true, 4);                                   //       y <= 4
  qp.set_d(X, X, 2); qp.set_d (Y, Y, 8); // !!specify 2D!!    x^2 + 4 y^2
  qp.set_c(Y, -32);                                       // -32y
  qp.set_c0(64);                                          // +64

  // solve the program, using ET as the exact type
  Solution s = CGAL::solve_quadratic_program(qp, ET());
  assert (s.solves_quadratic_program(qp));

  // output solution
  std::cout << s;
  return 0;
}
```

File: examples/QP_solver/first_qp.cpp

Asuming that GMP is installed, the output of the of the above program is:

```
status:          OPTIMAL
objective value: 8/1
variable values:
```

```
0: 2/1
1: 3/1
```

If GMP is not installed, the values are of course the same, but numerator and denominator might have a common divisor that is not factored out.

10.3.2 Constructing a Program from a Stream

Here, the program data must be available in *MPSFormat* (the *MPSFormat* page shows how our running example looks like in this format, and it briefly explains the format). Assuming that your working directory contains the file first_qp.mps, the following program will read and solve it, with the same output as before.

```cpp
#include <iostream>
#include <fstream>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// choose exact integral type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

// program and solution types
typedef CGAL::Quadratic_program_from_mps<int> Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

int main() {
  std::ifstream in ("first_qp.mps");
  Program qp(in);          // read program from file
  assert (qp.is_valid()); // we should have a valid mps file

  // solve the program, using ET as the exact type
  Solution s = CGAL::solve_quadratic_program(qp, ET());

  // output solution
  std::cout << s;
  return 0;
}
```

File: examples/QP_solver/first_qp_from_mps.cpp

10.3.3 Constructing a Program from Iterators

The following program again solves our running example from above, with the same output, but this time with iterators over data stored in suitable containers. You can see that we also store zero entries here (in D). For this toy problem, the previous two approaches (program from data/stream) are clearly preferable, but Section 10.5 shows an example where it makes sense to use the iterator-based approach.

```
#include <iostream>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// choose exact integral type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

// program and solution types
typedef CGAL::Quadratic_program_from_iterators
<int**,                                                // for A
 int*,                                                 // for b
 CGAL::Const_oneset_iterator<CGAL::Comparison_result>, // for r
 bool*,                                                // for fl
 int*,                                                 // for l
 bool*,                                                // for fu
 int*,                                                 // for u
 int**,                                                // for D
 int*>                                                 // for c
Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

int main() {
  int   Ax[] = {1, -1};                        // column for x
  int   Ay[] = {1,  2};                        // column for y
  int*  A[] = {Ax, Ay};                        // A comes columnwise
  int   b[] = {7, 4};                          // right-hand side
  CGAL::Const_oneset_iterator<CGAL::Comparison_result>
        r(    CGAL::SMALLER);                  // constraints are "<="
  bool fl[] = {true, true};                    // both x, y are
   lower-bounded
  int   l[] = {0, 0};
  bool fu[] = {false, true};                   // only y is upper-bounded
  int   u[] = {0, 4};                          // x's u-entry is ignored
  int  D1[] = {2};                             // 2D_{1,1}
  int  D2[] = {0, 8};                          // 2D_{2,1}, 2D_{2,2}
  int*  D[] = {D1, D2};                        // D-entries on/below
   diagonal
  int   c[] = {0, -32};
  int   c0  = 64;                              // constant term

  // now construct the quadratic program; the first two parameters are
  // the number of variables and the number of constraints (rows of A)
  Program qp (2, 2, A, b, r, fl, l, fu, u, D, c, c0);

  // solve the program, using ET as the exact type
```

```
  Solution s = CGAL::solve_quadratic_program(qp, ET());

  // output solution
  std::cout << s;
  return 0;
}
```

File: `examples/QP_solver/first_qp_from_iterators.cpp`

Note 1: The example shows an interesting feature of this approach: not all data need to come from containers. Here, the iterator over the vector of relations can be provided through the class *Const_oneset_iterator<T>*, since all entries of this vector are equal to *CGAL::SMALLER*. The same could have been done with the vector *fl* for the finiteness of the lower bounds.

Note 2: The program type looks a bit scary, with its total of 9 template arguments, one for each iterator type. In Section 10.5.1 we show how the explicit construction of this type can be circumvented.

10.4 Solving Linear and Nonnegative Programs

Let us reconsider the general form of (QP) from Section 10.1 above. If $D = 0$, the quadratic program is in fact a *linear program*, and in the case that the bound vectors l is the zero vector and all entries of u are ∞, the program is said to be *nonnegative*. The package offers dedicated models and solution methods for these special cases.

From an interface perspective, this is just syntactic sugar: in the model *Quadratic_program<NT>*, we can easily set the default bounds so that a nonnegative program results, and a linear program is obtained by simply not inserting any D-entries. Even in the iterator-based approach (see *QP_solver/first_qp_from_iterators.cpp*), linear and nonnegative programs can easily be defined through suitable *Const_oneset_iterator<T>*-style iterators.

The main reason for having dedicated solution methods for linear and nonnegative programs is efficiency: if the solver knows that the program is linear, it can save some computations compared to the general solver that unknowingly has to fiddle around with a zero D-matrix. As in Section 10.2.2 above, we can argue that checking in advance whether $D = 0$ is not an option in general, since this may require $\Omega(n^2)$ time on the dense interface.

Similarly, if the solver knows that the program is nonnegative, it will be more efficient than under the general bounds $\mathbf{l} \leq \mathbf{x} \leq \mathbf{u}$. You can argue that nonnegativity *is* something that could easily be checked in time $O(n)$ beforehand, but then again nonnegative programs are so frequent that the syntactic sugar aspect becomes somewhat important. After all, we can save four iterators in specifying a nonnegative linear program in terms of the concept *NonnegativeLinearProgram* rather than *LinearProgram*.

Often, there are no bounds at all for the variables, i.e., all entries of $\mathbf{l}$ are $-\infty$, and all entries of $\mathbf{u}$ are ∞ (this is called a *free* program). There is no dedicated solution method for this case (a free quadratic or linear program is treated like a general quadratic or linear program), but all predefined models make it easy to specify all sorts of default bounds, covering the free case.

10.4.1 The Linear Programming Solver

Let's go back to our first quadratic program from above and change it into a linear program by simply removing the quadratic part of the objective function:

$$\begin{array}{lrcl}
\text{minimize} & -32y+64 & & \\
\text{subject to} & x+y & \leq & 7 \\
& -x+2y & \leq & 4 \\
& x & \geq & 0 \\
& y & \geq & 0 \\
& y & \leq & 4
\end{array}$$

Figure 10.2 shows how this looks like. We will not visualize a linear objective function with contour lines but with arrows instead. The arrow represents the (direction) of the vector $-c$, and we are looking for a feasible solution that is "extreme" in the direction of the arrow. In our small example, this is the unique point "on" the two constraints $x_1+x_2 \leq 7$ and $-x_1+x_2 \leq 4$, the point $(10/3, 11/3)$ marked with a black dot. The optimal objective function value is $-32(11/3)+64 = -160/3$.

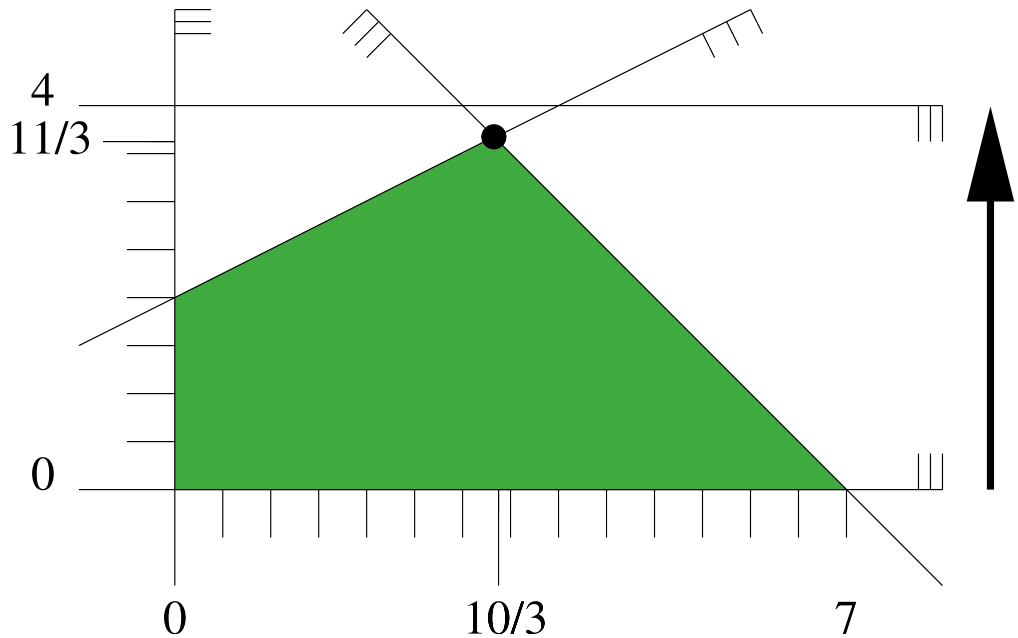

Figure 10.2: A linear program in two variables

Here is CGAL code for solving it, using the dedicated LP solver, and according to the three ways for constructing a program that we have already discussed in Section 10.3.

QP_solver/first_lp.cpp
QP_solver/first_lp_from_mps.cpp
QP_solver/first_lp_from_iterators.cpp

In all cases, the output is

```
status:          OPTIMAL
objective value: -160/3
variable values:
  0: 10/3
  1: 11/3
```

10.4.2 The Nonnegative Quadratic Programming Solver

If we go back to our first quadratic program and remove the constraint $y \leq 4$, we arrive at a nonnegative quadratic program:

$$\begin{array}{lrcl} \text{minimize} & x^2+4(y-4)^2 & (= & x^2+4y^2-32y+64) \\ \text{subject to} & x+y & \leq & 7 \\ & -x+2y & \leq & 4 \\ & x,y & \geq & 0 \end{array}$$

Figure 10.3 contains the illustration; since the constraint $y \leq 4$ was redundant, the feasible region and the optimal solution do not change.

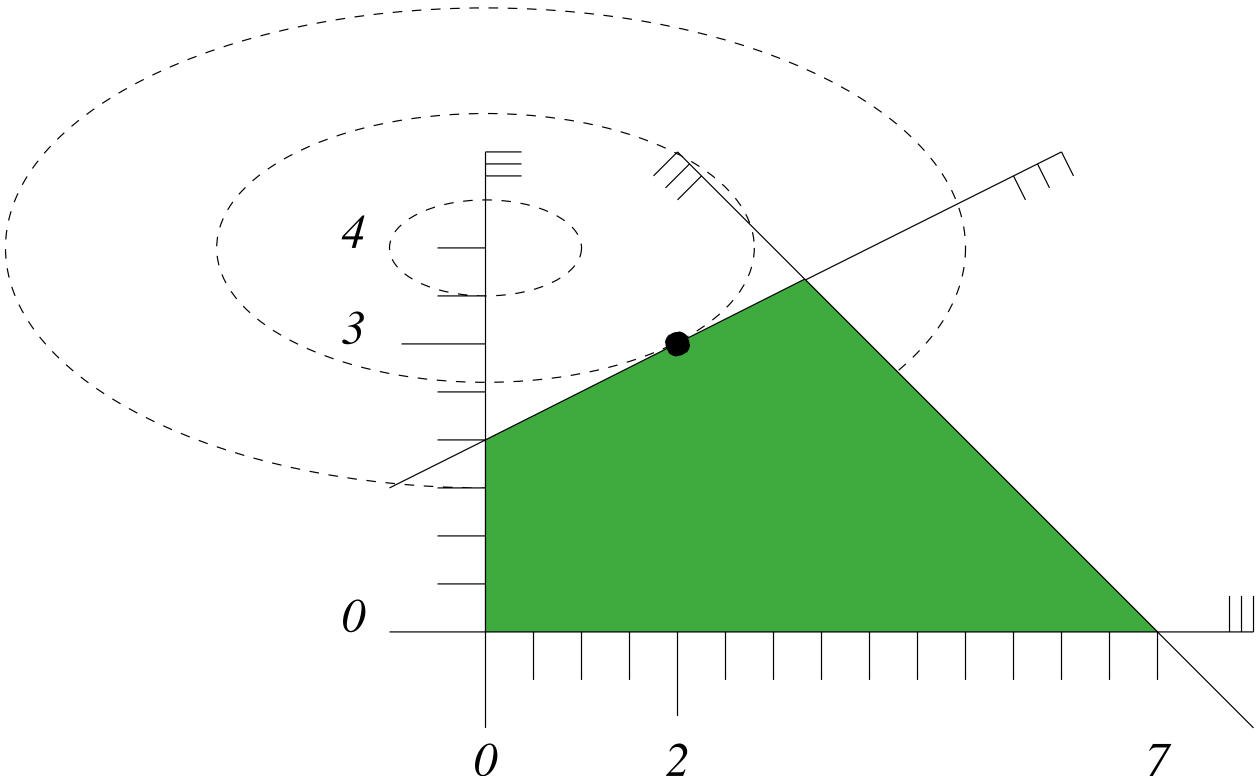

Figure 10.3: A nonnegative quadratic program in two variables

The following programs (using the dedicated solver for nonnegative quadratic programs) will therefore again output

```
status:          OPTIMAL
objective value: 8/1
variable values:
  0: 2/1
  1: 3/1
```

QP_solver/first_nonnegative_qp.cpp
QP_solver/first_nonnegative_qp_from_mps.cpp
QP_solver/first_nonnegative_qp_from_iterators.cpp

10.4.3 The Nonnegative Linear Programming Solver

Finally, a dedicated model and function is available for nonnnegative linear programs as well. Let's take our linear program from above and remove the constraint $y \leq 4$ to obtain a nonnegative linear program. At the same time we remove the constant objective function term to get a "minimal" input and a "shortest" program; the optimal value is $-32(11/3) = -352/3$.

$$\begin{array}{lrcl} \text{minimize} & -32y & & \\ \text{subject to} & x+y & \leq & 7 \\ & -x+2y & \leq & 4 \\ & x,y & \geq & 0 \end{array}$$

This can be solved by any of the following three programs

QP_solver/first_nonnegative_lp.cpp
QP_solver/first_nonnegative_lp_from_mps.cpp
QP_solver/first_nonnegative_lp_from_iterators.cpp

The output will always be

```
status:          OPTIMAL
objective value: -352/3
variable values:
  0: 10/3
  1: 11/3
```

10.5 Working from Iterators

Here we present a somewhat more advanced example that emphasizes the usefulness of solving linear and quadratic programs from iterators. Let's look at a situation in which a linear program is given implicitly, and access to it is gained through properly constructed iterators.

The problem we are going to solve is the following: given points $p_1, \ldots p_n$ in d-dimensional space and another point p: is p in the convex hull of $\{p_1, \ldots, p_n\}$? In formulas, this is the case if and only if there are real coefficients $\lambda_1, \ldots, \lambda_n$ such that p is a convex combination of $p_1, \ldots, p_n$:

$$p = \sum_{j=1}^{n} \lambda_j \, p_j, \quad \sum_{j=1}^{n} \lambda_j = 1, \quad \lambda_j \geq 0 \text{ for all } j.$$

The problem of testing the existence of such λ_j can be expressed as a linear program. It becomes particularly easy when we use the homogeneous representations of the points: if $q_1, \ldots, q_n, q \in \mathbb{R}^{d+1}$ are homogeneous coordinates for $p_1, \ldots, p_n, p$ with positive homogenizing coordinates $h_1, \ldots, h_n, h$, we have

$$q_j = h_j \cdot (p_j \mid 1) \text{ for all } j, \text{ and } q = h \cdot (p \mid 1).$$

Now, nonnegative $\lambda_1, \ldots, \lambda_n$ are suitable coefficients for a convex combination if and only if

$$\sum_{j=1}^{n} \lambda_j (p_j \mid 1) = (p \mid 1),$$

equivalently, if there are $\mu_1, \ldots, \mu_n$ (with $\mu_j = \lambda_j \cdot h/h_j$ for all j) such that

$$\sum_{j=1}^{n} \mu_j\, q_j = q, \quad \mu_j \geq 0 \text{ for all } j.$$

The linear program now tests for the existence of nonnegative μ_j that satisfy the latter equation. Below is the code; it defines a function that solves the linear program, given p and $p_1, \ldots, p_n$ (through an iterator range). The only (mild) trickery involved is the construction of the nested iterator through a fixed column of the constraint matrix A. We get this from transforming the iterator through the points using a functor that maps a point to an iterator through its homogeneous coordinates.

```
#include <boost/config.hpp>
#include <boost/iterator/transform_iterator.hpp>
#include <CGAL/Kernel_traits.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// unary function to get homogeneous begin-iterator of point
template <class Point_d>
struct Homogeneous_begin  {
  typedef typename Point_d::Homogeneous_const_iterator result_type;
  result_type operator() (const Point_d& p) const {
    return p.homogeneous_begin();
  }
};

// function to solve the LP that tests whether a point is in the
// convex hull of other points; the type ET is an exact type used
// for the internal computations
template <class Point_d, class RandomAccessIterator, class ET>
CGAL::Quadratic_program_solution<ET>
solve_convex_hull_containment_lp (const Point_d& p,
                                  RandomAccessIterator begin,
                                  RandomAccessIterator end, const ET&
    dummy)
{
  // Constraint matrix type: A[j][i] is the i-th homogeneous coordinate
    of p_j
  typedef boost::transform_iterator
    <Homogeneous_begin<Point_d>, RandomAccessIterator> A_it;
  // Right-hand side type: b[i] is the i-th homogeneous coordinate of p
  typedef typename Point_d::Homogeneous_const_iterator B_it;
  // Relation type ("=")
  typedef CGAL::Const_oneset_iterator<CGAL::Comparison_result> R_it;
  // input number type
  typedef typename CGAL::Kernel_traits<Point_d>::Kernel::RT RT;
  // Linear objective function type (c=0: we only test feasibility)
  typedef CGAL::Const_oneset_iterator<RT> C_it;
  // the nonnegative linear program type
  typedef
    CGAL::Nonnegative_linear_program_from_iterators<A_it, B_it, R_it,
   C_it>
    Program;
```

```
  // ok, we are prepared now: construct program and solve it
  Program lp (end-begin,          // number of variables
              p.dimension()+1,    // number of constraints
              A_it (begin), B_it (p.homogeneous_begin()),
              R_it (CGAL::EQUAL), C_it (0));
  return CGAL::solve_nonnegative_linear_program (lp, dummy);
}
```

File: examples/QP_solver/solve_convex_hull_containment_lp.h

To see this in action, let us call it with $p_1 = (0,0), p_2 = (10,0), p_3 = (0,10)$ fixed (they define a triangle) and all integral points p in $[0,10]^2$. We know that p is in the convex hull of $\{p_1, p_2, p_3\}$ if and only if its two coordinates sum up to 10 at most. As the exact type, we use *MP_Float* or *Gmpzf* (which is faster and preferable if GMP is installed).

```
#include <cassert>
#include <vector>
#include <CGAL/Cartesian_d.h>
#include <CGAL/MP_Float.h>
#include "solve_convex_hull_containment_lp.h"

// choose exact floating-point type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpzf.h>
typedef CGAL::Gmpzf ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

typedef CGAL::Cartesian_d<double> Kernel_d;
typedef Kernel_d::Point_d Point_d;

bool is_in_convex_hull (const Point_d& p,
                        std::vector<Point_d>::const_iterator begin,
                        std::vector<Point_d>::const_iterator end)
{
  CGAL::Quadratic_program_solution<ET> s =
    solve_convex_hull_containment_lp (p, begin, end, ET(0));
  return !s.is_infeasible();
}

int main()
{
  std::vector<Point_d> points;
  // convex hull: simplex spanned by {(0,0), (10,0), (0,10)}
  points.push_back (Point_d ( 0.0,  0.0));
  points.push_back (Point_d (10.0,  0.0));
  points.push_back (Point_d ( 0.0, 10.0));
  for (int i=0; i<=10; ++i)
    for (int j=0; j<=10; ++j) {
      // (i,j) is in the simplex iff i+j <= 10
      bool contained = is_in_convex_hull
```

```
        (Point_d (i, j), points.begin(), points.end());
      assert (contained == (i+j<=10));
    }

  return 0;
}
```

File: examples/QP_solver/convex_hull_containment.cpp

10.5.1 Using Makers

You already noticed in the previous example that the actual template arguments for *CGAL::Nonnegative_linear_program_from_iterators<A_it, B_it, R_it, C_it>* can be quite elaborate, and this only gets worse if you plug more iterators into each other. In general, you want to construct a program from given expressions for the iterators, but the types of these expressions are probably very complicated and difficult to look up.

You can avoid the explicit construction of the type *CGAL::Nonnegative_linear_program_from_iterators<A_it, B_it, R_it, C_it>* if you only need an expression of it, e.g. to pass it directly as an argument to the solving function. Here is an alternative version of *QP_solver/solve_convex_hull_containment_lp.h* that shows how this works. In effect, you get shorter and more readable code.

```
#include <boost/config.hpp>
#include <boost/iterator/transform_iterator.hpp>
#include <CGAL/Kernel_traits.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// unary function to get homogeneous begin-iterator of point
template <class Point_d>
struct Homogeneous_begin  {
  typedef typename Point_d::Homogeneous_const_iterator result_type;
  result_type operator() (const Point_d& p) const {
    return p.homogeneous_begin();
  }
};

// function to test whether point is in the convex hull of other points;
// the type ET is an exact type used for the computations
template <class Point_d, class RandomAccessIterator, class ET>
CGAL::Quadratic_program_solution<ET>
solve_convex_hull_containment_lp (const Point_d& p,
                                  RandomAccessIterator begin,
                                  RandomAccessIterator end, const ET&
   dummy)
{
  // construct program and solve it
  return CGAL::solve_nonnegative_linear_program
    (CGAL::make_nonnegative_linear_program_from_iterators
     (end-begin,
     // n
      p.dimension()+1,
     // m
```

```
      boost::transform_iterator
      <Homogeneous_begin<Point_d>, RandomAccessIterator>(begin),
     // A
      typename Point_d::Homogeneous_const_iterator
    (p.homogeneous_begin()),// b
      CGAL::Const_oneset_iterator<CGAL::Comparison_result>(CGAL::EQUAL),
     // ~
      CGAL::Const_oneset_iterator
      <typename CGAL::Kernel_traits<Point_d>::Kernel::RT> (0)), dummy);
     // c
}
```

File: examples/QP_solver/solve_convex_hull_containment_lp2.h

10.6 Important Variables and Constraints

If you have a solution $\mathbf{x}^*$ of a linear or quadratic program, the "important" variables are typically the ones that are not on their bounds. In case of a nonnegative program, these are the nonzero variables. Going back to the example of the previous Section 10.5, we can easily interpret their importance: the nonzero variables correspond to points p_j that actually contribute to the convex combination that yields p.

The following example shows how we can access the important variables, using the iterators *basic_variable_indices_begin()* and *basic_variable_indices_end()*.

We generate a set of points that form a 4-gon in $[0,4]^2$, and then find the ones that contribute to the convex combinations of all 25 lattice points in $[0,4]^2$. If the lattice point in question is not in the 4-gon, we simply output this fact.

```
#include <cassert>
#include <vector>
#include <CGAL/Cartesian_d.h>
#include <CGAL/MP_Float.h>
#include "solve_convex_hull_containment_lp2.h"

typedef CGAL::Cartesian_d<double> Kernel_d;
typedef Kernel_d::Point_d Point_d;
typedef CGAL::Quadratic_program_solution<CGAL::MP_Float> Solution;

int main()
{
  std::vector<Point_d> points;
  // convex hull: 4-gon spanned by {(1,0), (4,1), (4,4), (2,3)}
  points.push_back (Point_d (1, 0)); // point 0
  points.push_back (Point_d (4, 1)); // point 1
  points.push_back (Point_d (4, 4)); // point 2
  points.push_back (Point_d (2, 3)); // point 3

  // test all 25 integer points in [0,4]^2
  for (int i=0; i<=4; ++i)
    for (int j=0; j<=4; ++j) {
      Point_d p (i, j);
```

```
      Solution s = solve_convex_hull_containment_lp
        (p, points.begin(), points.end(), CGAL::MP_Float());
      std::cout << p;
      if (s.is_infeasible())
        std::cout << " is not in the convex hull\n";
      else {
        assert (s.is_optimal());
        std::cout << " is a convex combination of the points ";
        Solution::Index_iterator it = s.basic_variable_indices_begin();
        Solution::Index_iterator end = s.basic_variable_indices_end();
        for (; it != end; ++it) std::cout << *it << " ";
        std::cout << std::endl;
      }
    }
  return 0;
}
```

File: `examples/QP_solver/important_variables.cpp`

It turns out that exactly three of the four points contribute to any convex combination, even through there are lattice points that lie in the convex hull of less than three of the points. This shows that the set of basic variables that we access in the example does not necessarily coincide with the set of important variables as defined above. In fact, it is only guaranteed that a non-basic variable attains one of its bounds, but there might be basic variables that also have this property. In linear and quadratic programming terms, such a situation is called a *degeneracy*.

There is also the concept of an important constraint: this is typically a constraint in the system $A\mathbf{x} \gtreqless \mathbf{b}$ that is satisfied with equality at $\mathbf{x}^*$. Program *QP_solver/first_qp_basic_constraints.cpp* shows how these can be accessed, using the iterators *basic_constraint_indices_begin()* and *basic_constraint_indices_end()*.

Again, we have a disagreement between "basic" and "important": it is guaranteed that all basic constraints are satisfied with equality at $\mathbf{x}^*$, but there might be non-basic constraints that are satisfied with equality as well.

10.7 Solution Certificates

Suppose the solver tells you that the problem you have entered is infeasible. Why should you believe this? Similarly, you can quite easily verify that a claimed optimal solution is feasible, but why is there no better one?

Certificates are proofs that the solver can give you in order to convince you that what it claims is indeed true. The archetype of such a proof is *Farkas Lemma* [MG06].

Farkas Lemma: *Either* the inequality system

$$\begin{array}{rcl} A\mathbf{x} & \leq & \mathbf{b} \\ \mathbf{x} & \geq & 0 \end{array}$$

has a solution $\mathbf{x}^*$, *or* there exists a vector $\mathbf{y}$ such that

$$\begin{array}{rcl} \mathbf{y} & \geq & 0 \\ \mathbf{y}^T A & \geq & 0 \\ \mathbf{y}^T \mathbf{b} & < & 0, \end{array}$$

but not both.

Thus, if someone wants to convince you that the first system in the Farkas Lemma is infeasible, that person can simply give you a vector **y** that solves the second system. Since you can easily verify yourself that the **y** you got satisfies this second system, you now have a certificate for the infeasibility of the first system, assuming that you believe in Farkas Lemma.

Here we show how the solver can convince you. We first set up an infeasible linear program with constraints of the type $A\mathbf{x} \leq \mathbf{b}, \mathbf{x} \geq 0$; then we solve it and ask for a certificate. Finally, we verify the certificate by simply checking the inequalities of the second system in Farkas Lemma.

```
#include <cassert>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// choose exact integral type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

// program and solution types
typedef CGAL::Nonnegative_linear_program_from_iterators
<int**,                                                   // for A
 int*,                                                    // for b
 CGAL::Comparison_result*,                                // for r
 int*>                                                    // for c
Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

// we demonstrate Farkas Lemma: either the system
//     A x <= b
//       x >= 0
// has a solution, or there exists y such that
//       y >= 0
//    y^TA >= 0
//    y^Tb <  0
// In the following instance, the first system has no solution,
// since adding up the two inequalities gives x_2 <= -1:
//     x_1 - 2x_2  <=  1
//    -x_1 + 3x_2  <= -2
//     x_1,   x_2  >=  0

int main() {
  int  Ax1[] = { 1, -1};                           // column for x1
  int  Ax2[] = {-2,  3};                           // column for x2
  int*   A[] = {Ax1, Ax2};                         // A comes columnwise
  int    b[] = {1, -2};                            // right-hand side
  CGAL::Comparison_result
    r[] = {CGAL::SMALLER, CGAL::SMALLER};         // constraints are "<="
  int    c[] = {0, 0};                            // zero objective function

  // now construct the linear program; the first two parameters are
```

```
  // the number of variables and the number of constraints (rows of A)
  Program lp (2, 2, A, b, r, c);

  // solve the program, using ET as the exact type
  Solution s = CGAL::solve_nonnegative_linear_program(lp, ET());

  // get certificate for infeasibility
  assert (s.is_infeasible());
  Solution::Infeasibility_certificate_iterator y =
    s.infeasibility_certificate_begin();
  // check y >= 0
  assert (y[0] >= 0);
  assert (y[1] >= 0);
  // check y^T A >= 0
  assert (y[0] * A[0][0] + y[1] * A[0][1] >= 0);
  assert (y[0] * A[1][0] + y[1] * A[1][1] >= 0);
  // check y^T b < 0
  assert (y[0] * b[0] + y[1] * b[1] < 0);

  return 0;
}
```

File: examples/QP_solver/infeasibility_certificate.cpp

There are similar certificates for optimality and unboundedness that you can see in action in the programs *QP_solver/optimality_certificate.cpp* and *QP_solver/unboundedness_certificate.cpp*. The underlying variants of Farkas Lemma are somewhat more complicated, due to the mixed relations in $\gtreqless$ and the general bounds. The certificate section of *Quadratic_program_solution<ET>* gives the full picture and mathematically proves the correctness of the certificates.

10.8 Customizing the Solver

Sometimes it is necessary to alter the default behavior of the solver. This can be done by passing a suitably prepared object of the class *Quadratic_program_options* to the solution functions. Most options concern "soft" issues like verbosity, but there are two notable case where it is of critical importance to be able to change the defaults.

10.8.1 Exponent Overflow in Double Using Floating-Point Filters

The filtered version of the solver that is used for some problems by default on input type *double* internally constructs double-approximations of exact multiprecision values. If these exact values are extremely large, this may lead to *infinite double* values and incorrect results. In debug mode, the solver will notice this through a certificate cross-check in the end (or even earlier). In this case, it is advisable to explicitly switch to a non-filtered *pricing strategy*, see *Quadratic_program_pricing_strategy*.

Hint: If you have a program where the number of variables n and the number of constraints m have the same order of magnitude, the filtering will usually have no dramatic effect on the performance, so in that case you might as well switch to *QP_PARTIAL_DANTZIG* to be safe from the issue described here (see *QP_solver/cycling.cpp* for an example that shows how to change the pricing strategy).

10.8.2 The Solver Internally Cycles

Consider the following program. It reads a nonnegative linear program from the file `cycling.mps` (which is in the example directory as well), and then solves it in verbose mode, using *Bland's rule*, see *Quadratic_program_pricing_strategy*.

```
#include <iostream>
#include <fstream>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// choose exact floating-point type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpzf.h>
typedef CGAL::Gmpzf ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

// program and solution types
typedef CGAL::Quadratic_program_from_mps<double> Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

int main() {
  std::ifstream in ("cycling.mps");
  Program lp(in);          // read program from file
  assert (lp.is_valid()); // we should have a valid mps file...
  assert (lp.is_linear());      // ... and it should be linear...
  assert (lp.is_nonnegative()); // as well as nonnegative

  // solve the program, using ET as the exact type
  // choose verbose mode and Bland pricing
  CGAL::Quadratic_program_options options;
  options.set_verbosity(1);                         // verbose mode
  options.set_pricing_strategy(CGAL::QP_BLAND);     // Bland's rule
  options.set_auto_validation(true);                // automatic
    self-check
  Solution s = CGAL::solve_nonnegative_linear_program(lp, ET(), options);
  assert (s.is_valid());                      // did the self-check
    succeed?

  // output solution
  std::cout << s;
  return 0;
}
```

File: examples/QP_solver/cycling.cpp

If you comment the line

```
options.set_pricing_strategy(CGAL::QP_BLAND);          // Bland's rule
```

you will see that the solver cycles: the verbose mode outputs the same sequence of six iterations over and over again. By switching to *QP_BLAND*, the solution process typically slows down a bit (it may also speed up in some cases), but now it is guaranteed that no cycling occurs.

In general, the verbose mode can be of use when you are not sure whether the solver "has died", or whether it simply takes very long to solve your problem. We refer to the class *Quadratic_program_options* for further details.

10.9 Some Benchmarks for Convex Hull Containment

Here we want to show what you can expect from the solver's performance in a specific application; we don't know whether this application is typical in your case, and we make no claims whatsoever about the performance in other applications.

Still, the example shows that the performance can be dramatically affected by switching between pricing strategies, and we give some hints on how to achieve good performance in general.

The application is the one already discussed in Section 10.5 above: testing whether a point is in the convex hull of other points. To be able to switch between pricing strategies, we add another parameter of type *Quadratic_program_options* to the function *solve_convex_hull_containment_lp* that we pass on to the solution function:

```
#include <boost/config.hpp>
#include <boost/iterator/transform_iterator.hpp>
#include <CGAL/Kernel_traits.h>
#include <CGAL/QP_options.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// unary function to get homogeneous begin-iterator of point
template <class Point_d>
struct Homogeneous_begin  {
  typedef typename Point_d::Homogeneous_const_iterator result_type;
  result_type operator() (const Point_d& p) const {
    return p.homogeneous_begin();
  }
};

// function to test whether point is in the convex hull of other points;
// the type ET is an exact type used for the computations
template <class Point_d, class RandomAccessIterator, class ET>
CGAL::Quadratic_program_solution<ET>
solve_convex_hull_containment_lp (const Point_d& p,
                                  RandomAccessIterator begin,
                                  RandomAccessIterator end, const ET&
   dummy,
                                  const CGAL::Quadratic_program_options&
   o)
{
  // construct program and solve it
  return CGAL::solve_nonnegative_linear_program
    (CGAL::make_nonnegative_linear_program_from_iterators
     (end-begin,
      // n
```

```
      p.dimension()+1,
     // m
      boost::transform_iterator
      <Homogeneous_begin<Point_d>, RandomAccessIterator>(begin),
     // A
      typename Point_d::Homogeneous_const_iterator
    (p.homogeneous_begin()),// b
      CGAL::Const_oneset_iterator<CGAL::Comparison_result>(CGAL::EQUAL),
     // ~
      CGAL::Const_oneset_iterator
      <typename CGAL::Kernel_traits<Point_d>::Kernel::RT> (0)),
     // c
      dummy, o);
}
```

File: examples/QP_solver/solve_convex_hull_containment_lp3.h

Now let us test containment of the origin in the convex hull of n random points in $[0,1]^d$ (it will most likely not be contained, and it turns out that this is the most expensive case). In the program below, we use $d = 10$ and $n = 100,000$, and we comment on some other combinations of n and d below (feel free to experiment with still other values).

```
#include <vector>
#include <CGAL/Cartesian_d.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Random.h>
#include <CGAL/Timer.h>
#include "solve_convex_hull_containment_lp3.h"

// choose exact floating-point type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpzf.h>
typedef CGAL::Gmpzf ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

typedef CGAL::Cartesian_d<double> Kernel_d;
typedef Kernel_d::Point_d Point_d;

int main()
{
  const int d = 10;       // change this in order to experiment
  const int n = 100000;   // change this in order to experiment

  // generate n random d-dimensional points in [0,1]^d
  CGAL::Random rd;
  std::vector<Point_d> points;
  for (int j =0; j<n; ++j) {
    std::vector<double> coords;
    for (int i=0; i<d; ++i)
      coords.push_back(rd.get_double());
```

```
    points.push_back (Point_d (d, coords.begin(), coords.end()));
  }

  // benchmark all pricing strategies in turn
  CGAL::Quadratic_program_pricing_strategy strategy[] = {
    CGAL::QP_CHOOSE_DEFAULT,              // QP_PARTIAL_FILTERED_DANTZIG
    CGAL::QP_DANTZIG,                     // Dantzig's pivot rule...
    CGAL::QP_PARTIAL_DANTZIG,             // ... with partial pricing
    CGAL::QP_BLAND,                       // Bland's pivot rule
    CGAL::QP_FILTERED_DANTZIG,            // Dantzig's filtered pivot
   rule...
    CGAL::QP_PARTIAL_FILTERED_DANTZIG     // ... with partial pricing
  };

  CGAL::Timer t;
  for (int i=0; i<6; ++i) {
    // test strategy i
    CGAL::Quadratic_program_options options;
    options.set_pricing_strategy (strategy[i]);
    t.reset(); t.start();
    // is origin in convex hull of the points? (most likely, not)
    solve_convex_hull_containment_lp
      (Point_d (d, CGAL::ORIGIN), points.begin(), points.end(),
       ET(0), options);
    t.stop();
    std::cout << "Time (s) = " << t.time() << std::endl;
  }

  return 0;
}
```

File: examples/QP_solver/convex_hull_containment_benchmarks.cpp

If you compile with the macros NDEBUG or CGAL_QP_NO_ASSERTIONS set (this is essential for good performance!!), you will see runtimes that qualitatively look as follows (on your machine, the actual runtimes will roughly be some fixed multiples of the numbers in the table below, and they might vary with the random choices). The default choice of the pricing strategy in that case is *QP_PARTIAL_FILTERED_DANTZIG*.

strategy		runtime in seconds
CGAL::QP_CHOOSE_DEFAULT	—	0.32
CGAL::QP_DANTZIG	—	10.7
CGAL::QP_PARTIAL_DANTZIG	—	3.72
CGAL::QP_BLAND	—	3.65
CGAL::QP_FILTERED_DANTZIG	—	0.43
CGAL::QP_PARTIAL_FILTERED_DANTZIG	—	0.32

We clearly see the effect of filtering: we gain a factor of ten, roughly, compared to the next best non-filtered variant.

10.9.1 $d = 3$, $n = 1,000,000$

The filtering effect is amplified if the points/dimension ratio becomes larger. This is what you might see in dimension three, with one million points.

strategy		runtime in seconds
CGAL::QP_CHOOSE_DEFAULT	—	1.34
CGAL::QP_DANTZIG	—	47.6
CGAL::QP_PARTIAL_DANTZIG	—	15.6
CGAL::QP_BLAND	—	16.02
CGAL::QP_FILTERED_DANTZIG	—	1.89
CGAL::QP_PARTIAL_FILTERED_DANTZIG	—	1.34

In general, if your problem has a high variable/constraint or constraint/variable ratio, then filtering will typically pay off. In such cases, it might be beneficial to encode your problem using input type *double* in order to profit from the filtering (but see the issue discussed in Section 10.8.1).

10.9.2 $d = 100$, $n = 100,000$

Conversely, the filtering effect deteriorates if the points/dimension ratio becomes smaller.

strategy		runtime in seconds
CGAL::QP_CHOOSE_DEFAULT	—	3.05
CGAL::QP_DANTZIG	—	78.4
CGAL::QP_PARTIAL_DANTZIG	—	45.9
CGAL::QP_BLAND	—	33.2
CGAL::QP_FILTERED_DANTZIG	—	3.36
CGAL::QP_PARTIAL_FILTERED_DANTZIG	—	3.06

10.9.3 $d = 500$, $n = 1,000$

If the points/dimension ratio tends to a constant, filtering is no longer a clear winner. The reason is that in this case, the necessary exact calculations with multiprecision numbers dominate the overall runtime.

strategy		runtime in seconds
CGAL::QP_CHOOSE_DEFAULT	—	2.65
CGAL::QP_DANTZIG	—	5.55
CGAL::QP_PARTIAL_DANTZIG	—	5.6
CGAL::QP_BLAND	—	4.46
CGAL::QP_FILTERED_DANTZIG	—	2.65
CGAL::QP_PARTIAL_FILTERED_DANTZIG	—	2.61

In general, if you have a program where the number of variables and the number of constraints have the same order of magnitude, then the saving gained from using the filtered approach is typically small. In such a situation, you should consider switching to a non-filtered variant in order to avoid the rare issue discussed in Section 10.8.1 altogether.

Linear and Quadratic Programming Solver Reference Manual

Concepts

Classes

There is a class that represents the solution of a linear or quadratic program. An instance of this class is returned by any of the solution functions below.

We offer a number of predefined models for the above program concepts. The following two are simultaneously models for all four concepts and are probably the most convenient models; they allow you to construct linear or quadratic programs entry by entry, or from streams in *MPSFormat*. At any time, you can query these programs for linearity and nonnegativity and thus select the appropriate solution function.

Then there are specific models for any of the four program concepts above; these are useful if you want to maintain the program data yourself, since they simply wrap random access iterators over the program data and involve no further copying of data.

 Functions

In case you want to construct a program from complicated iterators (whose types you don't know, or simply don't want to bother with), we provide four makers.

There are four functions to solve a program, one for each program concept.

The solution process can customized by passing an object of the class

Programs can be written to an output stream in *MPSFormat*, using one of the following four functions.

Concept

QuadraticProgram

Definition

A model of QuadraticProgram describes a convex quadratic program of the form

$$\begin{array}{lll} \text{(QP)} & \text{minimize} & \mathbf{x}^T D\mathbf{x} + \mathbf{c}^T\mathbf{x} + c_0 \\ & \text{subject to} & A\mathbf{x} \gtreqless \mathbf{b}, \\ & & \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \end{array}$$

in n real variables $\mathbf{x} = (x_0, \ldots, x_{n-1})$. Here,

- A is an $m \times n$ matrix (the constraint matrix),
- $\mathbf{b}$ is an m-dimensional vector (the right-hand side),
- $\gtreqless$ is an m-dimensional vector of relations from $\{\leq, =, \geq\}$,
- $\mathbf{l}$ is an n-dimensional vector of lower bounds for $\mathbf{x}$, where $l_j \in \mathbb{R} \cup \{-\infty\}$ for all j
- $\mathbf{u}$ is an n-dimensional vector of upper bounds for $\mathbf{x}$, where $u_j \in \mathbb{R} \cup \{\infty\}$ for all j
- D is a symmetric positive-semidefinite $n \times n$ matrix (the quadratic objective function),
- $\mathbf{c}$ is an n-dimensional vector (the linear objective function), and
- c_0 is a constant.

The description is given by appropriate *random-access* iterators over the program data, see below. The program therefore comes in *dense* representation which includes zero entries.

Has Models

Quadratic_program<NT>
Quadratic_program_from_mps<NT>
Quadratic_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it>

Types

QuadraticProgram:: A_iterator	A random access iterator type to go columnwise over the constraint matrix A. The value type is a random access iterator type for an individual column that goes over the entries in that column.
QuadraticProgram:: B_iterator	A random access iterator type to go over the entries of the right-hand side $\mathbf{b}$.
QuadraticProgram:: R_iterator	A random access iterator type to go over the relations $\gtreqless$. The value type of *R_iterator* is *CGAL::Comparison_result*.

QuadraticProgram:: FL_iterator — A random access iterator type to go over the existence (finiteness) of the lower bounds $l_j, j = 0,\ldots,n-1$. The value type of *FL_iterator* is *bool*.

QuadraticProgram:: L_iterator — A random acess iterator type to go over the entries of the lower bound vector **l**.

QuadraticProgram:: UL_iterator — A random access iterator type to go over the existence (finiteness) of the upper bounds $u_j, j = 0,\ldots,n-1$. The value type of *UL_iterator* is *bool*.

QuadraticProgram:: U_iterator — A random acess iterator type to go over the entries of the upper bound vector **u**.

QuadraticProgram:: D_iterator — A random access iterator type to go rowwise over the matrix $2D$. The value type is a random access iterator type for an individual row that goes over the entries in that row, up to (and including) the entry on the main diagonal.

QuadraticProgram:: C_iterator — A random access iterator type to go over the entries of the linear objective function vector c.

Operations

int	*qp.get_n() const*	returns the number n of variables (number of columns of A) in *qp*.
int	*qp.get_m() const*	returns the number m of constraints (number of rows of A) in *qp*.
A_iterator	*qp.get_a() const*	returns an iterator over the columns of A. The corresponding past-the-end iterator is *get_a()+get_n()*. For $j = 0,\ldots,n-1$, $*(get\_a()+j)$ is a random access iterator for column j.
B_iterator	*qp.get_b() const*	returns an iterator over the entries of **b**. The corresponding past-the-end iterator is *get_b()+get_m()*.
R_iterator	*qp.get_r() const*	returns an iterator over the entries of $\gtreqless$. The corresponding past-the-end iterator is *get_r()+get_m()*. The value *CGAL::SMALLER* stands for $\leq$, *CGAL::EQUAL* stands for $=$, and *CGAL::LARGER* stands for $\geq$.
FL_iterator	*qp.get_fl() const*	returns an iterator over the existence of the lower bounds $l_j, j = 0,\ldots,n-1$. The corresponding past-the-end iterator is *get_fl()+get_n()*. If **(get_fl()+j)* has value $true$, the variable x_j has a lower bound given by **(get_l()+j)*, otherwise it has no lower bound.
L_iterator	*qp.get_l() const*	returns an iterator over the entries of **l**. The corresponding past-the-end iterator is *get_l()+get_n()*. If **(get_fl()+j)* has value $false$, the value **(get_l()+j)* is not accessed. *Precondition*: if both **(get_fl()+j)* and **(get_fu()+j)* have value $true$, then $*(get\_l()+j) \leq *(get\_u()+j)$

FU_iterator	*qp.get_fu() const*	returns an iterator over the existence of the upper bounds $u_j, j = 0, \ldots, n-1$. The corresponding past-the-end iterator is *get_fu()+get_n()*. If **(get_fu()+j)* has value $true$, the variable x_j has an upper bound given by **(get_u()+j)*, otherwise it has no upper bound.
L_iterator	*qp.get_u() const*	returns an iterator over the entries of **u**. The corresponding past-the-end iterator is *get_u()+get_n()*. If **(get_fu()+j)* has value $false$, the value **(get_u()+j)* is not accessed. *Precondition*: if both **(get_fl()+j)* and **(get_fu()+j)* have value $true$, then $*(get\_l()+j) \leq *(get\_u()+j)$
D_iterator	*qp.get_d() const*	returns an iterator over the rows of $2D$. The corresponding past-the-end iterator is *get_d()+get_n()*. For $i = 0, \ldots, n-1$, $*(get\_d()+i)$ is a random access iterator for the entries in row i *below or on the diagonal*. The valid range of this iterator is guaranteed to have length $i+1$ but not more. Values to the right of the diagonal are deduced from the symmetry requirement on D.
C_iterator	*qp.get_c() const*	returns an iterator over the entries of **c**. The corresponding past-the-end iterator is *get_c()+get_n()*.

std::iterator_traits<C_iterator>::value_type

	qp.get_c0() const	returns the constant term c_0 of the objective function.

Requirements

The value types of all iterator types (nested iterator types, respectively, for *A_iterator* and *D_iterator*) must be convertible to some common *IntegralDomain* ET.

MPSFormat

MPS is a commonly used file format for storing linear and quadratic programs according to the concepts *QuadraticProgram*, *LinearProgram*, *NonnegativeQuadraticProgram*, and *NonnegativeLinearProgram*, see also http://en.wikipedia.org/wiki/MPS_(format).

CGAL supports a large subset of this format, but there are MPS files around that we cannot read (for example, files that encode integrality constraints on the variables). Also, there might be some other MPS-based solvers that will not be able to read the MPS files written by CGAL, since we do not strictly adhere to the very rigid layout requirements of the original MPS format.

Let's look at an example first. The quadratic program

$$\begin{array}{lrcl}
\text{minimize} & x^2+4(y-4)^2 & (= & x^2+4y^2-32y+64) \\
\text{subject to} & x+y & \leq & 7 \\
 & -x+2y & \leq & 4 \\
 & x & \geq & 0 \\
 & y & \geq & 0 \\
 & y & \leq & 4
\end{array}$$

has the following description in MPS format.

```
NAME first_qp
ROWS
  N obj
  L c0
  L c1
COLUMNS
  x0  c0  1
  x0  c1  -1
  x1  obj  -32
  x1  c0  1
  x1  c1  2
RHS
  rhs obj -64
  rhs c0  7
  rhs c1  4
BOUNDS
  UP  BND  x1  4
QMATRIX
  x0  x0  2
  x1  x1  8
ENDATA
```

Here comes a semiformal description of the format in general.

NAME section

This (mandatory) section consists of a single line starting with `NAME`. Everything starting from the first non-whitespace after that until the end of the line constitutes the name of the problem.

ROWS section

In the (mandatory) `ROW` section, you find one line for every constraint, where the letter `L` indicates relation $\leq$, letter `G` stands for $\geq$, and `E` for $=$. In addition, there is a row for the linear objective function (indicated by letter `N`). In that section, names are asigned to the constraints (here: `c0, c1`) and the objective function (here: `obj`). An MPS file may encode several linear objective functions by using several rows starting with `N`, but we ignore all but the first.

COLUMNS section

The (mandatory) `COLUMNS` section encodes the constraint matrix A and the linear objective function vector c. Every line consists of one or two sequences of three tokens $j i val$, where j is the name of a variable (here, we have variables `x0,x1`), i is the name of a constraint or the objective function, and val is the value A_{ij} (if i names a constraint), or c_j (if i names the linear objective function). Values for pairs (i, j) that are not specified in this section default to 0. Otherwise, for every pair (i, j), the *last* specified value determines A_{ij} or c_j.

RHS section

This (mandatory) section encodes the right-hand side vector b and the constant term c_0 in the objective function. The first token in every line is an identifier (here: `rhs`). An MPS file may encode several right-hand sides b by using several such identifiers, but we ignore all lines having an identifier different from that of the first line.

The right-hand side identifier is succeeded by one or two sequences of tokens $i val$, where i names a constraint or the linear objective function, and val specifies the value b_i (if i names a constraint), or $-c_0$ (if i names the linear objective function). Values that are not specified in this section default to 0. Otherwise, for every i, the *last* specified value determines b_i or $-c_0$.

BOUNDS section

This (optional) section encodes the lower and upper bound vectors l and u for the variables. The default bounds for any variable x_j are $0 \leq x_j \leq \infty$; the `BOUNDS` section is used to override these defaults. In particular, if there is no `BOUNDS` section, the program is nonnegative and actually a model of the concept *NonnegativeQuadraticProgram* or *NonnegativeLinearProgram*.

The first token in every line is succeeded by an (optional) identifier (here: `BND`). An MPS file may encode several bound vectors l and u by using several such identifiers, but we ignore all lines having an identifier different from that of the first line. The first token t itself determines the type of the bound, and the token j after the bound identifier names the variable to which the bound applies In case of bound types `FX`, `LO`, and `UP`, there is another token *val* that specifices the bound value. Here is how bound type and value determine a bound for variable x_j. There may be several bound specifications for a single variable, and they are processed in order of appearance.

bound type	resulting bound
FX	$x_j = val$ (x_j becomes a fixed variable)
LO	$x_j \geq val$ (upper bound remains unchanged)
UP	$x_j \leq val$ (lower bound remains unchanged, except if $val < 0$; then, a zero lower bound is reset to $-\infty$)
FR	$-\infty \leq x_j \leq \infty$ (previous bounds are discarded)
MI	$x_j \geq -\infty$ (upper bound remains unchanged)
PL	$x_j \leq \infty$ (lower bound remains unchanged)

QMATRIX / QUADOBJ / DMATRIX section

This (optional) section encodes the quadratic objective function matrix D. Every line is a sequence $i\,j\,val$ of three tokens, where both i and j name variables, and *val* is the value $2D_{i,j}$ (in case of `QMATRIX` or `QUADOBJ`), or D_{ij} (in case of `DMATRIX`).

In case of `QMATRIX` and `DMATRIX`, *all* nonzero entries must be specified: if there is a line $i\,j\,val$, then there must also be a line $j\,i\,val$, since D is required to be symmetric. In case of `QUADOBJ`, only the entries of $2D$ on or below the diagonal must be specified, entries above the diagonal are deduced from symmetry. It is not allowed to specify two or more *different* nonzero values for an unordered pair $\{i, j\}$.

If this section is missing or does not contain nonzero values, the program is a model of the concept *LinearProgram*.

Miscellaneous

Our MPS format also supports an (optional) `RANGES` section, but we don't explain this here.

CGAL::Quadratic_program_solution<ET>

#include <CGAL/QP_solution.h>

Definition

An object of class *Quadratic_program_solution<ET>* represents the solution of a linear or convex quadratic program of the general form

$$
\begin{array}{lll}
\text{(QP)} & \text{minimize} & \mathbf{x}^T D\mathbf{x} + \mathbf{c}^T\mathbf{x} + c_0 \\
 & \text{subject to} & A\mathbf{x} \gtreqless \mathbf{b}, \\
 & & \mathbf{l} \leq \mathbf{x} \leq \mathbf{u}
\end{array}
$$

in n real variables $\mathbf{x} = (x_0, \ldots, x_{n-1})$.

If $D = 0$, the program is a linear program; if the variable bounds are $\mathbf{x} \geq 0$, we have a nonnegative program. Objects of type *Quadratic_program_solution<ET>* are returned by any of the four functions *solve_quadratic_program*, *solve_linear_program*, *solve_nonnegative_quadratic_program*, and *solve_nonnegative_linear_program*.

Example

QP_solver/first_qp.cpp

Terminology

If there is no $\mathbf{x}$ that satisfies all the (in)equalities, the program is called *infeasible*, otherwise, it is *feasible*, and any $\mathbf{x}$ that satisfies all (in)equalities is called a *feasible solution*.

If the objective function value becomes arbitrarily small over the *feasible region* (the set of feasible solutions), the program is called *unbounded*, and *bounded* otherwise.

Any program that is both feasible and bounded has at least one feasible solution $\mathbf{x}^*$ whose objective function value is not larger than that of any other feasible solution. This is called an *optimal solution*.

Every convex quadratic program (even if it is infeasible or unbounded) has a 'solution' in form of an object of the class *Quadratic_program_solution<ET>*.

Types

Quadratic_program_solution<ET>:: ET	The exact number type that was used to solve the program.
Quadratic_program_solution<ET>:: Variable_value_iterator	An iterator type with value type *Quotient<ET>* to go over the values of the variables in the solution.

Quadratic_program_solution<ET>:: Variable_numerator_iterator

An iterator type with value type *ET* to go over the numerators of the variable values with respect to a common denominator.

Quadratic_program_solution<ET>:: Index_iterator

An iterator type with value type *int* to go over the indices of the basic variables and the basic constraints.

Quadratic_program_solution<ET>:: Optimality_certificate_iterator

An iterator type with value type *Quotient<ET>* to go over an m-vector λ that proves optimality of the solution.

Quadratic_program_solution<ET>:: Optimality_certificate_numerator_iterator

An iterator type with value type *ET* to go over the numerators of the vector λ with respect to a common denominator.

Quadratic_program_solution<ET>:: Infeasibility_certificate_iterator

An iterator type with value type *ET* to go over an m-vector λ that proves infeasibility of the solution.

Quadratic_program_solution<ET>:: Unboundedness_certificate_iterator

An iterator type with value type *ET* to go over an n-vector $\mathbf{w}$ that proves unboundedness of the solution.

Creation

Quadratic_program_solution<ET> sol; — constructs a void instance of *Quadratic_program_solution<ET>* that is associated to no program.

Objects of type *Quadratic_program_solution<ET>* can be copied and assigned.

Objects of type *Quadratic_program_solution<ET>* that are associated to an actual program are returned by any of the four functions *solve_quadratic_program*, *solve_linear_program*, *solve_nonnegative_quadratic_program*, and *solve_nonnegative_linear_program*.

Example

QP_solver/first_qp.cpp

Operations

bool *sol.is_void() const* returns *true* iff *sol* is not associated to a program. The condition !*sol.is_void()* is a precondition for all access methods below.

Solution status

Here are the access methods for the status of the solution.

bool *sol.is_optimal() const* returns *true* iff *sol* is an optimal solution of the associated program.

bool *sol.is_infeasible() const*

returns *true* iff the associated program is infeasible.

bool *sol.is_unbounded() const*

returns *true* iff the associated program is unbounded.

Quadratic_program_status

sol.status() const returns the status of the solution; this is one of the values *QP_OPTIMAL*, *QP_INFEASIBLE*, and *QP_UNBOUNDED*, depending on whether the program asociated to *sol* has an optimal solution, is infeasible, or is unbounded.

int *sol.number_of_iterations() const*

returns the number of iterations that it took to solve the program asociated to *sol*.

Solution values

The actual solution (variable and objective function values) can be accessed as follows.

Quotient<ET> *sol.objective_value() const*

returns the objective function value of *sol*.

ET *sol.objective_value_numerator() const*

returns the numerator of the objective function value of *sol*.

ET *sol.objective_value_denominator() const*

returns the denominator of the objective function value of *sol*.

Variable_value_iterator

sol.variable_values_begin() const

returns a random-access iterator over the values of the variables in *sol*. The value type is *Quotient<ET>*, and the valid iterator range has length *n*.

Variable_value_iterator

sol.variable_values_end() const

returns the corresponding past-the-end iterator.

Variable_numerator_iterator

sol.variable_numerators_begin() const

returns a random-access iterator *it* over the values of the variables in *sol*, with respect to a common denominator of all variables. The value type is *ET*, and the valid iterator range has length *n*.

Variable_numerator_iterator

sol.variable_numerators_end() const

returns the corresponding past-the-end iterator.

ET *sol.variables_common_denominator() const*

returns the common denominator of the variable values as referred to by the previous two methods.

Basic variables and constraints

The solution of a linear or quadratic program distinguishes 'important' variables (the ones not attaining one of their bounds), and 'important' constraints (the ones being satisfied with equality). The following methods grant access to them.

Index_iterator *sol.basic_variable_indices_begin() const*

returns a random access iterator over the indices of the basic variables. The value type is *int*. It is guaranteed that any variable that is not basic in *sol* attains one of its bounds. In particular, if the bounds are of type $\mathbf{x} \geq 0$, all non-basic variables have value 0.

Index_iterator *sol.basic_variable_indices_end() const*

returns the corresponding past-the-end iterator.

int *sol.number_of_basic_variables() const*

returns the number of basic variables, equivalently the length of the range determined by the previous two iterators.

Example

QP_solver/important_variables.cpp

Index_iterator *sol.basic_constraint_indices_begin() const*

returns a random access iterator over the indices of the basic constraints in the system $A\mathbf{x} \gtreqless \mathbf{b}$. The value type is *int*. It is guaranteed that any basic constraint is satisfied with equality. In particular, if the system is of type $A\mathbf{x} = \mathbf{b}$, all constraints are basic.

Index_iterator *sol.basic_constraint_indices_end() const*

returns the corresponding past-the-end iterator.

int *sol.number_of_basic_constraints() const*

returns the number of basic constraint, equivalently the length of the range determined by the previous two iterators.

Example

QP_solver/first_qp_basic_constraints.cpp

Output

template <typename ET>
std::ostream& *std::ostream& out << sol*

writes the status of *sol* to the stream *out*. In case the status is *QP_OPTIMAL*, the optimal objective value and the values of the variables at the optimal solution are output as well. For more detailed information about the solution (like basic variables/constraints) please use the dedicated methods of *Quadratic_program_solution<ET>*.

Validity

The following four methods allow you to check whether *sol* indeed solves the program that you intended to solve. The methods use the certificates described in the advanced section below and thus save you from validating the certificates yourself (if you believe in the correctness of these methods; otherwise, you can look at their implementation to convince yourself).

By passing a suitable option to the solution function, you can make sure that this check is done automatically after the solution of the program, see *Quadratic_program_options*. If the check fails, a logfile is generated that contains the details, and an error message is written to *std::cerr* (see *QP_solver/cycling.cpp* for an example that uses this option).

template <class QuadraticProgram>
bool *sol.solves_quadratic_program(QuadraticProgram qp)*

returns *true* iff *sol* solves the quadratic program *qp*. If the result is *false*, you can get a message that describes the problem, through the method *get_error()*.

QP_solver/first_qp.cpp

template <class LinearProgram>
bool *sol.solves_linear_program(LinearProgram lp)*

returns *true* iff *sol* solves the linear program *lp*. If the result is *false*, you can get a message that describes the problem, through the method *get_error()*.

QP_solver/first_lp.cpp

template <class NonnegativeQuadraticProgram>
bool *sol.solves_nonnegative_quadratic_program(NonnegativeQuadraticProgram qp)*

returns *true* iff *sol* solves the nonnegative quadratic program *qp*. If the result is *false*, you can get a message that describes the problem, through the method *get_error()*.

QP_solver/first_nonnegative_qp.cpp

template <class NonnegativeLinearProgram>
bool *sol.solves_nonnegative_linear_program(NonnegativeLinearProgram lp)*

returns *true* iff *sol* solves the nonnegative linear program *lp*. If the result is *false*, you can get a message that describes the problem, through the method *get_error()*.

QP_solver/first_nonnegative_lp.cpp

bool *sol.is_valid() const* returns *false* iff the validation through one of the previous four functions has failed.

std::string *sol.get_error() const* returns an error message in case any of the previous four validation functions has returned *false*.

advanced

Certificates

A certificate is a vector that admits a simple proof for the correctness of the solution. Any non-void object of *Quadratic_program_solution<ET>* comes with such a certificate.

Lemma 1 (optimality certificate): A feasible n-vector $\mathbf{x}^*$ is an optimal solution of (QP) if an m-vector λ with the following properties exist.

1. if the i-th constraint is of type $\leq$ ($\geq$, respectively), then $\lambda_i \geq 0$ ($\lambda_i \leq 0$, respectively).
2. $\lambda^T(A\mathbf{x}^* - \mathbf{b}) = 0$.
3. $$(\mathbf{c}^T + \lambda^T A + 2\mathbf{x}^{*T} D)_j \quad \begin{array}{ll} \geq 0, & \text{if } x^*_j = l_j < u_j \\ = 0, & \text{if } l_j < x^*_j < u_j \\ \leq 0, & \text{if } l_j < u_j = x^*_j. \end{array}$$

Proof: Let $\mathbf{x}$ be any feasible solution. We need to prove that

$$\mathbf{c}^T\mathbf{x} + \mathbf{x}^T D\mathbf{x} \geq \mathbf{c}^T\mathbf{x}^* + \mathbf{x}^{*T} D\mathbf{x}^*.$$

For this, we argue as follows.

$$\begin{array}{rcll} \mathbf{c}^T\mathbf{x} + 2\mathbf{x}^{*T} D\mathbf{x} & \geq & \mathbf{c}^T\mathbf{x} + 2\mathbf{x}^{*T} D\mathbf{x} + \lambda^T(A\mathbf{x} - \mathbf{b}) & (\text{by } A\mathbf{x} \gtreqless \mathbf{b} \text{ and 1.}) \\ & = & (\mathbf{c}^T + \lambda^T A + 2\mathbf{x}^{*T} D)\mathbf{x} - \lambda^T b & \\ & \geq & (\mathbf{c}^T + \lambda^T A + 2\mathbf{x}^{*T} D)\mathbf{x}^* - \lambda^T b & (\text{by } \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \text{ and 3.}) \\ & = & \mathbf{c}^T\mathbf{x}^* + 2\mathbf{x}^{*T} D\mathbf{x}^* & (\text{by 2.}) \end{array}$$

After adding $\mathbf{x}^T D\mathbf{x} - \mathbf{x}^T D\mathbf{x} - \mathbf{x}^{*T} D\mathbf{x}^* = -\mathbf{x}^{*T} D\mathbf{x}^*$ to both sides of this inequality, we get

$$\mathbf{c}^T\mathbf{x} + \mathbf{x}^T D\mathbf{x} - (\mathbf{x} - \mathbf{x}^*)^T D(\mathbf{x} - \mathbf{x}^*) \geq \mathbf{c}^T\mathbf{x}^* + \mathbf{x}^{*T} D\mathbf{x}^*,$$

and since D is positive semidefinite, we have $(\mathbf{x} - \mathbf{x}^*)^T D(\mathbf{x} - \mathbf{x}^*) \geq 0$ and the lemma follows.

Optimality_certificate_iterator

sol.optimality_certifcate_begin() const

returns a random access iterator over the optimality certificate λ as given in Lemma 1, with respect to the solution $\mathbf{x}^*$ obtained from *sol.variable_values_begin()*. The value type is *Quotient<ET>*, and the valid iterator range has length m.
Precondition: *sol.is_optimal()*

Optimality_certificate_iterator

sol.optimality_certificate_end() const

returns the corresponding past-the-end iterator.

Optimality_certificate_numerator_iterator

sol.optimality_certifcate_numerators_begin() const

returns a random access iterator over the numerator values of the optimality certificate λ, with respect to the common denominator returned by *sol.variables_common_denominator()*. The value type is *ET*, and the valid iterator range has length m.

Optimality_certificate_numerator_iterator

sol.optimality_certificate_numerators_end() const

returns the corresponding past-the-end iterator.

Example

QP_solver/optimality_certificate.cpp

Lemma 2 (infeasibility certificate): The program (QP) is infeasible if an m-vector λ with the following properties exist.

1. if the i-th constraint is of type $\leq$ ($\geq$, respectively), then $\lambda_i \geq 0$ ($\lambda_i \leq 0$, respectively).
2. $$\lambda^T A_j \quad \begin{array}{ll} \geq 0 & \text{if } u_j = \infty \\ \leq 0 & \text{if } l_j = -\infty. \end{array}$$
3. $$\lambda^T \mathbf{b} \quad < \quad \sum_{j:\lambda^T A_j < 0} \lambda^T A_j u_j \quad + \quad \sum_{j:\lambda^T A_j > 0} \lambda^T A_j l_j.$$

Proof: Let us assume for the purpose of obtaining a contradiction that there is a feasible solution $\mathbf{x}$. Then we get

$$\begin{array}{rclll} 0 & \geq & \lambda^T(A\mathbf{x}-\mathbf{b}) & & \text{(by } A\mathbf{x} \gtreqless \mathbf{b} \text{ and 1.)} \\ & = & \sum_{j:\lambda^T A_j<0} \lambda^T A_j x_j & + \quad \sum_{j:\lambda^T A_j>0} \lambda^T A_j x_j - \lambda^T \mathbf{b} & \\ & \geq & \sum_{j:\lambda^T A_j<0} \lambda^T A_j u_j & + \quad \sum_{j:\lambda^T A_j>0} \lambda^T A_j l_j - \lambda^T \mathbf{b} & \text{(by } \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \text{ and 2.)} \\ & > & 0 & & \text{(by 3.),} \end{array}$$

and this is the desired contradiction $0 > 0$.

Infeasibility_certificate_iterator

sol.infeasibility_certificate_begin() const

returns a random access iterator over the infeasibility certificate λ as given in Lemma 2. The value type is *ET*, and the valid iterator range has length m.
Precondition: *sol.is_infeasible()*

Infeasibility_certificate_iterator

sol.infeasibility_certificate_end() const

returns the corresponding past-the-end iterator.

Example

QP_solver/infeasibility_certificate.cpp

Lemma 3 (unboundedness certificate:) Let $\mathbf{x}^*$ be a feasible solution of (QP). The program (QP) is unbounded if an n-vector $\mathbf{w}$ with the following properties exist.

1. if the i-th constraint is of type $\leq$ ($\geq, =$, respectively), then $(A\mathbf{w})_i \leq 0$ ($(A\mathbf{w})_i \geq 0, (A\mathbf{w})_i = 0$, respectively).
2. $$w_j \quad \begin{array}{ll} \geq 0 & \text{if } l_j \text{ is finite} \\ \leq 0 & \text{if } u_j \text{ is finite.} \end{array}$$
3. $\mathbf{w}^T D\mathbf{w} = 0$ and $(\mathbf{c}^T + 2\mathbf{x}^{*T} D)\mathbf{w} < 0$.

The vector $\mathbf{w}$ is called an *unbounded direction*.

Proof: For a real number t, consider the vector $\mathbf{x}(t) := \mathbf{x}^* + t\mathbf{w}$. By 1. and 2., $\mathbf{x}(t)$ is feasible for all $t \geq 0$. The objective function value of $\mathbf{x}(t)$ is

$$\begin{aligned} \mathbf{c}^T\mathbf{x}(t) + \mathbf{x}(t)^T D\mathbf{x}(t) &= \mathbf{c}^T\mathbf{x}^* + t\mathbf{c}^T\mathbf{w} + \mathbf{x}^{*T} D\mathbf{x}^* + 2t\mathbf{x}^{*T} D\mathbf{w} + t^2\mathbf{w}^T D\mathbf{w} \\ &= \mathbf{c}^T\mathbf{x}^* + \mathbf{x}^{*T} D\mathbf{x}^* + t(\mathbf{c}^T + 2\mathbf{x}^{*T} D)\mathbf{w} + t^2\mathbf{w}^T D\mathbf{w}. \end{aligned}$$

By condition 3., this tends to $-\infty$ for $t \to \infty$, so the problem is indeed unbounded.

Unboundedness_certificate_iterator

sol.unboundedness_certificate_begin() const

returns a random acess iterator over the unbounded direction $\mathbf{w}$ as given in Lemma 3,with respect to the solution $\mathbf{x}^*$ obtained from *sol.variable_values_begin()*. The value type is *ET*, and the valid iterator range has length n.
Precondition: *sol.is_unbounded()*

Unboundedness_certificate_iterator

sol.unboundedness_certificate_end()

returns the corresponding past-the-end iterator.

Example

QP_solver/unboundedness_certificate.cpp

Class

CGAL::Quadratic_program_status

#include <CGAL/QP_solution.h>

Definition

This is an enumeration type containing the values *QP_OPTIMAL*, *QP_INFEASIBLE*, and *QP_UNBOUNDED*. It indicates the status of a linear or quadratic program solution as represented by an object of type *Quadratic_program_solution<ET>*.

See Also

Quadratic_program_solution<ET>

CGAL::Quadratic_program<NT>

#include <CGAL/QP_models.h>

Class

Definition

An object of class *Quadratic_program<NT>* describes a convex quadratic program of the form

$$\begin{array}{lll}\text{(QP)} & \text{minimize} & \mathbf{x}^T D\mathbf{x}+\mathbf{c}^T\mathbf{x}+c_0 \\ & \text{subject to} & A\mathbf{x} \gtreqless \mathbf{b}, \\ & & \mathbf{l} \leq \mathbf{x} \leq \mathbf{u}\end{array}$$

in n real variables $\mathbf{x} = (x_0,\ldots,x_{n-1})$. Here,

- A is an $m \times n$ matrix (the constraint matrix),
- $\mathbf{b}$ is an m-dimensional vector (the right-hand side),
- $\gtreqless$ is an m-dimensional vector of relations from $\{\leq,=,\geq\}$,
- $\mathbf{l}$ is an n-dimensional vector of lower bounds for $\mathbf{x}$, where $l_j \in \mathbb{R} \cup \{-\infty\}$ for all j
- $\mathbf{u}$ is an n-dimensional vector of upper bounds for $\mathbf{x}$, where $u_j \in \mathbb{R} \cup \{\infty\}$ for all j
- D is a symmetric positive-semidefinite $n \times n$ matrix (the quadratic objective function),
- $\mathbf{c}$ is an n-dimensional vector (the linear objective function), and
- c_0 is a constant.

If $D = 0$, the program is a linear program; if the variable bounds are $x \geq 0$, we have a nonnegative program.

This class allows you to build your program entry by entry, using the set-methods below.

If you only need to wrap existing (random-access) iterators over your own data, then you may use any of the four models *Quadratic_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it>*, *Linear_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, C_it>*, *Nonnegative_quadratic_program_from_iterators<A_it, B_it, R_it, D_it, C_it>*, and *Nonnegative_linear_program_from_iterators<A_it, B_it, R_it, C_it>*.

If you want to read a quadratic program in *MPSFormat* from a stream, please use the model *Quadratic_program_from_mps<NT>*.

Is Model for the Concepts

QuadraticProgram
LinearProgram
NonnegativeQuadraticProgram
NonnegativeLinearProgram

Types

Quadratic_program<NT>:: NT	The number type of the program entries.

Creation

Quadratic_program<NT> qp(CGAL::Comparison_result default_r = CGAL::EQUAL, bool default_fl = true, NT default_l = 0, bool default_fu = false, NT default_u = 0)

constructs a quadratic program with no variables and no constraints, ready for data to be added. Unless relations are explicitly set, they will be of type *default_r*. Unless bounds are explicitly set, they will be as specified by *default_fl* (finite lower bound?), *default_l* (lower bound value if lower bound is finite), *default_fu* (finite upper bound?), and *default_l* (upper bound value if upper bound is finite). If all parameters take their default values, we thus get equality constraints and bounds $x \geq 0$ by default. Numerical entries that are not explicitly set will default to 0.
Precondition: if *default_fl* = *default_fu* = *true*, then *default_l* $\leq$ *default_u*

Operations

bool *qp.is_linear() const*

returns *true* if and only if *qp* is a linear program.

bool *qp.is_nonnegative() const*

returns *true* if and only if *qp* is a nonnegative program.

void *qp.set_a(int j, int i, NT val)*

sets the entry A_{ij} in column j and row i of the constraint matrix A of *qp* to *val*. An existing entry is overwritten. *qp* is enlarged if necessary to accomodate this entry.

void *qp.set_b(int i, NT val)*

sets the entry b_i of *qp* to *val*. An existing entry is overwritten. *qp* is enlarged if necessary to accomodate this entry.

void *qp.set_r(int i, CGAL::Comparison_result rel)*

sets the entry $\gtreqless_i$ of *qp* to *rel*. *CGAL::SMALLER* means that the i-th constraint is of type "$\leq$", *CGAL::EQUAL* means "$=$", and *CGAL::LARGER* encodes "$\geq$". An existing entry is overwritten. *qp* is enlarged if necessary to accomodate this entry.

void *qp.set_l(int j, bool is_finite, NT val = NT(0))*

if *is_finite*, this sets the entry l_j of *qp* to *val*, otherwise it sets l_j to $-\infty$. An existing entry is overwritten. *qp* is enlarged if necessary to accomodate this entry.

void *qp.set_u(int j, bool is_finite, NT val = NT(0))*

if *is_finite*, this sets the entry u_j of *qp* to *val*, otherwise it sets u_j to ∞. An existing entry is overwritten. *qp* is enlarged if necessary to accomodate this entry.

void *qp.set_c(int j, NT val)*

sets the entry c_j of *qp* to *val*. An existing entry is overwritten. *qp* is enlarged if necessary to accomodate this entry.

void *qp.set_c0(NT val)* sets the entry c_0 of *qp* to *val*. An existing entry is overwritten.

void *qp.set_d(int i, int j, NT val)*

sets the entries $2D_{ij}$ and $2D_{ji}$ of *qp* to *val*. Existing entries are overwritten. *qp* is enlarged if necessary to accomodate these entries.
Precondition: *j <= i*

Example

Nonnegative_linear_program_from_iterators<A_it, B_it, R_it, C_it>
Quadratic_program_from_mps<NT>

Class

CGAL::Quadratic_program_from_mps<NT>

#include <CGAL/QP_models.h>

Definition

An object of class *Quadratic_program_from_mps<NT>* describes a convex quadratic program of the general form

$$
\begin{array}{lll}
\text{(QP)} & \text{minimize} & \mathbf{x}^T D\mathbf{x} + \mathbf{c}^T\mathbf{x} + c_0 \\
 & \text{subject to} & A\mathbf{x} \gtreqless \mathbf{b}, \\
 & & \mathbf{l} \leq \mathbf{x} \leq \mathbf{u}
\end{array}
$$

in n real variables $\mathbf{x} = (x_0, \ldots, x_{n-1})$. Here,

- A is an $m \times n$ matrix (the constraint matrix),
- $\mathbf{b}$ is an m-dimensional vector (the right-hand side),
- $\gtreqless$ is an m-dimensional vector of relations from $\{\leq, =, \geq\}$,
- $\mathbf{l}$ is an n-dimensional vector of lower bounds for $\mathbf{x}$, where $l_j \in \mathbb{R} \cup \{-\infty\}$ for all j
- $\mathbf{u}$ is an n-dimensional vector of upper bounds for $\mathbf{x}$, where $u_j \in \mathbb{R} \cup \{\infty\}$ for all j
- D is a symmetric positive-semidefinite $n \times n$ matrix (the quadratic objective function),
- $\mathbf{c}$ is an n-dimensional vector (the linear objective function), and
- c_0 is a constant.

If $D = 0$, the program is a linear program; if the variable bounds are $x \geq 0$, we have a nonnegative program.

The program data are read from an input stream in *MPSFormat*. This is a commonly used format for encoding linear and quadratic programs that is understood by many solvers. All values are expected to be readable into type *NT*. The constructed program can be further manipulated by using the set-methods below.

Is Model for the Concepts

QuadraticProgram
LinearProgram
NonnegativeQuadraticProgram
NonnegativeLinearProgram

Types

Quadratic_program_from_mps<NT>:: NT	The number type of the program entries.

Creation

Quadratic_program_from_mps<NT> qp(std::istream& in);

reads *qp* from the input stream *in*.

Operations

bool *qp.is_valid() const*
returns *true* if and only if an MPS-encoded quadratic program could be extracted from the input stream.

std::string *qp.get_error() const*
if !*qp.is_valid()*, this method returns an error message explaining why the input does not conform to the *MPSFormat*.

std::string *qp.variable_name_by_index(int j) const*

returns the name of the j-th variable.
Precondition: j must not refer to a variable that has been added later, using one of the set methods below.

int *qp.variable_index_by_name(std::string name) const*

returns the index of the variable with name *name*. If there is no variable with this name, the result is -1.

std::string *qp.constraint_name_by_index(int i) const*

returns the name of the i-th constraint.
Precondition: i must not refer to a constraint that has been added later, using one of the set methods below.

int *qp.constraint_index_by_name(std::string name) const*

returns the index of the constraint with name *name*. If there is no constraint with this name, the result is -1.

bool *qp.is_linear() const*
returns *true* if and only if *qp* is a linear program.

bool *qp.is_nonnegative() const*

returns *true* if and only if *qp* is a nonnegative program.

void *qp.set_a(int j, int i, NT val)*

sets the entry A_{ij} in column j and row i of the constraint matrix A of *qp* to *val*. An existing entry is overwritten. *qp* is enlarged if necessary to accomodate this entry.

void *qp.set_b(int i, NT val)*

sets the entry b_i of *qp* to *val*. An existing entry is overwritten. *qp* is enlarged if necessary to accomodate this entry.

void *qp.set_r(int i, CGAL::Comparison_result rel)*

sets the entry $\gtreqless_i$ of *qp* to *rel*. *CGAL::SMALLER* means that the *i*-th constraint is of type "$\leq$", *CGAL::EQUAL* means "$=$", and *CGAL::LARGER* encodes "$\geq$". An existing entry is overwritten. *qp* is enlarged if necessary to accomodate this entry.

void *qp.set_l(int j, bool is_finite, NT val = NT(0))*

if *is_finite*, this sets the entry l_j of *qp* to *val*, otherwise it sets l_j to $-\infty$. An existing entry is overwritten. *qp* is enlarged if necessary to accomodate this entry.

void *qp.set_u(int j, bool is_finite, NT val = NT(0))*

if *is_finite*, this sets the entry u_j of *qp* to *val*, otherwise it sets u_j to ∞. An existing entry is overwritten. *qp* is enlarged if necessary to accomodate this entry.

void *qp.set_c(int j, NT val)*

sets the entry c_j of *qp* to *val*. An existing entry is overwritten. *qp* is enlarged if necessary to accomodate this entry.

void *qp.set_c0(NT val)* sets the entry c_0 of *qp* to *val*. An existing entry is overwritten.

void *qp.set_d(int i, int j, NT val)*

sets the entries $2D_{ij}$ and $2D_{ji}$ of *qp* to *val*. Existing entries are overwritten. *qp* is enlarged if necessary to accomodate these entries.
Precondition: *j <= i*

Nonnegative_linear_program_from_iterators<A_it, B_it, R_it, C_it>

Class

CGAL::Quadratic_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it>

#include <CGAL/QP_models.h>

Definition

An object of class *Quadratic_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it>* describes a convex quadratic program of the form

$$
\begin{array}{lll}
\text{(QP)} & \text{minimize} & \mathbf{x}^T D\mathbf{x} + \mathbf{c}^T\mathbf{x} + c_0 \\
 & \text{subject to} & A\mathbf{x} \gtreqless \mathbf{b}, \\
 & & \mathbf{l} \le \mathbf{x} \le \mathbf{u}
\end{array}
$$

in n real variables $\mathbf{x} = (x_0,\ldots,x_{n-1})$. Here,

- A is an $m \times n$ matrix (the constraint matrix),
- $\mathbf{b}$ is an m-dimensional vector (the right-hand side),
- $\gtreqless$ is an m-dimensional vector of relations from $\{\le, =, \ge\}$,
- $\mathbf{l}$ is an n-dimensional vector of lower bounds for $\mathbf{x}$, where $l_j \in \mathbb{R} \cup \{-\infty\}$ for all j
- $\mathbf{u}$ is an n-dimensional vector of upper bounds for $\mathbf{x}$, where $u_j \in \mathbb{R} \cup \{\infty\}$ for all j
- D is a symmetric positive-semidefinite $n \times n$ matrix (the quadratic objective function),
- $\mathbf{c}$ is an n-dimensional vector (the linear objective function), and
- c_0 is a constant.

This class is simply a wrapper for existing iterators, and it does not copy the program data.

It frequently happens that all values in one of the vectors from above are the same, for example if the system $Ax \gtreqless b$ is actually a system of equations $Ax = b$. To get an iterator over such a vector, it is not necessary to store multiple copies of the value in some container; an instance of the class *Const_oneset_iterator<T>*, constructed from the value in question, does the job more efficiently.

Is Model for the Concepts

QuadraticProgram

Creation

Quadratic_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it> qp(int n,
int m,
A_it a,
B_it b,
R_it r,
FL_it fl,
L_it l,
FU_it fu,
U_it u,
D_it d,
C_it c,
std::iterator_traits<C_it>value_type c0 = 0)

constructs *qp* from given random-access iterators and the constant *c0*. The passed iterators are merely stored, no copying of the program data takes place. How these iterators are supposed to encode the quadratic program is described in *QuadraticProgram*.

Example

QP_solver/first_qp_from_iterators.cpp

The following example for the simpler model *Nonnegative_linear_program_from_iterators<A_it, B_it, R_it, C_it>* should give you a flavor of the use of this model in practice.

Function

CGAL::make_quadratic_program_from_iterators

#include <CGAL/QP_models.h>

This template function creates an instance of *Quadratic_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it>* from given iterators. This function can be useful if the types of these iterators are too complicated (or of too little interest for you) to write them down explicitly.

template < A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it >
Quadratic_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it>

make_quadratic_program_from_iterators(int n,
int m,
A_it a,
B_it b,
R_it r,
FL_it fl,
L_it l,
FU_it fu,
U_it u,
D_it d,
C_it c,
std::iterator_traits<C_it>::value_type c0 = std::iterator_traits<C_it>::value_type(0))

returns an instance of *Quadratic_program_from_iterators< A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it>*, constructed from the given iterators.

Example

The following example demonstrates the typical usage of makers with the simpler function *make_nonnegative_linear_program_from_iterators*.

QP_solver/solve_convex_hull_containment_lp2.h
QP_solver/convex_hull_containment2.cpp

Function

CGAL::solve_quadratic_program

#include <CGAL/QP_functions.h>

This function solves a quadratic program, using some exact Integral Domain *ET* for its computations. Various options may be provided, see *Quadratic_program_options*.

template <QuadraticProgram, ET>
Quadratic_program_solution<ET>

solve_quadratic_program(QuadraticProgram qp,
ET,
Quadratic_program_options options = Quadratic_program_options())

returns the solution of the quadratic program *qp*, solved with exact number type *ET*.

Requirements

ET is a model of the concepts *IntegralDomain* and *RealEmbeddable*; it must be an exact type, and all entries of *qp* are convertible to *ET*.

Here are some recommended combinations of input type (the type of the *qp* entries) and *ET*.

input type	—	*ET*
double	—	*MP_Float*, *Gmpzf*, or *Gmpq*
int	—	*MP_Float*, or *Gmpz*
any exact type *NT*	—	*NT*

Note: by default, this function performs a large number of runtime-checks to ensure consistency during the solution process. However, these checks slow down the computations by a considerable factor. For maximum efficiency, it is advisable to define the macros `CGAL_QP_NO_ASSERTIONS` or `NDEBUG`.

Example

QP_solver/first_qp.cpp

Nonnegative_linear_program_from_iterators<A_it, B_it, R_it, C_it>

Class

CGAL::Quadratic_program_options

#include <CGAL/QP_options.h>

Definition

This is a class used for passing options to the linear and quadratic programming solvers. Currently, we support only options referring to

1. the verbosity,
2. the pricing strategy (see *Quadratic_program_pricing_strategy*),
3. the validation mode (see the Validity section of *Quadratic_program_solution*)

The idea is that this list grows in the future.

Creation

Quadratic_program_options options; — constructs an instance of *Quadratic_program_options* where all available options are at their defaults.

Operations

Here we just have set/get pairs for any option type.

Verbosity

void — *options.set_verbosity(int verbosity)*

sets the verbosity of the solver to the value *verbosity* when *options* is passed to any of the four solution functions. The provided value must be a number between 0 and 5. Verbosity 0 is the default and results in the solver running silently. Verbosity 1 prints a short summary of every iteration. Higher verbosity values print more information about the solution process, but these are mainly for debugging purposes and have no effect if you compile with `CGAL_QP_NO_ASSERTIONS` or `NDEBUG`.

int — *options.get_verbosity() const*

returns the verbosity level of *options*.

Pricing strategy

void *options.set_pricing_strategy(Quadratic_program_pricing_strategy pricing_strategy)*

sets the pricing strategy of the solver to the value *pricing_strategy* when *options* is passed to any of the four solution functions. The pricing strategy controls how the solver proceeds from any intermediate solution. For the available strategies and their behavior, see the documentation of the class *Quadratic_program_pricing_strategy*.

Quadratic_program_pricing_strategy

options.get_pricing_strategy() const

returns the pricing strategy of *options*.

Validation mode

void *options.set_auto_validation(bool validate)*

sets the automatic validation mode of the solver to the value *validate*. The default is *false*. By providing value *true* you can tell the solver to automatically check whether the program has correctly been solved, see the Validity section of the class *Quadratic_program_solution*.

bool *options.get_auto_validation() const*

returns the validation mode of *options*.

Example

QP_solver/cycling.cpp

Class

CGAL::Quadratic_program_pricing_strategy

#include <CGAL/QP_options.h>

Definition

This is an enumeration type containing the values *QP_CHOOSE_DEFAULT*, *QP_DANTZIG*, *QP_PARTIAL_DANTZIG*, *QP_FILTERED_DANTZIG*, *QP_PARTIAL_FILTERED_DANTZIG*, and*QP_BLAND*.

It indicates the pricing strategy to be used in solving a linear or quadratic program. This strategy determines how the solver gets from one intermediate solution to the next during any of its iterations.

Here we briefly describe when to choose which strategy.

QP_CHOOSE_DEFAULT

This is the default value of the pricing strategy in *Quadratic_program_options*, and it lets the solver choose the strategy that it thinks is most appropriate for the problem at hand. There are only few reasons to deviate from this default, but you are free to experiment, of course.

QP_PARTIAL_DANTZIG

If the input type is **not** *double*, this is usually the best choice for linear and quadratic programs of medium size.

QP_DANTZIG

If the input type is **not** *double*, this can sometimes make a difference (be faster or slowe) than *QP_PARTIAL_DANTZIG* for problems with a high variable/constraint or constraint/variable ratio.

QP_PARTIAL_FILTERED_DANTZIG

If the input type **is** *double*, this is usually the best choice for linear and quadratic programs of medium size. If the input type is not *double*, this choice is equivalent to *QP_PARTIAL_DANTZIG*.

Note: filtered strategies may in rare cases fail due to double exponent overflows, see Section 10.8.1. In this case, the slower fallback option is the non-filtered variant *QP_PARTIAL_DANTZIG* of this strategy.

QP_FILTERED_DANTZIG

If the input type **is** *double*, this can sometimes make a difference (be faster or slowe) than *QP_PARTIAL_FILTERED_DANTZIG* for problems with a high variable/constraint or constraint/variable ratio. If the input type is not *double*, this choice is equivalent to *QP_DANTZIG*.

Note: filtered strategies may in rare cases fail due to double exponent overflows, see Section 10.8.1. In this case, the slower fallback option is the non-filtered variant *QP_DANTZIG* of this strategy.

QP_BLAND

This is hardly ever the most efficient choice, but it is guaranteed to avoid internal cycling of the solution algorithm, see Section 10.8.2.

Quadratic_program_options

CGAL::print_quadratic_program

#include <CGAL/QP_functions.h>

This function writes a quadratic program to an output stream (in *MPSFormat*). The time complexity is $\Theta(n^2 + mn)$, even if the program is very sparse.

template <QuadraticProgram>
void *print_quadratic_program(std::ostream& out, QuadraticProgram qp, std::string problem_name = std::string("MY_MPS"))*

writes the quadratic program *qp* to *out* in *MPSFormat*. The name of the program will be the one provided by *problem_name*.

Requirements

Output operators are defined for all entry types of *qp*.

Example

QP_solver/print_first_qp.cpp

Geometry Kernels

Chapter 11

2D and 3D Geometry Kernel

Hervé Brönnimann, Andreas Fabri, Geert-Jan Giezeman, Susan Hert, Michael Hoffmann, Lutz Kettner, Sylvain Pion, and Stefan Schirra

Contents

11.1 Introduction

CGAL, the *Computational Geometry Algorithms Library*, is written in C++ and consists of three major parts. The first part is the kernel, which consists of constant-size non-modifiable geometric primitive objects and operations on these objects. The objects are represented both as stand-alone classes that are parameterized by a representation class, which specifies the underlying number types used for calculations and as members of the kernel classes, which allows for more flexibility and adaptability of the kernel. The second part is a collection of basic geometric data structures and algorithms, which are parameterized by traits classes that define the interface between the data structure or algorithm and the primitives they use. In many cases, the kernel classes provided in CGAL can be used as traits classes for these data structures and algorithms. The third part of the library consists of non-geometric support facilities, such as circulators, random sources, I/O support for debugging and for interfacing CGAL to various visualization tools.

This part of the reference manual covers the kernel. The kernel contains objects of constant size, such as point, vector, direction, line, ray, segment, triangle, iso-oriented rectangle and tetrahedron. With each type comes a set of functions which can be applied to an object of this type. You will typically find access functions (e.g. to the coordinates of a point), tests of the position of a point relative to the object, a function returning the bounding box, the length, or the area of an object, and so on. The CGAL kernel further contains basic operations such as affine transformations, detection and computation of intersections, and distance computations.

11.1.1 Robustness

The correctness proof of nearly all geometric algorithms presented in theory papers assumes exact computation with real numbers. This leads to a fundamental problem with the implementation of geometric algorithms. Naively, often the exact real arithmetic is replaced by inexact floating-point arithmetic in the implementation. This often leads to acceptable results for many input data. However, even for the implementation of the simplest geometric algorithms this simplification occasionally does not work. Rounding errors introduced by an inaccurate arithmetic may lead to inconsistent decisions, causing unexpected failures for some correct input data. There are many approaches to this problem, one of them is to compute exactly (compute so accurate that all decisions made by the algorithm are exact) which is possible in many cases but more expensive than standard floating-point arithmetic. C. M. Hoffmann [Hof89a, Hof89b] illustrates some of the problems arising in the implementation of geometric algorithms and discusses some approaches to solve them. A more recent overview is given in [Sch00]. The exact computation paradigm is discussed by Yap and Dubé [YD95] and Yap [Yap97].

In CGAL you can choose the underlying number types and arithmetic. You can use different types of arithmetic simultaneously and the choice can be easily changed, e.g. for testing. So you can choose between implementations with fast but occasionally inexact arithmetic and implementations guaranteeing exact computation and exact results. Of course you have to pay for the exactness in terms of execution time and storage space. See the dedicated chapter for more details on number types and their capabilities and performance.

11.2 Kernel Representations

Our object of study is the d-dimensional affine Euclidean space. Here we are mainly concerned with cases $d = 2$ and $d = 3$. Objects in that space are sets of points. A common way to represent the points is the use of Cartesian coordinates, which assumes a reference frame (an origin and d orthogonal axes). In that framework, a point is represented by a d-tuple $(c_0, c_1, \dots, c_{d-1})$, and so are vectors in the underlying linear space. Each point is represented uniquely by such Cartesian coordinates. Another way to represent points is by homogeneous coordinates. In that framework, a point is represented by a $(d+1)$-tuple $(h_0, h_1, \dots, h_d)$. Via the formulae $c_i = h_i/h_d$, the corresponding point with Cartesian coordinates $(c_0, c_1, \dots, c_{d-1})$ can be computed. Note that homogeneous coordinates are not unique. For $\lambda \neq 0$, the tuples $(h_0, h_1, \dots, h_d)$ and $(\lambda \cdot h_0, \lambda \cdot h_1, \dots, \lambda \cdot h_d)$ represent the same point. For a point with Cartesian coordinates $(c_0, c_1, \dots, c_{d-1})$ a possible homogeneous representation is $(c_0, c_1, \dots, c_{d-1}, 1)$. Homogeneous coordinates in fact allow to represent objects in a more general space, the projective space $\mathbb{P}^d$. In CGAL, we do not compute in projective geometry. Rather, we use homogeneous coordinates to avoid division operations, since the additional coordinate can serve as a common denominator.

11.2.1 Genericity Through Parameterization

Almost all the kernel objects (and the corresponding functions) are templates with a parameter that allows the user to choose the representation of the kernel objects. A type that is used as an argument for this parameter must fulfill certain requirements on syntax and semantics. The list of requirements defines an abstract kernel concept. For all kernel objects types, the types *CGAL::Type<Kernel>* and *Kernel::Type* are identical.

CGAL offers four families of concrete models for the concept Kernel, two based on the Cartesian representation of points and two based on the homogeneous representation of points. The interface of the kernel objects is designed such that it works well with both Cartesian and homogeneous representation. For example, points in 2D have a constructor with three arguments as well (the three homogeneous coordinates of the point). The common interfaces parameterized with a kernel class allow one to develop code independent of the chosen representation. We said "families" of models, because both families are parameterized too. A user can choose the number type used to represent the coordinates.

For reasons that will become evident later, a kernel class provides two typenames for number types, namely *Kernel::FT* and *Kernel::RT*. The type *Kernel::FT* must fulfill the requirements on what is called a *FieldNumberType* in CGAL. This roughly means that *Kernel::FT* is a type for which operations $+$, $-$, $*$ and $/$ are defined with semantics (approximately) corresponding to those of a field in a mathematical sense. Note that, strictly speaking, the built-in type *int* does not fulfill the requirements on a field type, since *int*s correspond to elements of a ring rather than a field, especially operation $/$ is not the inverse of $*$. The requirements on the type *Kernel::RT* are weaker. This type must fulfill the requirements on what is called a *RingNumberType* in CGAL. This roughly means that *Kernel::RT* is a type for which operations $+$, $-$, $*$ are defined with semantics (approximately) corresponding to those of a ring in a mathematical sense.

11.2.2 Cartesian Kernels

With *Cartesian<FieldNumberType>* you can choose a Cartesian representation of coordinates. When you choose Cartesian representation you have to declare at the same time the type of the coordinates. A number type used with the *Cartesian* representation class should be a FieldNumberType as described above. As mentioned above, the built-in type *int* is not a FieldNumberType. However, for some computations with Cartesian representation, no division operation is needed, i.e., a *RingNumberType* is sufficient in this case. With *Cartesian<FieldNumberType>*, both *Cartesian<FieldNumberType>::FT* and *Cartesian<FieldNumberType>::RT* are mapped to *FieldNumberType*.

Cartesian<FieldNumberType> uses reference counting internally to save copying costs. CGAL also provides *Simple_cartesian<FieldNumberType>*, a kernel that uses Cartesian representation but no reference counting. Debugging is easier with *Simple_cartesian<FieldNumberType>*, since the coordinates are stored within the class and hence direct access to the coordinates is possible. Depending on the algorithm, it can also be slightly more or less efficient than *Cartesian<FieldNumberType>*. Again, in *Simple_cartesian<FieldNumberType>* both *Simple_cartesian<FieldNumberType>::FT* and *Simple_cartesian<FieldNumberType>::RT* are mapped to *FieldNumberType*.

11.2.3 Homogeneous Kernels

Homogeneous coordinates permit to avoid division operations in numerical computations, since the additional coordinate can serve as a common denominator. Avoiding divisions can be useful for exact geometric computation. With *Homogeneous<RingNumberType>* you can choose a homogeneous representation for the coordinates of the kernel objects. As for the Cartesian representation, one has to declare the type used to store the coordinates. Since the homogeneous representation does not use divisions, the number type associated with a homogeneous representation class must be a model for the weaker concept *RingNumberType* only. However, some operations provided by this kernel involve divisions, for example computing squared distances or Cartesian coordinates. To keep the requirements on the number type parameter of *Homogeneous* low, the number type *Quotient<RingNumberType>* is used for operations that require divisions. This number type can be viewed as an adaptor which turns a *RingNumberType* into a *FieldNumberType*. It maintains numbers as quotients, i.e., a numerator and a denominator. With *Homogeneous<RingNumberType>*, *Homogeneous<RingNumberType>::FT* is equal to *Quotient<RingNumberType>*, while *Homogeneous<RingNumberType>::RT* is equal to *RingNumberType*.

Homogeneous<RingNumberType> uses reference counting internally to save copying costs. CGAL also provides *Simple_homogeneous<RingNumberType>*, a kernel that uses homogeneous representation but no reference counting. Debugging is easier with *Simple_homogeneous<RingNumberType>*, since the coordinates are stored within the class and hence direct access to the coordinates is possible. Depending on the algorithm, it can also be slightly more or less efficient than *Homogeneous<RingNumberType>*. Again, in *Simple_homogeneous<RingNumberType>* the type *Simple_homogeneous<RingNumberType>::FT* is equal to *Quotient<RingNumberType>* while *Simple_homogeneous<RingNumberType>::RT* is equal to *RingNumberType*.

11.2.4 Naming Conventions

The use of kernel classes not only avoids problems, it also makes all CGAL classes very uniform. They **always** consist of:

1. The *capitalized base name* of the geometric object, such as *Point*, *Segment*, or *Triangle*.
2. An *underscore* followed by the *dimension* of the object, for example _2, _3, or *_d*.
3. A *kernel class* as parameter, which itself is parameterized with a number type, such as *Cartesian<double>* or *Homogeneous<leda_integer>*.

11.2.5 Kernel as a Traits Class

Algorithms and data structures in the basic library of CGAL are parameterized by a traits class that subsumes the objects on which the algorithm or data structure operates as well as the operations to do so. For most of the algorithms and data structures in the basic library you can use a kernel as a traits class. For some algorithms you even do not have to specify the kernel; it is detected automatically using the types of the geometric objects passed to the algorithm. In some other cases, the algorithms or data structures needs more than is provided by the kernel concept. In these cases, a kernel can not be used as a traits class.

11.2.6 Choosing a Kernel and Predefined Kernels

If you start with integral Cartesian coordinates, many geometric computations will involve integral numerical values only. Especially, this is true for geometric computations that evaluate only predicates, which are tantamount to determinant computations. Examples are triangulation of point sets and convex hull computation. In this case, the Cartesian representation is probably the first choice, even with a ring type. You might use limited precision integer types like *int* or *long*, use *double* to present your integers (they have more bits in their mantissa than an *int* and overflow nicely), or an arbitrary precision integer type like the wrapper *Gmpz* for the GMP integers, *leda_integer*, or *MP_Float*. Note, that unless you use an arbitrary precision ring type, incorrect results might arise due to overflow.

If new points are to be constructed, for example the intersection point of two lines, computation of Cartesian coordinates usually involves divisions. Hence, one needs to use a *FieldNumberType* with Cartesian representation, or alternatively, switch to homogeneous representation. The type *double* is a – though imprecise – model for *FieldNumberType*. You can also put any *RingNumberType* into the *Quotient* adaptor to get a field type which then can be put into *Cartesian*. But using homogeneous representation on the *RingNumberType* is usually the better option. Other valid *FieldNumberType*s are *leda_rational* and *leda_real*.

If it is crucial for you that the computation is reliable, the right choice is probably a number type that guarantees exact computation. The *Filtered_kernel* provides a way to apply filtering techniques [BBP01] to achieve a kernel with exact and efficient predicates. Still other people will prefer the built-in type `double`, because they need speed and can live with approximate results, or even algorithms that, from time to time, crash or compute incorrect results due to accumulated rounding errors.

Predefined kernels. For the user's convenience, CGAL provides 3 typedefs to generally useful kernels.

- They are all Cartesian kernels.
- They all support constructions of points from `double` Cartesian coordinates.
- All these 3 kernels provide exact geometric predicates.
- They handle geometric constructions differently:
  - *Exact_predicates_exact_constructions_kernel*: provides exact geometric constructions, in addition to exact geometric predicates.
  - *Exact_predicates_exact_constructions_kernel_with_sqrt*: same as *Exact_predicates_exact_constructions_kernel*, but the number type it provides (*Exact_predicates_exact_constructions_kernel_with_sqrt::FT*) supports the square root operation exactly [1].
  - *Exact_predicates_inexact_constructions_kernel*: provides exact geometric predicates, but geometric constructions may be inexact due to round-off errors. It is however enough for most CGAL algorithms, and faster than both *Exact_predicates_exact_constructions_kernel* and *Exact_predicates_exact_constructions_kernel_with_sqrt*.

[1] Currently it requires having either LEDA or CORE installed

11.3 Kernel Geometry

11.3.1 Points and Vectors

In CGAL, we strictly distinguish between points, vectors and directions. A *point* is a point in the Euclidean space $\mathbb{E}^d$, a *vector* is the difference of two points p_2, p_1 and denotes the direction and the distance from p_1 to p_2 in the vector space $\mathbb{R}^d$, and a *direction* is a vector where we forget about its length. They are different mathematical concepts. For example, they behave different under affine transformations and an addition of two points is meaningless in affine geometry. By putting them in different classes we not only get cleaner code, but also type checking by the compiler which avoids ambiguous expressions. Hence, it pays twice to make this distinction.

CGAL defines a symbolic constant *ORIGIN* of type *Origin* which denotes the point at the origin. This constant is used in the conversion between points and vectors. Subtracting it from a point p results in the locus vector of p.

```
Point_2< Cartesian<double> >  p(1.0, 1.0), q;
Vector_2< Cartesian<double> >  v;
v = p - ORIGIN;
q = ORIGIN + v;
assert( p == q );
```

In order to obtain the point corresponding to a vector v you simply have to add v to *ORIGIN*. If you want to determine the point q in the middle between two points p_1 and p_2, you can write[2]

```
q = p_1 + (p_2 - p_1) / 2.0;
```

Note that these constructions do not involve any performance overhead for the conversion with the currently available representation classes.

11.3.2 Kernel Objects

Besides points (*Point_2<Kernel>*, *Point_3<Kernel>*, *Point_d<Kernel>*), vectors (*Vector_2<Kernel>*, *Vector_3<Kernel>*), and directions (*Direction_2<Kernel>*, *Direction_3<Kernel>*), CGAL provides lines, rays, segments, planes, triangles, tetrahedra, iso-rectangles, iso-cuboids, circles and spheres.

Lines (*Line_2<Kernel>*, *Line_3<Kernel>*) in CGAL are oriented. In two-dimensional space, they induce a partition of the plane into a positive side and a negative side. Any two points on a line induce an orientation of this line. A ray (*Ray_2<Kernel>*, *Ray_3<Kernel>*) is semi-infinite interval on a line, and this line is oriented from the finite endpoint of this interval towards any other point in this interval. A segment (*Segment_2<Kernel>*, *Segment_3<Kernel>*) is a bounded interval on a directed line, and the endpoints are ordered so that they induce the same direction as that of the line.

Planes are affine subspaces of dimension two in $\mathbb{E}^3$, passing through three points, or a point and a line, ray, or segment. CGAL provides a correspondence between any plane in the ambient space $\mathbb{E}^3$ and the embedding of $\mathbb{E}^2$ in that space. Just like lines, planes are oriented and partition space into a positive side and a negative side. In CGAL, there are no special classes for half-spaces. Half-spaces in 2D and 3D are supposed to be represented by oriented lines and planes, respectively.

[2] you might call *midpoint(p_1,p_2)* instead

Concerning polygons and polyhedra, the kernel provides triangles, iso-oriented rectangles, iso-oriented cuboids and tetrahedra. More complex polygons[3] and polyhedra or polyhedral surfaces can be obtained from the basic library (*Polygon_2*, *Polyhedron_3*), so they are not part of the kernel. As with any Jordan curves, triangles, iso-oriented rectangles and circles separate the plane into two regions, one bounded and one unbounded.

11.3.3 Orientation and Relative Position

Geometric objects in CGAL have member functions that test the position of a point relative to the object. Full dimensional objects and their boundaries are represented by the same type, e.g. half-spaces and hyperplanes are not distinguished, neither are balls and spheres and discs and circles. Such objects split the ambient space into two full-dimensional parts, a bounded part and an unbounded part (e.g. circles), or two unbounded parts (e.g. hyperplanes). By default these objects are oriented, i.e., one of the resulting parts is called the positive side, the other one is called the negative side. Both of these may be unbounded.

For these objects there is a function *oriented_side()* that determines whether a test point is on the positive side, the negative side, or on the oriented boundary. These function returns a value of type *Oriented_side*.

Those objects that split the space in a bounded and an unbounded part, have a member function *bounded_side()* with return type *Bounded_side*.

If an object is lower dimensional, e.g. a triangle in three-dimensional space or a segment in two-dimensional space, there is only a test whether a point belongs to the object or not. This member function, which takes a point as an argument and returns a Boolean value, is called *has_on()*

11.4 Predicates and Constructions

11.4.1 Predicates

Predicates are at the heart of a geometry kernel. They are basic units for the composition of geometric algorithms and encapsulate decisions. Hence their correctness is crucial for the control flow and hence for the correctness of an implementation of a geometric algorithm. CGAL uses the term predicate in a generalized sense. Not only components returning a Boolean value are called predicates but also components returning an enumeration type like a *Comparison_result* or an *Orientation*. We say components, because predicates are implemented both as functions and function objects (provided by a kernel class).

CGAL provides predicates for the orientation of point sets (*orientation*, *leftturn*, *rightturn*, *collinear*, *coplanar*), for comparing points according to some given order, especially for comparing Cartesian coordinates (e.g. *lexicographically_xy_smaller*), in-circle and in-sphere tests, and predicates to compare distances.

11.4.2 Constructions

Functions and function objects that generate objects that are neither of type *bool* nor enum types are called constructions. Constructions involve computation of new numerical values and may be imprecise due to rounding errors unless a kernel with an exact number type is used.

[3] Any sequence of points can be seen as a (not necessary simple) polygon or polyline. This view is used frequently in the basic library as well.

Affine transformations (*Aff_transformation_2<Kernel>*, *Aff_transformation_3<Kernel>*) allow to generate new object instances under arbitrary affine transformations. These transformations include translations, rotations (in 2D only) and scaling. Most of the geometric objects in a kernel have a member function *transform(Aff_transformation t)* which applies the transformation to the object instance.

CGAL also provides a set of functions that detect or compute the intersection between objects of the 2D kernel, and many objects in the 3D kernel, and functions to calculate their squared distance. Moreover, some member functions of kernel objects are constructions.

So there are routines that compute the square of the Euclidean distance, but no routines that compute the distance itself. Why? First of all, the two values can be derived from each other quite easily (by taking the square root or taking the square). So, supplying only the one and not the other is only a minor inconvenience for the user. Second, often either value can be used. This is for example the case when (squared) distances are compared. Third, the library wants to stimulate the use of the squared distance instead of the distance. The squared distance can be computed in more cases and the computation is cheaper. We do this by not providing the perhaps more natural routine, The problem of a distance routine is that it needs the *sqrt* operation. This has two drawbacks:

- The *sqrt* operation can be costly. Even if it is not very costly for a specific number type and platform, avoiding it is always cheaper.
- There are number types on which no *sqrt* operation is defined, especially integer types and rationals.

11.4.3 Polymorphic Return Values

Some functions can return different types of objects. A typical C++ solution to this problem is to derive all possible return types from a common base class, to return a pointer to this class and to perform a dynamic cast on this pointer. The class *Object* provides an abstraction. An object *obj* of the class *Object* can represent an arbitrary class. The only operations it provides is to make copies and assignments, so that you can put them in lists or arrays. Note that *Object* is NOT a common base class for the elementary classes. Therefore, there is no automatic conversion from these classes to *Object*. Rather this is done with the global function *make_object()*. This encapsulation mechanism requires the use of *object_cast* to access the encapsulated class (a less efficient way, which is now discouraged, used to be to use the *assign* function).

Example

In the following example, the object class is used as return value for the intersection computation, as there are possibly different return values.

```
{
    typedef Cartesian<double>  K;
    typedef K::Point_2         Point_2;
    typedef K::Segment_2       Segment_2;

    Segment_2 segment_1, segment_2;

    std::cin >> segment_1 >> segment_2;

    Object obj = intersection(segment_1, segment_2);

    if (const Point_2 *point = object_cast<Point_2>(&obj)) {
        /* do something with *point */
    } else if (const Segment_2 *segment = object_cast<Segment_2>(&obj)) {
```

```
        /* do something with *segment*/
    }

    /* there was no intersection */
}
```

The intersection routine itself looks roughly as follows:

```
template < class Kernel >
Object  intersection(Segment_2<Kernel> s1, Segment_2<Kernel> s2)
{

    if (/* intersection in a point */ ) {

       Point_2<Kernel> p = ...  ;
       return make_object(p);

    } else if (/* intersection in a segment */ ) {

       Segment_2<Kernel> s = ...  ;
       return make_object(s);
    }
    return Object();
}
```

11.4.4 Constructive Predicates

For testing where a point p lies with respect to a plane defined by three points q, r and s, one may be tempted to construct the plane *Plane_3<Kernel>(q,r,s)* and use the method *oriented_side(p)*. This may pay off if many tests with respect to the plane are made. Nevertheless, unless the number type is exact, the constructed plane is only approximated, and round-off errors may lead *oriented_side(p)* to return an orientation which is different from the orientation of p, q, r, and s.

In CGAL, we provide predicates in which such geometric decisions are made directly with a reference to the input points p, q, r, s, without an intermediary object like a plane. For the above test, the recommended way to get the result is to use *orientation(p,q,r,s)*. For exact number types, the situation is different. If several tests are to be made with the same plane, it pays off to construct the plane and to use *oriented_side(p)*.

11.5 Extensible Kernel

This manual section describe how users can plug user defined geometric classes in existing CGAL kernels. This is best illustrated by an example.

11.5.1 Introduction

CGAL defines the concept of a geometry kernel. Such a kernel provides types, construction objects and generalized predicates. Most implementations of Computational Geometry algorithms and data structures in the basic library of CGAL were done in a way that classes or functions can be parametrized with a geometric traits class.

In most cases this geometric traits class must be a model of the CGAL geometry kernel concept (but there are some exceptions).

11.5.2 An Extensive Example

Assume you have the following point class, where the coordinates are stored in an array of *doubles*, where we have another data member *color*, which shows up in the constructor.

```
#ifndef MY_POINTC2_H
#define MY_POINTC2_H

#include <CGAL/Origin.h>
#include <CGAL/Bbox_2.h>

class MyPointC2 {

private:
  double vec[2];
  int col;

public:

  MyPointC2()
    : col(0)
  {
    *vec = 0;
    *(vec+1) = 0;
  }

  MyPointC2(const double x, const double y, int c = 0)
    : col(c)
  {
    *vec = x;
    *(vec+1) = y;
  }

  const double& x() const  { return *vec; }

  const double& y() const { return *(vec+1); }

  double & x() { return *vec; }

  double& y() { return *(vec+1); }
```

```
  int color() const { return col; }

  int& color() { return col; }

  bool operator==(const MyPointC2 &p) const
  {
    return ( *vec == *(p.vec) )  && ( *(vec+1) == *(p.vec + 1) && ( col
   == p.col) );
  }

  bool operator!=(const MyPointC2 &p) const
  {
      return !(*this == p);
  }

};

#endif // MY_POINTC2_H
```

File: examples/Kernel_23/MyPointC2.h

As said earlier the class is pretty minimalistic, for example it has no *bbox()* method. One might assume that a basic library algorithm which computes a bounding box (e.g, to compute the bounding box of a polygon), will not compile. Luckily it will, because it does not use of member functions of geometric objects, but it makes use of the functor *Kernel::Construct_bbox_2*.

To make the right thing happen with *MyPointC2* we have to provide the following functor.

```
#ifndef MYCONSTRUCT_BBOX_2_H
#define MYCONSTRUCT_BBOX_2_H

template <class ConstructBbox_2>
class MyConstruct_bbox_2 : public ConstructBbox_2 {
public:
  using ConstructBbox_2::operator();

  CGAL::Bbox_2 operator()(const MyPointC2& p) const {
    return CGAL::Bbox_2(p.x(), p.y(), p.x(), p.y());
  }
};

#endif //MYCONSTRUCT_BBOX_2_H
```

File: examples/Kernel_23/MyConstruct_bbox_2.h

Things are similar for random access to the Cartesian coordinates of a point. As the coordinates are stored in an array of *doubles* we can use *double** as random access iterator.

```
#ifndef MYCONSTRUCT_COORD_ITERATOR_H
```

```
#define MYCONSTRUCT_COORD_ITERATOR_H

class MyConstruct_coord_iterator {
public:
  const double* operator()(const MyPointC2& p)
  {
    return &p.x();
  }

  const double* operator()(const MyPointC2& p, int)
  {
    const double* pyptr = &p.y();
    pyptr++;
    return pyptr;
  }
};

#endif //MYCONSTRUCT_COORD_ITERATOR_H
```

File: examples/Kernel_23/MyConstruct_coord_iterator.h

The last functor we have to provide is the one which constructs points. That is you are not forced to add the constructor with the *Origin* as parameter to your class, nor the constructor with homogeneous coordinates. The functor is a kind of glue layer between the CGAL algorithms and your class.

```
#ifndef MYCONSTRUCT_POINT_2_H
#define MYCONSTRUCT_POINT_2_H

template <typename K, typename OldK>
class MyConstruct_point_2
{
  typedef typename K::RT         RT;
  typedef typename K::Point_2    Point_2;
  typedef typename K::Line_2     Line_2;
  typedef typename Point_2::Rep  Rep;
public:
  typedef Point_2                result_type;

  // Note : the CGAL::Return_base_tag is really internal CGAL stuff.
  // Unfortunately it is needed for optimizing away copy-constructions,
  // due to current lack of delegating constructors in the C++ standard.
  Rep // Point_2
  operator()(CGAL::Return_base_tag, CGAL::Origin o) const
  { return Rep(o); }

  Rep // Point_2
  operator()(CGAL::Return_base_tag, const RT& x, const RT& y) const
  { return Rep(x, y); }

  Rep // Point_2
  operator()(CGAL::Return_base_tag, const RT& x, const RT& y, const RT&
   w) const
  { return Rep(x, y, w); }
```

```
  Point_2
  operator()(CGAL::Origin o) const
  { return MyPointC2(0, 0, 0); }

  Point_2
  operator()(const RT& x, const RT& y) const
  {
    return MyPointC2(x, y, 0);
  }

  Point_2
  operator()(const Line_2& l) const
  {
    typename OldK::Construct_point_2 base_operator;
    Point_2 p = base_operator(l);
    return p;
  }

  Point_2
  operator()(const Line_2& l, int i) const
  {
    typename OldK::Construct_point_2 base_operator;
    return base_operator(l, i);
  }

  // We need this one, as such a functor is in the Filtered_kernel
  Point_2
  operator()(const RT& x, const RT& y, const RT& w) const
  {
    if(w != 1){
      return MyPointC2(x/w, y/w, 0);
    } else {
      return MyPointC2(x,y, 0);
    }
  }
};

#endif //MYCONSTRUCT_POINT_2_H
```

File: examples/Kernel_23/MyConstruct_point_2.h

Now we are ready to put the puzzle together. We won't explain it in detail, but you see that there are *typedefs* to the new point class and the functors. All the other types are inherited.

```
#ifndef MYKERNEL_H
#define MYKERNEL_H

#include <CGAL/Cartesian.h>
#include "MyPointC2.h"
#include "MySegmentC2.h"
#include "MyConstruct_bbox_2.h"
#include "MyConstruct_coord_iterator.h"
```

```
#include "MyConstruct_point_2.h"

// K_ is the new kernel, and K_Base is the old kernel
template < typename K_, typename K_Base >
class MyCartesian_base
  : public K_Base::template Base<K_>::Type
{
  typedef typename K_Base::template Base<K_>::Type   OldK;
public:
  typedef K_                                  Kernel;
  typedef MyPointC2                           Point_2;
  typedef MySegmentC2<Kernel>                 Segment_2;
  typedef MyConstruct_point_2<Kernel, OldK>         Construct_point_2;
  typedef const double*                       Cartesian_const_iterator_2;
  typedef MyConstruct_coord_iterator
   Construct_cartesian_const_iterator_2;
  typedef MyConstruct_bbox_2<typename OldK::Construct_bbox_2>
                                              Construct_bbox_2;

  Construct_point_2
  construct_point_2_object() const
  { return Construct_point_2(); }

  Construct_bbox_2
  construct_bbox_2_object() const
  { return Construct_bbox_2(); }

  Construct_cartesian_const_iterator_2
  construct_cartesian_const_iterator_2_object() const
  { return Construct_cartesian_const_iterator_2(); }

  template < typename Kernel2 >
  struct Base { typedef MyCartesian_base<Kernel2, K_Base>  Type; };
};

template < typename FT_ >
struct MyKernel
  : public CGAL::Type_equality_wrapper<
                MyCartesian_base<MyKernel<FT_>, CGAL::Cartesian<FT_> >,
                MyKernel<FT_> >
{};

#endif // MYKERNEL_H
```

File: examples/Kernel_23/MyKernel.h

Finally, we give an example how this new kernel can be used. Predicates and constructions work with the new point, they can be a used to construct segments and triangles with, and data structures from the Basic Library, as the Delaunay triangulation work with them.

The kernel itself can be made robust by plugging it in the *Filtered_kernel*.

```
#include <CGAL/basic.h>
#include <CGAL/Filtered_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/squared_distance_2.h>
#include <cassert>
#include "MyKernel.h"
#include "MyPointC2_iostream.h"

typedef MyKernel<double>                   MK;
typedef CGAL::Filtered_kernel_adaptor<MK>  K;
typedef CGAL::Delaunay_triangulation_2<K>  Delaunay_triangulation_2;

typedef K::Point_2         Point;
typedef K::Segment_2       Segment;
typedef K::Ray_2           Ray;
typedef K::Line_2          Line;
typedef K::Triangle_2      Triangle;
typedef K::Iso_rectangle_2 Iso_rectangle;

const int RED= 1;
const int BLACK=2;

int main()
{
  Point a(0,0), b(1,0), c(1,1), d(0,1);
  a.color()=RED;
  b.color()=BLACK;
  d.color()=RED;

  Delaunay_triangulation_2 dt;
  dt.insert(a);

  K::Orientation_2 orientation;
  orientation(a,b,c);

  Point p(1,2), q;
  p.color() = RED;
  q.color() = BLACK;
  std::cout << p << std::endl;

  K::Compute_squared_distance_2 squared_distance;

  std::cout << "squared_distance(a, b) == "
            << squared_distance(a, b) << std::endl;

  Segment s1(p,q), s2(a, c);

  K::Construct_midpoint_2 construct_midpoint_2;

  Point mp = construct_midpoint_2(p,q);

  assert(s1.source().color() == RED);
```

```
  K::Intersect_2 intersection;

  CGAL::Object o = intersection(s1, s2);

  K::Construct_cartesian_const_iterator_2 construct_it;
  K::Cartesian_const_iterator_2  cit = construct_it(a);
  assert(*cit == a.x());

  cit = construct_it(a,0);

  cit--;
  assert(*cit == a.y());

  Line l1(a,b), l2(p, q);

  intersection(l1, l2);

  intersection(s1, l1);

  Ray r1(d,b), r2(d,c);
  intersection(r1, r2);

  intersection(r1, l1);

  squared_distance(r1, r2);
  squared_distance(r1, l2);
  squared_distance(r1, s2);

  Triangle t1(a,b,c), t2(a,c,d);
  intersection(t1, t2);
  intersection(t1, l1);

  intersection(t1, s1);

  intersection(t1, r1);

  Iso_rectangle i1(a,c), i2(d,p);
  intersection(i1, i2);
  intersection(i1, s1);

  intersection(i1, r1);
  intersection(i1, l1);

  t1.orientation();

  std::cout << s1.source() << std::endl;

  std::cout << t1.bbox() << std::endl;

  std::cout << "done" << std::endl;
  return 0;
}
```

File: `examples/Kernel_23/MyKernel.cpp`

11.5.3 Limitations

The point class must have member functions *x()* and *y()* (and *z()* for the 3d point). We will probably introduce function objects that take care of coordinate access.

As we enforce type equality between *MyKernel::Point_2* and *Point_2<MyKernel>*, the constructor with the color as third argument is not available.

11.6 Projection Traits Classes

It is sometimes useful to apply 2D algorithms to the projection of 3D points on a plane. Examples are triangulated terrains, which are points with elevation, or surface reconstruction from parallel slices, where one wants to check the simplicity or orientation of polygons.

For this purpose CGAL provides several projection traits classes, which are a model of traits class concepts of 2D triangulations, 2D polygon and 2D convex hull traits classes. The projection traits classes are listed in the "*Is Model for the Concepts*" sections of the concepts.

11.7 Design and Implementation History

At a meeting at Utrecht University in January 1995, Olivier Devillers, Andreas Fabri, Wolfgang Freiseisen, Geert-Jan Giezeman, Mark Overmars, Stefan Schirra, Otfried Schwarzkopf (now Otfried Cheong), and Sven Schönherr discussed the foundations of the CGAL kernel. Many design and software engineering issues were addressed, e.g. naming conventions, coupling of classes (flat versus deep class hierarchy), memory allocation, programming conventions, mutability of atomic objects, points and vectors, storing additional information, orthogonality of operations on the kernel objects, viewing non-constant-size objects like polygons as dynamic data structures (and hence not as part of the (innermost) kernel).

The people attending the meeting delegated the compilation of a draft specification to Stefan Schirra. The resulting draft specification was intentionally modeled on CGAL's precursors C++GAL and PLAGEO as well as on the geometric part of LEDA. The specification already featured coexistence of Cartesian and homogeneous representation of point/vector data and parameterization by number type(s). During the discussion of the draft a kernel design group was formed. The members of this group were Andreas Fabri, Geert-Jan Giezeman, Lutz Kettner, Stefan Schirra, and Sven Schönherr. The work of the kernel design group led to significant changes and improvements of the original design, e.g. the strong separation between points and vectors. Probably the most important enhancement was the design of a common superstructure for the previously uncoupled Cartesian and homogeneous representations. One can say, that the kernel was designed by this group. The kernel was later revised based on suggestions by Hervé Brönnimann, Bernd Gärtner, Michael Hoffmann, and Lutz Kettner.

A first version of the kernel was internally made available at the beginning of the CGAL-project (ESPRIT LTR IV project number 21957). Since then many more people contributed to the evolution of the kernel through discussions on the CGAL mailing lists. The implementation based on Cartesian representation was (initially) provided by Andreas Fabri, the homogeneous representation (initially) by Stefan Schirra. Intersection and distance computations were implemented by Geert-Jan Giezeman. Further work has been done by Susan Hert on the overall maintenance of the kernel. Philippe Guigue has provided efficient intersection tests for 3D triangles. Andreas Fabri, Michael Hoffmann and Sylvain Pion have improved the support for the extensibility and adaptability of the kernel. Pedro Machado Manhães de Castro and Monique Teillaud introduced 3D circles. In 2010, Pierre Alliez, Stéphane Tayeb and Camille Wormser added intersection constructions for 3D triangles and efficient intersection tests for bounding boxes.

11.7.1 Acknowledgment

This work was supported by the Graduiertenkolleg 'Algorithmische Diskrete Mathematik', under grant DFG We 1265/2-1, and by ESPRIT IV Long Term Research Projects No. 21957 (CGAL) and No. 28155 (GALIA).

2D and 3D Geometry Kernel Reference Manual

Kernel Classes and Operations

Predefined Kernels

Classes for 2D Geometry

Classes for 3D Geometry

Classes for dD Geometry

Constants and Enumerations

Distance and Intersection Operations

Predicates and Constructions

11.8 Concepts

Concept

Kernel

The concept of a *kernel* is defined by a set of requirements on the provision of certain types and access member functions to create objects of these types. The types are function object classes to be used within the algorithms and data structures of CGAL. This allows you to use any model of a kernel as a traits class in the CGAL algorithms and data structures, unless they require types beyond those provided by a kernel.

A kernel provides types, construction objects, and generalized predicates. The former replace constructors of the kernel classes and constructive procedures in the kernel. There are also function objects replacing operators, especially for equality testing.

Has Models

CGAL::Cartesian<FieldNumberType> . . . . page 588
CGAL::Homogeneous<RingNumberType> . . . . page 1070
CGAL::Simple_cartesian<FieldNumberType> . . . . page 602
CGAL::Simple_homogeneous<RingNumberType> . . . . page 603
CGAL::Filtered_kernel<CK> . . . . page 592
CGAL::Exact_predicates_exact_constructions_kernel . . . . page 606
CGAL::Exact_predicates_exact_constructions_kernel_with_sqrt . . . . page 607
CGAL::Exact_predicates_inexact_constructions_kernel . . . . page 608

Types

Kernel:: FT	a model of *FieldNumberType*
Kernel:: RT	a model of *RingNumberType*

The following types describe the return types of predicates. They typically map to *bool* and CGAL kernel enum types, except when an interval arithmetic number type is used such as within the filtering kernels, in which case it is *Uncertain<bool>* or similar.

Kernel:: Boolean	*bool* or *Uncertain<bool>*
Kernel:: Sign	*CGAL::Sign* or *Uncertain<CGAL::Sign>*
Kernel:: Comparison_result	*CGAL::Comparison_result* or *Uncertain< CGAL::Comparison_result>*
Kernel:: Orientation	*CGAL::Orientation* or *Uncertain<CGAL::Orientation>*
Kernel:: Oriented_side	*CGAL::Oriented_side* or *Uncertain<CGAL::Oriented_side>*
Kernel:: Bounded_side	*CGAL::Bounded_side* or *Uncertain<CGAL::Bounded_side>*
Kernel:: Angle	*CGAL::Angle* or *Uncertain<CGAL::Angle>*

Constants

static const bool	*Has_filtered_predicates;*

A Boolean value indicating whether the predicates are filtered (as in *Filtered_kernel*). This helps propagating such decisions to traits classes which are built on top of a kernel, so that they can decide to filter their own predicates or not.

Coordinate Access

Kernel:: Cartesian_const_iterator_2	a model of *Kernel::CartesianConstIterator_2*

Geometric Objects

Kernel:: Point_2	a model of *Kernel::Point_2*
Kernel:: Vector_2	a model of *Kernel::Vector_2*
Kernel:: Direction_2	a model of *Kernel::Direction_2*
Kernel:: Line_2	a model of *Kernel::Line_2*
Kernel:: Ray_2	a model of *Kernel::Ray_2*
Kernel:: Segment_2	a model of *Kernel::Segment_2*
Kernel:: Triangle_2	a model of *Kernel::Triangle_2*
Kernel:: Iso_rectangle_2	a model of *Kernel::IsoRectangle_2*
Kernel:: Circle_2	a model of *Kernel::Circle_2*
Kernel:: Object_2	a model of *Kernel::Object_2*

Constructions

Kernel:: Construct_point_2	a model of *Kernel::ConstructPoint_2*
Kernel:: Construct_vector_2	a model of *Kernel::ConstructVector_2*
Kernel:: Construct_direction_2	a model of *Kernel::ConstructDirection_2*
Kernel:: Construct_segment_2	a model of *Kernel::ConstructSegment_2*
Kernel:: Construct_line_2	a model of *Kernel::ConstructLine_2*
Kernel:: Construct_ray_2	a model of *Kernel::ConstructRay_2*
Kernel:: Construct_circle_2	a model of *Kernel::ConstructCircle_2*
Kernel:: Construct_triangle_2	a model of *Kernel::ConstructTriangle_2*
Kernel:: Construct_iso_rectangle_2	a model of *Kernel::ConstructIsoRectangle_2*
Kernel:: Construct_object_2	a model of *Kernel::ConstructObject_2*
Kernel:: Construct_scaled_vector_2	a model of *Kernel::ConstructScaledVector_2*
Kernel:: Construct_translated_point_2	a model of *Kernel::ConstructTranslatedPoint_2*
Kernel:: Construct_point_on_2	a model of *Kernel::ConstructPointOn_2*
Kernel:: Construct_projected_point_2	a model of *Kernel::ConstructProjectedPoint_2*
Kernel:: Construct_projected_xy_point_2	a model of *Kernel::ConstructProjectedXYPoint_2*
Kernel:: Construct_cartesian_const_iterator_2	a model of *Kernel::ConstructCartesianConstIterator_2*
Kernel:: Construct_vertex_2	a model of *Kernel::ConstructVertex_2*
Kernel:: Construct_bbox_2	a model of *Kernel::ConstructBbox_2*
Kernel:: Construct_perpendicular_vector_2	a model of *Kernel::ConstructPerpendicularVector_2*
Kernel:: Construct_perpendicular_direction_2	a model of *Kernel::ConstructPerpendicularDirection_2*
Kernel:: Construct_perpendicular_line_2	a model of *Kernel::ConstructPerpendicularLine_2*
Kernel:: Construct_max_vertex_2	a model of *Kernel::ConstructMaxVertex_2*
Kernel:: Construct_midpoint_2	a model of *Kernel::ConstructMidpoint_2*

Kernel:: Construct_equidistant_line_3	a model of *Kernel::ConstructEquidistantLine_3*
Kernel:: Construct_min_vertex_2	a model of *Kernel::ConstructMinVertex_2*
Kernel:: Construct_center_2	a model of *Kernel::ConstructCenter_2*
Kernel:: Construct_centroid_2	a model of *Kernel::ConstructCentroid_2*
Kernel:: Construct_circumcenter_2	a model of *Kernel::ConstructCircumcenter_2*
Kernel:: Construct_bisector_2	a model of *Kernel::ConstructBisector_2*
Kernel:: Construct_opposite_direction_2	a model of *Kernel::ConstructOppositeDirection_2*
Kernel:: Construct_opposite_segment_2	a model of *Kernel::ConstructOppositeSegment_2*
Kernel:: Construct_opposite_ray_2	a model of *Kernel::ConstructOppositeRay_2*
Kernel:: Construct_opposite_line_2	a model of *Kernel::ConstructOppositeLine_2*
Kernel:: Construct_opposite_triangle_2	a model of *Kernel::ConstructOppositeTriangle_2*
Kernel:: Construct_opposite_circle_2	a model of *Kernel::ConstructOppositeCircle_2*
Kernel:: Construct_opposite_vector_2	a model of *Kernel::ConstructOppositeVector_2*

If the result type is not determined, there is no *Construct_* prefix:

Kernel:: Intersect_2	a model of *Kernel::Intersect_2*
Kernel:: Assign_2	a model of *Kernel::Assign_2*

If the result type is a number type, the prefix is *Compute_*:

Kernel:: Compute_squared_distance_2	a model of *Kernel::ComputeSquaredDistance_2*
Kernel:: Compute_squared_length_2	a model of *Kernel::ComputeSquaredLength_2*
Kernel:: Compute_squared_radius_2	a model of *Kernel::ComputeSquaredRadius_2*
Kernel:: Compute_area_2	a model of *Kernel::ComputeArea_2*
Kernel:: Compute_determinant_2	a model of *Kernel::ComputeDeterminant_2*

Generalized Predicates

Kernel:: Angle_2	a model of *Kernel::Angle_2*
Kernel:: Equal_2	a model of *Kernel::Equal_2*
Kernel:: Equal_x_2	a model of *Kernel::EqualX_2*
Kernel:: Equal_y_2	a model of *Kernel::EqualY_2*
Kernel:: Less_x_2	a model of *Kernel::LessX_2*
Kernel:: Less_y_2	a model of *Kernel::LessY_2*
Kernel:: Less_xy_2	a model of *Kernel::LessXY_2*
Kernel:: Less_yx_2	a model of *Kernel::LessYX_2*
Kernel:: Compare_x_2	a model of *Kernel::CompareX_2*
Kernel:: Compare_x_at_y_2	a model of *Kernel::CompareXAtY_2*
Kernel:: Compare_y_2	a model of *Kernel::CompareY_2*
Kernel:: Compare_xy_2	a model of *Kernel::CompareXY_2*
Kernel:: Compare_yx_2	a model of *Kernel::CompareYX_2*
Kernel:: Compare_y_at_x_2	a model of *Kernel::CompareYAtX_2*
Kernel:: Compare_distance_2	a model of *Kernel::CompareDistance_2*
Kernel:: Compare_angle_with_x_axis_2	a model of *Kernel::CompareAngleWithXAxis_2*
Kernel:: Compare_slope_2	a model of *Kernel::CompareSlope_2*
Kernel:: Less_distance_to_point_2	a model of *Kernel::LessDistanceToPoint_2*
Kernel:: Less_signed_distance_to_line_2	a model of *Kernel::LessSignedDistanceToLine_2*
Kernel:: Less_rotate_ccw_2	a model of *Kernel::LessRotateCCW_2*
Kernel:: Left_turn_2	a model of *Kernel::LeftTurn_2*
Kernel:: Collinear_2	a model of *Kernel::Collinear_2*
Kernel:: Orientation_2	a model of *Kernel::Orientation_2*
Kernel:: Side_of_oriented_circle_2	a model of *Kernel::SideOfOrientedCircle_2*

Kernel:: Side_of_bounded_circle_2	a model of *Kernel::SideOfBoundedCircle_2*
Kernel:: Is_horizontal_2	a model of *Kernel::IsHorizontal_2*
Kernel:: Is_vertical_2	a model of *Kernel::IsVertical_2*
Kernel:: Is_degenerate_2	a model of *Kernel::IsDegenerate_2*
Kernel:: Has_on_2	a model of *Kernel::HasOn_2*
Kernel:: Collinear_has_on_2	a model of *Kernel::CollinearHasOn_2*
Kernel:: Has_on_bounded_side_2	a model of *Kernel::HasOnBoundedSide_2*
Kernel:: Has_on_unbounded_side_2	a model of *Kernel::HasOnUnboundedSide_2*
Kernel:: Has_on_boundary_2	a model of *Kernel::HasOnBoundary_2*
Kernel:: Has_on_positive_side_2	a model of *Kernel::HasOnPositiveSide_2*
Kernel:: Has_on_negative_side_2	a model of *Kernel::HasOnNegativeSide_2*
Kernel:: Oriented_side_2	a model of *Kernel::OrientedSide_2*
Kernel:: Bounded_side_2	a model of *Kernel::BoundedSide_2*
Kernel:: Are_parallel_2	a model of *Kernel::AreParallel_2*
Kernel:: Are_ordered_along_line_2	a model of *Kernel::AreOrderedAlongLine_2*
Kernel:: Are_strictly_ordered_along_line_2	a model of *Kernel::AreStrictlyOrderedAlongLine_2*
Kernel:: Collinear_are_ordered_along_line_2	a model of *Kernel::CollinearAreOrderedAlongLine_2*
Kernel:: Collinear_are_strictly_ordered_along_line_2	a model of *Kernel::CollinearAreStrictlyOrderedAlongLine_2*
Kernel:: Counterclockwise_in_between_2	a model of *Kernel::CounterclockwiseInBetween_2*

Kernel:: Construct_opposite_line_3	a model of *Kernel::ConstructOppositeLine_3*
Kernel:: Construct_opposite_plane_3	a model of *Kernel::ConstructOppositePlane_3*
Kernel:: Construct_opposite_sphere_3	a model of *Kernel::ConstructOppositeSphere_3*
Kernel:: Construct_opposite_vector_3	a model of *Kernel::ConstructOppositeVector_3*

If the result type is not determined, there is no *Construct_* prefix:

Kernel:: Intersect_3	a model of *Kernel::Intersect_3*
Kernel:: Assign_3	a model of *Kernel::Assign_3*

If the result type is a number type, the prefix is *Compute_*:

Kernel:: Compute_area_3	a model of *Kernel::ComputeArea_3*
Kernel:: Compute_squared_area_3	a model of *Kernel::ComputeSquaredArea_3*
Kernel:: Compute_area_divided_by_pi_3	a model of *Kernel::ComputeAreaDividedByPi_3*
Kernel:: Compute_approximate_area_3	a model of *Kernel::ComputeApproximateArea_3*
Kernel:: Compute_determinant_3	a model of *Kernel::ComputeDeterminant_3*
Kernel:: Compute_squared_distance_3	a model of *Kernel::ComputeSquaredDistance_3*
Kernel:: Compute_squared_length_3	a model of *Kernel::ComputeSquaredLength_3*

Kernel:: Compute_squared_length_divided_by_pi_square_3	a model of *Kernel::ComputeSquaredLengthDividedByPiSquare_3*
Kernel:: Compute_approximate_squared_length_3	a model of *Kernel::ComputeApproximateSquaredLength_3*
Kernel:: Compute_squared_radius_3	a model of *Kernel::ComputeSquaredRadius_3*
Kernel:: Compute_volume_3	a model of *Kernel::ComputeVolume_3*

Generalized Predicates

Kernel:: Angle_3	a model of *Kernel::Angle_3*
Kernel:: Equal_3	a model of *Kernel::Equal_3*
Kernel:: Equal_x_3	a model of *Kernel::EqualX_3*
Kernel:: Equal_y_3	a model of *Kernel::EqualY_3*
Kernel:: Equal_z_3	a model of *Kernel::EqualZ_3*
Kernel:: Equal_xy_3	a model of *Kernel::EqualXY_3*
Kernel:: Less_x_3	a model of *Kernel::LessX_3*
Kernel:: Less_y_3	a model of *Kernel::LessY_3*
Kernel:: Less_z_3	a model of *Kernel::LessZ_3*
Kernel:: Less_xy_3	a model of *Kernel::LessXY_3*
Kernel:: Less_xyz_3	a model of *Kernel::LessXYZ_3*
Kernel:: Compare_x_3	a model of *Kernel::CompareX_3*
Kernel:: Compare_y_3	a model of *Kernel::CompareY_3*
Kernel:: Compare_z_3	a model of *Kernel::CompareZ_3*
Kernel:: Compare_xy_3	a model of *Kernel::CompareXY_3*
Kernel:: Compare_xyz_3	a model of *Kernel::CompareXYZ_3*
Kernel:: Less_signed_distance_to_plane_3	a model of *Kernel::LessSignedDistanceToPlane_3*
Kernel:: Less_distance_to_point_3	a model of *Kernel::LessDistanceToPoint_3*
Kernel:: Compare_dihedral_angle_3	a model of *Kernel::CompareDihedralAngle_3*
Kernel:: Compare_distance_3	a model of *Kernel::CompareDistance_3*
Kernel:: Collinear_3	a model of *Kernel::Collinear_3*
Kernel:: Coplanar_3	a model of *Kernel::Coplanar_3*
Kernel:: Orientation_3	a model of *Kernel::Orientation_3*
Kernel:: Coplanar_orientation_3	a model of *Kernel::CoplanarOrientation_3*
Kernel:: Coplanar_side_of_bounded_circle_3	a model of *Kernel::CoplanarSideOfBoundedCircle_3*
Kernel:: Side_of_oriented_sphere_3	a model of *Kernel::SideOfOrientedSphere_3*
Kernel:: Side_of_bounded_sphere_3	a model of *Kernel::SideOfBoundedSphere_3*
Kernel:: Is_degenerate_3	a model of *Kernel::IsDegenerate_3*
Kernel:: Has_on_3	a model of *Kernel::HasOn_3*
Kernel:: Has_on_bounded_side_3	a model of *Kernel::HasOnBoundedSide_3*
Kernel:: Has_on_unbounded_side_3	a model of *Kernel::HasOnUnboundedSide_3*
Kernel:: Has_on_boundary_3	a model of *Kernel::HasOnBoundary_3*
Kernel:: Has_on_positive_side_3	a model of *Kernel::HasOnPositiveSide_3*
Kernel:: Has_on_negative_side_3	a model of *Kernel::HasOnNegativeSide_3*
Kernel:: Oriented_side_3	a model of *Kernel::OrientedSide_3*
Kernel:: Bounded_side_3	a model of *Kernel::BoundedSide_3*
Kernel:: Are_parallel_3	a model of *Kernel::AreParallel_3*
Kernel:: Are_ordered_along_line_3	a model of *Kernel::AreOrderedAlongLine_3*
Kernel:: Are_strictly_ordered_along_line_3	a model of *Kernel::AreStrictlyOrderedAlongLine_3*
Kernel:: Collinear_are_ordered_along_line_3	a model of *Kernel::CollinearAreOrderedAlongLine_3*

Kernel:: Collinear_are_strictly_ordered_along_line_3	
	a model of *Kernel::CollinearAreStrictlyOrderedAlongLine_3*
Kernel:: Do_intersect_3	a model of *Kernel::DoIntersect_3*

Operations

For each of the function objects above, there must exist a member function that requires no arguments and returns an instance of that function object. The name of the member function is the uncapitalized name of the type returned with the suffix *_object* appended. For example, for the function object *Kernel::Construct_vector_2* the following member function must exist:

Kernel::Construct_vector_2	*kernel.construct_vector_2_object() const*

Class

11.9 Kernel Classes and Operations

CGAL::Cartesian<FieldNumberType>

#include <CGAL/Cartesian.h>

Definition

A model for *Kernel* that uses Cartesian coordinates to represent the geometric objects. In order for *Cartesian<FieldNumberType>* to model Euclidean geometry in E^2 and/or E^3, for some mathematical field E (*e.g.*, the rationals $\mathbb{Q}$ or the reals $\mathbb{R}$), the template parameter *FieldNumberType* must model the mathematical field E. That is, the field operations on this number type must compute the mathematically correct results. If the number type provided as a model for *FieldNumberType* is only an approximation of a field (such as the built-in type *double*), then the geometry provided by the kernel is only an approximation of Euclidean geometry.

Is Model for the Concepts

Kernel . . . . page 581

Types

typedef FieldNumberType *FT;*
typedef FieldNumberType *RT;*

Implementation

All geometric objects in *Cartesian<FieldNumberType>* are reference counted.

See Also

CGAL::Simple_cartesian<FieldNumberType> . . . . page 602

CGAL::Cartesian_converter<K1, K2, NTConverter>

Class

Definition

Cartesian_converter<K1, K2, NTConverter> converts objects from the kernel traits *K1* to the kernel traits *K2* using *Converter* to do the conversion. Those traits must be of the form *Cartesian<FT1>* and *Cartesian<FT2>* (or the equivalent with *Simple_cartesian*). It then provides the following operators to convert objects from *K1* to *K2*.

The third template parameter *NTConverter* is a function object that must provide *K2::FT operator()(K1::FT n)* that converts *n* to an *K2::FT* which has the same value.

The default value of this parameter is *CGAL::NT_converter<K1::FT, K2::FT>*.

#include <CGAL/Cartesian_converter.h>

Creation

Cartesian_converter<K1, K2, NTConverter> conv;

Default constructor.

Operations

K2::Point_2 *conv.operator()(K1::Point_2 p)*

returns a *K2::Point_2* which coordinates are those of *p*, converted by *NTConverter*.

Similar operators are defined for the other kernel traits types *Point_3*, *Vector_2*...

Example

In the following example, we compute exactly the intersection point between a line and a triangle, and we then create a double approximation of this point.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Quotient.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Cartesian_converter.h>

typedef CGAL::Simple_cartesian<double>                        IK;
typedef CGAL::Simple_cartesian<CGAL::Quotient<CGAL::MP_Float> >  EK;
typedef CGAL::Cartesian_converter<IK,EK>
   IK_to_EK;
typedef CGAL::Cartesian_converter<EK,IK>
   EK_to_IK;
```

```
int main(){
  IK::Triangle_3 t1(
    IK::Point_3(0.,0.,0.),
    IK::Point_3(1.,0.,-1.),
    IK::Point_3(0.,1.,3.)
  );

  IK::Line_3 l1(
    IK::Point_3(0.2,0.25,-7),
    IK::Point_3(0.25,0.3,4)
  );

  IK_to_EK to_exact;

  EK::Triangle_3 t2=to_exact(t1);
  EK::Line_3     l2=to_exact(l1);

  CGAL::Object inter=CGAL::intersection(t2,l2);
  const EK::Point_3& exact_pt=CGAL::object_cast<EK::Point_3>(inter);

  EK_to_IK to_inexact;

  IK::Point_3 inexact_pt = to_inexact(exact_pt);
  return 0;
}
```

Function

Class

CGAL::Filtered_kernel<CK>

Definition

*Filtered_kernel<CK>*is a kernel that uses the filtering technique based on interval arithmetic from [BBP01] to achieve exact and efficient predicates. In addition, a few selected important predicates are implemented using the formally proved, semi-static, filtering techniques from [MP05].

The geometric constructions are exactly those of the kernel *CK*, which means that they are not necessarily exact.

#include <CGAL/Filtered_kernel.h>

Parameters

The first parameter, *CK*, is the "Construction Kernel", namely the kernel from which are taken the types of the geometric objects as well as the geometric constructions.

The second parameter, *UseStaticFilters*, is a Boolean value which activates or not an additional layer of semi-static filters. It defaults to *true* (activated), unless the *CGAL_NO_STATIC_FILTERS* macro is defined. This option is mostly for debugging and testing, there should be no production use for deactivating static filters.

Is Model for the Concepts

Kernel

Types

typedef EK	*Exact_kernel;*	The type of the exact kernel.
typedef FK	*Approximate_kernel;*	The type of the approximate "filtering" kernel.

Constants

static const bool	*Has_static_filters;*	A Boolean value corresponding to the second template argument. Tells whether static filters are provided.

Example

The following example shows how to produce a kernel whose geometric objects and constructions are those of *Simple_cartesian<double>* but the predicates are exact.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Filtered_kernel.h>

typedef CGAL::Simple_cartesian<double> CK;
typedef CGAL::Filtered_kernel<CK> K;
```

Implementation

The implementation uses *CGAL::Filtered_predicate<EP, FP, C2E, C2F>* over each predicate of the kernel traits interface. Additionally, faster static filters may be used for a few selected critical predicates.

Class

CGAL::Filtered_kernel_adaptor<CK>

Definition

*Filtered_kernel_adaptor<CK>*is a kernel that uses the filtering technique [BBP01] to obtain a kernel with exact and efficient predicate functors. The geometric constructions are exactly those of the kernel *CK*, which means that they are not necessarily exact.

In contrast to *Filtered_kernel*, the global functions are those of *CK*.

Is Model for the Concepts

Kernel

#include <CGAL/Filtered_kernel.h>

Example

The following example shows how to produce a kernel whose geometric objects and constructions are those of *Simple_cartesian<double>* The predicate functors of the kernel are exact, the global functions are not.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Filtered_kernel.h>

typedef CGAL::Simple_cartesian<double> CK;
typedef CGAL::Filtered_kernel_adaptor<CK> K;

typedef K::Point_2 p(0,0), q(1,1), r(1,5);

CGAL::orientation(p,q,r);                // not exact

typedef K::Orientation_2 orientation;
orientation(p,q,r);                      // exact
```

CGAL::Filtered_predicate<EP, FP, C2E, C2F>

Class

Definition

Filtered_predicate<EP, FP, C2E, C2F> is an adaptor for predicate function objects that allows one to produce efficient and exact predicates. It is used to build *CGAL::Filtered_kernel<CK>* and can be used for other predicates too.

EP is the exact but supposedly slow predicate that is able to evaluate the predicate correctly. It will be called only when the filtering predicate, *FP*, cannot compute the correct result. This failure of *FP* must be done by throwing an exception.

To convert the geometric objects that are the arguments of the predicate, we use the function objects *C2E* and *C2F*, which must be of the form *Cartesian_converter* or *Homogeneous_converter*.

#include <CGAL/Filtered_predicate.h>

Types

typedef FP::result_type	*result_type;*	The return type of the function operators. It must also be the same type as *EP::result_type*.

Creation

Filtered_predicate<EP, FP, C2E, C2F> fo; — Default constructor.

Operations

template <class A1>
result_type *fo.operator()(A1 a1)* — The unary function operator for unary predicates.

template <class A1, class A2>
result_type *fo.operator()(A1 a1, A2 a2)*

The binary function operator for binary predicates.

Similar function operators are defined for up to 7 arguments.

Example

The following example defines an efficient and exact version of the orientation predicate over three points using the Cartesian representation with double coordinates and without reference counting (*Simple_cartesian< double>::Point_2*). Of course, the orientation predicate can already be found in the kernel, but you can follow this example to filter your own predicates. It uses the fast but inexact predicate based on interval arithmetic for filtering and the slow but exact predicate based on multi-precision floats when the filtering predicate fails.

```cpp
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Filtered_predicate.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Cartesian_converter.h>

typedef CGAL::Simple_cartesian<double> K;
typedef CGAL::Simple_cartesian<CGAL::Interval_nt_advanced> FK;
typedef CGAL::Simple_cartesian<CGAL::MP_Float> EK;
typedef CGAL::Cartesian_converter<K, EK> C2E;
typedef CGAL::Cartesian_converter<K, FK> C2F;

// Define my predicate, parameterized by a kernel.
template < typename K >
struct My_orientation_2
{
  typedef typename K::RT            RT;
  typedef typename K::Point_2       Point_2;

  typedef typename K::Orientation   result_type;

  result_type
  operator()(const Point_2 &p, const Point_2 &q, const Point_2 &r) const
  {
    RT prx = p.x() - r.x();
    RT pry = p.y() - r.y();
    RT qrx = q.x() - r.x();
    RT qry = q.y() - r.y();
    return CGAL::sign( prx*qry - qrx*pry );
  }
};

typedef CGAL::Filtered_predicate<My_orientation_2<EK>,
                                 My_orientation_2<FK>, C2E, C2F>
   Orientation_2;

int main()
{
  K::Point_2 p(1,2), q(2,3), r(3,4);
  Orientation_2 orientation;
  orientation(p, q, r);
  return 0;
}
```

File: examples/Filtered_kernel/Filtered_predicate.cpp

CGAL::Homogeneous<RingNumberType>

Class

#include <CGAL/Homogeneous.h>

Definition

A model for a *Kernel* using homogeneous coordinates to represent the geometric objects. In order for *Homogeneous<RingNumberType>* to model Euclidean geometry in E^2 and/or E^3, for some mathematical ring E (*e.g.*, the integers $\mathbb{Z}$ or the rationals $\mathbb{Q}$), the template parameter *RingNumberType* must model the mathematical ring E. That is, the ring operations on this number type must compute the mathematically correct results. If the number type provided as a model for *RingNumberType* is only an approximation of a ring (such as the built-in type *double*), then the geometry provided by the kernel is only an approximation of Euclidean geometry.

Is Model for the Concepts

Kernel . . . . page 581

Types

typedef Quotient<RingNumberType>	*FT;*
typedef RingNumberType	*RT;*

Implementation

This model of a kernel uses reference counting.

CGAL::Homogeneous_converter<K1, K2, RTConverter, FTConverter>

Definition

*Homogeneous_converter<K1, K2, RTConverter, FTConverter>*converts objects from the kernel traits *K1* to the kernel traits *K2*. Those traits must be of the form *Homogeneous<RT1>* and *Homogeneous<RT2>* (or the equivalent with *Simple_homogeneous*). It then provides the following operators to convert objects from *K1* to *K2*.

The third template parameter *RT_Converter* is a function object that must provide *K2::RT operator()(const K1::RT &n);* that converts *n* to an *K2::RT* that has the same value.

The default value of this parameter is *CGAL::NT_converter<K1::RT, K2::RT>*, which uses the conversion operator from *K1::RT* to *K2::RT*.

Similarly, the fourth template parameter must provide *K2::FT operator()(const K1::FT &n);* that converts *n* to an *K2::FT* that has the same value. Its default value is *CGAL::NT_converter<K1::FT, K2::FT>*.

#include <CGAL/Homogeneous_converter.h>

Creation

Homogeneous_converter<K1, K2, RTConverter, FTConverter> conv;

Default constructor.

Operations

K2::Point_2 *conv.operator()(K1::Point_2 p)*

returns a *K2::Point_2* which coordinates are those of *p*, converted by *RTConverter*.

Similar operators are defined for the other kernel traits geometric types *Point_3*, *Vector_2*...

CGAL::Kernel_traits<T>

#include <CGAL/Kernel_traits.h>

Class

Definition

The class *Kernel_traits<T>* provides access to the kernel model to which the argument type *T* belongs. (Provided *T* belongs to some kernel model.) The default implementation assumes there is a local type *T::Kernel* referring to the kernel model of *T*. If this type does not exist, a specialization of *Kernel_traits<T>* can be used to provide the desired information.

This class is, for example, useful in the following context. Assume you want to write a generic function that accepts two points p and q as argument and constructs the line segment between p and q. In order to specify the return type of this function, you need to know what is the segment type corresponding to the Point type representing p and q. Using *Kernel_traits<T>*, this can be done as follows.

```
template < class Point >
typename Kernel_traits<Point>::Kernel::Segment
construct_segment(Point p, Point q)
{ ... }
```

Types

typedef T::R	*Kernel;*	If *T* is a type *K::Point_2* of some kernel model *K*, then *Kernel* is equal to *K*.

Class

CGAL::Simple_cartesian<FieldNumberType>

#include <CGAL/Simple_cartesian.h>

Definition

A model for a *Kernel* using Cartesian coordinates to represent the geometric objects. In order for *Simple_cartesian<FieldNumberType>* to model Euclidean geometry in E^2 and/or E^3, for some mathematical field E (*e.g.*, the rationals $\mathbb{Q}$ or the reals $\mathbb{R}$), the template parameter *FieldNumberType* must model the mathematical field E. That is, the field operations on this number type must compute the mathematically correct results. If the number type provided as a model for *FieldNumberType* is only an approximation of a field (such as the built-in type *double*), then the geometry provided by the kernel is only an approximation of Euclidean geometry.

Is Model for the Concepts

Kernel . . . . page 581

Types

typedef FieldNumberType *FT;*

typedef FieldNumberType *RT;*

Implementation

In contrast to *Cartesian*, no reference counting is used internally. This eases debugging, but may slow down algorithms that copy objects intensively.

See Also

CGAL::Homogeneous<RingNumberType> . . . . page 1070
CGAL::Simple_cartesian<FieldNumberType> . . . . page 602

Class

CGAL::Projection_traits_xy_3<K>

Definition

The class *Projection_traits_xy_3<K>* is an adapter to apply 2D algorithms to the projections of 3D data on the *xy*-plane.

CGAL provides also predefined geometric traits classes *Projection_traits_yz_3<K>* and *Projection_traits_xz_3<K>* to deal with projections on the *zx*- and the *zy*-plane, respectively.

Parameters

The template parameter *K* has to be instantiated by a model of the *Kernel* concept. *Projection_traits_xy_3<K>* uses types and predicates defined in *K*.

#include <CGAL/Projection_traits_xy_3.h>

Is Model for the Concepts

The class is a model of several 2D triangulation traits class concepts, except that it does not provide the type and constructors required to build the dual Voronoi diagram. The class is also a model of the concepts *PolygonTraits_2* and *ConvexHullTraits_2*.

TriangulationTraits_2 .... page 2541
DelaunayTriangulationTraits_2 .... page 2513
ConstrainedTriangulationTraits_2 .... page 2495
PolygonTraits_2 .... page 1470
ConvexHullTraits_2 .... page 1381

Types

typedef Point_3<K>	*Point_2;*
typedef Segment_3<K>	*Segment_2;*
typedef Triangle_3<K>	*Triangle_2;*
typedef Line_3<K>	*Line_2;*

typedef K::Object_3	*Object_2;*

The functors provided by this class are those listed in the concepts, except that it does not provide the type and constructors required to build the dual Voronoi diagram. The functors operate on the 2D projection of their arguments. They come with preconditions that projections of the arguments are non-degenerate, eg. a line segment does not project on a single point, two points do not project on the same point, etc.

In the following, we specify the choice of the *z*-coordinate in case a new point is constructed.

Projection_traits_xy_3<K>:: Intersect_2

A construction object. Provides the operator :
Object_2 operator()(Segment_2 s1, Segment_2 s2); which returns a 3D object whose projection on the xy-plane is the intersection of the projections of *s1* and *s2*. If non empty, the returned object is either a segment or a point. Its embedding in 3D is computed as the interpolation between *s1* and *s2*, meaning that any point *p* of the returned object is the midpoint of segment *p1p2* where *p1* and *p2* are the two points of *s1* and *s2* respectively, both projecting on *p*.
Precondition: The projection of *s1* and the projection of *s2* are non-degenerate *2D* segments.

Creation

Projection_traits_xy_3<K> traits;

default constructor.

Projection_traits_xy_3<K> traits(Projection_traits_xy_3 tr);

Copy constructor.

Projection_traits_xy_3 *traits.operator=(Projection_traits_xy_3 tr)*

11.11 Kernel Objects

11.11.1 Two-dimensional Objects

CGAL::Aff_transformation_2<Kernel>

Definition

The class *Aff_transformation_2<Kernel>* represents two-dimensional affine transformations. The general form of an affine transformation is based on a homogeneous representation of points. Thereby all transformations can be realized by matrix multiplications.

Multiplying the transformation matrix by a scalar does not change the represented transformation. Therefore, any transformation represented by a matrix with rational entries can be represented by a transformation matrix with integer entries as well. (Multiply the matrix with the common denominator of the rational entries.) Hence, it is sufficient to use the number type *Kernel::RT* to represent the entries of the transformation matrix.

CGAL offers several specialized affine transformations. Different constructors are provided to create them. They are parameterized with a symbolic name to denote the transformation type, followed by additional parameters. The symbolic name tags solve ambiguities in the function overloading and they make the code more readable, i.e., what type of transformation is created.

Since two-dimensional points have three homogeneous coordinates, we have a 3×3 matrix $(m_{ij})_{i,\, j=0\ldots 2}$.

If the homogeneous representations are normalized (the homogenizing coordinate is 1), then the upper left 2×2 matrix realizes linear transformations. In the matrix form of a translation, the translation vector $(v_0,\, v_1,\, 1)$ appears in the last column of the matrix. The entries m_{20} and m_{21} are always zero and therefore do not appear in the constructors.

Creation

Aff_transformation_2<Kernel> t(Identity_transformation);

introduces an identity transformation.

Aff_transformation_2<Kernel> t(const Translation, Vector_2<Kernel> v);

introduces a translation by a vector *v*.

Aff_transformation_2<Kernel> t(const Rotation,
Direction_2<Kernel> d,
Kernel::RT num,

Kernel::RT den = RT(1))

approximates the rotation over the angle indicated by direction d, such that the differences between the sines and cosines of the rotation given by d and the approximating rotation are at most num/den each.
Precondition: $num/den > 0$ and $d! = 0$.

Aff_transformation_2<Kernel> t(const Rotation, Kernel::RT sine_rho, Kernel::RT cosine_rho, Kernel::RT hw = RT(1))

introduces a rotation by the angle *rho*.
Precondition: $sine\_rho^2 + cosine\_rho^2 == hw^2$.

Aff_transformation_2<Kernel> t(const Scaling, Kernel::RT s, Kernel::RT hw = RT(1));

introduces a scaling by a scale factor s/hw.

Aff_transformation_2<Kernel> t(Kernel::RT m00, Kernel::RT m01, Kernel::RT m02, Kernel::RT m10, Kernel::RT m11, Kernel::RT m12, Kernel::RT hw = RT(1))

introduces a general affine transformation in the 3×3 matrix form $\begin{pmatrix} m_{00} & m_{01} & m_{02} \\ m_{10} & m_{11} & m_{12} \\ 0 & 0 & hw \end{pmatrix}$. The sub-matrix $\frac{1}{hw}\begin{pmatrix} m_{00} & m_{01} \\ m_{10} & m_{11} \end{pmatrix}$ contains the scaling and rotation information, the vector $\frac{1}{hw}\begin{pmatrix} m_{02} \\ m_{12} \end{pmatrix}$ contains the translational part of the transformation.

Aff_transformation_2<Kernel> t(Kernel::RT m00, Kernel::RT m01, Kernel::RT m10, Kernel::RT m11, Kernel::RT hw = RT(1))

introduces a general linear transformation $\begin{pmatrix} m_{00} & m_{01} & 0 \\ m_{10} & m_{11} & 0 \\ 0 & 0 & hw \end{pmatrix}$, i.e. there is no translational part.

Operations

The main thing to do with transformations is to apply them on geometric objects. Each class *Class_2<Kernel>* representing a geometric object has a member function:

Class_2<Kernel> transform(Aff_transformation_2<Kernel> t).

The transformation classes provide a member function *transform()* for points, vectors, directions, and lines:

Point_2<Kernel>	*t.transform(Point_2<Kernel> p) const*
Vector_2<Kernel>	*t.transform(Vector_2<Kernel> p) const*
Direction_2<Kernel>	*t.transform(Direction_2<Kernel> p) const*
Line_2<Kernel>	*t.transform(Line_2<Kernel> p) const*

CGAL provides function operators for these member functions:

Point_2<Kernel>	*t.operator()(Point_2<Kernel> p) const*
Vector_2<Kernel>	*t.operator()(Vector_2<Kernel> p) const*
Direction_2<Kernel>	*t.operator()(Direction_2<Kernel> p) const*
Line_2<Kernel>	*t.operator()(Line_2<Kernel> p) const*

Miscellaneous

Aff_transformation_2<Kernel>		
	t.operator(s) const*	composes two affine transformations.
Aff_transformation_2<Kernel>		
	t.inverse() const	gives the inverse transformation.
bool	*t.is_even() const*	returns *true*, if the transformation is not reflecting, i.e. the determinant of the involved linear transformation is non-negative.
bool	*t.is_odd() const*	returns *true*, if the transformation is reflecting.

The matrix entries of a matrix representation of a *Aff_transformation_2<Kernel>* can be accessed trough the following member functions:

Kernel::FT	*t.cartesian(int i, int j) const*	
Kernel::FT	*t.m(int i, int j) const*	returns entry m_{ij} in a matrix representation in which m_{22} is 1.
Kernel::RT	*t.homogeneous(int i, int j) const*	
Kernel::RT	*t.hm(int i, int j) const*	returns entry m_{ij} in some fixed matrix representation.

For affine transformations no I/O operators are defined.

rational_rotation_approximation

Example

```
typedef Cartesian<double>        K;
typedef Aff_transformation_2<K>  Transformation;
typedef Point_2<K>               Point;
typedef Vector_2<K>              Vector;
typedef Direction_2<K>           Direction;

Transformation rotate(ROTATION, sin(pi), cos(pi));
Transformation rational_rotate(ROTATION,Direction(1,1), 1, 100);
Transformation translate(TRANSLATION, Vector(-2, 0));
Transformation scale(SCALING, 3);

Point q(0, 1);
q = rational_rotate(q);

Point p(1, 1);

p = rotate(p);

p = translate(p);

p = scale(p);
```

The same would have been achieved with

```
Transformation transform = scale * (translate * rotate);
p = transform(Point(1.0, 1.0));
```

CGAL::Bbox_2

#include <CGAL/Bbox_2.h>

Definition

An object *b* of the class *Bbox_2* is a bounding box in the two-dimensional Euclidean plane $\mathbb{E}^2$. This class is not templated.

Creation

Bbox_2 b(double x_min, double y_min, double x_max, double y_max);

introduces a bounding box *b* with lower left corner at *(xmin, ymin)* and with upper right corner at *(xmax, ymax)*.

Operations

bool	*b.operator==(c) const*	
		Test for equality.
bool	*b.operator!=(q) const*	
		Test for inequality.
int	*b.dimension() const*	Returns 2.
double	*b.xmin() const*	
double	*b.ymin() const*	
double	*b.xmax() const*	
double	*b.ymax() const*	
double	*b.min(int i) const*	Returns *xmin()* if *i==0* or *ymin()* if *i==1*. *Precondition*: i==0 or i==1
double	*b.max(int i) const*	Returns *xmax()* if *i==0* or *ymax()* if *i==1*. *Precondition*: i==0 or i==1
Bbox_2	*b.operator+(c) const*	returns a bounding box of *b* and *c*.

Class

CGAL::Circle_2<Kernel>

Definition

An object of type *Circle_2<Kernel>* is a circle in the two-dimensional Euclidean plane $\mathbb{E}^2$. The circle is oriented, i.e. its boundary has clockwise or counterclockwise orientation. The boundary splits $\mathbb{E}^2$ into a positive and a negative side, where the positive side is to the left of the boundary. The boundary also splits $\mathbb{E}^2$ into a bounded and an unbounded side. Note that the circle can be degenerated, i.e. the squared radius may be zero.

Creation

Circle_2<Kernel> c(Point_2<Kernel> center, Kernel::FT squared_radius, Orientation ori = COUNTERCLOCKWISE)

introduces a variable c of type *Circle_2<Kernel>*. It is initialized to the circle with center *center*, squared radius *squared_radius* and orientation *ori*.
Precondition: $ori \neq COLLINEAR$, and further, $squared\_radius \geq 0$.

Circle_2<Kernel> c(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r);

introduces a variable c of type *Circle_2<Kernel>*. It is initialized to the unique circle which passes through the points p, q and r. The orientation of the circle is the orientation of the point triple p, q, r.
Precondition: p, q, and r are not collinear.

Circle_2<Kernel> c(Point_2<Kernel> p, Point_2<Kernel> q, Orientation ori = COUNTERCLOCKWISE);

introduces a variable c of type *Circle_2<Kernel>*. It is initialized to the circle with diameter $\overline{pq}$ and orientation *ori*.
Precondition: $ori \neq COLLINEAR$.

Circle_2<Kernel> c(Point_2<Kernel> center, Orientation ori = COUNTERCLOCKWISE);

introduces a variable c of type *Circle_2<Kernel>*. It is initialized to the circle with center *center*, squared radius zero and orientation *ori*.
Precondition: $ori \neq COLLINEAR$.
Postcondition: $c.is\_degenerate() = true$.

Access Functions

Point_2<Kernel>	*c.center() const*	returns the center of c.

Kernel::FT	*c.squared_radius() const*	
		returns the squared radius of *c*.
Orientation	*c.orientation() const*	returns the orientation of *c*.
bool operator	*c.==(circle2) const*	returns *true*, iff *c* and *circle2* are equal, i.e. if they have the same center, same squared radius and same orientation.
bool operator	*c.!=(circle2) const*	returns *true*, iff *c* and *circle2* are not equal.

Predicates

bool	*c.is_degenerate() const*	
		returns *true*, iff *c* is degenerate, i.e. if *c* has squared radius zero.
Oriented_side	*c.oriented_side(Point_2<Kernel> p) const*	
		returns either the constant *ON_ORIENTED_BOUNDARY*, *ON_POSITIVE_SIDE*, or *ON_NEGATIVE_SIDE*, iff *p* lies on the boundary, properly on the positive side, or properly on the negative side of *c*, resp.
Bounded_side	*c.bounded_side(Point_2<Kernel> p) const*	
		returns *ON_BOUNDED_SIDE*, *ON_BOUNDARY*, or *ON_UNBOUNDED_SIDE* iff *p* lies properly inside, on the boundary, or properly outside of *c*, resp.
bool	*c.has_on_positive_side(Point_2<Kernel> p) const*	
bool	*c.has_on_negative_side(Point_2<Kernel> p) const*	
bool	*c.has_on_boundary(Point_2<Kernel> p) const*	
bool	*c.has_on_bounded_side(Point_2<Kernel> p) const*	
bool	*c.has_on_unbounded_side(Point_2<Kernel> p) const*	

Miscellaneous

Circle_2<Kernel>	*c.opposite() const*	returns the circle with the same center and squared radius as *c* but with opposite orientation.
Circle_2<Kernel>	*c.orthogonal_transform(Aff_transformation_2<Kernel> at) const*	
		returns the circle obtained by applying *at* on *c*. *Precondition*: *at* is an orthogonal transformation.

Bbox_2	*c.bbox() const*	returns a bounding box containing c.

Kernel::Circle_2 . . . . page 783

CGAL::Direction_2<Kernel>

Class

Definition

An object of the class *Direction_2<Kernel>* is a vector in the two-dimensional vector space $\mathbb{R}^2$ where we forget about its length. They can be viewed as unit vectors, although there is no normalization internally, since this is error prone. Directions are used whenever the length of a vector does not matter. They also characterize a set of parallel oriented lines that have the same orientations. For example, you can ask for the direction orthogonal to an oriented plane, or the direction of an oriented line. Further, they can be used to indicate angles. The slope of a direction is *dy()/dx()*.

Creation

Direction_2<Kernel> d(Vector_2<Kernel> v); introduces the direction d of vector v.

Direction_2<Kernel> d(Line_2<Kernel> l); introduces the direction d of line l.

Direction_2<Kernel> d(Ray_2<Kernel> r); introduces the direction d of ray r.

Direction_2<Kernel> d(Segment_2<Kernel> s); introduces the direction d of segment s.

Direction_2<Kernel> d(Kernel::RT x, Kernel::RT y);

introduces a direction d passing through the origin and the point with Cartesian coordinates (x,y).

Operations

Kernel::RT	*d.delta(int i) const*	returns values, such that *d== Direction_2<Kernel> (delta(0),delta(1))*. *Precondition*: : $0 \leq i \leq 1$.
Kernel::RT	*d.dx() const*	returns *delta(0)*.
Kernel::RT	*d.dy() const*	returns *delta(1)*.

There is a total order on directions. We compare the angles between the positive x-axis and the directions in counterclockwise order.

bool	*d.operator==(e) const*
bool	*d.operator!=(e) const*
bool	*d.operator<(e) const*
bool	*d.operator>(e) const*
bool	*d.operator<=(e) const*
bool	*d.operator>=(e) const*

Furthermore, we have

bool	*d.counterclockwise_in_between(d1, d2) const*	
		returns true, iff *d* is not equal to *d1*, and while rotating counterclockwise starting at *d1*, *d* is reached strictly before *d2* is reached. Note that true is returned if *d1* == *d2*, unless also *d* == *d1*.
Direction_2<Kernel>	*d.operator-() const*	The direction opposite to *d*.

Miscellaneous

Vector_2<Kernel>	*d.vector() const*	returns a vector that has the same direction as *d*.
Direction_2<Kernel>	*d.transform(Aff_transformation_2<Kernel> t) const*	
		returns the direction obtained by applying *t* on *d*.

See Also

Kernel::Direction_2 . . . . page 785

CGAL::Iso_rectangle_2<Kernel>

Class

Definition

An object s of the data type *Iso_rectangle_2<Kernel>* is a rectangle in the Euclidean plane $\mathbb{E}^2$ with sides parallel to the x and y axis of the coordinate system.

Although they are represented in a canonical form by only two vertices, namely the lower left and the upper right vertex, we provide functions for "accessing" the other vertices as well. The vertices are returned in counterclockwise order.

Iso-oriented rectangles and bounding boxes are quite similar. The difference however is that bounding boxes have always double coordinates, whereas the coordinate type of an iso-oriented rectangle is chosen by the user.

Creation

Iso_rectangle_2<Kernel> r(Point_2<Kernel> p, Point_2<Kernel> q);

introduces an iso-oriented rectangle r with diagonal opposite vertices p and q. Note that the object is brought in the canonical form.

Iso_rectangle_2<Kernel> r(Point_2<Kernel> p, Point_2<Kernel> q, int);

introduces an iso-oriented rectangle r with diagonal opposite vertices p and q. The *int* argument value is only used to distinguish the two overloaded functions.
Precondition: $p.x() <= q.x()$ and $p.y() <= q.y()$.

Iso_rectangle_2<Kernel> r(Point_2<Kernel> left,
Point_2<Kernel> right,
Point_2<Kernel> bottom,
Point_2<Kernel> top)

introduces an iso-oriented rectangle r whose minimal x coordinate is the one of *left*, the maximal x coordinate is the one of *right*, the minimal y coordinate is the one of *bottom*, the maximal y coordinate is the one of *top*.

Iso_rectangle_2<Kernel> r(Kernel::RT min_hx,
Kernel::RT min_hy,
Kernel::RT max_hx,
Kernel::RT max_hy,
Kernel::RT hw = RT(1))

introduces an iso-oriented rectangle r with diagonal opposite vertices (*min_hx/hw*, *min_hy/hw*) and (*max_hx/hw*, *max_hy/hw*).
Precondition: $hw \neq 0$.

Operations

bool	*r.operator==(r2) const*	
		Test for equality: two iso-oriented rectangles are equal, iff their lower left and their upper right vertices are equal.
bool	*r.operator!=(r2) const*	
		Test for inequality.
Point_2<Kernel>	*r.vertex(int i) const*	returns the i'th vertex modulo 4 of *r* in counterclockwise order, starting with the lower left vertex.
Point_2<Kernel>	*r.operator[](int i) const*	
		returns *vertex(i)*.
Point_2<Kernel>	*r.min() const*	returns the lower left vertex of *r* (= *vertex(0)*).
Point_2<Kernel>	*r.max() const*	returns the upper right vertex of *r* (= *vertex(2)*).
Kernel::FT	*r.xmin() const*	returns the x coordinate of lower left vertex of *r*.
Kernel::FT	*r.ymin() const*	returns the y coordinate of lower left vertex of *r*.
Kernel::FT	*r.xmax() const*	returns the x coordinate of upper right vertex of *r*.
Kernel::FT	*r.ymax() const*	returns the y coordinate of upper right vertex of *r*.
Kernel::FT	*r.min_coord(int i) const*	
		returns the i'th Cartesian coordinate of the lower left vertex of *r*. *Precondition*: $0 \leq i \leq 1$.
Kernel::FT	*r.max_coord(int i) const*	
		returns the i'th Cartesian coordinate of the upper right vertex of *r*. *Precondition*: $0 \leq i \leq 1$.

Predicates

bool	*r.is_degenerate() const*	
		r is degenerate, if all vertices are collinear.

Bounded_side	*r.bounded_side(Point_2<Kernel> p) const*	
		returns either *ON_UNBOUNDED_SIDE*, *ON_BOUNDED_SIDE*, or the constant *ON_BOUNDARY*, depending on where point p is.
bool	*r.has_on_boundary(Point_2<Kernel> p) const*	
bool	*r.has_on_bounded_side(Point_2<Kernel> p) const*	
bool	*r.has_on_unbounded_side(Point_2<Kernel> p) const*	

Miscellaneous

Kernel::FT	*r.area() const*	returns the area of r.
Bbox	*r.bbox() const*	returns a bounding box containing r.
Iso_rectangle_2<Kernel>		
	r.transform(Aff_transformation_2<Kernel> t) const	
		returns the iso-oriented rectangle obtained by applying t on the lower left and the upper right corner of r. *Precondition*: The angle at a rotation must be a multiple of $\pi/2$, otherwise the resulting rectangle does not have the same side length. Note that rotating about an arbitrary angle can even result in a degenerate iso-oriented rectangle.

See Also

Kernel::IsoRectangle_2 . . . . page 788

Class

CGAL::Line_2<Kernel>

Definition

An object l of the data type *Line_2<Kernel>* is a directed straight line in the two-dimensional Euclidean plane $\mathbb{E}^2$. It is defined by the set of points with Cartesian coordinates (x,y) that satisfy the equation

$$l:\ ax+by+c=0.$$

The line splits $\mathbb{E}^2$ in a *positive* and a *negative* side. A point p with Cartesian coordinates (px,py) is on the positive side of l, iff $a\,px+b\,py+c>0$, it is on the negative side of l, iff $a\,px+b\,py+c<0$. The positive side is to the left of l.

Creation

Line_2<Kernel> l(Kernel::RT a, Kernel::RT b, Kernel::RT c);

introduces a line l with the line equation in Cartesian coordinates $ax+by+c=0$.

Line_2<Kernel> l(Point_2<Kernel> p, Point_2<Kernel> q);

introduces a line l passing through the points p and q. Line l is directed from p to q.

Line_2<Kernel> l(Point_2<Kernel> p, Direction_2<Kernel> d);

introduces a line l passing through point p with direction d.

Line_2<Kernel> l(Point_2<Kernel> p, Vector_2<Kernel> v);

introduces a line l passing through point p and oriented by v.

Line_2<Kernel> l(Segment_2<Kernel> s); introduces a line l supporting the segment s, oriented from source to target.

Line_2<Kernel> l(Ray_2<Kernel> r); introduces a line l supporting the ray r, with same orientation.

Operations

bool	*l.operator==(h) const*	Test for equality: two lines are equal, iff they have a non empty intersection and the same direction.

bool	*l.operator!=(h) const*	Test for inequality.
Kernel::RT	*l.a() const*	returns the first coefficient of l.
Kernel::RT	*l.b() const*	returns the second coefficient of l.
Kernel::RT	*l.c() const*	returns the third coefficient of l.
Point_2<Kernel>	*l.point(int i) const*	returns an arbitrary point on *l*. It holds *point(i) == point(j)*, iff *i==j*. Furthermore, *l* is directed from *point(i)* to *point(j)*, for all $i < j$.
Point_2<Kernel>	*l.projection(Point_2<Kernel> p) const*	returns the orthogonal projection of *p* onto *l*.
Kernel::FT	*l.x_at_y(Kernel::FT y) const*	returns the *x*-coordinate of the point at *l* with given *y*-coordinate. *Precondition*: *l* is not horizontal.
Kernel::FT	*l.y_at_x(Kernel::FT x) const*	returns the *y*-coordinate of the point at *l* with given *x*-coordinate. *Precondition*: *l* is not vertical.

Predicates

bool	*l.is_degenerate() const*	line *l* is degenerate, if the coefficients *a* and *b* of the line equation are zero.
bool	*l.is_horizontal() const*	
bool	*l.is_vertical() const*	
Oriented_side	*l.oriented_side(Point_2<Kernel> p) const*	returns *ON_ORIENTED_BOUNDARY*, *ON_NEGATIVE_SIDE*, or the constant *ON_POSITIVE_SIDE*, depending on the position of *p* relative to the oriented line *l*.

For convenience we provide the following Boolean functions:

bool	*l.has_on(Point_2<Kernel> p) const*
bool	*l.has_on_positive_side(Point_2<Kernel> p) const*
bool	*l.has_on_negative_side(Point_2<Kernel> p) const*

Miscellaneous

Vector_2<Kernel>	*l.to_vector() const*	returns a vector having the direction of *l*.
Direction_2<Kernel>	*l.direction() const*	returns the direction of *l*.
Line_2<Kernel>	*l.opposite() const*	returns the line with opposite direction.
Line_2<Kernel>	*l.perpendicular(Point_2<Kernel> p) const*	returns the line perpendicular to *l* and passing through *p*, where the direction is the direction of *l* rotated counterclockwise by 90 degrees.
Line_2<Kernel>	*l.transform(Aff_transformation_2<Kernel> t) const*	returns the line obtained by applying *t* on a point on *l* and the direction of *l*.

Example

Let us first define two Cartesian two-dimensional points in the Euclidean plane $\mathbb{E}^2$. Their dimension and the fact that they are Cartesian is expressed by the suffix *_2* and the representation type *Cartesian*.

```
Point_2< Cartesian<double> >  p(1.0,1.0), q(4.0,7.0);
```

To define a line *l* we write:

```
Line_2< Cartesian<double> > l(p,q);
```

Kernel::Line_2 . . . . page 789

CGAL::Point_2<Kernel>

Class

Definition

An object of the class *Point_2<Kernel>* is a point in the two-dimensional Euclidean plane $\mathbb{E}^2$.

Remember that *Kernel::RT* and *Kernel::FT* denote a *RingNumberType* and a *FieldNumberType*, respectively. For the kernel model *Cartesian<T>*, the two types are the same. For the kernel model *Homogeneous<T>*, *Kernel::RT* is equal to *T*, and *Kernel::FT* is equal to *Quotient<T>*.

Types

Point_2<Kernel>:: Cartesian_const_iterator

An iterator for enumerating the Cartesian coordinates of a point.

Creation

Point_2<Kernel> p(Origin ORIGIN);

introduces a variable p with Cartesian coordinates $(0,0)$.

Point_2<Kernel> p(int x, int y);

introduces a point p initialized to (x,y).

Point_2<Kernel> p(double x, double y);

introduces a point p initialized to (x,y) provided *RT* supports construction from *double*.

Point_2<Kernel> p(Kernel::RT hx, Kernel::RT hy, Kernel::RT hw = RT(1));

introduces a point p initialized to $(hx/hw, hy/hw)$.
Precondition: $hw \neq$ *Kernel::RT(0)*

Point_2<Kernel> p(Kernel::FT x, Kernel::FT y);

introduces a point p initialized to (x,y).

Operations

bool *p.operator==(q) const*

Test for equality. Two points are equal, iff their x and y coordinates are equal. The point can be compared with *ORIGIN*.

bool *p.operator!=(q) const*

Test for inequality. The point can be compared with *ORIGIN*.

There are two sets of coordinate access functions, namely to the homogeneous and to the Cartesian coordinates. They can be used independently from the chosen kernel model.

Kernel::RT *p.hx() const*

returns the homogeneous x coordinate.

Kernel::RT *p.hy() const*

returns the homogeneous y coordinate.

Kernel::RT *p.hw() const*

returns the homogenizing coordinate.

Note that you do not loose information with the homogeneous representation, because the *FieldNumberType* is a quotient.

Kernel::FT *p.x() const*

returns the Cartesian x coordinate, that is hx/hw.

Kernel::FT *p.y() const*

returns the Cartesian y coordinate, that is hy/hw.

The following operations are for convenience and for compatibility with higher dimensional points. Again they come in a Cartesian and in a homogeneous flavor.

Kernel::RT *p.homogeneous(int i) const*

returns the i'th homogeneous coordinate of p, starting with 0.
Precondition: $0 \leq i \leq 2$.

Kernel::FT *p.cartesian(int i) const*

returns the i'th Cartesian coordinate of p, starting with 0.
Precondition: $0 \leq i \leq 1$.

Kernel::FT *p.operator[](int i) const*

returns *cartesian(i)*.
Precondition: $0 \leq i \leq 1$.

Cartesian_const_iterator *p.cartesian_begin() const*

returns an iterator to the Cartesian coordinates of p, starting with the 0th coordinate.

Cartesian_const_iterator *p.cartesian_end() const*

returns an off the end iterator to the Cartesian coordinates of p.

int *p.dimension() const*

returns the dimension (the constant 2).

Bbox_2 *p.bbox() const*

returns a bounding box containing p. Note that bounding boxes are not parameterized with whatsoever.

Point_2<Kernel> *p.transform(Aff_transformation_2<Kernel> t) const*

returns the point obtained by applying t on p.

Operators

The following operations can be applied on points:

bool *operator<(p, q)*

returns true iff p is lexicographically smaller than q, i.e. either if $p.x() < q.x()$ or if $p.x() == q.x()$ and $p.y() < q.y()$.

bool *operator>(p, q)*

returns true iff p is lexicographically greater than q.

bool *operator<=(p, q)*

returns true iff p is lexicographically smaller or equal to q.

bool *operator>=(p, q)*

returns true iff p is lexicographically greater or equal to q.

Vector_2<Kernel> *operator-(p, q)*

returns the difference vector between q and p. You can substitute *ORIGIN* for either p or q, but not for both.

Point_2<Kernel> *operator+(p, Vector_2<Kernel> v)*

returns the point obtained by translating p by the vector v.

Point_2<Kernel> *operator-(p, Vector_2<Kernel> v)*

returns the point obtained by translating *p* by the vector -*v*.

Example

The following declaration creates two points with Cartesian double coordinates.

```
Point_2< Cartesian<double> > p, q(1.0, 2.0);
```

The variable `p` is uninitialized and should first be used on the left hand side of an assignment.

```
p = q;

std::cout << p.x() << "  " << p.y() << std::endl;
```

CGAL::Ray_2<Kernel>

Definition

An object r of the data type *Ray_2<Kernel>* is a directed straight ray in the two-dimensional Euclidean plane $\mathbb{E}^2$. It starts in a point called the *source* of r and goes to infinity.

Creation

Ray_2<Kernel> r(Point_2<Kernel> p, Point_2<Kernel> q);

introduces a ray r with source p and passing through point q.

Ray_2<Kernel> r(Point_2<Kernel> p, Direction_2<Kernel> d);

introduces a ray r starting at source p with direction d.

Ray_2<Kernel> r(Point_2<Kernel> p, Vector_2<Kernel> v);

introduces a ray r starting at source p with the direction of v.

Ray_2<Kernel> r(Point_2<Kernel> p, Line_2<Kernel> l);

introduces a ray r starting at source p with the same direction as l.

Operations

bool *r.operator==(h) const*

Test for equality: two rays are equal, iff they have the same source and the same direction.

bool *r.operator!=(h) const*

Test for inequality.

Point_2<Kernel>	*r.source() const*	returns the source of r.
Point_2<Kernel>	*r.point(int i) const*	returns a point on r. *point(0)* is the source, *point(i)*, with $i > 0$, is different from the source. *Precondition*: $i \geq 0$.

Direction_2<Kernel>	*r.direction() const*	returns the direction of *r*.
Vector_2<Kernel>	*r.to_vector() const*	returns a vector giving the direction of *r*.
Line_2<Kernel>	*r.supporting_line() const*	
		returns the line supporting *r* which has the same direction.
Ray_2<Kernel>	*r.opposite() const*	returns the ray with the same source and the opposite direction.

Predicates

bool	*r.is_degenerate() const*	
		ray *r* is degenerate, if the source and the second defining point fall together (that is if the direction is degenerate).
bool	*r.is_horizontal() const*	
bool	*r.is_vertical() const*	
bool	*r.has_on(Point_2<Kernel> p) const*	
		A point is on *r*, iff it is equal to the source of *r*, or if it is in the interior of *r*.
bool	*r.collinear_has_on(Point_2<Kernel> p) const*	
		checks if point *p* is on *r*. This function is faster than function *has_on()* if the precondition checking is disabled. *Precondition*: *p* is on the supporting line of *r*.

Miscellaneous

Ray_2<Kernel>	*r.transform(Aff_transformation_2<Kernel> t) const*	
		returns the ray obtained by applying *t* on the source and on the direction of *r*.

See Also

Kernel::Ray_2 . . . . page 798

CGAL::Segment_2<Kernel>

Class

Definition

An object s of the data type *Segment_2<Kernel>* is a directed straight line segment in the two-dimensional Euclidean plane $\mathbb{E}^2$, i.e. a straight line segment $[p,q]$ connecting two points $p,q \in \mathbb{R}^2$. The segment is topologically closed, i.e. the end points belong to it. Point p is called the *source* and q is called the *target* of s. The length of s is the Euclidean distance between p and q. Note that there is only a function to compute the square of the length, because otherwise we had to perform a square root operation which is not defined for all number types, which is expensive, and may not be exact.

Creation

Segment_2<Kernel> s(Point_2<Kernel> p, Point_2<Kernel> q);

introduces a segment s with source p and target q. The segment is directed from the source towards the target.

Operations

bool	*s.operator==(q) const*	Test for equality: Two segments are equal, iff their sources and targets are equal.
bool	*s.operator!=(q) const*	Test for inequality.
Point_2<Kernel>	*s.source() const*	returns the source of s.
Point_2<Kernel>	*s.target() const*	returns the target of s.
Point_2<Kernel>	*s.min() const*	returns the point of s with lexicographically smallest coordinate.
Point_2<Kernel>	*s.max() const*	returns the point of s with lexicographically largest coordinate.
Point_2<Kernel>	*s.vertex(int i) const*	returns source or target of s: *vertex(0)* returns the source of s, *vertex(1)* returns the target of s. The parameter i is taken modulo 2, which gives easy access to the other vertex.
Point_2<Kernel>	*s.point(int i) const*	returns *vertex(i)*.
Point_2<Kernel>	*s.operator[ ](int i) const*	returns *vertex(i)*.
Kernel::FT	*s.squared_length() const*	returns the squared length of s.
Direction_2<Kernel>	*s.direction() const*	returns the direction from source to target of s.

Vector_2<Kernel>	*s.to_vector() const*	returns the vector *s.target() - s.source()*.
Segment_2<Kernel>	*s.opposite() const*	returns a segment with source and target point interchanged.
Line_2<Kernel>	*s.supporting_line() const*	returns the line l passing through s. Line l has the same orientation as segment s.

Predicates

bool	*s.is_degenerate() const*	segment s is degenerate, if source and target are equal.
bool	*s.is_horizontal() const*	
bool	*s.is_vertical() const*	
bool	*s.has_on(Point_2<Kernel> p) const*	A point is on s, iff it is equal to the source or target of s, or if it is in the interior of s.
bool	*s.collinear_has_on(Point_2<Kernel> p) const*	checks if point p is on segment s. This function is faster than function *has_on()*. *Precondition*: p is on the supporting line of s.

Miscellaneous

Bbox_2	*s.bbox() const*	returns a bounding box containing s.
Segment_2<Kernel>	*s.transform(Aff_transformation_2<Kernel> t) const*	returns the segment obtained by applying t on the source and the target of s.

Kernel::Segment_2 . . . . page 800

CGAL::Triangle_2<Kernel>

Class

Definition

An object t of the class *Triangle_2<Kernel>* is a triangle in the two-dimensional Euclidean plane $\mathbb{E}^2$. Triangle t is oriented, i.e., its boundary has clockwise or counterclockwise orientation. We call the side to the left of the boundary the positive side and the side to the right of the boundary the negative side.

The boundary of a triangle splits the plane in two open regions, a bounded one and an unbounded one.

Creation

Triangle_2<Kernel> t(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r);

introduces a triangle t with vertices p, q and r.

Operations

bool	*t.operator==(t2) const*	Test for equality: two triangles are equal, iff there exists a cyclic permutation of the vertices of $t2$, such that they are equal to the vertices of t.
bool	*t.operator!=(t2) const*	Test for inequality.
Point_2<Kernel>	*t.vertex(int i) const*	returns the i'th vertex modulo 3 of t.
Point_2<Kernel>	*t.operator[ ](int i) const*	returns *vertex(i)*.

Predicates

bool	*t.is_degenerate() const*	triangle t is degenerate, if the vertices are collinear.
Orientation	*t.orientation() const*	returns the orientation of t.

Oriented_side	*t.oriented_side(Point_2<Kernel> p) const*	
		returns *ON_ORIENTED_BOUNDARY*, or *POSITIVE_SIDE*, or the constant *ON_NEGATIVE_SIDE*, determined by the position of point *p*. *Precondition*: *t* is not degenerate.
Bounded_side	*t.bounded_side(Point_2<Kernel> p) const*	
		returns the constant *ON_BOUNDARY*, *ON_BOUNDED_SIDE*, or else *ON_UNBOUNDED_SIDE*, depending on where point *p* is. *Precondition*: *t* is not degenerate.

For convenience we provide the following Boolean functions:

bool	*t.has_on_positive_side(Point_2<Kernel> p) const*	
bool	*t.has_on_negative_side(Point_2<Kernel> p) const*	
bool	*t.has_on_boundary(Point_2<Kernel> p) const*	
bool	*t.has_on_bounded_side(Point_2<Kernel> p) const*	
bool	*t.has_on_unbounded_side(Point_2<Kernel> p) const*	
		Precondition: *t* is not degenerate.

Miscellaneous

Triangle_2<Kernel>	*t.opposite()*	returns a triangle where the boundary is oriented the other way round (this flips the positive and the negative side, but not the bounded and unbounded side).
Kernel::FT	*t.area() const*	returns the signed area of *t*.
Bbox_2	*t.bbox() const*	returns a bounding box containing *t*.
Triangle_2<Kernel>	*t.transform(Aff_transformation_2<Kernel> at) const*	
		returns the triangle obtained by applying *at* on the three vertices of *t*.

Kernel::Triangle_2 . . . . page 804

CGAL::Vector_2<Kernel>

Class

Definition

An object of the class *Vector_2<Kernel>* is a vector in the two-dimensional vector space $\mathbb{R}^2$. Geometrically spoken, a vector is the difference of two points p_2, p_1 and denotes the direction and the distance from p_1 to p_2.

CGAL defines a symbolic constant *NULL_VECTOR*. We will explicitly state where you can pass this constant as an argument instead of a vector initialized with zeros.

Types

Vector_2<Kernel>:: Cartesian_const_iterator

An iterator for enumerating the Cartesian coordinates of a vector.

Creation

Vector_2<Kernel> v(Point_2<Kernel> a, Point_2<Kernel> b);

introduces the vector $b-a$.

Vector_2<Kernel> v(Segment_2<Kernel> s);

introduces the vector $s.target() - s.source()$.

Vector_2<Kernel> v(Ray_2<Kernel> r);

introduces the vector having the same direction as r.

Vector_2<Kernel> v(Line_2<Kernel> l);

introduces the vector having the same direction as l.

Vector_2<Kernel> v(Null_vector NULL_VECTOR);

introduces a null vector v.

Vector_2<Kernel> v(int x, int y); introduces a vector v initialized to (x,y).

Vector_2<Kernel> v(double x, double y);

introduces a vector v initialized to (x,y).

Vector_2<Kernel> v(Kernel::RT hx, Kernel::RT hy, Kernel::RT hw = RT(1));

introduces a vector v initialized to $(hx/hw, hy/hw)$.
Precondition: $hw \neq 0$

Vector_2<Kernel> v(Kernel::FT x, Kernel::FT y);

introduces a vector v initialized to (x, y).

Operations

bool *v.operator==(w) const*

Test for equality: two vectors are equal, iff their x and y coordinates are equal. You can compare a vector with the *NULL_VECTOR*.

bool *v.operator!=(w) const*

Test for inequality. You can compare a vector with the *NULL_VECTOR*.

There are two sets of coordinate access functions, namely to the homogeneous and to the Cartesian coordinates. They can be used independently from the chosen kernel model.

Kernel::RT *v.hx() const*

returns the homogeneous x coordinate.

Kernel::RT *v.hy() const*

returns the homogeneous y coordinate.

Kernel::RT *v.hw() const*

returns the homogenizing coordinate.

Note that you do not loose information with the homogeneous representation, because the *FieldNumberType* is a quotient.

Kernel::FT *v.x() const*

returns the x-coordinate of v, that is hx/hw.

Kernel::FT *v.y() const*

returns the y-coordinate of v, that is hy/hw.

The following operations are for convenience and for compatibility with higher dimensional vectors. Again they come in a Cartesian and homogeneous flavor.

Kernel::RT *v.homogeneous(int i) const*

returns the i'th homogeneous coordinate of v, starting with 0.
Precondition: $0 \leq i \leq 2$.

Kernel::FT *v.cartesian(int i) const*

returns the i'th Cartesian coordinate of v, starting at 0.
Precondition: $0 \leq i \leq 1$.

Kernel::FT *v.operator[](int i) const*

returns *cartesian(i)*.
Precondition: $0 \leq i \leq 1$.

Cartesian_const_iterator *v.cartesian_begin() const*

returns an iterator to the Cartesian coordinates of v, starting with the 0th coordinate.

Cartesian_const_iterator *v.cartesian_end() const*

returns an off the end iterator to the Cartesian coordinates of v.

int *v.dimension() const*

returns the dimension (the constant 2).

Direction_2<Kernel> *v.direction() const*

returns the direction which passes through v.

Vector_2<Kernel> *v.transform(Aff_transformation_2<Kernel> t) const*

returns the vector obtained by applying t on v.

Vector_2<Kernel> *v.perpendicular(Orientation o) const*

returns the vector perpendicular to v in clockwise or counterclockwise orientation.

Operators

The following operations can be applied to vectors:

Vector_2<Kernel> *v.operator+(w) const*

Addition.

Vector_2<Kernel> *v.operator-(w) const*

Subtraction.

Vector_2<Kernel> *v.operator-() const*

returns the opposite vector.

Kernel::FT *v.operator*(w) const*

returns the scalar product (= inner product) of the two vectors.

Vector_2<Kernel> *operator*(v, Kernel::RT s)*

Multiplication with a scalar from the right.

Vector_2<Kernel> *operator*(v, Kernel::FT s)*

Multiplication with a scalar from the right.

Vector_2<Kernel> *operator*(Kernel::RT s, v)*

Multiplication with a scalar from the left.

Vector_2<Kernel> *operator*(Kernel::FT s, v)*

Multiplication with a scalar from the left.

Vector_2<Kernel> *v.operator/(Kernel::RT s) const*

Division by a scalar.

Kernel::FT *v.squared_length() const*

returns the squared length of *v*.

11.11.2 Three-dimensional Objects

CGAL::Bbox_3

#include <CGAL/Bbox_3.h>

Definition

An object *b* of the class *Bbox_3* is a bounding box in the three-dimensional Euclidean space $\mathbb{E}^3$.

Creation

Bbox_3 b(double x_min, double y_min, double z_min, double x_max, double y_max, double z_max);

introduces a bounding box *b* with lexicographically smallest corner point at *(xmin, ymin, zmin)* lexicographically largest corner point at *(xmax, ymax, zmax)*.

Operations

bool	*b.operator==(c) const*	Test for equality.
bool	*b.operator!=(q) const*	Test for inequality.
int	*b.dimension() const*	Returns 3.
double	*b.xmin() const*	
double	*b.ymin() const*	
double	*b.zmin() const*	
double	*b.xmax() const*	
double	*b.ymax() const*	
double	*b.zmax() const*	
double	*b.min(int i) const*	Returns *xmin()* if *i==0* or *ymin()* if *i==1* or *zmin()* if *i==2*. *Precondition*: i¡=0 and i¡=2
double	*b.max(int i) const*	Returns *xmax()* if *i==0* or *ymax()* if *i==1* or *zmax()* if *i==2*. *Precondition*: i==0 and i¡=2
Bbox_3	*b.operator+(c) const*	returns a bounding box of *b* and *c*.

CGAL::Aff_transformation_3<Kernel>

Definition

The class *Aff_transformation_3<Kernel>* represents three-dimensional affine transformations. The general form of an affine transformation is based on a homogeneous representation of points. Thereby all transformations can be realized by matrix multiplication.

Multiplying the transformation matrix by a scalar does not change the represented transformation. Therefore, any transformation represented by a matrix with rational entries can be represented by a transformation matrix with integer entries as well. (Multiply the matrix with the common denominator of the rational entries.) Hence, it is sufficient to use the number type *Kernel::RT* to represent the entries of the transformation matrix.

CGAL offers several specialized affine transformations. Different constructors are provided to create them. They are parameterized with a symbolic name to denote the transformation type, followed by additional parameters. The symbolic name tags solve ambiguities in the function overloading and they make the code more readable, i.e., what type of transformation is created.

In three-dimensional space we have a 4×4 matrix $(m_{ij})_{i,\,j=0\ldots3}$. Entries m_{30}, m_{31}, and m_{32} are always zero and therefore do not appear in the constructors.

Creation

Aff_transformation_3<Kernel> t(Identity_transformation);

introduces an identity transformation.

Aff_transformation_3<Kernel> t(const Translation, Vector_3<Kernel> v);

introduces a translation by a vector v.

Aff_transformation_3<Kernel> t(const Scaling, Kernel::RT s, Kernel::RT hw = RT(1));

introduces a scaling by a scale factor s/hw.

Aff_transformation_3<Kernel> t(Kernel::RT m00,
Kernel::RT m01,
Kernel::RT m02,
Kernel::RT m03,
Kernel::RT m10,
Kernel::RT m11,
Kernel::RT m12,
Kernel::RT m13,
Kernel::RT m20,
Kernel::RT m21,
Kernel::RT m22,
Kernel::RT m23,

Kernel::RT hw = RT(1))

introduces a general affine transformation of the matrix form $\begin{pmatrix} m_{00} & m_{01} & m_{02} & m_{03} \\ m_{10} & m_{11} & m_{12} & m_{13} \\ m_{20} & m_{21} & m_{22} & m_{23} \\ 0 & 0 & 0 & hw \end{pmatrix}$. The part $\frac{1}{hw}$ $\begin{pmatrix} m_{00} & m_{01} & m_{02} \\ m_{10} & m_{11} & m_{12} \\ m_{20} & m_{21} & m_{22} \end{pmatrix}$ defines the scaling and rotational part of the transformation, while the vector $\frac{1}{hw}\begin{pmatrix} m_{03} \\ m_{13} \\ m_{23} \end{pmatrix}$ contains the translational part.

Aff_transformation_3<Kernel> t(Kernel::RT m00,
Kernel::RT m01,
Kernel::RT m02,
Kernel::RT m10,
Kernel::RT m11,
Kernel::RT m12,
Kernel::RT m20,
Kernel::RT m21,
Kernel::RT m22,
Kernel::RT hw = RT(1))

introduces a general linear transformation of the matrix form $\begin{pmatrix} m_{00} & m_{01} & m_{02} & 0 \\ m_{10} & m_{11} & m_{12} & 0 \\ m_{20} & m_{21} & m_{22} & 0 \\ 0 & 0 & 0 & hw \end{pmatrix}$, i.e. an affine transformation without translational part.

Operations

Each class *Class_3<Kernel>* representing a geometric object in 3D has a member function:

Class_3<Kernel> transform(Aff_transformation_3<Kernel> t).

The transformation classes provide a member function *transform()* for points, vectors, directions, and planes:

Point_3<Kernel>	*t.transform(Point_3<Kernel> p) const*
Vector_3<Kernel>	*t.transform(Vector_3<Kernel> p) const*
Direction_3<Kernel>	*t.transform(Direction_3<Kernel> p) const*
Plane_3<Kernel>	*t.transform(Plane_3<Kernel> p) const*

CGAL provides four function operators for these member functions:

Point_3<Kernel>	*t.operator()(Point_3<Kernel> p) const*
Vector_3<Kernel>	*t.operator()(Vector_3<Kernel> p) const*
Direction_3<Kernel>	*t.operator()(Direction_3<Kernel> p) const*
Plane_3<Kernel>	*t.operator()(Plane_3<Kernel> p) const*

Aff_transformation_3<Kernel>		
	t.operator(s) const*	composes two affine transformations.
Aff_transformation_3<Kernel>		
	t.inverse() const	gives the inverse transformation.
bool	*t.is_even() const*	returns *true*, if the transformation is not reflecting, i.e. the determinant of the involved linear transformation is non-negative.
bool	*t.is_odd() const*	returns *true*, if the transformation is reflecting.

The matrix entries of a matrix representation of a *Aff_transformation_3<Kernel>* can be accessed trough the following member functions:

Kernel::FT	*t.cartesian(int i, int j) const*	
Kernel::FT	*t.m(int i, int j) const*	returns entry m_{ij} in a matrix representation in which m_{33} is 1.
Kernel::RT	*t.homogeneous(int i, int j) const*	
Kernel::RT	*t.hm(int i, int j) const*	returns entry m_{ij} in some fixed matrix representation.

For affine transformations no I/O operators are defined.

CGAL::Direction_3<Kernel>

Definition

An object of the class *Direction_3<Kernel>* is a vector in the three-dimensional vector space $\mathbb{R}^3$ where we forget about their length. They can be viewed as unit vectors, although there is no normalization internally, since this is error prone. Directions are used whenever the length of a vector does not matter. They also characterize a set of parallel lines that have the same orientation or the direction normal to parallel planes that have the same orientation. For example, you can ask for the direction orthogonal to an oriented plane, or the direction of an oriented line.

Creation

Direction_3<Kernel> d(Vector_3<Kernel> v);

introduces a direction d initialized with the direction of vector v.

Direction_3<Kernel> d(Line_3<Kernel> l);

introduces the direction d of line l.

Direction_3<Kernel> d(Ray_3<Kernel> r);

introduces the direction d of ray r.

Direction_3<Kernel> d(Segment_3<Kernel> s);

introduces the direction d of segment s.

Direction_3<Kernel> d(Kernel::RT x, Kernel::RT y, Kernel::RT z);

introduces a direction d initialized with the direction from the origin to the point with Cartesian coordinates (x, y, z).

Operations

Kernel::RT	*d.delta(int i) const*	returns values, such that *d== Direction_3<Kernel> (delta(0),delta(1),delta(2))*. *Precondition*: : $0 \leq i \leq 2$.
Kernel::RT	*d.dx() const*	returns *delta(0)*.
Kernel::RT	*d.dy() const*	returns *delta(1)*.
Kernel::RT	*d.dz() const*	returns *delta(2)*.
bool	*d.operator==(e) const*	Test for equality.
bool	*d.operator!=(e) const*	Test for inequality.
Direction_3<Kernel>	*d.operator-() const*	The direction opposite to d.
Vector_3<Kernel>	*d.vector() const*	returns a vector that has the same direction as d.
Direction_3<Kernel>	*d.transform(Aff_transformation_3<Kernel> t) const*	returns the direction obtained by applying t on d.

Class

CGAL::Iso_cuboid_3<Kernel>

Definition

An object s of the data type *Iso_cuboid_3<Kernel>* is a cuboid in the Euclidean space $\mathbb{E}^3$ with edges parallel to the x, y and z axis of the coordinate system.

Although they are represented in a canonical form by only two vertices, namely the lexicographically smallest and largest vertex with respect to Cartesian xyz coordinates, we provide functions for "accessing" the other vertices as well.

Iso-oriented cuboids and bounding boxes are quite similar. The difference however is that bounding boxes have always double coordinates, whereas the coordinate type of an iso-oriented cuboid is chosen by the user.

Creation

Iso_cuboid_3<Kernel> c(Point_3<Kernel> p, Point_3<Kernel> q);

introduces an iso-oriented cuboid c with diagonal opposite vertices p and q. Note that the object is brought in the canonical form.

Iso_cuboid_3<Kernel> c(Point_3<Kernel> p, Point_3<Kernel> q, int);

introduces an iso-oriented cuboid c with diagonal opposite vertices p and q. The *int* argument value is only used to distinguish the two overloaded functions.
Precondition: $p.x() <= q.x()$, $p.y() <= q.y()$ and $p.z() <= q.z()$.

Iso_cuboid_3<Kernel> c(Point_3<Kernel> left,
Point_3<Kernel> right,
Point_3<Kernel> bottom,
Point_3<Kernel> top,
Point_3<Kernel> far,
Point_3<Kernel> close)

introduces an iso-oriented cuboid c whose minimal x coordinate is the one of *left*, the maximal x coordinate is the one of *right*, the minimal y coordinate is the one of *bottom*, the maximal y coordinate is the one of *top*, the minimal z coordinate is the one of *far*, the maximal z coordinate is the one of *close*.

Iso_cuboid_3<Kernel> c(Kernel::RT min_hx,
Kernel::RT min_hy,
Kernel::RT min_hz,
Kernel::RT max_hx,
Kernel::RT max_hy,
Kernel::RT max_hz,

Kernel::RT hw = RT(1))

introduces an iso-oriented cuboid *c* with diagonal opposite vertices (*min_hx/hw*, *min_hy/hw*, *min_hz/hw*) and (*max_hx/hw*, *max_hy/hw*, *max_hz/hw*).
Precondition: $hw \neq 0$.

Operations

bool *c.operator==(c2) const*

Test for equality: two iso-oriented cuboid are equal, iff their lower left and their upper right vertices are equal.

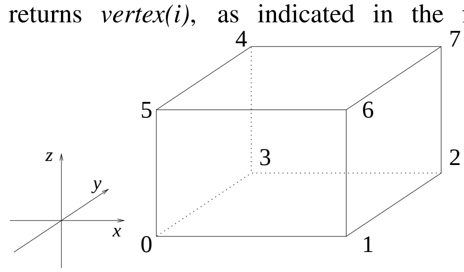
bool *c.operator!=(c2) const*

Test for inequality.

Point_3<Kernel> *c.vertex(int i) const* returns the i'th vertex modulo 8 of *c*. starting with the lower left vertex.

Point_3<Kernel> *c.operator[ ](int i) const*

returns *vertex(i)*, as indicated in the figure below:



Point_3<Kernel> *c.min() const* returns the smallest vertex of *c* (= *vertex(0)*).

Point_3<Kernel> *c.max() const* returns the largest vertex of *c* (= *vertex(7)*).

Kernel::FT	*c.xmin() const*	returns smallest Cartesian *x*-coordinate in *c*.
Kernel::FT	*c.ymin() const*	returns smallest Cartesian *y*-coordinate in *c*.
Kernel::FT	*c.zmin() const*	returns smallest Cartesian *z*-coordinate in *c*.
Kernel::FT	*c.xmax() const*	returns largest Cartesian *x*-coordinate in *c*.
Kernel::FT	*c.ymax() const*	returns largest Cartesian *y*-coordinate in *c*.
Kernel::FT	*c.zmax() const*	returns largest Cartesian *z*-coordinate in *c*.

Kernel::FT *c.min_coord(int i) const*

returns *i*-th Cartesian coordinate of the smallest vertex of *c*.
Precondition: $0 \leq i \leq 2$.

Kernel::FT	*c.max_coord(int i) const*	
		returns i-th Cartesian coordinate of the largest vertex of c. *Precondition*: $0 \leq i \leq 2$.

Predicates

bool	*c.is_degenerate() const*	
		c is degenerate, if all vertices are coplanar.
Bounded_side	*c.bounded_side(Point_3<Kernel> p) const*	
		returns either *ON_UNBOUNDED_SIDE*, *ON_BOUNDED_SIDE*, or the constant *ON_BOUNDARY*, depending on where point p is.
bool	*c.has_on_boundary(Point_3<Kernel> p) const*	
bool	*c.has_on_bounded_side(Point_3<Kernel> p) const*	
bool	*c.has_on_unbounded_side(Point_3<Kernel> p) const*	

Miscellaneous

Kernel::FT	*c.volume() const*	returns the volume of c.
Bbox_3	*c.bbox() const*	returns a bounding box containing c.
Iso_cuboid_3<Kernel>	*c.transform(Aff_transformation_3<Kernel> t) const*	
		returns the iso-oriented cuboid obtained by applying t on the smallest and the largest of c. *Precondition*: The angle at a rotation must be a multiple of $\pi/2$, otherwise the resulting cuboid does not have the same size. Note that rotating about an arbitrary angle can even result in a degenerate iso-oriented cuboid.

Kernel::IsoCuboid_3 . . . . page 787

CGAL::Line_3<Kernel>

Class

Definition

An object l of the data type *Line_3<Kernel>* is a directed straight line in the three-dimensional Euclidean space $\mathbb{E}^3$.

Creation

Line_3<Kernel> l(Point_3<Kernel> p, Point_3<Kernel> q);

introduces a line l passing through the points p and q. Line l is directed from p to q.

Line_3<Kernel> l(Point_3<Kernel> p, Direction_3<Kernel> d);

introduces a line l passing through point p with direction d.

Line_3<Kernel> l(Point_3<Kernel> p, Vector_3<Kernel> v);

introduces a line l passing through point p and oriented by v.

Line_3<Kernel> l(Segment_3<Kernel> s); returns the line supporting the segment s, oriented from source to target.

Line_3<Kernel> l(Ray_3<Kernel> r); returns the line supporting the ray r, with the same orientation.

Operations

bool *l.operator==(h) const*

Test for equality: two lines are equal, iff they have a non empty intersection and the same direction.

bool *l.operator!=(h) const* Test for inequality.

Point_3<Kernel> *l.projection(Point_3<Kernel> p) const*

returns the orthogonal projection of p on l.

Point_3<Kernel> *l.point(int i) const* returns an arbitrary point on l. It holds *point(i) = point(j)*, iff *i=j*.

Predicates

bool	*l.is_degenerate() const*	
		returns *true* iff line *l* is degenerated to a point.
bool	*l.has_on(Point_3<Kernel> p) const*	
		returns *true* iff *p* lies on *l*.

Miscellaneous

Plane_3<Kernel>	*l.perpendicular_plane(Point_3<Kernel> p) const*	
		returns the plane perpendicular to *l* passing through *p*.
Line_3<Kernel>	*l.opposite() const*	returns the line with opposite direction.
Vector_3<Kernel>	*l.to_vector() const*	returns a vector having the same direction as *l*.
Direction_3<Kernel>	*l.direction() const*	returns the direction of *l*.
Line_3<Kernel>	*l.transform(Aff_transformation_3<Kernel> t) const*	
		returns the line obtained by applying *t* on a point on *l* and the direction of *l*.

Kernel::Line_3 . . . . page 790

CGAL::Plane_3<Kernel>

Class

Definition

An object h of the data type *Plane_3<Kernel>* is an oriented plane in the three-dimensional Euclidean space $\mathbb{E}^3$. It is defined by the set of points with Cartesian coordinates (x,y,z) that satisfy the plane equation

$$h: \; a\,x + b\,y + c\,z + d = 0.$$

The plane splits $\mathbb{E}^3$ in a *positive* and a *negative side*. A point p with Cartesian coordinates (px, py, pz) is on the positive side of h, iff $a\,px + b\,py + c\,pz + d > 0$. It is on the negative side, iff $a\,px + b\,py + c\,pz + d < 0$.

Creation

Plane_3<Kernel> h(Kernel::RT a, Kernel::RT b, Kernel::RT c, Kernel::RT d);

creates a plane h defined by the equation $a\,px + b\,py + c\,pz + d = 0$. Notice that h is degenerate if $a = b = c = 0$.

Plane_3<Kernel> h(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r);

creates a plane h passing through the points p, q and r. The plane is oriented such that p, q and r are oriented in a positive sense (that is counterclockwise) when seen from the positive side of h. Notice that h is degenerate if the points are collinear.

Plane_3<Kernel> h(Point_3<Kernel> p, Vector_3<Kernel> v);

introduces a plane h that passes through point p and that is orthogonal to v.

Plane_3<Kernel> h(Point_3<Kernel> p, Direction_3<Kernel> d);

introduces a plane h that passes through point p and that has as an orthogonal direction equal to d.

Plane_3<Kernel> h(Line_3<Kernel> l, Point_3<Kernel> p);

introduces a plane h that is defined through the three points *l.point(0)*, *l.point(1)* and p.

Plane_3<Kernel> h(Ray_3<Kernel> r, Point_3<Kernel> p);

introduces a plane h that is defined through the three points *r.point(0)*, *r.point(1)* and p.

Plane_3<Kernel> h(Segment_3<Kernel> s, Point_3<Kernel> p);

introduces a plane *h* that is defined through the three points *s.source()*, *s.target()* and *p*.

Plane_3<Kernel> h(Circle_3<Kernel> c); introduces a plane *h* that is defined as the plane containing the circle.

Operations

bool *h.operator==(h2) const*

Test for equality: two planes are equal, iff they have a non empty intersection and the same orientation.

bool *h.operator!=(h2) const*

Test for inequality.

Kernel::RT	*h.a() const*	returns the first coefficient of *h*.
Kernel::RT	*h.b() const*	returns the second coefficient of *h*.
Kernel::RT	*h.c() const*	returns the third coefficient of *h*.
Kernel::RT	*h.d() const*	returns the fourth coefficient of *h*.

Line_3<Kernel> *h.perpendicular_line(Point_3<Kernel> p) const*

returns the line that is perpendicular to *h* and that passes through point *p*. The line is oriented from the negative to the positive side of *h*.

Point_3<Kernel> *h.projection(Point_3<Kernel> p) const*

returns the orthogonal projection of *p* on *h*.

Plane_3<Kernel> *h.opposite() const* returns the plane with opposite orientation.

Point_3<Kernel> *h.point() const* returns an arbitrary point on *h*.

Vector_3<Kernel> *h.orthogonal_vector() const*

returns a vector that is orthogonal to *h* and that is directed to the positive side of *h*.

Direction_3<Kernel> *h.orthogonal_direction() const*

returns the direction that is orthogonal to *h* and that is directed to the positive side of *h*.

Vector_3<Kernel>	*h.base1() const*	returns a vector orthogonal to *orthogonal_vector()*.
Vector_3<Kernel>	*h.base2() const*	returns a vector that is both orthogonal to *base1()*, and to *orthogonal_vector()*, and such that the result of *orientation(point(), point() + base1(), point()+base2(), point() + orthogonal_vector())* is positive.

2D Conversion

The following functions provide conversion between a plane and CGAL's two-dimensional space. The transformation is affine, but not necessarily an isometry. This means, the transformation preserves combinatorics, but not distances.

Point_2<Kernel> *h.to_2d(Point_3<Kernel> p) const*

returns the image point of the projection of p under an affine transformation, which maps h onto the xy-plane, with the z-coordinate removed.

Point_3<Kernel> *h.to_3d(Point_2<Kernel> p) const*

returns a point q, such that *to_2d(to_3d(p))* is equal to p.

Predicates

Oriented_side *h.oriented_side(Point_3<Kernel> p) const*

returns either *ON_ORIENTED_BOUNDARY*, or the constant *ON_POSITIVE_SIDE*, or the constant *ON_NEGATIVE_SIDE*, determined by the position of p relative to the oriented plane h.

For convenience we provide the following Boolean functions:

bool	*h.has_on(Point_3<Kernel> p) const*
bool	*h.has_on_positive_side(Point_3<Kernel> p) const*
bool	*h.has_on_negative_side(Point_3<Kernel> p) const*
bool	*h.has_on(Line_3<Kernel> l) const*
bool	*h.has_on(Circle_3<Kernel> l) const*

bool *h.is_degenerate() const*

Plane h is degenerate, if the coefficients a, b, and c of the plane equation are zero.

Miscellaneous

Plane_3<Kernel> *h.transform(Aff_transformation_3<Kernel> t) const*

returns the plane obtained by applying t on a point of h and the orthogonal direction of h.

See Also

Kernel::Plane_3 . . . . page 793

CGAL::Point_3<Kernel>

Class

Definition

An object of the class *Point_3<Kernel>* is a point in the three-dimensional Euclidean space $\mathbb{E}^3$.

Remember that *Kernel::RT* and *Kernel::FT* denote a RingNumberType and a FieldNumberType, respectively. For the kernel model *Cartesian<T>*, the two types are the same. For the kernel model *Homogeneous<T>*, *Kernel::RT* is equal to *T*, and *Kernel::FT* is equal to *Quotient<T>*.

Types

Point_3<Kernel>:: Cartesian_const_iterator

An iterator for enumerating the Cartesian coordinates of a point.

Creation

Point_3<Kernel> p(Origin ORIGIN);

introduces a point with Cartesian coordinates$(0,0,0)$.

Point_3<Kernel> p(int x, int y, int z);

introduces a point *p* initialized to (x,y,z).

Point_3<Kernel> p(double x, double y, double z);

introduces a point *p* initialized to (x,y,z) provided *RT* supports it.

Point_3<Kernel> p(Kernel::RT hx, Kernel::RT hy, Kernel::RT hz, Kernel::RT hw = RT(1));

introduces a point *p* initialized to $(hx/hw, hy/hw, hz/hw)$.
Precondition: $hw \neq 0$.

Point_3<Kernel> p(Kernel::FT x, Kernel::FT y, Kernel::FT z);

introduces a point *p* initialized to (x,y,z).

Operations

bool *p.operator==(q) const*

Test for equality: Two points are equal, iff their *x*, *y* and *z* coordinates are equal.

bool *p.operator!=(q) const*

Test for inequality.

There are two sets of coordinate access functions, namely to the homogeneous and to the Cartesian coordinates. They can be used independently from the chosen kernel model.

Kernel::RT *p.hx() const*

returns the homogeneous x coordinate.

Kernel::RT *p.hy() const*

returns the homogeneous y coordinate.

Kernel::RT *p.hz() const*

returns the homogeneous z coordinate.

Kernel::RT *p.hw() const*

returns the homogenizing coordinate.

Note that you do not loose information with the homogeneous representation, because the FieldNumberType is a quotient.

Kernel::FT *p.x() const*

returns the Cartesian x coordinate, that is hx/hw.

Kernel::FT *p.y() const*

returns the Cartesian y coordinate, that is hy/hw.

Kernel::FT *p.z() const*

returns the Cartesian z coordinate, that is hz/hw.

The following operations are for convenience and for compatibility with code for higher dimensional points. Again they come in a Cartesian and in a homogeneous flavor.

Kernel::RT *p.homogeneous(int i) const*

returns the i'th homogeneous coordinate of p, starting with 0.
Precondition: $0 \leq i \leq 3$.

Kernel::FT *p.cartesian(int i) const*

returns the i'th Cartesian coordinate of p, starting with 0.
Precondition: $0 \leq i \leq 2$.

Kernel::FT *p.operator[](int i) const*

returns *cartesian(i)*.
Precondition: $0 \leq i \leq 2$.

Cartesian_const_iterator *p.cartesian_begin() const*

returns an iterator to the Cartesian coordinates of *p*, starting with the 0th coordinate.

Cartesian_const_iterator *p.cartesian_end() const*

returns an off the end iterator to the Cartesian coordinates of *p*.

int *p.dimension() const*

returns the dimension (the constant 3).

Bbox_3 *p.bbox() const*

returns a bounding box containing *p*.

Point_3<Kernel> *p.transform(Aff_transformation_3<Kernel> t) const*

returns the point obtained by applying *t* on *p*.

Operators

The following operations can be applied on points:

bool *operator<(p, q)*

returns true iff *p* is lexicographically smaller than *q* (the lexicographical order being defined on the Cartesian coordinates).

bool *operator>(p, q)*

returns true iff *p* is lexicographically greater than *q*.

bool *operator<=(p, q)*

returns true iff *p* is lexicographically smaller or equal to *q*.

bool *operator>=(p, q)*

returns true iff *p* is lexicographically greater or equal to *q*.

Vector_3<Kernel> *operator-(p, q)*

returns the difference vector between *q* and *p*. You can substitute *ORIGIN* for either *p* or *q*, but not for both.

Point_3<Kernel> *operator+(p, Vector_3<Kernel> v)*

returns the point obtained by translating p by the vector v.

Point_3<Kernel> *operator-(p, Vector_3<Kernel> v)*

returns the point obtained by translating p by the vector -v.

Kernel::Point_3 . . . . page 796

CGAL::Ray_3<Kernel>

Class

Definition

An object r of the data type *Ray_3<Kernel>* is a directed straight ray in the three-dimensional Euclidean space $\mathbb{E}^3$. It starts in a point called the *source* of r and it goes to infinity.

Creation

Ray_3<Kernel> r(Point_3<Kernel> p, Point_3<Kernel> q);

introduces a ray r with source p and passing through point q.

Ray_3<Kernel> r(Point_3<Kernel> p, Direction_3<Kernel> d);

introduces a ray r with source p and with direction d.

Ray_3<Kernel> r(Point_3<Kernel> p, Vector_3<Kernel> v);

introduces a ray r with source p and with a direction given by v.

Ray_3<Kernel> r(Point_3<Kernel> p, Line_3<Kernel> l);

introduces a ray r starting at source p with the same direction as l.

Operations

bool *r.operator==(h) const*

Test for equality: two rays are equal, iff they have the same source and the same direction.

bool *r.operator!=(h) const*

Test for inequality.

Point_3<Kernel> *r.source() const* returns the source of r

Point_3<Kernel> *r.point(int i) const* returns a point on r. *point(0)* is the source. *point(i)*, with $i > 0$, is different from the source.
Precondition: $i \geq 0$.

Direction_3<Kernel>	*r.direction() const*	returns the direction of *r*.
Vector_3<Kernel>	*r.to_vector() const*	returns a vector giving the direction of *r*.
Line_3<Kernel>	*r.supporting_line() const*	returns the line supporting *r* which has the same direction.
Ray_3<Kernel>	*r.opposite() const*	returns the ray with the same source and the opposite direction.
bool	*r.is_degenerate() const*	ray *r* is degenerate, if the source and the second defining point fall together (that is if the direction is degenerate).
bool	*r.has_on(Point_3<Kernel> p) const*	A point is on *r*, iff it is equal to the source of *r*, or if it is in the interior of *r*.
Ray_3<Kernel>	*r.transform(Aff_transformation_3<Kernel> t) const*	returns the ray obtained by applying *t* on the source and on the direction of *r*.

See Also

Kernel::Ray_3 . . . . page 799

CGAL::Segment_3<Kernel>

Definition

An object s of the data type *Segment_3<Kernel>* is a directed straight line segment in the three-dimensional Euclidean space $\mathbb{E}^3$, i.e. a straight line segment $[p,q]$ connecting two points $p,q \in \mathbb{R}^3$. The segment is topologically closed, i.e. the end points belong to it. Point p is called the *source* and q is called the *target* of s. The length of s is the Euclidean distance between p and q. Note that there is only a function to compute the square of the length, because otherwise we had to perform a square root operation which is not defined for all number types, which is expensive, and may not be exact.

Creation

Segment_3<Kernel> s(Point_3<Kernel> p, Point_3<Kernel> q);

introduces a segment s with source p and target q. It is directed from the source towards the target.

Operations

bool	*s.operator==(q) const*	Test for equality: Two segments are equal, iff their sources and targets are equal.
bool	*s.operator!=(q) const*	Test for inequality.
Point_3<Kernel>	*s.source() const*	returns the source of s.
Point_3<Kernel>	*s.target() const*	returns the target of s.
Point_3<Kernel>	*s.min() const*	returns the point of s with smallest coordinate (lexicographically).
Point_3<Kernel>	*s.max() const*	returns the point of s with largest coordinate (lexicographically).
Point_3<Kernel>	*s.vertex(int i) const*	returns source or target of s: *vertex(0)* returns the source, *vertex(1)* returns the target. The parameter i is taken modulo 2, which gives easy access to the other vertex.
Point_3<Kernel>	*s.point(int i) const*	returns *vertex(i)*.
Point_3<Kernel>	*s.operator[](int i) const*	returns *vertex(i)*.

Kernel::FT	*s.squared_length() const*	
		returns the squared length of *s*.
Vector_3<Kernel>	*s.to_vector() const*	returns the vector *s.target() - s.source()*.
Direction_3<Kernel>	*s.direction() const*	returns the direction from source to target.
Segment_3<Kernel>	*s.opposite() const*	returns a segment with source and target interchanged.
Line_3<Kernel>	*s.supporting_line() const*	
		returns the line *l* passing through *s*. Line *l* has the same orientation as segment *s*, that is from the source to the target of *s*.
bool	*s.is_degenerate() const*	
		segment *s* is degenerate, if source and target fall together.
bool	*s.has_on(Point_3<Kernel> p) const*	
		A point is on *s*, iff it is equal to the source or target of *s*, or if it is in the interior of *s*.
Bbox_3	*s.bbox() const*	returns a bounding box containing *s*.
Segment_3<Kernel>	*s.transform(Aff_transformation_3<Kernel> t) const*	
		returns the segment obtained by applying *t* on the source and the target of *s*.

Kernel::Segment_3 . . . . page 801

CGAL::Circle_3<Kernel>

Class

Definition

An object of type *Circle_3<Kernel>* is a circle in the three-dimensional Euclidean space $\mathbb{E}^3$. Note that the circle can be degenerate, i.e. the squared radius may be zero.

Creation

Circle_3<Kernel> c(Point_3<Kernel> center, Kernel::FT sq_r, Plane_3<Kernel> plane);

introduces a variable *c* of type *Circle_3<Kernel>*. It is initialized to the circle of center *center* and squared radius *sq_r* in plane *plane*.
Precondition: *center* lies in *plane* and $sq\_r \geq 0$.

Circle_3<Kernel> c(Point_3<Kernel> center, Kernel::FT sq_r, Vector_3<Kernel> n);

introduces a variable *c* of type *Circle_3<Kernel>*. It is initialized to the circle of center *center* and squared radius *sq_r* in a plane normal to the vector *n*.
Precondition: $sq\_r \geq 0$.

Circle_3<Kernel> c(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r);

introduces a variable *c* of type *Circle_3<Kernel>*. It is initialized to the circle passing through the three points.
Precondition: The three points are not collinear.

Circle_3<Kernel> c(Sphere_3<Kernel> sphere1, Sphere_3<Kernel> sphere2);

introduces a variable *c* of type *Circle_3<Kernel>*. It is initialized to the circle along which the two spheres intersect.
Precondition: The two spheres intersect along a circle.

Circle_3<Kernel> c(Sphere_3<Kernel> sphere, Plane_3<Kernel> plane);

introduces a variable *c* of type *Circle_3<Kernel>*. It is initialized to the circle along which the sphere and the plane intersect.
Precondition: The sphere and the plane intersect along a circle.

Circle_3<Kernel> c(Plane_3<Kernel> plane, Sphere_3<Kernel> sphere);

introduces a variable *c* of type *Circle_3<Kernel>*. It is initialized to the circle along which the sphere and the plane intersect.
Precondition: The sphere and the plane intersect along a circle.

Access Functions

Point_3<Kernel>	*c.center() const*	returns the center of *c*.
Kernel::FT	*c.squared_radius() const*	returns the squared radius of *c*.
Plane_3<Kernel>	*c.supporting_plane() const*	returns the supporting plane of *c*.
Sphere_3<Kernel>	*c.diametral_sphere() const*	returns the diametral sphere of *c*.
Kernel::FT	*c.area_divided_by_pi() const*	returns the area of *c*, divided by π.
double	*c.approximate_area() const*	returns an approximation of the area of *c*.
Kernel::FT	*c.squared_length_divided_by_pi_square() const*	returns the squared length of *c*, divided by π^2.
double	*c.approximate_squared_length() const*	returns an approximation of the squared length (i.e. perimeter) of *c*.

Predicates

bool	*c.has_on(Point_3<Kernel> p) const*	

Operations

bool operator	*==(c1, c2)*	returns *true*, iff *c1* and *c2* are equal, i.e. if they have the same center, the same squared radius and the same supporting plane.
bool operator	*!=(c1, c2)*	

Bbox_3	*c.bbox() const*	returns a bounding box containing c.

See Also

Kernel::Circle_3 . . . . page 784

CGAL::Sphere_3<Kernel>

Definition

An object of type *Sphere_3<Kernel>* is a sphere in the three-dimensional Euclidean space $\mathbb{E}^3$. The sphere is oriented, i.e. its boundary has clockwise or counterclockwise orientation. The boundary splits $\mathbb{E}^3$ into a positive and a negative side, where the positive side is to the left of the boundary. The boundary also splits $\mathbb{E}^3$ into a bounded and an unbounded side. Note that the sphere can be degenerated, i.e. the squared radius may be zero.

Creation

Sphere_3<Kernel> c(Point_3<Kernel> center,
Kernel::FT squared_radius,
Orientation orientation = COUNTERCLOCKWISE)

introduces a variable *c* of type *Sphere_3<Kernel>*. It is initialized to the sphere with center *center*, squared radius *squared_radius* and orientation *orientation*.
Precondition: *orientation* $\neq$ *COPLANAR*, and furthermore, *squared_radius* ≥ 0.

Sphere_3<Kernel> c(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r, Point_3<Kernel> s);

introduces a variable *c* of type *Sphere_3<Kernel>*. It is initialized to the unique sphere which passes through the points *p*, *q*, *r* and *s*. The orientation of the sphere is the orientation of the point quadruple *p*, *q*, *r*, *s*.
Precondition: *p*, *q*, *r*, and *s* are not coplanar.

Sphere_3<Kernel> c(Point_3<Kernel> p,
Point_3<Kernel> q,
Point_3<Kernel> r,
Orientation o = COUNTERCLOCKWISE)

introduces a variable *c* of type *Sphere_3<Kernel>*. It is initialized to the smallest sphere which passes through the points *p*, *q*, and *r*. The orientation of the sphere is *o*.
Precondition: *o* is not *COPLANAR*.

Sphere_3<Kernel> c(Point_3<Kernel> p, Point_3<Kernel> q, Orientation o = COUNTERCLOCKWISE);

introduces a variable *c* of type *Sphere_3<Kernel>*. It is initialized to the smallest sphere which passes through the points *p* and *q*. The orientation of the sphere is *o*.
Precondition: *o* is not *COPLANAR*.

Sphere_3<Kernel> c(Point_3<Kernel> center, Orientation orientation = COUNTERCLOCKWISE);

introduces a variable *c* of type *Sphere_3<Kernel>*. It is initialized to the sphere with center *center*, squared radius zero and orientation *orientation*.
Precondition: *orientation* $\neq$ *COPLANAR*.
Postcondition: *c.is_degenerate() = true*.

Sphere_3<Kernel> c(Circle_3<Kernel> c);

introduces a variable *c* of type *Sphere_3<Kernel>*. It is initialized to the diametral sphere of the circle.

Access Functions

Point_3<Kernel> *c.center() const*

returns the center of *c*.

Kernel::FT *c.squared_radius() const*

returns the squared radius of *c*.

Orientation *c.orientation() const*

returns the orientation of *c*.

bool operator *c.==(sphere2) const*

returns *true*, iff *c* and *sphere2* are equal, i.e. if they have the same center, same squared radius and same orientation.

bool operator *c.!=(sphere2) const*

returns *true*, iff *c* and *sphere2* are not equal.

Predicates

bool *c.is_degenerate() const*

returns *true*, iff *c* is degenerate, i.e. if *c* has squared radius zero.

Oriented_side *c.oriented_side(Point_3<Kernel> p) const*

returns either the constant *ON_ORIENTED_BOUNDARY*, *ON_POSITIVE_SIDE*, or *ON_NEGATIVE_SIDE*, iff *p* lies on the boundary, properly on the positive side, or properly on the negative side of *c*, resp.

Bounded_side *c.bounded_side(Point_3<Kernel> p) const*

returns *ON_BOUNDED_SIDE*, *ON_BOUNDARY*, or *ON_UNBOUNDED_SIDE* iff *p* lies properly inside, on the boundary, or properly outside of *c*, resp.

bool *c.has_on_positive_side(Point_3<Kernel> p) const*
bool *c.has_on_negative_side(Point_3<Kernel> p) const*
bool *c.has_on_boundary(Point_3<Kernel> p) const*

bool	*c.has_on_bounded_side(Point_3<Kernel> p) const*	
bool	*c.has_on_unbounded_side(Point_3<Kernel> p) const*	
bool	*c.has_on(Point_3<Kernel> p) const*	
bool	*c.has_on(Circle_3<Kernel> p) const*	

Miscellaneous

Sphere_3<Kernel>	*c.opposite() const*	returns the sphere with the same center and squared radius as c but with opposite orientation.
Sphere_3<Kernel>	*c.orthogonal_transform(Aff_transformation_3<Kernel> at) const*	returns the sphere obtained by applying *at* on c. *Precondition*: *at* is an orthogonal transformation.
Bbox_3	*c.bbox() const*	returns a bounding box containing c.

See Also

Kernel::Sphere_3 . . . . page 802

CGAL::Tetrahedron_3<Kernel>

Class

Definition

An object t of the class *Tetrahedron_3<Kernel>* is an oriented tetrahedron in the three-dimensional Euclidean space $\mathbb{E}^3$.

It is defined by four vertices p_0, p_1, p_2 and p_3. The orientation of a tetrahedron is the orientation of its four vertices. That means it is positive when p_3 is on the positive side of the plane defined by p_0, p_1 and p_2.

The tetrahedron itself splits the space $\mathbb{E}^3$ in a *positive* and a *negative* side.

The boundary of a tetrahedron splits the space in two open regions, a bounded one and an unbounded one.

Creation

Tetrahedron_3<Kernel> t(Point_3<Kernel> p0, Point_3<Kernel> p1, Point_3<Kernel> p2, Point_3<Kernel> p3)

introduces a tetrahedron t with vertices p_0, p_1, p_2 and p_3.

Operations

bool *t.operator==(t2) const*

Test for equality: two tetrahedra t and $t2$ are equal, iff t and $t2$ have the same orientation and their sets (not sequences) of vertices are equal.

bool *t.operator!=(t2) const*

Test for inequality.

Point_3<Kernel> *t.vertex(int i) const* returns the i'th vertex modulo 4 of t.

Point_3<Kernel> *t.operator[](int i) const*

returns *vertex(int i)*.

Predicates

bool *t.is_degenerate() const*

Tetrahedron t is degenerate, if the vertices are coplanar.

Orientation	*t.orientation() const*	
Oriented_side	*t.oriented_side(Point_3<Kernel> p) const*	
		Precondition: : *t* is not degenerate.
Bounded_side	*t.bounded_side(Point_3<Kernel> p) const*	
		Precondition: : *t* is not degenerate.

For convenience we provide the following Boolean functions:

bool	*t.has_on_positive_side(Point_3<Kernel> p) const*
bool	*t.has_on_negative_side(Point_3<Kernel> p) const*
bool	*t.has_on_boundary(Point_3<Kernel> p) const*
bool	*t.has_on_bounded_side(Point_3<Kernel> p) const*
bool	*t.has_on_unbounded_side(Point_3<Kernel> p) const*

Miscellaneous

Kernel::FT	*t.volume() const*	returns the signed volume of *t*.
Bbox_3	*t.bbox() const*	returns a bounding box containing *t*.
Tetrahedron_3<Kernel>	*t.transform(Aff_transformation_3<Kernel> at) const*	
		returns the tetrahedron obtained by applying *at* on the three vertices of *t*.

CGAL::Triangle_3<Kernel>

Class

Definition

An object t of the class *Triangle_3<Kernel>* is a triangle in the three-dimensional Euclidean space $\mathbb{E}^3$. As the triangle is not a full-dimensional object there is only a test whether a point lies on the triangle or not.

Creation

Triangle_3<Kernel> t(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r);

introduces a triangle t with vertices p, q and r.

Operations

bool	*t.operator==(t2) const*	
		Test for equality: two triangles t and t_2 are equal, iff there exists a cyclic permutation of the vertices of $t2$, such that they are equal to the vertices of t.
bool	*t.operator!=(t2) const*	
		Test for inequality.
Point_3<Kernel>	*t.vertex(int i) const*	returns the i'th vertex modulo 3 of t.
Point_3<Kernel>	*t.operator[](int i) const*	
		returns *vertex(int i)*.
Plane_3<Kernel>	*t.supporting_plane()*	returns the supporting plane of t, with same orientation.

Predicates

bool	*t.is_degenerate() const*	
		t is degenerate if its vertices are collinear.
bool	*t.has_on(Point_3<Kernel> p) const*	
		A point is on t, if it is on a vertex, an edge or the face of t.

Miscellaneous

Kernel::FT	*t.squared_area() const*	
		returns a square of the area of *t*.
Bbox_3	*t.bbox() const*	returns a bounding box containing *t*.
Triangle_3<Kernel>	*t.transform(Aff_transformation_3<Kernel> at) const*	
		returns the triangle obtained by applying *at* on the three vertices of *t*.

CGAL::Vector_3<Kernel>

Definition

An object of the class *Vector_3<Kernel>* is a vector in the three-dimensional vector space $\mathbb{R}^3$. Geometrically spoken a vector is the difference of two points p_2, p_1 and denotes the direction and the distance from p_1 to p_2.

CGAL defines a symbolic constant *NULL_VECTOR*. We will explicitly state where you can pass this constant as an argument instead of a vector initialized with zeros.

Types

Vector_3<Kernel>:: Cartesian_const_iterator

An iterator for enumerating the Cartesian coordinates of a vector.

Creation

Vector_3<Kernel> v(Point_3<Kernel> a, Point_3<Kernel> b);

introduces the vector $b-a$.

Vector_3<Kernel> v(Segment_3<Kernel> s);

introduces the vector $s.target() - s.source()$.

Vector_3<Kernel> v(Ray_3<Kernel> r);

introduces a vector having the same direction as r.

Vector_3<Kernel> v(Line_3<Kernel> l);

introduces a vector having the same direction as l.

Vector_3<Kernel> v(Null_vector NULL_VECTOR);

introduces a null vector v.

Vector_3<Kernel> v(int x, int y, int z);

introduces a vector v initialized to (x,y,z).

Vector_3<Kernel> v(double x, double y, double z);

introduces a vector v initialized to (x,y,z).

Vector_3<Kernel> v(Kernel::RT hx, Kernel::RT hy, Kernel::RT hz, Kernel::RT hw = RT(1));

introduces a vector v initialized to $(hx/hw, hy/hw, hz/hw)$.

Vector_3<Kernel> v(Kernel::FT x, Kernel::FT y, Kernel::FT z);

introduces a vector v initialized to (x,y,z).

Operations

bool *v.operator==(w) const*

Test for equality: two vectors are equal, iff their x, y and z coordinates are equal. You can compare a vector with the *NULL_VECTOR*.

bool *v.operator!=(w) const*

Test for inequality. You can compare a vector with the *NULL_VECTOR*.

There are two sets of coordinate access functions, namely to the homogeneous and to the Cartesian coordinates. They can be used independently from the chosen kernel model.

Kernel::RT *v.hx() const*

returns the homogeneous x coordinate.

Kernel::RT *v.hy() const*

returns the homogeneous y coordinate.

Kernel::RT *v.hz() const*

returns the homogeneous z coordinate.

Kernel::RT *v.hw() const*

returns the homogenizing coordinate.

Note that you do not loose information with the homogeneous representation, because the *FieldNumberType* is a quotient.

Kernel::FT *v.x() const*

returns the x-coordinate of v, that is hx/hw.

Kernel::FT *v.y() const*

returns the y-coordinate of v, that is hy/hw.

Kernel::FT *v.z() const*

returns the z coordinate of v, that is hz/hw.

The following operations are for convenience and for compatibility with higher dimensional vectors. Again they come in a Cartesian and homogeneous flavor.

Kernel::RT *v.homogeneous(int i) const*

returns the i'th homogeneous coordinate of v, starting with 0.
Precondition: $0 \leq i \leq 3$.

Kernel::FT *v.cartesian(int i) const*

returns the i'th Cartesian coordinate of v, starting at 0.
Precondition: $0 \leq i \leq 2$.

Kernel::FT *v.operator[](int i) const*

returns *cartesian(i)*.
Precondition: $0 \leq i \leq 2$.

Cartesian_const_iterator *v.cartesian_begin() const*

returns an iterator to the Cartesian coordinates of v, starting with the 0th coordinate.

Cartesian_const_iterator *v.cartesian_end() const*

returns an off the end iterator to the Cartesian coordinates of v.

int *v.dimension() const*

returns the dimension (the constant 3).

Vector_3<Kernel> *v.transform(Aff_transformation_3<Kernel> t) const*

returns the vector obtained by applying t on v.

Direction_3<Kernel> *v.direction() const*

returns the direction of v.

Operators

The following operations can be applied on vectors:

Vector_3<Kernel> *v.operator+(w) const*

Addition.

Vector_3<Kernel> *v.operator-(w) const*

Subtraction.

Vector_3<Kernel> *v.operator-() const*

Returns the opposite vector.

Kernel::FT *v.operator*(w) const*

returns the scalar product (= inner product) of the two vectors.

Vector_3<Kernel> *operator*(v, Kernel::RT s)*

Multiplication with a scalar from the right.

Vector_3<Kernel> *operator*(v, Kernel::FT s)*

Multiplication with a scalar from the right.

Vector_3<Kernel> *operator*(Kernel::RT s, v)*

Multiplication with a scalar from the left.

Vector_3<Kernel> *operator*(Kernel::FT s, v)*

Multiplication with a scalar from the left.

Vector_3<Kernel> *v.operator/(Kernel::RT s) const*

Division by a scalar.

Kernel::FT *v.squared_length() const*

returns the squared length of *v*.

Constant

CGAL::ORIGIN

const Origin   *ORIGIN;*

Definition

A symbolic constant which denotes the point at the origin. This constant is used in the conversion between points and vectors.

Example

```
Point_2< Cartesian<Exact_NT> >  p(1.0, 1.0), q;
Vector2< Cartesian<Exact_NT> >  v;
v = p - ORIGIN;
q = ORIGIN + v;
assert( p == q );

11.13 Global Functions

CGAL::angle

Angle *angle(Vector_2<Kernel> u, Vector_2<Kernel> v)*

returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the angle formed by the two vectors *u* and *v*.

Angle *angle(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*

returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the angle formed by the three points *p*, *q*, *r* (*q* being the vertex of the angle). The returned value is the same as *angle(p - q, r - q)*.

Angle *angle(Point_2<Kernel> p,*
Point_2<Kernel> q,
Point_2<Kernel> r,
Point_2<Kernel> s)

returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the angle formed by the two vectors *pq*, *rs*. The returned value is the same as *angle(q - p, s - r)*.

Angle *angle(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the angle formed by the three points *p*, *q*, *r* (*q* being the vertex of the angle).

CGAL::are_ordered_along_line

bool	*are_ordered_along_line(*	*Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*

returns *true*, iff the three points are collinear and q lies between p and r. Note that *true* is returned, if $q{=}{=}p$ or $q{=}{=}r$.

bool	*are_ordered_along_line(*	*Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

returns *true*, iff the three points are collinear and q lies between p and r. Note that *true* is returned, if $q{=}{=}p$ or $q{=}{=}r$.

See Also

CGAL::are_strictly_ordered_along_line

bool *are_strictly_ordered_along_line(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*

returns *true*, iff the three points are collinear and q lies strictly between p and r. Note that *false* is returned, if $q==p$ or $q==r$.

bool *are_strictly_ordered_along_line(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

returns *true*, iff the three points are collinear and q lies strictly between p and r. Note that *false* is returned, if $q==p$ or $q==r$.

Function

Function

CGAL::area

Kernel::FT	*area(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*	
		returns the signed area of the triangle defined by the points p, q and r.

CGAL::barycenter

Point_2<Kernel> *barycenter(Point_2<Kernel> p1, Kernel::FT w1, Point_2<Kernel> p2)*

compute the barycenter of the points $p1$ and $p2$ with corresponding weights $w1$ and $1 - w1$.

Point_2<Kernel> *barycenter(Point_2<Kernel> p1,*
Kernel::FT w1,
Point_2<Kernel> p2,
Kernel::FT w2)

compute the barycenter of the points $p1$ and $p2$ with corresponding weights $w1$ and $w2$.
Precondition: w1+w2 != 0.

Point_2<Kernel> *barycenter(Point_2<Kernel> p1,*
Kernel::FT w1,
Point_2<Kernel> p2,
Kernel::FT w2,
Point_2<Kernel> p3)

compute the barycenter of the points $p1$, $p2$ and $p3$ with corresponding weights $w1$, $w2$ and $1 - w1 - w2$.

Point_2<Kernel> *barycenter(Point_2<Kernel> p1,*
Kernel::FT w1,
Point_2<Kernel> p2,
Kernel::FT w2,
Point_2<Kernel> p3,
Kernel::FT w3)

compute the barycenter of the points $p1$, $p2$ and $p3$ with corresponding weights $w1$, $w2$ and $w3$.
Precondition: w1+w2+w3 != 0.

Point_2<Kernel> *barycenter(Point_2<Kernel> p1,*
Kernel::FT w1,
Point_2<Kernel> p2,
Kernel::FT w2,
Point_2<Kernel> p3,
Kernel::FT w3,
Point_2<Kernel> p4)

compute the barycenter of the points $p1$, $p2$, $p3$ and $p4$ with corresponding weights $w1$, $w2$, $w3$ and $1 - w1 - w2 - w3$.

Point_2<Kernel> *barycenter(Point_2<Kernel> p1,*
Kernel::FT w1,
Point_2<Kernel> p2,
Kernel::FT w2,
Point_2<Kernel> p3,
Kernel::FT w3,
Point_2<Kernel> p4,
Kernel::FT w4)

compute the barycenter of the points $p1$, $p2$, $p3$ and $p4$ with corresponding weights $w1$, $w2$, $w3$ and $w4$.
Precondition: w1+w2+w3+w4 != 0.

Point_3<Kernel> *barycenter(Point_3<Kernel> p1, Kernel::FT w1, Point_3<Kernel> p2)*

compute the barycenter of the points $p1$ and $p2$ with corresponding weights $w1$ and $1-w1$.

Point_3<Kernel> *barycenter(Point_3<Kernel> p1,*
Kernel::FT w1,
Point_3<Kernel> p2,
Kernel::FT w2)

compute the barycenter of the points $p1$ and $p2$ with corresponding weights $w1$ and $w2$.
Precondition: w1+w2 != 0.

Point_3<Kernel> *barycenter(Point_3<Kernel> p1,*
Kernel::FT w1,
Point_3<Kernel> p2,
Kernel::FT w2,
Point_3<Kernel> p3)

compute the barycenter of the points $p1$, $p2$ and $p3$ with corresponding weights $w1$, $w2$ and $1-w1-w2$.

Point_3<Kernel> *barycenter(Point_3<Kernel> p1,*
Kernel::FT w1,
Point_3<Kernel> p2,
Kernel::FT w2,
Point_3<Kernel> p3,
Kernel::FT w3)

compute the barycenter of the points $p1$, $p2$ and $p3$ with corresponding weights $w1$, $w2$ and $w3$.
Precondition: w1+w2+w3 != 0.

Point_3<Kernel> *barycenter(Point_3<Kernel> p1,*

Kernel::FT w1,
Point_3<Kernel> p2,
Kernel::FT w2,
Point_3<Kernel> p3,
Kernel::FT w3,
Point_3<Kernel> p4)

compute the barycenter of the points $p1$, $p2$, $p3$ and $p4$ with corresponding weights $w1$, $w2$, $w3$ and $1-w1-w2-w3$.

Point_3<Kernel> *barycenter(Point_3<Kernel> p1,*
Kernel::FT w1,
Point_3<Kernel> p2,
Kernel::FT w2,
Point_3<Kernel> p3,
Kernel::FT w3,
Point_3<Kernel> p4,
Kernel::FT w4)

compute the barycenter of the points $p1$, $p2$, $p3$ and $p4$ with corresponding weights $w1$, $w2$, $w3$ and $w4$.
Precondition: w1+w2+w3+w4 != 0.

See Also

CGAL::centroid . . . . page 3969

CGAL::bisector

Line_2<Kernel> *bisector(Point_2<Kernel> p, Point_2<Kernel> q)*

constructs the bisector line of the two points p and q. The bisector is oriented in such a way that p lies on its positive side.
Precondition: p and q are not equal.

Line_2<Kernel> *bisector(Line_2<Kernel> l1, Line_2<Kernel> l2)*

constructs the bisector of the two lines $l1$ and $l2$. In the general case, the bisector has the direction of the vector which is the sum of the normalized directions of the two lines, and which passes through the intersection of *l1* and *l2*. If *l1* and *l2* are parallel, then the bisector is defined as the line which has the same direction as *l1*, and which is at the same distance from *l1* and *l2*. This function requires that *Kernel::RT* supports the *sqrt()* operation.

Plane_3<Kernel> *bisector(Point_3<Kernel> p, Point_3<Kernel> q)*

constructs the bisector plane of the two points p and q. The bisector is oriented in such a way that p lies on its positive side.
Precondition: p and q are not equal.

Plane_3<Kernel> *bisector(Plane_3<Kernel> h1, Plane_3<Kernel> h2)*

constructs the bisector of the two planes $h1$ and $h2$. In the general case, the bisector has a normal vector which has the same direction as the sum of the normalized normal vectors of the two planes, and passes through the intersection of *h1* and *h2*. If *h1* and *h2* are parallel, then the bisector is defined as the plane which has the same oriented normal vector as *l1*, and which is at the same distance from *h1* and *h2*. This function requires that *Kernel::RT* supports the *sqrt()* operation.

CGAL::centroid

Function

Point_2<Kernel> *centroid(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*

compute the centroid of the points p, q, and r.

Point_2<Kernel> *centroid(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r, Point_2<Kernel> s)*

compute the centroid of the points p, q, r, and s.

Point_2<Kernel> *centroid(Triangle_2<Kernel> t)*

compute the centroid of the triangle t.

Point_3<Kernel> *centroid(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

compute the centroid of the points p, q, and r.

Point_3<Kernel> *centroid(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r, Point_3<Kernel> s)*

compute the centroid of the points p, q, r, and s.

Point_3<Kernel> *centroid(Triangle_3<Kernel> t)*

compute the centroid of the triangle t.

Point_3<Kernel> *centroid(Tetrahedron_3<Kernel> t)*

compute the centroid of the tetrahedron t.

See Also

CGAL::barycenter . . . . page 3971

CGAL::circumcenter

Point_2<Kernel> *circumcenter(Point_2<Kernel> p, Point_2<Kernel> q)*

compute the center of the smallest circle passing through the points p and q. Note: this is the same as *CGAL::midpoint(p, q)* but is provided for homogeneity.

Point_2<Kernel> *circumcenter(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*

compute the center of the circle passing through the points p, q, and r.
Precondition: p, q, and r are not collinear.

Point_2<Kernel> *circumcenter(Triangle_2<Kernel> t)*

compute the center of the circle passing through the vertices of t.
Precondition: t is not degenerate.

Point_3<Kernel> *circumcenter(Point_3<Kernel> p, Point_3<Kernel> q)*

compute the center of the smallest sphere passing through the points p and q. Note: this is the same as *CGAL::midpoint(p, q)* but is provided for homogeneity.

Point_3<Kernel> *circumcenter(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

compute the center of the circle passing through the points p, q, and r.
Precondition: p, q, and r are not collinear.

Point_3<Kernel> *circumcenter(Triangle_3<Kernel> t)*

compute the center of the circle passing through the vertices of t.
Precondition: t is not degenerate.

Point_3<Kernel> *circumcenter(Point_3<Kernel> p,*
Point_3<Kernel> q,
Point_3<Kernel> r,
Point_3<Kernel> s)

compute the center of the sphere passing through the points p, q, r, and s.
Precondition: p, q, r, and s are not coplanar.

Point_3<Kernel> *circumcenter(Tetrahedron_3<Kernel> t)*

compute the center of the sphere passing through the vertices of t.
Precondition: t is not degenerate.

Function

CGAL::collinear

bool *collinear(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*

returns *true*, iff p, q, and r are collinear.

bool *collinear(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

returns *true*, iff p, q, and r are collinear.

See Also

CGAL::collinear_are_ordered_along_line

Function

bool *collinear_are_ordered_along_line(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*

returns *true*, iff q lies between p and r.
Precondition: p, q and r are collinear.

bool *collinear_are_ordered_along_line(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

returns *true*, iff q lies between p and r.
Precondition: p, q and r are collinear.

CGAL::compare_distance_to_point

Function

Comparison_result *compare_distance_to_point(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*

compares the distances of points q and r to point p. returns *SMALLER*, iff q is closer to p than r, *LARGER*, iff r is closer to p than q, and *EQUAL* otherwise.

Comparison_result *compare_distance_to_point(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

compares the distances of points q and r to point p. returns *SMALLER*, iff q is closer to p than r, *LARGER*, iff r is closer to p than q, and *EQUAL* otherwise.

Function

CGAL::compare_lexicographically

Comparison_result *compare_lexicographically(Point_2<Kernel> p, Point_2<Kernel> q)*

Compares the Cartesian coordinates of points p and q lexicographically in xy order: first x-coordinates are compared, if they are equal, y-coordinates are compared. This is the same function as *compare_xy* and exists for compatibility with *Point_d<Kernel>*.

Comparison_result *compare_lexicographically(Point_3<Kernel> p, Point_3<Kernel> q)*

Compares the Cartesian coordinates of points p and q lexicographically in xyz order: first x-coordinates are compared, if they are equal, y-coordinates are compared, and if both x- and y- coordinate are equal, z-coordinates are compared. This is the same function as *compare_xyz* and exists for compatibility with *Point_d<Kernel>*.

CGAL::compare_signed_distance_to_line

Comparison_result *compare_signed_distance_to_line(Line_2<Kernel> l, Point_2<Kernel> p, Point_2<Kernel> q)*

returns *LARGER* iff the signed distance of p and l is larger than the signed distance of q and l, *SMALLER*, iff it is smaller, and *EQUAL* iff both are equal.

Comparison_result *compare_signed_distance_to_line(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r, Point_2<Kernel> s)*

returns *LARGER* iff the signed distance of r and l is larger than the signed distance of s and l, *SMALLER*, iff it is smaller, and *EQUAL* iff both are equal, where l is the directed line through p and q.

Function

CGAL::compare_signed_distance_to_plane

Comparison_result *compare_signed_distance_to_plane(Plane_3<Kernel> h, Point_3<Kernel> p, Point_3<Kernel> q)*

returns *LARGER* iff the signed distance of p and h is larger than the signed distance of q and h, *SMALLER*, iff it is smaller, and *EQUAL* iff both are equal.

Comparison_result *compare_signed_distance_to_plane(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r, Point_3<Kernel> s, Point_3<Kernel> t)*

returns *LARGER* iff the signed distance of s and h is larger than the signed distance of t and h, *SMALLER*, iff it is smaller, and *EQUAL* iff both are equal, where h is the oriented plane through p, q and r.

CGAL::compare_slopes

Function

Comparison_result *compare_slopes(Line_2<Kernel> l1, Line_2<Kernel> l2)*

compares the slopes of the lines *l1* and *l2*

Comparison_result *compare_slopes(Segment_2<Kernel> s1, Segment_2<Kernel> s2)*

compares the slopes of the segments *s1* and *s2*

Function

CGAL::compare_dihedral_angle

Comparison_result *compare_dihedral_angle(Point_3<K> a1, Point_3<K> b1, Point_3<K> c1, Point_3<K> d1, K::FT cosine)*

compares the dihedral angles θ_1 and θ_2, where θ_1 is the dihedral angle, in $[0,\pi]$, of the tetrahedron (a_1,b_1,c_1,d_1) at the edge (a_1,b_1), and θ_2 is the angle in $[0,\pi]$ such that $cos(\theta_2) = cosine$. The result is the same as *compare_dihedral_angle(b1-a1, c1-a1, d1-a1, cosine)*.
Precondition: a_1, b_1, c_1 are not collinear, and a_1, b_1, d_1 are not collinear.

Comparison_result *compare_dihedral_angle(Point_3<K> a1, Point_3<K> b1, Point_3<K> c1, Point_3<K> d1, Point_3<K> a2, Point_3<K> b2, Point_3<K> c2, Point_3<K> d2)*

compares the dihedral angles θ_1 and θ_2, where θ_i is the dihedral angle in the tetrahedron (a_i,b_i,c_i,d_i) at the edge (a_i,b_i). These two angles are computed in $[0,\pi]$. The result is the same as *compare_dihedral_angle(b1-a1, c1-a1, d1-a1, b2-a2, c2-a2, d2-a2)*.
Precondition: For $i \in \{1,2\}$, a_i, b_i, c_i are not collinear, and a_i, b_i, d_i are not collinear.

Comparison_result *compare_dihedral_angle(K::Vector_3 u1, K::Vector_3 v1, K::Vector_3 w1, K::FT cosine)*

compares the dihedral angles θ_1 and θ_2, where θ_1 is the dihedral angle, in $[0,\pi]$, between the vectorial planes defined by (u_1,v_1) and (u_1,w_1), and θ_2 is the angle in $[0,\pi]$ such that $cos(\theta_2) = cosine$.
Precondition: u_1 and v_1 are not collinear, and u_1 and w_1 are not collinear.

Comparison_result *compare_dihedral_angle(K::Vector_3 u1, K::Vector_3 v1, K::Vector_3 w1, K::Vector_3 u2, K::Vector_3 v2,* *K::Vector_3 w2)*

compares the dihedral angles θ_1 and θ_2, where θ_i is the dihedral angle between the vectorial planes defined by (u_i, v_i) and (u_i, w_i). These two angles are computed in $[0, \pi]$.
Precondition: For $i \in \{1, 2\}$, u_i and v_i are not collinear, and u_i and w_i are not collinear.

Function

CGAL::compare_squared_distance

Comparison_result *compare_squared_distance(Point_2<Kernel> p, Point_2<Kernel> q, typename Kernel::FT d2)*

compares the squared distance of points p and q to $d2$.

Comparison_result *compare_squared_distance(Point_3<Kernel> p, Point_3<Kernel> q, typename Kernel::FT d2)*

compares the squared distance of points p and q to $d2$.

CGAL::compare_squared_radius

Comparison_result *compare_squared_radius(Point_3<Kernel> p, typename Kernel::FT sr)*

compares the squared radius of the sphere of radius 0 centered at p to sr. This returns the opposite sign of sr.

Comparison_result *compare_squared_radius(Point_3<Kernel> p, Point_3<Kernel> q, typename Kernel::FT sr)*

compares the squared radius of the sphere defined by the points p and q to sr.

Comparison_result *compare_squared_radius(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r, typename Kernel::FT sr)*

compares the squared radius of the sphere defined by the points p, q, and r to sr.

Comparison_result *compare_squared_radius(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r, Point_3<Kernel> s, typename Kernel::FT sr)*

compares the squared radius of the sphere defined by the points p, q, r, and r to sr.

CGAL::compare_x

Depending on which CGAL kernel is used, different versions of this global function are available. This is described below.

With the basic 2D and 3D Kernel (see Chapter 11)

Comparison_result *compare_x(Point_2<Kernel> p, Point_2<Kernel> q)*

compares the x-coordinates of p and q.

Comparison_result *compare_x(Point_3<Kernel> p, Point_3<Kernel> q)*

compares the x-coordinates of p and q.

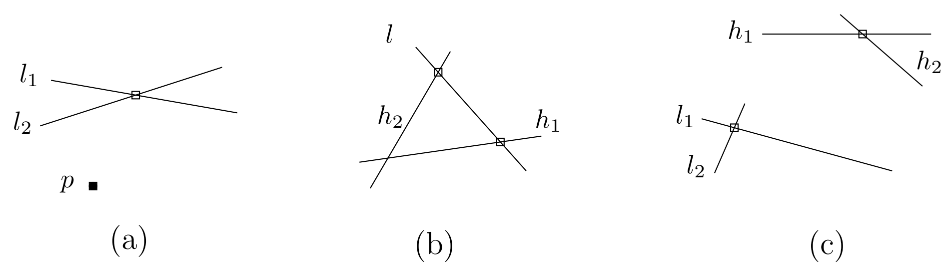

Figure 11.1: Comparison of the x or y-coordinates of the (implicitly given) points in the boxes.

Comparison_result *compare_x(Point_2<Kernel> p, Line_2<Kernel> l1, Line_2<Kernel> l2)*

compares the x-coordinates of p and the intersection of lines $l1$ and $l2$ (Figure 11.1 (a)).

Comparison_result *compare_x(Line_2<Kernel> l, Line_2<Kernel> h1, Line_2<Kernel> h2)*

compares the x-coordinates of the intersection of line l with line $h1$ and with line $h2$ (Figure 11.1 (b)).

Comparison_result *compare_x(Line_2<Kernel> l1,*
Line_2<Kernel> l2,
Line_2<Kernel> h1,
Line_2<Kernel> h2)

compares the x-coordinates of the intersection of lines $l1$ and $l2$ and the intersection of lines $h1$ and $h2$ (Figure 11.1 (c)).

With the 2D Circular Kernel (see Chapter 13)

#include <CGAL/global_functions_circular_kernel_2.h>

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

Comparison_result *compare_x(Circular_arc_point_2<CircularKernel> p, Circular_arc_point_2<CircularKernel> q)*

compares the x-coordinates of p and q.

Comparison_result *compare_x(Circular_arc_point_2<CircularKernel> p, Point_2<CircularKernel> q)*

compares the x-coordinates of p and q.

With the 3D Spherical Kernel (see Chapter 14)

#include <CGAL/global_functions_spherical_kernel_3.h>

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

Comparison_result *compare_x(Circular_arc_point_3<SphericalKernel> p, Circular_arc_point_3<SphericalKernel> q)*

compares the x-coordinates of p and q.

Comparison_result *compare_x(Circular_arc_point_3<SphericalKernel> p, Point_3<SphericalKernel> q)*

compares the x-coordinates of p and q.

See Also

CGAL::compare_xy

Depending on which CGAL kernel is used, different versions of this global function are available. This is described below.

With the basic 2D and 3D Kernel (see Chapter 11)

Comparison_result *compare_xy(Point_2<Kernel> p, Point_2<Kernel> q)*

Compares the Cartesian coordinates of points p and q lexicographically in xy order: first x-coordinates are compared, if they are equal, y-coordinates are compared.

Comparison_result *compare_xy(Point_3<Kernel> p, Point_3<Kernel> q)*

Compares the Cartesian coordinates of points p and q lexicographically in xy order: first x-coordinates are compared, if they are equal, y-coordinates are compared.

With the 2D Circular Kernel (see Chapter 13)

#include <CGAL/global_functions_circular_kernel_2.h>

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

Comparison_result *compare_xy(Circular_arc_point_2<CircularKernel> p, Circular_arc_point_2<CircularKernel> q)*

Compares the x and y Cartesian coordinates of points p and q lexicographically.

Comparison_result *compare_xy(Circular_arc_point_2<CircularKernel> p, Point_2<CircularKernel> q)*

Compares the x and y Cartesian coordinates of points p and q lexicographically.

With the 3D Spherical Kernel (see Chapter 14)

#include <CGAL/global_functions_spherical_kernel_3.h>

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

Comparison_result *compare_xy(Circular_arc_point_3<SphericalKernel> p, Circular_arc_point_3<SphericalKernel> q)*

Compares the x and y Cartesian coordinates of points p and q lexicographically.

Comparison_result *compare_xy(Circular_arc_point_3<SphericalKernel> p, Point_3<SphericalKernel> q)*

Compares the x and y Cartesian coordinates of points p and q lexicographically.

Function

CGAL::compare_xyz

Depending on which CGAL kernel is used, different versions of this global function are available. This is described below.

With the basic 3D Kernel (see Chapter 11)

Comparison_result *compare_xyz(Point_3<Kernel> p, Point_3<Kernel> q)*

Compares the Cartesian coordinates of points p and q lexicographically in xyz order: first x-coordinates are compared, if they are equal, y-coordinates are compared, and if both x- and y- coordinate are equal, z-coordinates are compared.

With the 3D Spherical Kernel (see Chapter 14)

#include <CGAL/global_functions_spherical_kernel_3.h>

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

Comparison_result *compare_xyz(Circular_arc_point_3<SphericalKernel> p, Circular_arc_point_3<SphericalKernel> q)*

Compares the Cartesian coordinates of points p and q lexicographically.

Comparison_result *compare_xyz(Circular_arc_point_3<SphericalKernel> p, Point_3<SphericalKernel> q)*

Compares the Cartesian coordinates of points p and q lexicographically.

CGAL::compare_z . . . . . . page 724

CGAL::compare_x_at_y

Comparison_result *compare_x_at_y(Point_2<Kernel> p, Line_2<Kernel> h)*

compares the x-coordinates of p and the horizontal projection of p on h (Figure 11.2 (a)).
Precondition: h is not horizontal.

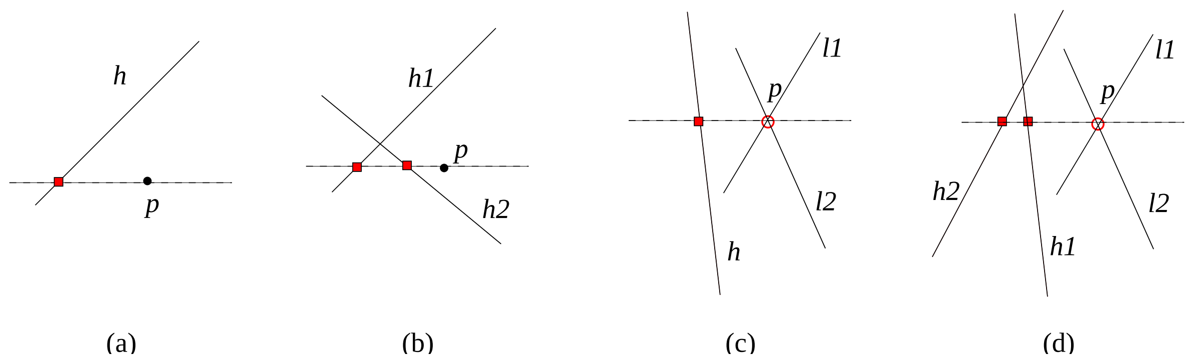

Figure 11.2: Comparison of the x-coordinates of the (implicitly given) points in the boxes, at a y-coordinate. The y-coordinate is either given explicitly (disc) or implicitly (circle).

Comparison_result *compare_x_at_y(Point_2<Kernel> p, Line_2<Kernel> h1, Line_2<Kernel> h2)*

This function compares the x-coordinates of the horizontal projection of p on *h1* and on *h2* (Figure 11.2 (b)).
Precondition: *h1* and *h2* are not horizontal.

Comparison_result *compare_x_at_y(Line_2<Kernel> l1, Line_2<Kernel> l2, Line_2<Kernel> h)*

Let p be the intersection of lines $l1$ and $l2$. This function compares the x-coordinates of p and the horizontal projection of p on h (Figure 11.2 (c)).
Precondition: *l1* and *l2* intersect and are not horizontal; h is not horizontal.

Comparison_result *compare_x_at_y(Line_2<Kernel> l1,*
Line_2<Kernel> l2,
Line_2<Kernel> h1,
Line_2<Kernel> h2)

Let p be the intersection of lines $l1$ and $l2$. This function compares the x-coordinates of the horizontal projection of p on *h1* and on *h2* (Figure 11.2 (d)).
Precondition: *l1* and *l2* intersect and are not horizontal; *h1* and *h2* are not horizontal.

CGAL::compare_y

Depending on which CGAL kernel is used, different versions of this global function are available. This is described below.

With the basic 2D and 3D Kernel (see Chapter 11)

Comparison_result *compare_y(Point_2<Kernel> p, Point_2<Kernel> q)*

compares Cartesian y-coordinates of p and q.

Comparison_result *compare_y(Point_3<Kernel> p, Point_3<Kernel> q)*

compares Cartesian y-coordinates of p and q.

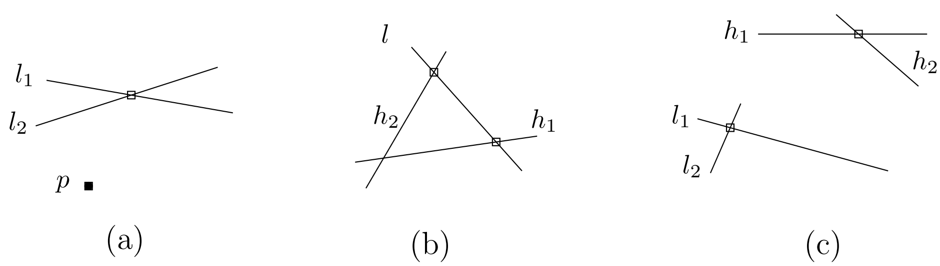

Figure 11.3: Comparison of the x or y-coordinates of the (implicitly given) points in the boxes.

Comparison_result *compare_y(Point_2<Kernel> p, Line_2<Kernel> l1, Line_2<Kernel> l2)*

compares the y-coordinates of p and the intersection of lines $l1$ and $l2$ (Figure 11.3 (a)).

Comparison_result *compare_y(Line_2<Kernel> l, Line_2<Kernel> h1, Line_2<Kernel> h2)*

compares the y-coordinates of the intersection of line l with line $h1$ and with line $h2$ (Figure 11.3 (b)).

Comparison_result *compare_y(Line_2<Kernel> l1,*
Line_2<Kernel> l2,
Line_2<Kernel> h1,
Line_2<Kernel> h2)

compares the y-coordinates of the intersection of lines $l1$ and $l2$ and the intersection of lines $h1$ and $h2$ (Figure 11.3 (c)).

With the 2D Circular Kernel (see Chapter 13)

#include <CGAL/global_functions_circular_kernel_2.h>

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

Comparison_result *compare_y(Circular_arc_point_2<CircularKernel> p, Circular_arc_point_2<CircularKernel> q)*

compares the y-coordinates of p and q.

Comparison_result *compare_y(Circular_arc_point_2<CircularKernel> p, Point_2<CircularKernel> q)*

compares the y-coordinates of p and q.

With the 3D Spherical Kernel (see Chapter 14)

#include <CGAL/global_functions_spherical_kernel_3.h>

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

Comparison_result *compare_y(Circular_arc_point_3<SphericalKernel> p, Circular_arc_point_3<SphericalKernel> q)*

compares the y-coordinates of p and q.

Comparison_result *compare_y(Circular_arc_point_3<SphericalKernel> p, Point_3<SphericalKernel> q)*

compares the y-coordinates of p and q.

CGAL::compare_xy . . . . page 714
CGAL::compare_xyz . . . . page 716
CGAL::compare_x . . . . page 712
CGAL::compare_x_at_y . . . . page 717

CGAL::compare_y_at_x . . . . page 721
CGAL::compare_z . . . . page 724

CGAL::compare_y_at_x

Depending on which CGAL kernel is used, different versions of this global function are available. This is described below.

With the basic 2D and 3D Kernel (see Chapter 11)

Comparison_result *compare_y_at_x(Point_2<Kernel> p, Line_2<Kernel> h)*

compares the y-coordinates of p and the vertical projection of p on h (Figure 11.4 (d)).
Precondition: h is not vertical.

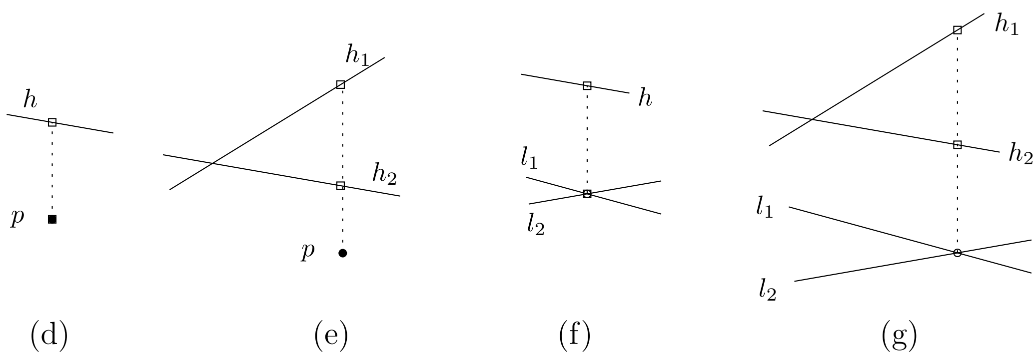

Figure 11.4: Comparison of the y-coordinates of the (implicitly given) points in the boxes, at an x-coordinate. The x-coordinate is either given explicitly (disc) or implicitly (circle).

Comparison_result *compare_y_at_x(Point_2<Kernel> p, Line_2<Kernel> h1, Line_2<Kernel> h2)*

compares the y-coordinates of the vertical projection of p on *h1* and on *h2* (Figure 11.4 (e)).
Precondition: *h1* and *h2* are not vertical.

Comparison_result *compare_y_at_x(Line_2<Kernel> l1, Line_2<Kernel> l2, Line_2<Kernel> h)*

Let p be the intersection of lines $l1$ and $l2$. This function compares the y-coordinates of p and the vertical projection of p on h (Figure 11.4 (f)).
Precondition: *l1*, *l2* intersect and h is not vertical.

Comparison_result *compare_y_at_x(Line_2<Kernel> l1,*
Line_2<Kernel> l2,
Line_2<Kernel> h1,
Line_2<Kernel> h2)

Let p be the intersection of lines $l1$ and $l2$. This function compares the y-coordinates of the vertical projection of p on *h1* and on *h2* (Figure 11.4 (g)).
Precondition: *l1* and *l2* intersect; *h1* and *h2* are not vertical.

Comparison_result *compare_y_at_x(Point_2<Kernel> p, Segment_2<Kernel> s)*

compares the y-coordinates of p and the vertical projection of p on s. If s is vertical, then return *EQUAL* when p lies on s, *SMALLER* when p lies under s, and *LARGER* otherwise.
Precondition: p is within the x range of s.

Comparison_result *compare_y_at_x(Point_2<Kernel> p, Segment_2<Kernel> s1, Segment_2<Kernel> s2)*

compares the y-coordinates of the vertical projection of p on $s1$ and on $s2$. If $s1$ or $s2$ is vertical, then return *EQUAL* if they intersect, otherwise return *SMALLER* if $s1$ lies below $s2$, and return *LARGER* otherwise.
Precondition: p is within the x range of $s1$ and $s2$.

With the 2D Circular Kernel (see Chapter 13)

#include <CGAL/global_functions_circular_kernel_2.h>

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

Comparison_result *compare_y_at_x(Circular_arc_point_2<CircularKernel> p, Circular_arc_2<CircularKernel> a)*

Same as above, for a point and a circular arc.

Comparison_result *compare_y_at_x(Circular_arc_point_2<CircularKernel> p, Line_arc_2<CircularKernel> a)*

Same as above, for a point and a line segment.

CGAL::compare_z . . . . . . page 724

Function

CGAL::compare_z

Depending on which CGAL kernel is used, different versions of this global function are available. This is described below.

With the basic 3D Kernel (see Chapter 11)

Comparison_result *compare_z(Point_3<Kernel> p, Point_3<Kernel> q)*

compares the z-coordinates of p and q.

With the 3D Spherical Kernel (see Chapter 14)

#include <CGAL/global_functions_spherical_kernel_3.h>

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

Comparison_result *compare_z(Circular_arc_point_3<SphericalKernel> p, Circular_arc_point_3<SphericalKernel> q)*

compares the z-coordinates of p and q.

Comparison_result *compare_z(Circular_arc_point_3<SphericalKernel> p, Point_3<SphericalKernel> q)*

compares the z-coordinates of p and q.

See Also

CGAL::coplanar

Function

bool *coplanar(Point_3<Kernel> p,*
Point_3<Kernel> q,
Point_3<Kernel> r,
Point_3<Kernel> s)

returns *true*, if p, q, r, and s are coplanar.

See Also

CGAL::coplanar_orientation . . . . . . page 726
CGAL::coplanar_side_of_bounded_circle . . . . . . page 727

Function

CGAL::coplanar_orientation

Orientation *coplanar_orientation(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r, Point_3<Kernel> s)*

Let P be the plane defined by the points p, q, and r. Note that the order defines the orientation of P. The function computes the orientation of points p, q, and s in P: Iff p, q, s are collinear, *COLLINEAR* is returned. Iff P and the plane defined by p, q, and s have the same orientation, *POSITIVE* is returned; otherwise *NEGATIVE* is returned. *Precondition*: p, q, r, and s are coplanar and p, q, and r are not collinear.

Orientation *coplanar_orientation(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

If p,q,r are collinear, then *COLLINEAR* is returned. If not, then p,q,r define a plane P. The return value in this case is either *POSITIVE* or *NEGATIVE*, but we don't specify it explicitly. However, we guarantee that all calls to this predicate over 3 points in P will return a coherent orientation if considered a 2D orientation in P.

See Also

CGAL::coplanar . . . page 725
CGAL::coplanar_side_of_bounded_circle . . . page 727
CGAL::orientation . . . page 1116

Function

CGAL::coplanar_side_of_bounded_circle

Bounded_side *coplanar_side_of_bounded_circle(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r, Point_3<Kernel> s)*

returns the bounded side of the circle defined by p, q, and r on which s lies.
Precondition: p, q, r, and s are coplanar and p, q, and r are not collinear.

See Also

CGAL::coplanar_orientation . . . . page 726

Function

CGAL::cross_product

Vector_3<Kernel> *cross_product(Vector_3<Kernel> u, Vector_3<Kernel> v)*

returns the cross product of u and v.

CGAL::determinant

Kernel::FT *determinant(Vector_2<Kernel> v, Vector_2<Kernel> w)*

returns the determinant of v and w.

Kernel::FT *determinant(Vector_3<Kernel> u, Vector_3<Kernel> v, Vector_3<Kernel> w)*

returns the determinant of u, v and w.

Function

CGAL::do_intersect

bool *do_intersect(Type1 obj1, Type2 obj2)*

checks whether *obj1* and *obj2* intersect. Two objects *obj1* and *obj2* intersect if there is a point *p* that is part of both *obj1* and *obj2*. The intersection region of those two objects is defined as the set of all points *p* that are part of both *obj1* and *obj2*. Note that for objects like triangles and polygons that enclose a bounded region, this region is part of the object.

Depending on which CGAL kernel is used, *Type1* and *Type2* can be of different types.

With the basic 2D and 3D Kernel (see Chapter 11)

#include <CGAL/intersections.h>

The types *Type1* and *Type2* can be any of the following:

- *Point_2<Kernel>*
- *Line_2<Kernel>*
- *Ray_2<Kernel>*
- *Segment_2<Kernel>*
- *Triangle_2<Kernel>*
- *Iso_rectangle_2<Kernel>*

Also, *Type1* and *Type2* can be both of type

- *Line_2<Kernel>*
- *Circle_2<Kernel>*

In three-dimensional space, the types *Type1* and *Type2* can be any of the following:

- *Plane_3<Kernel>*
- *Line_3<Kernel>*
- *Ray_3<Kernel>*
- *Segment_3<Kernel>*
- *Triangle_3<Kernel>*.
- *Bbox_3*.

Also, *Type1* and *Type2* can be respectively of types

- *Triangle_3<Kernel>* and *Tetrahedron_3<Kernel>*
- *Plane_3<Kernel>* and *Sphere_3<Kernel>* (or the contrary)
- *Sphere_3<Kernel>* and *Sphere_3<Kernel>*.

With the 2D Circular Kernel (see Chapter 13)

#include <CGAL/Circular_kernel_intersections.h>

If this kernel is used, in addition to the combinations of 2D types previously listed, *Type1* and *Type2* can be any of the following:

- *Line_2<CircularKernel>*
- *Circle_2<CircularKernel>*
- *Line_arc_2<CircularKernel>*
- *Circular_arc_2<CircularKernel>*

An example illustrating this is presented in Chapter 13.

With the 3D Spherical Kernel (see Chapter 14)

#include <CGAL/Spherical_kernel_intersections.h>

If this kernel is used, in addition to the combinations of 3D types previously listed, *Type1* and *Type2* can be any of the following:

- *Line_3<SphericalKernel>*
- *Circle_3<SphericalKernel>*
- *Plane_3<SphericalKernel>*
- *Sphere_3<SphericalKernel>*
- *Line_arc_3<SphericalKernel>*
- *Circular_arc_3<SphericalKernel>*

An example illustrating this is presented in Chapter 14.

Also, another predicate is provided with this kernel:

bool *do_intersect(Type1 obj1, Type2 obj2, Type3 obj3)*

checks whether *obj1*, *obj2* and *obj3* intersect.

where *Type1*, *Type2* and *Type3* can be:

- *Sphere_3<SphericalKernel>*
- *Plane_3<SphericalKernel>*

Function

CGAL::do_overlap

#include <CGAL/Bbox_2.h>

bool *do_overlap(Bbox_2 bb1, Bbox_2 bb2)*

returns *true* iff *bb1* and *bb2* overlap, i.e., iff their intersection is non-empty.

#include <CGAL/Bbox_3.h>

bool *do_overlap(Bbox_3 bb1, Bbox_3 bb2)*

returns *true* iff *bb1* and *bb2* overlap, i.e., iff their intersection is non-empty.

CGAL::enum_cast

Function

#include <CGAL/enum.h>

template < typename T, typename U >		
T	*enum_cast(U u)*	converts between the various enums provided by the CGAL kernel. The conversion preserves the order of the values.

Function

CGAL::equidistant_line

Line_3<Kernel> *equidistant_line(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

constructs the line which is at the same distance from the three points p, q and r.
Precondition: p, q and r are not collinear.

CGAL::has_larger_distance_to_point

Function

bool *has_larger_distance_to_point(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*

returns *true* iff the distance between q and p is larger than the distance between r and p.

bool *has_larger_distance_to_point(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

returns *true* iff the distance between q and p is larger than the distance between r and p.

CGAL::intersection

Depending on which CGAL kernel is used, different versions of this global function are available. This is described below.

With the basic 2D and 3D Kernel (see Chapter 11)

#include <CGAL/intersections.h>

Object *intersection(Type1<Kernel> obj1, Type2<Kernel> obj2)*

Two objects *obj1* and *obj2* intersect if there is a point *p* that is part of both *obj1* and *obj2*. The intersection region of those two objects is defined as the set of all points *p* that are part of both *obj1* and *obj2*. Note that for objects like triangles and polygons that enclose a bounded region, this region is considered part of the object. If a segment lies completely inside a triangle, then those two objects intersect and the intersection region is the complete segment.

The possible value for types *Type1* and *Type2* and the possible return values wrapped in *Object* are the following:

type A	type B	return type
Iso_rectangle_2	*Iso_rectangle_2*	*Iso_rectangle_2*
Iso_rectangle_2	*Line_2*	*Point_2* *Segment_2*
Iso_rectangle_2	*Ray_2*	*Point_2* *Segment_2*
Iso_rectangle_2	*Segment_2*	*Point_2* *Segment_2*
Iso_rectangle_2	*Triangle_2*	*Point_2* *Segment_2* *Triangle_2* *std::vector<Point_2>*
Line_2	*Line_2*	*Point_2* *Line_2*
Line_2	*Ray_2*	*Point_2* *Ray_2*
Line_2	*Segment_2*	*Point_2* *Segment_2*
Line_2	*Triangle_2*	*Point_2* *Segment_2*
Ray_2	*Ray_2*	*Point_2* *Segment_2* *Ray_2*

continued

Ray_2	*Segment_2*	*Point_2* *Segment_2*
Ray_2	*Triangle_2*	*Point_2* *Segment_2*
Segment_2	*Segment_2*	*Point_2* *Segment_2*
Segment_2	*Triangle_2*	*Point_2* *Segment_2*
Triangle_2	*Triangle_2*	*Point_2* *Segment_2* *Triangle_2* *std::vector<Point_2>*
Line_3	*Line_3*	*Point_3* *Line_3*
Line_3	*Plane_3*	*Point_3* *Line_3*
Line_3	*Ray_3*	*Point_3* *Ray_3*
Line_3	*Segment_3*	*Point_3* *Segment_3*
Line_3	*Triangle_3*	*Point_3* *Segment_3*
Plane_3	*Plane_3*	*Line_3* *Plane_3*
Plane_3	*Ray_3*	*Point_3* *Ray_3*
Plane_3	*Segment_3*	*Point_3* *Segment_3*
Plane_3	*Sphere_3*	*Point_3* *Circle_3*
Plane_3	*Triangle_3*	*Triangle_3* *Segment_3* *Point_3*
Ray_3	*Ray_3*	*Point_3* *Ray_3* *Segment_3*
Ray_3	*Segment_3*	*Point_3* *Segment_3*
Ray_3	*Triangle_3*	*Point_3* *Segment_3*
Segment_3	*Segment_3*	*Point_3* *Segment_3*
Segment_3	*Triangle_3*	*Point_3* *Segment_3*
Sphere_3	*Sphere_3*	*Point_3* *Circle_3* *Sphere_3*

continued

Triangle_3	*Triangle_3*	*Point_3* *Segment_3* *Triangle_3* *std::vector<Point_3>*

There is also an intersection function between 3 planes.

Object *intersection(Plane_3<Kernel> pl1, Plane_3<Kernel> pl2, Plane_3<Kernel> pl3)*

returns the intersection of 3 planes, which can be either a point, a line, a plane, or empty.

With the 2D Circular Kernel (see Chapter 13)

#include <CGAL/Circular_kernel_intersections.h>

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

Since both the number of intersections, if any, and their type, depend on the arguments, the function returns an output iterator on *Object*'s, as presented below.

template < class OutputIterator >
OutputIterator *intersection(Type1 obj1, Type2 obj2, OutputIterator intersections)*

Copies in the output iterator the intersection elements between the two objects. *intersections* iterates on elements of type *CGAL::Object*, in lexicographic order,

where *Type1* and *Type2* can both be either

- *Line_2<CircularKernel>* or
- *Line_arc_2<CircularKernel>* or
- *Circle_2<CircularKernel>* or
- *Circular_arc_2<CircularKernel>*.

Depending on the types *Type1* and *Type2*, these elements can be assigned to

- *std::pair<Circular_arc_point_2<CircularKernel>, unsigned>*, where the unsigned integer is the multiplicity of the corresponding intersection point between *obj1* and *obj2*,
- *Circular_arc_2<CircularKernel>* in case of an overlap of two circular arcs,
- *Line_arc_2<CircularKernel>* in case of an overlap of two line segments or
- *Line_2<CircularKernel>* or *Circle_2<CircularKernel>* in case of two equal input lines or circles.

With the 3D Spherical Kernel (see Chapter 14)

#include <CGAL/Spherical_kernel_intersections.h>

If this kernel is used, in addition to the function and the combination of 3D types described above, two other versions of the function are provided.

Since both the number of intersections, if any, and their type, depend on the arguments, the functions return an output iterator on *Object*'s, as presented below.

The **first function** is:

template < class OutputIterator >
OutputIterator *intersection(Type1 obj1, Type2 obj2, OutputIterator intersections)*

Copies in the output iterator the intersection elements between the two objects. *intersections* iterates on elements of type *CGAL::Object*, in lexicographic order, when this ordering is defined on the computed objects,

where *Type1* and *Type2* can both be either:

- *Sphere_3<SphericalKernel>*,
- *Plane_3<SphericalKernel>*,
- *Line_3<SphericalKernel>*,
- *Circle_3<SphericalKernel>*,
- *Line_arc_3<SphericalKernel>* or
- *Circular_arc_3<SphericalKernel>*,

and depending on the types *Type1* and *Type2*, the computed *CGAL::Object*s can be assigned to

- *std::pair<Circular_arc_point_3<SphericalKernel>, unsigned>*, where the unsigned integer is the multiplicity of the corresponding intersection point between *obj1* and *obj2*,
- *Type1*, when *Type1* and *Type2* are equal, and if the two objets *obj1* and *obj2* are equal,
- *Line_3<SphericalKernel>* or *Circle_3<SphericalKernel>* when *Type1* and *Type2* are two-dimensional objets intersecting along a curve (2 planes, or 2 spheres, or one plane and one sphere),
- *Circular_arc_3<SphericalKernel>* in case of an overlap of two circular arcs or
- *Line_arc_3<SphericalKernel>* in case of an overlap of two line segments.

The **second function** is:

template < class OutputIterator >
OutputIterator *intersection(Type1 obj1, Type2 obj2, Type3 obj3, OutputIterator intersections)*

Copies in the output iterator the intersection elements between the three objects. *intersections* iterates on elements of type *CGAL::Object*, in lexicographic order when this ordering is defined on the computed objects where *Type1*, *Type2* and *Type3* can be either

- *Sphere_3<SphericalKernel>* or
- *Plane_3<SphericalKernel>*

and depending of these types, the computed *CGAL::Object*s can be assigned to

- *std::pair<Circular_arc_point_3<SphericalKernel>, unsigned>*, where the unsigned integer is the multiplicity of the corresponding intersection point,
- *Circle_3<SphericalKernel>* or
- *Type1*, when *Type1*, *Type2* and *Type3* are equal, and if the three objets *obj1* and *obj2* and *obj3* are equal.

Example

The following example demonstrates the most common use of *intersection* routines with the basic 2D and 3D Kernels.

```
#include <CGAL/intersections.h>

void foo(CGAL::Segment_2<Kernel> seg, CGAL::Line_2<Kernel> line)
{
    CGAL::Object result = CGAL::intersection(seg, line);
    if (const CGAL::Point_2<Kernel> *ipoint = CGAL::object_cast<CGAL::Point_2<Kernel> >(&result)) {

        // handle the point intersection case with *ipoint.

    } else
        if (const CGAL::Segment_2<Kernel> *iseg = CGAL::object_cast<CGAL::Segment_2<Kernel> >(&result)) {

            // handle the segment intersection case with *iseg.

        } else {

            // handle the no intersection case.
        }
}
```

Examples illustrating the use of this function in the case of the 2D Circular Kernel and the 3D Spherical Kernel are presented respectively in Chapters 13 and 14.

CGAL::max_vertex

Point_2<Kernel> *max_vertex(Iso_box_2<Kernel> ir)*

computes the vertex with the lexicographically largest coordinates of the iso rectangle *ir*.

Point_3<Kernel> *max_vertex(Iso_cuboid_3<Kernel> ic)*

computes the vertex with the lexicographically largest coordinates of the iso cuboid *ic*.

CGAL::midpoint

Point_2<Kernel>	*midpoint(Point_2<Kernel> p, Point_2<Kernel> q)*	
		computes the midpoint of the segment *pq*.
Point_3<Kernel>	*midpoint(Point_3<Kernel> p, Point_3<Kernel> q)*	
		computes the midpoint of the segment *pq*.

CGAL::normal

Vector_3<Kernel> *normal(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

computes the normal vector for the vectors *q*-*p* and *r*-*p*.
Precondition: The points *p*, *q*, and *r* must not be collinear.

Function

Function

CGAL::min_vertex

Point_2<Kernel> *min_vertex(Iso_box_2<Kernel> ir)*

computes the vertex with the lexicographically smallest coordinates of the iso rectangle *ir*.

Point_3<Kernel> *min_vertex(Iso_cuboid_3<Kernel> ic)*

computes the vertex with the lexicographically smallest coordinates of the iso cuboid *ic*.

CGAL::operator+

Point_2<Kernel> *operator+(Point_2<Kernel> p, Vector_2<Kernel> v)*

returns the point obtained by translating *p* by vector *v*.

Point_3<Kernel> *operator+(Point_3<Kernel> p, Vector_3<Kernel> v)*

returns a point obtained by translating *p* by vector *v*.

See Also

CGAL::operator- . . . . page 758
*CGAL::operator** . . . . page 759

Function

CGAL::operator-

Vector_2<Kernel>	*operator-(Point_2<Kernel> p, Point_2<Kernel> q)*	
		returns the difference vector between q and p. You can substitute *ORIGIN* for either p or q ,but not for both.
Point_2<Kernel>	*operator-(Point_2<Kernel> p, Vector_2<Kernel> v)*	
		returns the point obtained by translating p by the vector -v.
Vector_3<Kernel>	*operator-(Point_3<Kernel> p, Point_3<Kernel> q)*	
		returns the difference vector between q and p. You can substitute *ORIGIN* for either p or q, but not both.
Point_3<Kernel>	*operator-(Point_3<Kernel> p, Vector_3<Kernel> v)*	
		returns a point obtained by translating p by the vector $-v$.

See Also

CGAL::operator+ . . . . page 757
*CGAL::operator** . . . . page 759

CGAL::operator*

Vector_2<Kernel>	*operator*(Kernel::RT s, Vector_2<Kernel> w)*	
		Multiplication with a scalar from the left.
Vector_3<Kernel>	*operator*(Kernel::RT s, Vector_3<Kernel> w)*	
		Multiplication with a scalar from the left.

See Also

CGAL::operator+ . . . . page 757
CGAL::operator- . . . . page 758

Function

Function

CGAL::opposite

#include <CGAL/enum.h>

Oriented_side	*opposite(Oriented_side o)*	
		returns the opposite side (for example *ON_POSITIVE_SIDE* if *o==ON_NEGATIVE_SIDE*), or *ON_ORIENTED_BOUNDARY* if *o==ON_ORIENTED_BOUNDARY*.
Bounded_side	*opposite(Bounded_side o)*	
		returns the opposite side (for example *BOUNDED_SIDE* if *o==UNBOUNDED_SIDE*), or returns *ON_BOUNDARY* if *o==ON_BOUNDARY*.

CGAL::orthogonal_vector

Vector_3<Kernel> *orthogonal_vector(Plane_3<Kernel> p)*

computes an orthogonal vector of the plane *p*, which is directed to the positive side of this plane.

Vector_3<Kernel> *orthogonal_vector(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

computes an orthogonal vector of the plane defined by *p*, *q* and *r*, which is directed to the positive side of this plane.

Function

Function

CGAL::orientation

Orientation	*orientation(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*	
		returns *LEFT_TURN*, if r lies to the left of the oriented line l defined by p and q, returns *RIGHT_TURN* if r lies to the right of l, and returns *COLLINEAR* if r lies on l.
Orientation	*orientation(Vector_2<Kernel> u, Vector_2<Kernel> v)*	
		returns *LEFT_TURN* if u and v form a left turn, returns *RIGHT_TURN* if u and v form a right turn, and returns *COLLINEAR* if u and v are collinear.
Orientation	*orientation(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r, Point_3<Kernel> s)*	
		returns *POSITIVE*, if s lies on the positive side of the oriented plane h defined by p, q, and r, returns *NEGATIVE* if s lies on the negative side of h, and returns *COPLANAR* if s lies on h.
Orientation	*orientation(Vector_3<Kernel> u, Vector_3<Kernel> v, Vector_3<Kernel> w)*	
		returns *POSITIVE* if u, v and w are positively oriented, returns *NEGATIVE* if u, v and w are negatively oriented, and returns *COPLANAR* if u, v and w are coplanar.

CGAL::parallel

Function

bool *parallel(Line_2<Kernel> l1, Line_2<Kernel> l2)*

returns *true*, if *l1* and *l2* are parallel or if one of those (or both) is degenerate.

bool *parallel(Ray_2<Kernel> r1, Ray_2<Kernel> r2)*

returns *true*, if *r1* and *r2* are parallel or if one of those (or both) is degenerate.

bool *parallel(Segment_2<Kernel> s1, Segment_2<Kernel> s2)*

returns *true*, if *s1* and *s2* are parallel or if one of those (or both) is degenerate.

bool *parallel(Line_3<Kernel> l1, Line_3<Kernel> l2)*

returns *true*, if *l1* and *l2* are parallel or if one of those (or both) is degenerate.

bool *parallel(Plane_3<Kernel> h1, Plane_3<Kernel> h2)*

returns *true*, if *h1* and *h2* are parallel or if one of those (or both) is degenerate.

bool *parallel(Ray_3<Kernel> r1, Ray_3<Kernel> r2)*

returns *true*, if *r1* and *r2* are parallel or if one of those (or both) is degenerate.

bool *parallel(Segment_3<Kernel> s1, Segment_3<Kernel> s2)*

returns *true*, if *s1* and *s2* are parallel or if one of those (or both) is degenerate.

CGAL::quotient_cartesian_to_homogeneous

#include <CGAL/cartesian_homogeneous_conversion.h>

Point_2< Homogeneous<RT> >

quotient_cartesian_to_homogeneous(Point_2< Cartesian< Quotient<RT> > > cp)

converts 2d point *cp* with Cartesian representation with number type *Quotient<RT>* into a 2d point with homogeneous representation with number type *RT*.

Point_3< Homogeneous<RT> >

quotient_cartesian_to_homogeneous(Point_3< Cartesian< Quotient<RT> > > cp)

converts 3d point *cp* with Cartesian representation with number type *Quotient<RT>* into a 3d point with homogeneous representation with number type *RT*.

CGAL::radical_plane

Plane_3<Kernel> *radical_plane(Sphere_3<Kernel> s1, Sphere_3<Kernel> s2)*

returns the radical plane of the two spheres.
Precondition: $s1$ and $s2$ are not cocentric.

Function

CGAL::radical_line

Line_2<Kernel> *radical_line(Circle_2<Kernel> c1, Circle_2<Kernel> c2)*

returns the radical line of the two circles.
Precondition: $c1$ and $c2$ are not cocentric.

CGAL::rational_rotation_approximation

#include <CGAL/rational_rotation.h>

template <RingNumberType>
void *rational_rotation_approximation(RingNumberType dirx, RingNumberType diry, RingNumberType* & *sin_num, RingNumberType* & *cos_num, RingNumberType* & *denom, RingNumberType eps_num, RingNumberType eps_den)*

computes integers *sin_num*, *cos_num* and *denom*, such that *sin_num/denom* approximates the sine of direction (*dirx*,*diry*). The difference between the sine and the approximating rational is bounded by *eps_num/eps_den*.
Precondition: $eps\_num \neq 0$.

Implementation

The approximation is based on Farey sequences as described in the rational rotation method presented by Canny and Ressler at the 8th SoCG 1992. We use a slower version which needs no division operation in the approximation.

Function

Function

CGAL::right_turn

bool *right_turn(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*

returns *true* iff *p*, *q*, and *r* form a right turn.

See Also

CGAL::collinear . . . . page 700

CGAL::orientation . . . . page 1116

CGAL::side_of_bounded_circle

Bounded_side *side_of_bounded_circle(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r, Point_2<Kernel> t)*

returns the relative position of point t to the circle defined by p, q and r. The order of the points p, q and r does not matter.
Precondition: p, q and r are not collinear.

Bounded_side *side_of_bounded_circle(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> t)*

returns the position of the point t relative to the circle that has pq as its diameter.

See Also

CGAL::coplanar_side_of_bounded_circle .... page 727
CGAL::side_of_oriented_circle .... page 771

Function

Function

CGAL::side_of_bounded_sphere

Bounded_side *side_of_bounded_sphere(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r, Point_3<Kernel> s, Point_3<Kernel> t)*

returns the relative position of point t to the sphere defined by p, q, r, and s. The order of the points p, q, r, and s does not matter.
Precondition: p, q, r and s are not coplanar.

Bounded_side *side_of_bounded_sphere(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r, Point_3<Kernel> t)*

returns the position of the point t relative to the sphere passing through p, q, and r and whose center is in the plane defined by these three points.

Bounded_side *side_of_bounded_sphere(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> t)*

returns the position of the point t relative to the sphere that has pq as its diameter.

See Also

CGAL::side_of_oriented_sphere . . . . page 1119

CGAL::side_of_oriented_circle

Oriented_side *side_of_oriented_circle(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r, Point_2<Kernel> test)*

returns the relative position of point *test* to the oriented circle defined by p, q and r. The order of the points p, q and r is important, since it determines the orientation of the implicitly constructed circle.
If p, q and r are collinear, the circle degenerates in a line. *ON_ORIENTED_BOUNDARY* is returned if $test$ is also collinear or if two points are identical, otherwise, *side_of_oriented_circle(r, q, test, p)* is returned.

Function

See Also

CGAL::side_of_bounded_circle .... page 769

CGAL::side_of_oriented_sphere

Oriented_side *side_of_oriented_sphere(Point_3<Kernel> p,*
Point_3<Kernel> q,
Point_3<Kernel> r,
Point_3<Kernel> s,
Point_3<Kernel> test)

returns the relative position of point *test* to the oriented sphere defined by p, q, r and s. The order of the points p, q, r, and s is important, since it determines the orientation of the implicitly constructed sphere. If the points p, q, r and s are positive oriented, positive side is the bounded interior of the sphere.
In case of degeneracies, *ON_ORIENTED_BOUNDARY* is returned if all points are coplanar. Otherwise, there is a cyclic permutation of the five points that puts four non coplanar points first, it is used to answer the predicate: e.g. *side_of_oriented_sphere(q, r, s, test, p)* is returned if q, r, s, and *test* are non coplanar.

See Also

CGAL::squared_area

Function

Kernel::FT	*squared_area(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*	
		returns the squared area of the triangle defined by the points p, q and r.

CGAL::squared_distance

#include <CGAL/squared_distance_2.h>
#include <CGAL/squared_distance_3.h>

Kernel::FT *squared_distance(Type1<Kernel> obj1, Type2<Kernel> obj2)*

computes the square of the Euclidean distance between two geometric objects. For arbitrary geometric objects *obj1* and *obj2* the squared distance is defined as the minimal *squared_distance(p1, p2)*, where *p1* is a point of *obj1* and *p2* is a point of *obj2*. Note that for objects that have an inside (a bounded region), this inside is part of the object. So, the squared distance from a point inside is zero, not the squared distance to the closest point on the boundary.

In 2D, the types *Type1* and *Type2* can be any of the following:

- *Point_2*
- *Line_2*
- *Ray_2*
- *Segment_2*
- *Triangle_2*

In 3D, the types *Type1* and *Type2* can be any of the following:

- *Point_3*
- *Line_3*
- *Ray_3*
- *Segment_3*
- *Plane_3*

CGAL::squared_radius

FT *squared_radius(Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)*

compute the squared radius of the circle passing through the points p, q, and r.
Precondition: p, q, and r are not collinear.

FT *squared_radius(Point_2<Kernel> p, Point_2<Kernel> q)*

compute the squared radius of the smallest circle passing through p, and q, i.e. one fourth of the squared distance between p and q.

FT *squared_radius(Point_2<Kernel> p)*

compute the squared radius of the smallest circle passing through p, i.e. 0.

FT *squared_radius(Point_3<Kernel> p,*
Point_3<Kernel> q,
Point_3<Kernel> r,
Point_3<Kernel> s)

compute the squared radius of the sphere passing through the points p, q, r and s.
Precondition: p, q, r and s are not coplanar.

FT *squared_radius(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

compute the squared radius of the sphere passing through the points p, q, and r and whose center is in the same plane as those three points.

FT *squared_radius(Point_3<Kernel> p, Point_3<Kernel> q)*

compute the squared radius of the smallest circle passing through p, and q, i.e. one fourth of the squared distance between p and q.

FT *squared_radius(Point_3<Kernel> p)*

compute the squared radius of the smallest circle passing through p, i.e. 0.

CGAL::unit_normal

Vector_3<Kernel> *unit_normal(Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)*

computes the unit normal vector for the vectors q-p and r-p.
Precondition: The points p, q, and r must not be collinear.

Function

Function

CGAL::volume

Kernel::FT *volume(Point_3<Kernel> p0,*
Point_3<Kernel> p1,
Point_3<Kernel> p2,
Point_3<Kernel> p3)

Computes the signed volume of the tetrahedron defined by the four points *p0*, *p1*, *p2* and *p3*.

See Also

CGAL::Tetrahedron_3<Kernel> . . . . page 669

CGAL::x_equal

bool *x_equal(Point_2<Kernel> p, Point_2<Kernel> q)*

returns *true*, iff *p* and *q* have the same *x*-coordinate.

bool *x_equal(Point_3<Kernel> p, Point_3<Kernel> q)*

returns *true*, iff *p* and *q* have the same *x*-coordinate.

11.15 Kernel Function Object Concepts

Kernel::Angle_2

A model for this must provide:

Angle *fo.operator()(Kernel::Vector_2 u, Kernel::Vector_2 v)*

returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the angle formed by the two vectors *u* and *v*.

Angle *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q, Kernel::Point_2 r)*

returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the angle formed by the three points *p*, *q*, *r* (*q* being the vertex of the angle). The returned value is the same as *operator()(p - q, r - q)*.

Angle *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q, Kernel::Point_2 r, Kernel::Point_2 s)*

returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the angle formed by the two vectors *pq*, *rs*. The returned value is the same as *operator()(q - p, s - r)*.

See Also

CGAL::angle . . . . page 689

Functor
Concept

Kernel::Angle_3

A model for this must provide:

Angle	*fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*
	returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the angle formed by the three points p, q, r (q being the vertex of the angle).

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::angle . . . . page 689

Kernel::AreOrderedAlongLine_2

A model for this must provide:

bool *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q, Kernel::Point_2 r)*

returns *true*, iff the three points are collinear and q lies between p and r. Note that *true* is returned, if $q{=}{=}p$ or $q{=}{=}r$.

Functor
Concept

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::are_ordered_along_line .... page 690

Kernel::AreOrderedAlongLine_3

A model for this must provide:

bool	*fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*
	returns *true*, iff the three points are collinear and q lies between p and r. Note that *true* is returned, if $q{=}{=}p$ or $q{=}{=}r$.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::are_ordered_along_line . . . . page 690

Kernel::AreParallel_2

A model for this must provide:

bool *fo.operator()(Kernel::Line_2 l1, Kernel::Line_2 l2)*

returns *true*, if *l1* and *l2* are parallel or if one of those (or both) is degenerate.

bool *fo.operator()(Kernel::Ray_2 r1, Kernel::Ray_2 r2)*

returns *true*, if *r1* and *r2* are parallel or if one of those (or both) is degenerate.

bool *fo.operator()(Kernel::Segment_2 s1, Kernel::Segment_2 s2)*

returns *true*, if *s1* and *s2* are parallel or if one of those (or both) is degenerate.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::parallel . . . . page 763

Kernel::AreParallel_3

A model for this must provide:

bool *fo.operator()(Kernel::Line_3 l1, Kernel::Line_3 l2)*

returns *true*, if *l1* and *l2* are parallel or if one of those (or both) is degenerate.

bool *fo.operator()(Kernel::Plane_3 h1, Kernel::Plane_3 h2)*

returns *true*, if *h1* and *h2* are parallel or if one of those (or both) is degenerate.

bool *fo.operator()(Kernel::Ray_3 r1, Kernel::Ray_3 r2)*

returns *true*, if *r1* and *r2* are parallel or if one of those (or both) is degenerate.

bool *fo.operator()(Kernel::Segment_3 s1, Kernel::Segment_3 s2)*

returns *true*, if *s1* and *s2* are parallel or if one of those (or both) is degenerate.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::parallel . . . . page 763

Kernel::AreStrictlyOrderedAlongLine_2

A model for this must provide:

bool *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q, Kernel::Point_2 r)*

returns *true*, iff the three points are collinear and q lies strictly between p and r. Note that *false* is returned, if q==p or q==r.

Functor
Concept

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::are_strictly_ordered_along_line . . . . page 691

Functor
Concept

Kernel::AreStrictlyOrderedAlongLine_3

A model for this must provide:

bool	*fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*
	returns *true*, iff the three points are collinear and q lies strictly between p and r. Note that *false* is returned, if $q{=}{=}p$ or $q{=}{=}r$.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::are_strictly_ordered_along_line . . . . page 691

Kernel::Assign_2

A model for this must provide:

template <class T>
bool *fo.operator()(T& t, Kernel::Object_2 o)*

assigns o to t if o was constructed from an object of type T. Returns *true*, if the assignment was possible.

Functor
Concept

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Object . . . . page 4167
Kernel::Object_2 . . . . page 791
Kernel::Intersect_2 . . . . page 1011

Kernel::Assign_3

A model for this must provide:

template <class T>
bool *fo.operator()(T& t, Kernel::Object_3 o)*

assigns o to t if o was constructed from an object of type T. Returns *true*, if the assignment was possible.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Object . . . . page 4167
Kernel::Object_3 . . . . page 792
Kernel::Intersect_3 . . . . page 1012

Kernel::BoundedSide_2

A model for this must provide:

Bounded_side *fo.operator()(Kernel::Circle_2 c, Kernel::Point_2 p)*

returns either *ON_UNBOUNDED_SIDE*, *ON_BOUNDED_SIDE*, or the constant *ON_BOUNDARY*, depending on where point p is relative to circle c.

Bounded_side *fo.operator()(Kernel::Triangle_2 t, Kernel::Point_2 p)*

returns either *ON_UNBOUNDED_SIDE*, *ON_BOUNDED_SIDE*, or the constant *ON_BOUNDARY*, depending on where point p is relative to triangle t.

Bounded_side *fo.operator()(Kernel::Iso_rectangle_2 r, Kernel::Point_2 p)*

returns either *ON_UNBOUNDED_SIDE*, *ON_BOUNDED_SIDE*, or the constant *ON_BOUNDARY*, depending on where point p is relative to rectangle r.

Refines

AdaptableFunctor (with two arguments)

See Also

Functor
Concept

Kernel::BoundedSide_3

A model for this must provide:

Bounded_side *fo.operator()(Kernel::Sphere_3 s, Kernel::Point_3 p)*

returns either *ON_UNBOUNDED_SIDE*, *ON_BOUNDED_SIDE*, or the constant *ON_BOUNDARY*, depending on where point *p* is with respect to sphere *s*.

Bounded_side *fo.operator()(Kernel::Tetrahedron_3 t, Kernel::Point_3 p)*

returns either *ON_UNBOUNDED_SIDE*, *ON_BOUNDED_SIDE*, or the constant *ON_BOUNDARY*, depending on where point *p* is with respect to tetrahedron *t*.

Bounded_side *fo.operator()(Kernel::Iso_cuboid_3 c, Kernel::Point_3 p)*

returns either *ON_UNBOUNDED_SIDE*, *ON_BOUNDED_SIDE*, or the constant *ON_BOUNDARY*, depending on where point *p* is with respect to iso-cuboid *c*.

Kernel::CollinearAreOrderedAlongLine_2

A model for this must provide:

bool *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q, Kernel::Point_2 r)*

returns *true*, iff q lies between p and r.
Precondition: p, q and r are collinear.

Functor
Concept

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::collinear_are_ordered_along_line . . . . page 701

Functor
Concept

Kernel::CollinearAreOrderedAlongLine_3

A model for this must provide:

bool	*fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*
	returns *true*, iff q lies between p and r. *Precondition*: p, q and r are collinear.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::collinear_are_ordered_along_line . . . . page 701

Kernel::CollinearAreStrictlyOrderedAlongLine_2

A model for this must provide:

bool	*fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q, Kernel::Point_2 r)*
	returns *true*, iff *q* lies strictly between *p* and *r*. *Precondition*: *p, q* and *r* are collinear.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::collinear_are_strictly_ordered_along_line . . . . page 702

Kernel::CollinearAreStrictlyOrderedAlongLine_3

A model for this must provide:

bool *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*

returns *true*, iff q lies strictly between p and r.
Precondition: p, q and r are collinear.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::collinear_are_strictly_ordered_along_line . . . . page 702

Kernel::CollinearHasOn_2

A model for this must provide:

bool *fo.operator()(Kernel::Ray_2 r, Kernel::Point_2 p)*

checks if point p is on r.
Precondition: p is on the supporting line of r.

bool *fo.operator()(Kernel::Segment_2 s, Kernel::Point_2 p)*

checks if point p is on s.
Precondition: p is on the supporting line of s.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Ray_2<Kernel> . . . . page 629
CGAL::Segment_2<Kernel> . . . . page 631

Kernel::Collinear_2

A model for this must provide:

bool	*fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q, Kernel::Point_2 r)*
	returns *true*, if *p*, *q*, and *r* are collinear.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::collinear . . . . page 700

Kernel::Collinear_3

A model for this must provide:

bool	*fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*	
		returns *true*, if p, q, and r are collinear.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::collinear . . . . page 700

Kernel::CompareAngleWithXAxis_2

A model for this must provide:

Comparison_result *fo.operator()(Kernel::Direction_2 d, Kernel::Direction_2 e)*

compares the angles between the positive x-axis and the directions in counterclockwise order.

Refines

AdaptableFunctor (with two arguments)

Kernel::CompareDihedralAngle_3

A model for this must provide:

Comparison_result *fo.operator()(K::Point_3 a1, K::Point_3 b1, K::Point_3 c1, K::Point_3 d1, K::FT cosine)*

compares the dihedral angles θ_1 and θ_2, where θ_1 is the dihedral angle, in $[0,\pi]$, of the tetrahedron (a_1,b_1,c_1,d_1) at the edge (a_1,b_1), and θ_2 is the angle in $[0,\pi]$ such that $cos(\theta_2) = cosine$. The result is the same as *operator()(b1-a1, c1-a1, d1-a1, cosine)*.
Precondition: a_1, b_1, c_1 are not collinear, and a_1, b_1, d_1 are not collinear.

Comparison_result *fo.operator()(K::Point_3 a1, K::Point_3 b1, K::Point_3 c1, K::Point_3 d1, K::Point_3 a2, K::Point_3 b2, K::Point_3 c2, K::Point_3 d2)*

compares the dihedral angles θ_1 and θ_2, where θ_i is the dihedral angle in the tetrahedron (a_i,b_i,c_i,d_i) at the edge (a_i,b_i). These two angles are computed in $[0,\pi]$. The result is the same as *operator()(b1-a1, c1-a1, d1-a1, b2-a2, c2-a2, d2-a2)*.
Precondition: For $i \in \{1,2\}$, a_i, b_i, c_i are not collinear, and a_i, b_i, d_i are not collinear.

Comparison_result *fo.operator()(K::Vector_3 u1, K::Vector_3 v1, K::Vector_3 w1, K::FT cosine)*

compares the dihedral angles θ_1 and θ_2, where θ_1 is the dihedral angle, in $[0,\pi]$, between the vectorial planes defined by (u_1,v_1) and (u_1,w_1), and θ_2 is the angle in $[0,\pi]$ such that $cos(\theta_2) = cosine$.
Precondition: u_1 and v_1 are not collinear, and u_1 and w_1 are not collinear.

Comparison_result *fo.operator()(K::Vector_3 u1, K::Vector_3 v1, K::Vector_3 w1, K::Vector_3 u2, K::Vector_3 v2,* *K::Vector_3 w2)*

compares the dihedral angles θ_1 and θ_2, where θ_i is the dihedral angle between the vectorial planes defined by (u_i, v_i) and (u_i, w_i). These two angles are computed in $[0, \pi]$.
Precondition: For $i \in \{1, 2\}$, u_i and v_i are not collinear, and u_i and w_i are not collinear.

Kernel::CompareDistance_2

A model for this must provide:

Comparison_result *fo.operator()(Type1 obj1, Type2 obj2, Type3 obj3)*

compares the squared distance between *obj1* and *obj2* to the squared distance between *obj1* and *obj3*

Comparison_result *fo.operator()(Type1 obj1, Type2 obj2, Type3 obj3, Type4 obj4)*

compares the squared distance between *obj1* and *obj2* to the squared distance between *obj3* and *obj4*

for all tuples of types *Type1*, *Type2*, *Type3* and *Type4* in the following set of types:

- *Kernel::Point_2*
- *Kernel::Line_2*
- *Kernel::Ray_2*
- *Kernel::Segment_2*
- *Kernel::Triangle_2*

Refines

AdaptableFunctor (with three arguments)

Kernel::CompareSquaredDistance_2

A model for this must provide:

Comparison_result *fo.operator()(Type1 obj1, Type2 obj2, Kernel::FT d2)*

compares the squared distance between the two geometrical objects *obj1* and *obj2* to the value *d2*

for all pairs *Type1* and *Type2*, where the types *Type1* and *Type2* can be any of the following:

- *Kernel::Point_2*
- *Kernel::Line_2*
- *Kernel::Ray_2*
- *Kernel::Segment_2*
- *Kernel::Triangle_2*

Kernel::CompareSquaredRadius_3

A model for this must provide:

Comparison_result *fo.operator()(Kernel::Point_3 p, Kernel::FT sr)*

compares the squared radius of the sphere of radius 0 centered at *p* to *sr*. This returns the opposite sign of *sr*.

Comparison_result *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::FT sr)*

compares the squared radius of the sphere defined by the points *p* and *q* to *sr*.

Comparison_result *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r, Kernel::FT sr)*

compares the squared radius of the sphere defined by the points *p*, *q*, and *r* to *sr*.

Comparison_result *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r, Kernel::Point_3 s, Kernel::FT sr)*

compares the squared radius of the sphere defined by the points *p*, *q*, , *r*, and *s* to *sr*.

Kernel::CompareXAtY_2

A model for this must provide:

Comparison_result *fo.operator()(Kernel::Point_2 p, Kernel::Line_2 h)*

compares the x-coordinates of p and the horizontal projection of p on h (Figure 11.5 (a)).

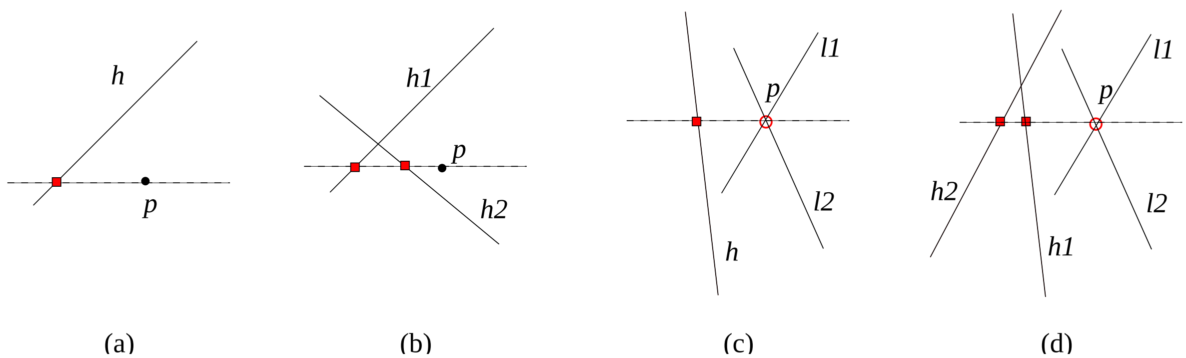

Figure 11.5: Comparison of the x-coordinates of the (implicitly given) points in the boxes, at a y-coordinate. The y-coordinate is either given explicitly (disc) or implicitly (circle).

Comparison_result *fo.operator()(Kernel::Point_2 p, Kernel::Line_2 h1, Kernel::Line_2 h2)*

compares the x-coordinates of the horizontal projection of p on $h1$ and on $h2$ (Figure 11.5 (b)).

Comparison_result *fo.operator()(Kernel::Line_2 l1, Kernel::Line_2 l2, Kernel::Line_2 h)*

Let p be the intersection of lines $l1$ and $l2$. This function compares the x-coordinates of p and the horizontal projection of p on h (Figure 11.5 (c)).

Comparison_result *fo.operator()(Kernel::Line_2 l1,*
Kernel::Line_2 l2,
Kernel::Line_2 h1,
Kernel::Line_2 h2)

Let p be the intersection of lines $l1$ and $l2$. This function compares the x-coordinates of the horizontal projection of p on $h1$ and on $h2$ (Figure 11.5 (d)).

Kernel::CompareYAtX_2

A model for this must provide:

Comparison_result *fo.operator()(Kernel::Point_2 p, Kernel::Line_2 h)*

compares the y-coordinates of p and the vertical projection of p on h (Figure 11.7 (d)).
Precondition: h is not vertical.

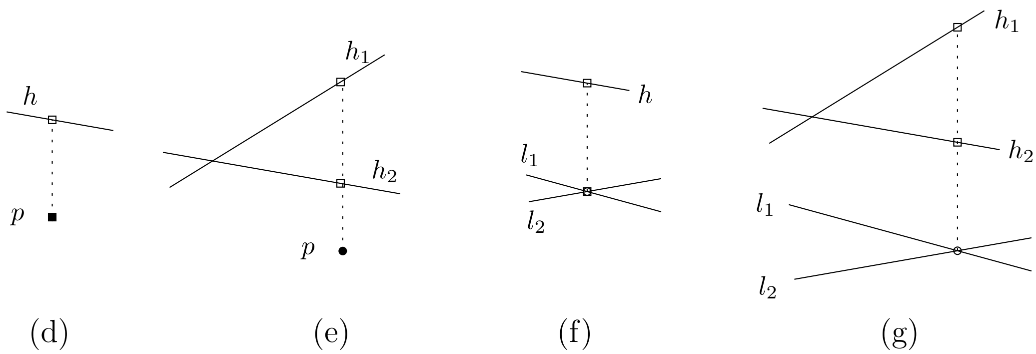

Figure 11.7: Comparison of the y-coordinates of the (implicitly given) points in the boxes, at an x-coordinate. The x-coordinate is either given explicitly (disc) or implicitly (circle).

Comparison_result *fo.operator()(Kernel::Point_2 p, Kernel::Line_2 h1, Kernel::Line_2 h2)*

This function compares the y-coordinates of the vertical projection of p on *h1* and on *h2* (Figure 11.4 (e)).
Precondition: *h1* and *h2* are not vertical.

Comparison_result *fo.operator()(Kernel::Line_2 l1, Kernel::Line_2 l2, Kernel::Line_2 h)*

Let p be the intersection of lines $l1$ and $l2$. This function compares the y-coordinates of p and the vertical projection of p on h (Figure 11.4 (f)).
Precondition: *l1*, *l2* intersect and h is not vertical.

Comparison_result *fo.operator()(Kernel::Line_2 l1,*
Kernel::Line_2 l2,
Kernel::Line_2 h1,
Kernel::Line_2 h2)

Let p be the intersection of lines $l1$ and $l2$. This function compares the y-coordinates of the vertical projection of p on *h1* and on *h2* (Figure 11.4 (g)).
Precondition: *l1* and *l2* intersect; *h1* and *h2* are not vertical.

Comparison_result *fo.operator()(Kernel::Point_2 p, Kernel::Segment_2 s)*

compares the *y*-coordinates of *p* and the vertical projection of *p* on *s*. If *s* is vertical, then return *EQUAL* when *p* lies on *s*, *SMALLER* when *p* lies under s, and *LARGER* otherwise.
Precondition: *p* is within the x range of *s*.

Comparison_result *fo.operator()(Kernel::Point_2 p, Kernel::Segment_2 s1, Kernel::Segment_2 s2)*

This function compares the *y*-coordinates of the vertical projection of *p* on *s1* and on *s2*. If *s1* or *s2* is vertical, then return *EQUAL* if they intersect, otherwise return *SMALLER* if *s1* lies below *s2*, and return *LARGER* otherwise.
Precondition: *p* is within the x range of *s1* and *s2*.

Kernel::ComputeSquaredLengthDividedByPiSquare_3

A model for this must provide:

Kernel::FT	*fo.operator()(Kernel::Circle_3 c)*	
		returns the squared length of c, divided by π^2.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Circle_3<Kernel> . . . . page 663

Kernel::ComputeSquaredRadius_2

A model for this must provide:

Kernel::FT *fo.operator()(Kernel::Circle_2 c)*

returns the squared radius of c.

Kernel::FT *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q, Kernel::Point_2 r)*

returns the squared radius of the circle passing through p, q and r.
Precondition: p, q and r are not collinear.

Kernel::FT *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q)*

returns the squared radius of the smallest circle passing through p, and q, i.e. one fourth of the squared distance between p and q.

Kernel::FT *fo.operator()(Kernel::Point_2 p)*

returns the squared radius of the smallest circle passing through p, i.e. 0.

Refines

AdaptableFunctor (with one argument)

Kernel::ConstructBisector_2

A model for this must provide:

Kernel::Line_2 *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q)*

constructs the bisector of p and q. The bisector is oriented in such a way that p lies on its positive side.
Precondition: p and q are not equal.

Kernel::Line_2 *fo.operator()(Kernel::Line_2 l1, Kernel::Line_2 l2)*

constructs the bisector of the two lines $l1$ and $l2$. In the general case, the bisector has the direction of the vector which is the sum of the normalized directions of the two lines, and which passes through the intersection of *l1* and *l2*. If *l1* and *l2* are parallel, then the bisector is defined as the line which has the same direction as *l1*, and which is at the same distance from *l1* and *l2*. This function requires that *Kernel::RT* supports the *sqrt()* operation.

Refines

CGAL::bisector . . . . page 696

Kernel::ConstructBisector_3

A model for this must provide:

Kernel::Plane_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q)*

constructs the bisector plane of p and q. The bisector is oriented in such a way that p lies on its positive side. *Precondition*: p and q are not equal.

Kernel::Plane_3 *fo.operator()(Kernel::Plane_3 h1, Kernel::Plane_3 h2)*

constructs the bisector of the two planes $h1$ and $h2$. In the general case, the bisector has a normal vector which has the same direction as the sum of the normalized normal vectors of the two planes, and passes through the intersection of *h1* and *h2*. If *h1* and *h2* are parallel, then the bisector is defined as the plane which has the same oriented normal vector as *l1*, and which is at the same distance from *h1* and *h2*. This function requires that *Kernel::RT* supports the *sqrt()* operation.

Kernel::ConstructCircle_2

A model for this must provide:

Kernel::Circle_2 *fo.operator()(Kernel::Point_2 center,
Kernel::FT squared_radius,
Orientation orientation = COUNTERCLOCKWISE)*

introduces a variable of type *Kernel::Circle_2*. It is initialized to the circle with center *center*, squared radius *squared_radius* and orientation *orientation*.
Precondition: *orientation* $\neq$ *COLLINEAR*, and further, *squared_radius* ≥ 0.

Kernel::Circle_2 *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q, Kernel::Point_2 r)*

introduces a variable of type *Kernel::Circle_2*. It is initialized to the unique circle which passes through the points p, q and r. The orientation of the circle is the orientation of the point triple p, q, r.
Precondition: p, q, and r are not collinear.

Kernel::Circle_2 *fo.operator()(Kernel::Point_2 p,
Kernel::Point_2 q,
Orientation orientation = COUNTERCLOCKWISE)*

introduces a variable of type *Kernel::Circle_2*. It is initialized to the circle with diameter $\overline{pq}$ and orientation *orientation*.
Precondition: *orientation* $\neq$ *COLLINEAR*.

Kernel::Circle_2 *fo.operator()(Kernel::Point_2 center,
Orientation orientation = COUNTERCLOCKWISE)*

introduces a variable of type *Kernel::Circle_2*. It is initialized to the circle with center *center*, squared radius zero and orientation *orientation*.
Precondition: *orientation* $\neq$ *COLLINEAR*.
Postcondition: *.is_degenerate() = true*.

Refines

AdaptableFunctor (with three arguments)

Kernel::ConstructCircle_3

A model for this must provide:

Kernel::Circle_3 *fo.operator()(Kernel::Point_3 center, Kernel::FT sq_r, Kernel::Plane_3 plane)*

introduces a variable of type *Kernel::Circle_3*. It is initialized to the circle with center *center*, and squared radius *sq_r* in the plane *plane*.
Precondition: *center* lies in *plane* and $sq\_r \geq 0$.

Kernel::Circle_3 *fo.operator()(Kernel::Point_3 center, Kernel::FT sq_r, Kernel::Vector_3 n)*

introduces a variable of type *Kernel::Circle_3*. It is initialized to the circle with center *center*, and squared radius *sq_r* in the plane containing *center* and normal to *n*.
Precondition: $sq\_r \geq 0$.

Kernel::Circle_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*

introduces a variable of type *Kernel::Point_3*. It is initialized to the circle passing through the three points.
Precondition: The three points are not collinear.

Kernel::Circle_3 *fo.operator()(Kernel::Sphere_3 sphere1, Kernel::Sphere_3 sphere2)*

introduces a variable of type *Kernel::Circle_3*. It is initialized to the circle along which the two spheres intersect.
Precondition: The two spheres intersect along a circle.

Kernel::Circle_3 *fo.operator()(Kernel::Sphere_3 sphere, Kernel::Plane_3 plane)*

introduces a variable of type *Kernel::Circle_3*. It is initialized to the circle along which the sphere and the plane intersect.
Precondition: The sphere and the plane intersect along a circle.

Kernel::Circle_3 *fo.operator()(Kernel::Plane_3 plane, Kernel::Sphere_3 sphere)*

introduces a variable of type *Kernel::Circle_3*. It is initialized to the circle along which the sphere and the plane intersect.
Precondition: The sphere and the plane intersect along a circle.

Functor Concept

Kernel::ConstructCircumcenter_3

A model for this must provide:

Kernel::Point_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q)*

compute the center of the smallest circle passing through the points p and q. Note : this is the same as *Kernel::ConstructMidPoint_3*.

Kernel::Point_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r, Kernel::Point_3 s)*

compute the center of the sphere passing through the points p, q, r, and s.
Precondition: p, q, r, and s are not coplanar.

Kernel::Point_3 *fo.operator()(Kernel::Tetrahedron_3 t)*

compute the center of the sphere passing through the vertices of t.
Precondition: t is not degenerate.

Kernel::Point_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*

compute the center of the circle passing through the points p, q and r.
Precondition: p, q and r are not collinear.

Kernel::Point_3 *fo.operator()(Kernel::Triangle_3 t)*

compute the center of the circle passing through the vertices of t.
Precondition: t is not degenerate.

Kernel::ConstructEquidistantLine_3

A model for this must provide:

Kernel::Line_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*

constructs the line which is at the same distance from the three points p, q and r.
Precondition: p, q and r are not collinear.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::equidistant_line . . . . page 734

Kernel::ConstructIsoCuboid_3

A model for this must provide:

Kernel::Iso_cuboid_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q)*

introduces an iso-oriented cuboid with diagonal opposite vertices p and q such that p is the lexicographically smallest point in the cuboid.

Kernel::Iso_cuboid_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, int)*

introduces an iso-oriented cuboid with diagonal opposite vertices p and q. The *int* argument value is only used to distinguish the two overloaded functions.
Precondition: $p.x() <= q.x()$, $p.y() <= q.y()$ and $p.z() <= q.z()$.

Kernel::Iso_cuboid_3 *fo.operator()(Kernel::Point_3 left,
Kernel::Point_3 right,
Kernel::Point_3 bottom,
Kernel::Point_3 top,
Kernel::Point_3 far,
Kernel::Point_3 close)*

introduces an iso-oriented cuboid *fo* whose minimal x coordinate is the one of *left*, the maximal x coordinate is the one of *right*, the minimal y coordinate is the one of *bottom*, the maximal y coordinate is the one of *top*, the minimal z coordinate is the one of *far*, the maximal z coordinate is the one of *close*.

Kernel::ConstructOppositeCircle_2

A model for this must provide:

Kernel::Circle_2	*fo.operator()(Kernel::Circle_2 c)*
	returns the circle with the same center and squared radius as *c*, but with opposite orientation.

Functor Concept

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Circle_2<Kernel> . . . . page 614

Kernel::ConstructOppositeDirection_2

A model for this must provide:

Kernel::Direction_2	*fo.operator()(Kernel::Direction_2 d)*	
		returns the direction opposite to d.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Direction_2<Kernel> . . . . page 617

Kernel::ConstructOppositeDirection_3

A model for this must provide:

Kernel::Direction_3	*fo.operator()(Kernel::Direction_3 d)*
	returns the direction opposite to d.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Direction_3<Kernel> . . . . page 644

Kernel::ConstructOppositeLine_2

A model for this must provide:

Kernel::Line_2	*fo.operator()(Kernel::Line_2 l)*	
		returns the line representing the same set of points as *l*, but with opposite direction.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Line_2<Kernel> . . . . page 622

Kernel::ConstructOppositeLine_3

A model for this must provide:

Kernel::Line_3 *fo.operator()(Kernel::Line_3 l)*

returns the line representing the same set of points as *l*, but with opposite direction.

Functor
Concept

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Line_3<Kernel> . . . . page 649

Functor
Concept

Kernel::ConstructOppositePlane_3

A model for this must provide:

Kernel::Plane_3 *fo.operator()(Kernel::Plane_3 p)*

returns the plane representing the same set of points as p, but with opposite orientation.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Plane_3<Kernel> . . . . page 651

Kernel::ConstructOppositeRay_2

A model for this must provide:

Kernel::Ray_2 *fo.operator()(Kernel::Ray_2 r)*

returns the ray with the same source as *r*, but in opposite direction.

Functor
Concept

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Ray_2<Kernel> . . . . page 629

Functor
Concept

Kernel::ConstructOppositeRay_3

A model for this must provide:

Kernel::Ray_3	*fo.operator()(Kernel::Ray_3 r)*	
		returns the ray with the same source as *r*, but in opposite direction.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Ray_3<Kernel> . . . . page 659

Kernel::ConstructOppositeSegment_2

Functor Concept

A model for this must provide:

Kernel::Segment_2	*fo.operator()(Kernel::Segment_2 s)*	
		returns the segment representing the same set of points as *s*, but with opposite orientation.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Segment_2<Kernel> . . . . page 631

Kernel::ConstructOppositeSegment_3

A model for this must provide:

Kernel::Segment_3 *fo.operator()(Kernel::Segment_3 s)*

returns the segment representing the same set of points as *s*, but with opposite orientation.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Segment_3<Kernel> . . . . page 661

Kernel::ConstructOppositeSphere_3

A model for this must provide:

Kernel::Sphere_3 *fo.operator()(Kernel::Sphere_3 s)*

returns the sphere with the same center and squared radius as *s*, but with opposite orientation.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Sphere_3<Kernel> . . . . page 666

Functor
Concept

Kernel::ConstructOppositeTriangle_2

A model for this must provide:

Kernel::Triangle_2 *fo.operator()(Kernel::Triangle_2 t)*

returns the triangle with opposite orientation to *t* (this flips the positive and the negative side, but not bounded and unbounded side).

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Triangle_2<Kernel> . . . . page 633

Kernel::ConstructOppositeVector_2

A model for this must provide:

Kernel::Vector_2	*fo.operator()(Kernel::Vector_2 v)*
	returns the vector *-v*.

Functor
Concept

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Vector_2<Kernel> . . . . page 635

Functor
Concept

Kernel::ConstructOppositeVector_3

A model for this must provide:

Kernel::Vector_3	*fo.operator()(Kernel::Vector_3 v)*	
		returns the vector *-v*.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Vector_3<Kernel> . . . . page 673

Kernel::ConstructOrthogonalVector_3

A model for this must provide:

Kernel::Vector_3 *fo.operator()(Kernel::Plane_3 p)*

returns a vector that is orthogonal to the plane *p* and directed to the positive side of *p*.

Kernel::Vector_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*

returns a vector that is orthogonal to the plane defined by *Kernel::ConstructPlane_3()(p, q, r)* and directed to the positive side of this plane.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Plane_3<Kernel> . . . . page 651
Kernel::ConstructCrossProductVector_3 . . . . page 905

Functor
Concept

Kernel::ConstructPerpendicularDirection_2

A model for this must provide:

Kernel::Direction_2	*fo.operator()(Kernel::Direction_2 d, Orientation o)*	
		introduces a direction orthogonal to d. If o is *CLOCKWISE*, d is rotated clockwise; if o is *COUNTERCLOCKWISE*, d is rotated counterclockwise. *Precondition*: o is not *COLLINEAR*.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Direction_2<Kernel> . . . . page 617

Kernel::ConstructPerpendicularLine_2

A model for this must provide:

Kernel::Line_2 *fo.operator()(Kernel::Line_2 l, Kernel::Point_2 p)*

returns the line perpendicular to l and passing through p, where the direction is the direction of l rotated counterclockwise by 90 degrees.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Line_2<Kernel> . . . . page 622

Functor
Concept

Kernel::ConstructPerpendicularLine_3

A model for this must provide:

Kernel::Line_3 *fo.operator()(Kernel::Plane_3 pl, Kernel::Point_3 p)*

returns the line that is perpendicular to *pl* and that passes through point *p*. The line is oriented from the negative to the positive side of *pl*

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Plane_3<Kernel> . . . . page 651

Kernel::ConstructPerpendicularPlane_3

A model for this must provide:

Kernel::Plane_3 *fo.operator()(Kernel::Line_3 l, Kernel::Point_3 p)*

returns the plane perpendicular to l passing through p, such that the normal direction of the plane coincides with the direction of the line.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Plane_3<Kernel> . . . . page 651

Kernel::ConstructPerpendicularVector_2

A model for this must provide:

Kernel::Vector_2	*fo.operator()(Kernel::Vector_2 v, Orientation o)*	
		returns *v* rotated clockwise by 90 degrees, if *o* is *CLOCKWISE*, and rotated counterclockwise otherwise. *Precondition*: *o* is not *COLLINEAR*.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Vector_2<Kernel> . . . . page 635

Kernel::ConstructPlane_3

A model for this must provide:

Kernel::Plane_3 *fo.operator()(Kernel::RT a, Kernel::RT b, Kernel::RT c, Kernel::RT d)*

creates a plane defined by the equation $ax+by+cz+d=0$. Notice that it is degenerate if $a=b=c=0$.

Kernel::Plane_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*

creates a plane passing through the points p, q and r. The plane is oriented such that p, q and r are oriented in a positive sense (that is counterclockwise) when seen from the positive side of the plane. Notice that it is degenerate if the points are collinear.

Kernel::Plane_3 *fo.operator()(Kernel::Point_3 p, Kernel::Direction_3 d)*

introduces a plane that passes through point p and that has as an orthogonal direction equal to d.

Kernel::Plane_3 *fo.operator()(Kernel::Point_3 p, Kernel::Vector_3 v)*

introduces a plane that passes through point p and that is orthogonal to v.

Kernel::Plane_3 *fo.operator()(Kernel::Line_3 l, Kernel::Point_3 p)*

introduces a plane that is defined through the three points *l.point(0)*, *l.point(1)* and p.

Kernel::Plane_3 *fo.operator()(Kernel::Ray_3 r, Kernel::Point_3 p)*

introduces a plane that is defined through the three points *r.point(0)*, *r.point(1)* and p.

Kernel::Plane_3 *fo.operator()(Kernel::Segment_3 s, Kernel::Point_3 p)*

introduces a plane that is defined through the three points *s.source()*, *s.target()* and p.

Kernel::Plane_3 *fo.operator()(Kernel::Circle_3 c)*

introduces a plane that is defined as the plane containing the circle.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Plane_3<Kernel> . . . . page 651

Kernel::ConstructPointOn_2

A model for this must provide:

Kernel::Point_2 *fo.operator()(Kernel::Line_2 l, int i)*

returns an arbitrary point on *l*. It holds *point(i)* == *point(j)*, iff *i==j*. Furthermore, is directed from *point(i)* to *point(j)*, for all $i < j$.

Kernel::Point_2 *fo.operator()(Kernel::Ray_2 r, int i)*

returns a point on r. *point(0)* is the source, *point(i)*, with $i > 0$, is different from the source.
Precondition: $i \geq 0$.

Kernel::Point_2 *fo.operator()(Kernel::Segment_2 s, int i)*

returns source or target of *s*: *point(0)* returns the source of *s*, *point(1)* returns the target of *s*. The parameter *i* is taken modulo 2, which gives easy access to the other end point.

Refines

AdaptableFunctor (with two arguments)

CGAL::Segment_2<Kernel> . . . . page 631

Kernel::ConstructPointOn_3

A model for this must provide:

Kernel::Point_3 *fo.operator()(Kernel::Line_3 l, int i)*

returns an arbitrary point on l. It holds *point(i)* == *point(j)*, iff *i==j*. Furthermore, is directed from *point(i)* to *point(j)*, for all $i < j$.

Kernel::Point_3 *fo.operator()(Kernel::Plane_3 h)*

returns an arbitrary point on h.

Kernel::Point_3 *fo.operator()(Kernel::Ray_3 r, int i)*

returns a point on r. *point(0)* is the source, *point(i)*, with $i > 0$, is different from the source.
Precondition: $i \geq 0$.

Kernel::Point_3 *fo.operator()(Kernel::Segment_3 s, int i)*

returns source or target of s: *point(0)* returns the source of s, *point(1)* returns the target of s. The parameter i is taken modulo 2, which gives easy access to the other end point.

Kernel::ConstructPoint_2

A model for this must provide:

Kernel::Point_2	*fo.operator()(Origin ORIGIN)*
	introduces a variable with Cartesian coordinates $(0,0)$.

Functor
Concept

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Point_2<Kernel> . . . . page 625

Kernel::ConstructPoint_3

A model for this must provide:

Kernel::Point_3 *fo.operator()(Origin ORIGIN)*

introduces a point with Cartesian coordinates $(0,0,0)$.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Point_3<Kernel> . . . . page 655

Kernel::ConstructProjectedPoint_2

A model for this must provide:

Kernel::Point_2 *fo.operator()(Kernel::Line_2 l, Kernel::Point_2 p)*

returns the orthogonal projection of *p* onto *l*.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Line_2<Kernel> . . . . page 622

Kernel::ConstructProjectedPoint_3

A model for this must provide:

Kernel::Point_3 *fo.operator()(Kernel::Line_3 l, Kernel::Point_3 p)*

returns the orthogonal projection of *p* onto *l*.

Kernel::Point_3 *fo.operator()(Kernel::Plane_3 h, Kernel::Point_3 p)*

returns the orthogonal projection of *p* onto *h*.

Refines

AdaptableFunctor (with two arguments)

CGAL::Line_3<Kernel> . . . . page 649
CGAL::Plane_3<Kernel> . . . . page 651

Kernel::ConstructProjectedXYPoint_2

A model for this must provide:

Kernel::Point_2	*fo.operator()(Kernel::Plane_3 h, Kernel::Point_3 p)*	
		returns the image point of the projection of p under an affine transformation, which maps h onto the xy-plane, with the z-coordinate removed.

Functor
Concept

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Plane_3<Kernel> . . . . page 651

Kernel::ConstructRadicalLine_2

A model for this must provide:

Kernel::Line_2 *fo.operator()(Kernel::Circle_2 c1, Kernel::Circle_2 c2)*

returns the radical line of the circles.
Precondition: The two circles don't have the same center.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Circle_2<Kernel> . . . . page 614

Kernel::ConstructRadicalPlane_3

A model for this must provide:

Kernel::Plane_3	*fo.operator()(Kernel::Sphere_3 sphere1, Kernel::Sphere_3 sphere2)*	
		returns the radical plane of the spheres. *Precondition*: The two spheres don't have the same center.

Refines

AdaptableFunctor (with two argument)

See Also

CGAL::Sphere_3<Kernel> . . . . page 666

Kernel::ConstructRay_2

A model for this must provide:

Kernel::Ray_2 *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q)*

introduces a ray with source p and passing through point q.

Kernel::Ray_2 *fo.operator()(Kernel::Point_2 p, Kernel::Vector_2 v)*

introduces a ray starting at source p with the direction given by v.

Kernel::Ray_2 *fo.operator()(Kernel::Point_2 p, Kernel::Direction_2 d)*

introduces a ray starting at source p with direction d.

Kernel::Ray_2 *fo.operator()(Kernel::Point_2 p, Kernel::Line_2 l)*

introduces a ray starting at source p with the same direction as l.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Ray_2<Kernel> . . . . page 629

Kernel::ConstructRay_3

A model for this must provide:

Kernel::Ray_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q)*

introduces a ray with source p and passing through point q.

Kernel::Ray_3 *fo.operator()(Kernel::Point_3 p, Kernel::Vector_3 v)*

introduces a ray with source p and with the direction given by v.

Kernel::Ray_3 *fo.operator()(Kernel::Point_3 p, Kernel::Direction_3 d)*

introduces a ray with source p and with direction d.

Kernel::Ray_3 *fo.operator()(Kernel::Point_3 p, Kernel::Line_3 l)*

introduces a ray with source p and with the same direction as l.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Ray_3<Kernel> . . . . page 659

Kernel::ConstructScaledVector_2

A model for this must provide:

Kernel::Vector_2	*fo.operator()(Kernel::Vector_2 v, Kernel::RT scale)*	
		produces the vector *v* scaled by a factor *scale*.
Kernel::Vector_2	*fo.operator()(Kernel::Vector_2 v, Kernel::FT scale)*	
		produces the vector *v* scaled by a factor *scale*.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Vector_2<Kernel> . . . . page 635

Kernel::ConstructScaledVector_3

A model for this must provide:

Kernel::Vector_3 *fo.operator()(Kernel::Vector_3 v, Kernel::RT scale)*

produces the vector *v* scaled by a factor *scale*.

Kernel::Vector_3 *fo.operator()(Kernel::Vector_3 v, Kernel::FT scale)*

produces the vector *v* scaled by a factor *scale*.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Vector_3<Kernel> . . . . page 673

Kernel::ConstructSecondPoint_2

A model for this must provide:

Kernel::Point_2	*fo.operator()(Kernel::Ray_2 r)*
	returns a point different from the source on the ray *r*.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Ray_2<Kernel> . . . . page 629

Kernel::ConstructSegment_2

A model for this must provide:

Kernel::Segment_2	*fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q)*	
		introduces a segment with source p and target q. The segment is directed from the source towards the target.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Segment_2<Kernel> . . . . page 631

Functor
Concept

Kernel::ConstructSegment_3

A model for this must provide:

Kernel::Segment_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q)*

introduces a segment with source p and target q. It is directed from the source towards the target.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Segment_3<Kernel> . . . . page 661

Kernel::ConstructSource_2

Functor
Concept

A model for this must provide:

Kernel::Point_2 *fo.operator()(Kernel::Segment_2 s)*

returns the source of the segment s.

Kernel::Point_2 *fo.operator()(Kernel::Ray_2 r)*

returns the source of the ray r.

Refines

AdaptableFunctor (with one argument)

See Also

CGAL::Segment_2<Kernel> . . . . page 631
CGAL::Ray_2<Kernel> . . . . page 629

Kernel::ConstructSphere_3

A model for this must provide:

Kernel::Sphere_3 *fo.operator()(Kernel::Point_3 center, Kernel::FT squared_radius, Orientation orientation = COUNTERCLOCKWISE)*

introduces a sphere initialized to the sphere with center *center*, squared radius *squared_radius* and orientation *orientation*.
Precondition: *orientation* $\neq$ *COPLANAR*, and furthermore, *squared_radius* ≥ 0.

Kernel::Sphere_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r, Kernel::Point_3 s)*

introduces a sphere initialized to the unique sphere which passes through the points p, q, r and s. The orientation of the sphere is the orientation of the point quadruple p, q, r, s.
Precondition: p, q, r, and s are not coplanar.

Kernel::Sphere_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r, Orientation o = COUNTERCLOCKWISE)*

introduces a sphere initialized to the smallest sphere which passes through the points p, q, and r. The orientation of the sphere is o.
Precondition: o is not *COPLANAR*.

Kernel::Sphere_3 *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Orientation o = COUNTERCLOCKWISE)*

introduces a sphere initialized to the smallest sphere which passes through the points p and q. The orientation of the sphere is o.
Precondition: o is not *COPLANAR*.

Kernel::Sphere_3 *fo.operator()(Kernel::Point_3 center, Orientation orientation = COUNTERCLOCKWISE)*

introduces a sphere s initialized to the sphere with center *center*, squared radius zero and orientation *orientation*.
Precondition: *orientation* $\neq$ *COPLANAR*.
Postcondition: *s.is_degenerate()* = *true*.

Kernel::Sphere_3   *fo.operator()(Kernel::Circle_3 c)*

introduces a sphere initialized to the diametral sphere of the circle.

Refines

AdaptableFunctor (with four arguments)

CGAL::Segment_2<Kernel> . . . . page 631

Functor
Concept

Kernel::ConstructTetrahedron_3

A model for this must provide:

Kernel::Tetrahedron_3 *fo.operator()(Kernel::Point_3 p0,*
Kernel::Point_3 p1,
Kernel::Point_3 p2,
Kernel::Point_3 p3)

introduces a tetrahedron with vertices p_0, p_1, p_2 and p_3.

Refines

AdaptableFunctor (with four arguments)

See Also

CGAL::Tetrahedron_3<Kernel> . . . . page 669

Kernel::ConstructTranslatedPoint_2

A model for this must provide:

Kernel::Point_2 *fo.operator()(Kernel::Point_2 p, Kernel::Vector_2 v)*

returns the point obtained by translating *p* by the vector *v*.

Kernel::Point_2 *fo.operator()(Origin o, Kernel::Vector_2 v)*

returns the point obtained by translating a point at the origin by the vector *v*.

Refines

AdaptableFunctor (with two arguments)

See Also

CGAL::Point_2<Kernel> . . . . page 625

Kernel::ConstructTranslatedPoint_3

A model for this must provide:

Kernel::Point_3 *fo.operator()(Kernel::Point_3 p, Kernel::Vector_3 v)*

returns the point obtained by translating p by the vector v.

Kernel::Point_3 *fo.operator()(Origin o, Kernel::Vector_3 v)*

returns the point obtained by translating a point at the origin by the vector v.

Refines

AdaptableFunctor (with two arguments)

Functor
Concept

Kernel::ConstructTriangle_3

A model for this must provide:

Kernel::Triangle_3	*fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*
	introduces a triangle with vertices p, q and r.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::Triangle_3<Kernel> . . . . page 671

Kernel::ConstructUnitNormal_3

A model for this must provide:

Kernel::Vector_3	*fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*	
		computes the unit normal of the vectors*q-p* and *r-p*. This requires that *Kernel::FT* supports the *sqrt* operation.

Refines

AdaptableFunctor (with three arguments)

See Also

CGAL::normal . . . . page 755
CGAL::unit_normal . . . . page 777

Kernel::ConstructVector_2

A model for this must provide:

Kernel::Vector_2 *fo.operator()(Kernel::Point_2 a, Kernel::Point_2 b)*

introduces the vector $b - a$.

Kernel::Vector_2 *fo.operator()(Origin o, Kernel::Point_2 b)*

introduces the vector b.

Kernel::Vector_2 *fo.operator()(Kernel::Point_2 a, Origin o)*

introduces the vector $-a$.

Kernel::Vector_2 *fo.operator()(Kernel::Segment_2 s)*

introduces the vector $s.target() - s.source()$.

Kernel::Vector_2 *fo.operator()(Kernel::Ray_2 r)*

introduces a vector having the same direction as r.

Kernel::Vector_2 *fo.operator()(Kernel::Line_2 l)*

introduces a vector having the same direction as l.

Kernel::Vector_2 *fo.operator()(Null_vector NULL_VECTOR)*

introduces a null vector .

Refines

AdaptableFunctor (with two arguments)

Kernel::ConstructVertex_3

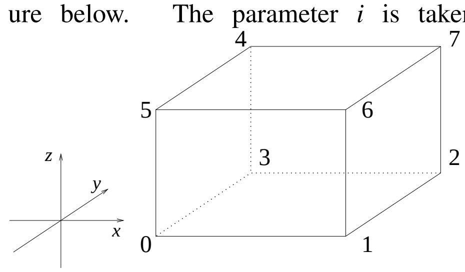
A model for this must provide:

Kernel::Point_3 *fo.operator()(Kernel::Segment_3 s, int i)*

returns source or target of *s*: *fo(s,0)* returns the source of *s*, *fo(s,1)* returns the target of *s*. The parameter *i* is taken modulo 2.

Kernel::Point_3 *fo.operator()(Kernel::Iso_cuboid_3 c, int i)*

returns the i'th vertex of *c*, as indicated in the figure below. The parameter *i* is taken modulo 8.



Kernel::Point_3 *fo.operator()(Kernel::Triangle_3 t, int i)*

returns the i'th vertex of *t*. The parameter *i* is taken modulo 3.

Kernel::Point_3 *fo.operator()(Kernel::Tetrahedron_3 t, int i)*

returns the i'th vertex of *t*. The parameter *i* is taken modulo 4.

Concept

Kernel::CartesianConstIterator_2

A type representing an iterator to the Cartesian coordinates of a point in two dimensions.

Refines

CopyConstructible, Assignable, DefaultConstructible

See Also

Kernel::ConstructCartesianConstIterator_2 . . . . page 894

Kernel::CartesianConstIterator_3

A type representing an iterator to the Cartesian coordinates of a point in three dimensions.

Refines

CopyConstructible, Assignable, DefaultConstructible

See Also

Kernel::ConstructCartesianConstIterator_3 . . . . page 895

Concept

Kernel::CoplanarOrientation_3

A model for this must provide:

Orientation *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r, Kernel::Point_3 s)*

Let P be the plane defined by the points p, q, and r. Note that the order defines the orientation of P. The function computes the orientation of points p, q, and s in P: Iff p, q, s are collinear, *COLLINEAR* is returned. Iff P and the plane defined by p, q, and s have the same orientation, *POSITIVE* is returned; otherwise *NEGATIVE* is returned. *Precondition*: p, q, r, and s are coplanar and p, q, and r are not collinear.

Orientation *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r)*

If p,q,r are collinear, then *COLLINEAR* is returned. If not, then p,q,r define a plane P. The return value in this case is either *POSITIVE* or *NEGATIVE*, but we don't specify it explicitly. However, we guarantee that all calls to this predicate over 3 points in P will return a coherent orientation if considered a 2D orientation in P.

Kernel::CoplanarSideOfBoundedCircle_3

A model for this must provide:

Bounded_side *fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r, Kernel::Point_3 s)*

returns the bounded side of the circle defined by p, q, and r on which s lies.
Precondition: p, q, r, and s are coplanar and p, q, and r are not collinear.

Refines

AdaptableFunctor (with four arguments)

Concept

Kernel::SideOfOrientedCircle_2

A model for this must provide:

Oriented_side *fo.operator()(Kernel::Point_2 p, Kernel::Point_2 q, Kernel::Point_2 r, Kernel::Point_2 t)*

returns the relative position of point t to the oriented circle defined by p, q and r. The order of the points p, q and r is important, since it determines the orientation of the implicitly constructed circle.
If p, q and r are collinear, the circle degenerates in a line. *ON_ORIENTED_BOUNDARY* is returned if t is also collinear or if two points are identical, otherwise, *side_of_oriented_circle(r, q, t, p)* is returned.

Refines

AdaptableFunctor (with four arguments)

See Also

CGAL::side_of_oriented_circle . . . . page 771

Kernel::SideOfOrientedSphere_3

A model for this must provide:

Oriented_side	*fo.operator()(Kernel::Point_3 p, Kernel::Point_3 q, Kernel::Point_3 r, Kernel::Point_3 s, Kernel::Point_3 t)*	

returns the relative position of point t to the oriented sphere defined by p, q, r and s. The order of the points p, q, r, and s is important, since it determines the orientation of the implicitly constructed sphere. If the points p, q, r and s are positive oriented, positive side is the bounded interior of the sphere.
In case of degeneracies, *ON_ORIENTED_BOUNDARY* is returned if all points are coplanar. Otherwise, there is a cyclic permutation of the five points that puts four non coplanar points first, it is used to answer the predicate: e.g. *side_of_oriented_sphere(q, r, s, t, p)* is returned if q, r, s, and t are non coplanar.

11.16 Dimension handling tools

CGAL::Ambient_dimension<T, K>

Definition

The class *Ambient_dimension<T, K>* allows to retrieve the dimension of the ambient space of a type *T* in a kernel *K*.

Parameters

The parameter *K* has the default value *Kernel_traits<T>::Kernel>*.

#include <CGAL/Dimension.h>

Constants

static const int	*value;*	The dimension value as a compile-time integral constant. It is implemented as *K::Dimension<T>::type::value*. It exists only when the dimension is a compile-time constant.

Types

Ambient_dimension<T, K>:: type	Either *Dimension_tag<dim>* if the dimension is a compile-time constant of value *dim*, or *Dynamic_dimension_tag* otherwise. It is implemented as *K::Ambient_dimension<T>::type*.

Example

The following retrieves the dimension of a point type.

```
typedef K::Point_2 Point;
int dimension = Ambient_dimension<Point, K>::value;
assert(dimension == 2);
```

CGAL::Dimension_tag<int dim> . . . . page 1044
CGAL::Dynamic_dimension_tag . . . . page 1045
CGAL::Feature_dimension<T, K> . . . . page 1043

Class

CGAL::Feature_dimension<T, K>

Definition

The class *Feature_dimension<T, K>* allows to retrieve the geometric dimension of a type *T* in a kernel *K*.

Parameters

The parameter *K* has the default value *Kernel_traits<T>::Kernel*.

#include <CGAL/Dimension.h>

Constants

static const int	*value;*	The dimension value as a compile-time integral constant. It is implemented as *K::Feature_dimension<T> ::type::value*. It exists only when the dimension is a compile-time constant.

Types

Feature_dimension<T, K>:: type	Either *Dimension_tag<dim>* if the dimension is a compile-time constant of value *dim*, or *Dynamic_dimension_tag* otherwise. It is implemented as *K::Feature_dimension<T>::type*.

Example

The following retrieves the dimension of a point type.

```
typedef K::Point_2 Point;
int dimension = Feature_dimension<Point, K>::value;
assert(dimension == 0);
```

See Also

CGAL::Dimension_tag<int dim> . . . . page 1044
CGAL::Dynamic_dimension_tag . . . . page 1045
CGAL::Ambient_dimension<T, K> . . . . page 1042

Class

CGAL::Dimension_tag<int dim>

Definition

An object of the class *Dimension_tag<int dim>* is an empty object which can be used for dispatching functions based on the dimension of an object, as provided by the *dim* parameter. It is useful in cases where it is not more practical to pass the dimension as a template parameter directly.

#include <CGAL/Dimension.h>

Constants

static const int	*value;*	The value of the *dim* parameter.

Example

The following code declares two functions constructing two points at the origin, either in 2D or in 3D.

```
Point_2<K> get_origin(Dimension_tag<2>) { return Point_2<K>(ORIGIN); }
Point_3<K> get_origin(Dimension_tag<3>) { return Point_3<K>(ORIGIN); }

std::cout << get_origin(Dimension_tag<2>())) << std::endl;
```

CGAL::Dynamic_dimension_tag

Class

Definition

An object of the class *Dynamic_dimension_tag* is an empty object which can be used for dispatching functions based on the dimension of an object. *Dynamic_dimension_tag* indicates that the dimension is not known at compile-time. *Dimension_tag* is the tag class dealing with compile-time dimensions.

#include <CGAL/Dimension.h>

Example

The following code declares two functions constructing two points at the origin, either in 2D or in 3D.

```
Point_2<K> get_origin(Dimension_tag<2>) { return Point_2<K>(ORIGIN); }
Point_3<K> get_origin(Dimension_tag<3>) { return Point_3<K>(ORIGIN); }
Point_d<K> get_origin(Dynamic_dimension_tag) { return Point_d<K>(ORIGIN); }

std::cout << get_origin(Dynamic_dimension_tag()) << std::endl;
```

Chapter 12

dD Geometry Kernel

Michael Seel

Contents

12.1 Introduction

This part of the reference manual covers the higher-dimensional kernel. The kernel contains objects of constant size, such as point, vector, direction, line, ray, segment, circle. With each type comes a set of functions which can be applied to an object of this type. You will typically find access functions (e.g. to the coordinates of a point), tests of the position of a point relative to the object, a function returning the bounding box, the length, or the area of an object, and so on. The CGAL kernel further contains basic operations such as affine transformations, detection and computation of intersections, and distance computations. Note that this section partly recapitulates facts already mentioned for the lower-dimensional kernel.

12.1.1 Robustness

The correctness proof of nearly all geometric algorithms presented in theory papers assumes exact computation with real numbers. This leads to a fundamental problem with the implementation of geometric algorithms. Naively, often the exact real arithmetic is replaced by inexact floating-point arithmetic in the implementation. This often leads to acceptable results for many input data. However, even for the implementation of the simplest geometric algorithms this simplification occasionally does not work. Rounding errors introduced by inaccurate arithmetic may lead to inconsistent decisions, causing unexpected failures for some correct input data. There are many approaches to this problem, one of them is to compute exactly (compute so accurate that all decisions made by the algorithm are exact) which is possible in many cases but more expensive than standard floating-point arithmetic. C. M. Hoffmann [Hof89a, Hof89b] illustrates some of the problems arising in the implementation of geometric algorithms and discusses some approaches to solve them. A more recent overview is given in [Sch00]. The exact computation paradigm is discussed by Yap and Dubé [YD95] and Yap [Yap97].

In CGAL you can choose the underlying number types and arithmetic. You can use different types of arithmetic simultaneously and the choice can be easily changed, e.g. for testing. So you can choose between implementations with fast but occasionally inexact arithmetic and implementations guaranteeing exact computation and exact results. Of course you have to pay for the exactness in terms of execution time and storage space. See the dedicated chapter for more details on number types and their capabilities and performance.

12.1.2 Genericity

To increase generic usage of objects and predicates the higher-dimensional kernel makes heavy use of iterator ranges as defined in the STL for modeling tuples. Iterators conceptualize C++ pointers.

For an iterator range *[first,last)* we define *T = tuple [first,last)* as the ordered tuple $(T[0],T[1],\ldots T[d-1])$ where $S[i] = *++^{(i)}\mathit{first}$ (the element obtained by i times forwarding the iterator by operator ++ and then dereferencing it to get the value to which it points). We write *d = size [first,last)* and *S = set [first,last)* to denote the unordered set of elements of the corresponding tuple.

This extends the syntax of random access iterators to input iterators. If we index the tuple as above then we require that $++^{(d+1)}\mathit{first} = \mathit{last}$.

12.2 Kernel Representations

Our object of study is the d-dimensional affine Euclidean space, where d is a parameter of our geometry. Objects in that space are sets of points. A common way to represent the points is the use of Cartesian coordinates, which assumes a reference frame (an origin and d orthogonal axes). In that framework, a point is represented by a

d-tuple $(c_0, c_1, \ldots, c_{d-1})$, and so are vectors in the underlying linear space. Each point is represented uniquely by such Cartesian coordinates.

Another way to represent points is by homogeneous coordinates. In that framework, a point is represented by a $(d+1)$-tuple $(h_0, h_1, \ldots, h_d)$. Via the formulae $c_i = h_i/h_d$, the corresponding point with Cartesian coordinates $(c_0, c_1, \ldots, c_{d-1})$ can be computed. Note that homogeneous coordinates are not unique. For $\lambda \neq 0$, the tuples $(h_0, h_1, \ldots, h_d)$ and $(\lambda \cdot h_0, \lambda \cdot h_1, \ldots, \lambda \cdot h_d)$ represent the same point. For a point with Cartesian coordinates $(c_0, c_1, \ldots, c_{d-1})$ a possible homogeneous representation is $(c_0, c_1, \ldots, c_{d-1}, 1)$. Homogeneous coordinates in fact allow to represent objects in a more general space, the projective space $\mathbb{P}^d$. In CGAL, we do not compute in projective geometry. Rather, we use homogeneous coordinates to avoid division operations, since the additional coordinate can serve as a common denominator.

12.2.1 Genericity through Parameterization

Almost all the kernel objects (and the corresponding functions) are templates with a parameter that allows the user to choose the representation of the kernel objects. A type that is used as an argument for this parameter must fulfill certain requirements on syntax and semantics. The list of requirements defines an abstract kernel concept. In CGAL such a kernel concept is often also called a *representation class* and denoted by *R*. A representation class provides the actual implementations of the kernel objects. For all kernel objects *Kernel_object*, the types *CGAL::Kernel_object*<*R*> and *R::Kernel_object* are identical.

CGAL offers two families of concrete models for the concept representation class, one based on the Cartesian representation of points and one based on the homogeneous representation of points. The interface of the kernel objects is designed such that it works well with both Cartesian and homogeneous representation, for example, points have a constructor with a range of coordinates plus a common denominator (the $d+1$ homogeneous coordinates of the point). The common interfaces parameterized with a representation class allow one to develop code independent of the chosen representation. We said "families" of models, because both families are parameterized too. A user can choose the number type used to represent the coordinates and the linear algebra module used to calculate the result of predicates and constructions.

For reasons that will become evident later, a representation class provides two typenames for number types, namely *R::FT* and *R::RT* and one typename for the linear algebra module *R::LA*. The type *R::FT* must fulfill the requirements on what is called a *field type* in CGAL. This roughly means that *R::FT* is a type for which operations $+$, $-$, $*$ and $/$ are defined with semantics (approximately) corresponding to those of a field in a mathematical sense. Note that, strictly speaking, the built-in type *int* does not fulfill the requirements on a field type, since *int*s correspond to elements of a ring rather than a field, especially operation $/$ is not the inverse of $*$. The requirements on the type *R::RT* are weaker. This type must fulfill the requirements on what is called an *Euclidean ring type* in CGAL. This roughly means that *R::RT* is a type for which operations $+$, $-$, $*$ are defined with semantics (approximately) corresponding to those of a ring in a mathematical sense. A very limited division operation $/$ must be available as well. It must work for exact (i.e., no remainder) integer divisions only. Furthermore, both number types should fulfill CGAL's requirements on a number type.

12.2.2 Cartesian Kernel

With *Cartesian_d*<*FieldNumberType,LinearAlgebra*> you can choose Cartesian representation of coordinates. The type *LinearAlgebra* must me a linear algebra module working on numbers of type *FieldNumberType*. The second parameter defaults to module delivered with the kernel so for short a user can just write *Cartesian_d*< *FieldNumberType*> when not providing her own linear algebra.

When you choose Cartesian representation you have to declare at least the type of the coordinates. A number type used with the *Cartesian_d* representation class should be a *field type* as described above. Both *Carte-*

sian<FieldNumberType>::FT and *Cartesian<FieldNumberType>::RT* are mapped to number type *FieldNumberType*. *Cartesian_d<FieldNumberType,LinearAlgebra>::LA* is mapped to the type *LinearAlgebra*. *Cartesian<FieldNumberType>* uses reference counting internally to save copying costs.

12.2.3 Homogeneous Kernel

As we mentioned before, homogeneous coordinates permit to avoid division operations in numerical computations, since the additional coordinate can serve as a common denominator. Avoiding divisions can be useful for exact geometric computation. With *Homogeneous_d<RingNumberType,LinearAlgebra>* you can choose homogeneous representation of coordinates with the kernel objects. As for Cartesian representation you have to declare at the same time the type used to store the homogeneous coordinates. Since the homogeneous representation allows one to avoid the divisions, the number type associated with a homogeneous representation class must be a model for the weaker concept Euclidean ring type only.

The type *LinearAlgebra* must me a linear algebra module working on numbers of type *RingNumberType*. Again the second parameter defaults to module delivered with the kernel so for short one can just write *Homogeneous_d<RingNumberType>* when replacing the default is no issue.

However, some operations provided by this kernel involve division operations, for example computing squared distances or returning a Cartesian coordinate. To keep the requirements on the number type parameter of *Homogeneous* low, the number type *Quotient<RingNumberType>* is used instead. This number type turns a ring type into a field type. It maintains numbers as quotients, i.e. a numerator and a denominator. Thereby, divisions are circumvented. With *Homogeneous_d<RingNumberType>*, *Homogeneous_d<RingNumberType>::FT* is equal to *Quotient<RingNumberType>* while *Homogeneous_d<RingNumberType>::RT* is equal to *RingNumberType*. *Homogeneous_d<RingNumberType,LinearAlgebra>::LA* is mapped to the type *LinearAlgebra*.

12.2.4 Naming conventions

The use of representation classes not only avoids problems, it also makes all CGAL classes very uniform. They **always** consist of:

1. The *capitalized base name* of the geometric object, such as *Point*, *Segment*, *Triangle*.
2. Followed by *_d*.
3. A *representation class* as parameter, which itself is parameterized with a number type, such as *Cartesian_d<double>* or *Homogeneous_d<leda_integer>*.

12.2.5 Kernel as a Traits Class

Algorithms and data structures in the basic library of CGAL are parameterized by a traits class that subsumes the objects on which the algorithm or data structure operates as well as the operations to do so. For most of the algorithms and data structures in the basic library you can use a kernel as a traits class. For some algorithms you even do not have to specify the kernel; it is detected automatically using the types of the geometric objects passed to the algorithm. In some other cases, the algorithms or data structures needs more than is provided by a kernel. In these cases, a kernel can not be used as a traits class.

12.2.6 Choosing a Kernel

If you start with integral Cartesian coordinates, many geometric computations will involve integral numerical values only. Especially, this is true for geometric computations that evaluate only predicates, which are tantamount to determinant computations. Examples are triangulation of point sets and convex hull computation.

The dimension d of our affine space determines the dimension of the matrix computations in the mathematical evaluation of predicates. As rounding errors accumulate fast the homogeneous representation used with multi-precision integers is the kernel of choice for well-behaved algorithms. Note, that unless you use an arbitrary precision integer type, incorrect results might arise due to overflow.

If new points are to be constructed, for example the intersection point of two lines, computation of Cartesian coordinates usually involves divisions, so you need to use a field type with Cartesian representation or have to switch to homogeneous representation. *double* is a possible, but imprecise field type. You can also put any ring type into *Quotient* to get a field type and put it into *Cartesian*, but you better put the ring type into *Homogeneous*. *leda_rational* and *leda_real* are valid field types, too.

Still other people will prefer the built-in type `double`, because they need speed and can live with approximate results, or even algorithms that, from time to time, crash or compute incorrect results due to accumulated rounding errors.

12.2.7 Inclusion of Header Files

You need just to include a representation class to obtain the geometric objects of the kernel that you would like to use with the representation class, i.e., *CGAL/Cartesian_d.h* or *CGAL/Homogeneous_d.h*

12.3 Kernel Geometry

12.3.1 Points and Vectors

In CGAL, we strictly distinguish between points, vectors and directions. A *point* is a point in the Euclidean space $\mathbb{E}^d$, a *vector* is the difference of two points p_2, p_1 and denotes the direction and the distance from p_1 to p_2 in the vector space $\mathbb{R}^d$, and a *direction* is a vector where we forget about its length. They are different mathematical concepts. For example, they behave different under affine transformations and an addition of two points is meaningless in affine geometry. By putting them in different classes we not only get cleaner code, but also type checking by the compiler which avoids ambiguous expressions. Hence, it pays twice to make this distinction.

CGAL defines a symbolic constant *ORIGIN* of type *Origin* which denotes the point at the origin. This constant is used in the conversion between points and vectors. Subtracting it from a point p results in the locus vector of p.

```
double coord[] = {1.0, 1.0, 1.0, 1.0};
Point_d< Cartesian_d<double> > p(4,coord,coord+4), q(4);
Vector_d< Cartesian_d<double> > v(4);
v = p - ORIGIN;
q = ORIGIN + v;
assert( p == q );
```

In order to obtain the point corresponding to a vector v you simply have to add v to *ORIGIN*. If you want to determine the point q in the middle between two points p_1 and p_2, you can write[1]

```
q = p_1 + (p_2 - p_1) / 2.0;
```

Note that these constructions do not involve any performance overhead for the conversion with the currently available representation classes.

12.3.2 Kernel Objects

Besides points (*Point_d*<*R*>), vectors (*Vector_d*<*R*>), and directions (*Direction_d*<*R*>), CGAL provides lines, rays, segments, hyperplanes, and spheres.

Lines (*Line_d*<*R*>) in CGAL are oriented. A ray (*Ray_d*<*R*>) is a semi-infinite interval on a line, and this line is oriented from the finite endpoint of this interval towards any other point in this interval. A segment (*Segment_d*< *R*>) is a bounded interval on a directed line, and the endpoints are ordered so that they induce the same direction as that of the line.

Hyperplanes are affine subspaces of dimension $d-1$ in $\mathbb{E}^d$, passing through d points. Hyperplanes are oriented and partition space into a positive side and a negative side. In CGAL, there are no special classes for halfspaces. Halfspaces are supposed to be represented by oriented hyperplanes. All kernel objects are equality comparable via *operator*== and *operator!*=. For those oriented objects whose orientation can be reversed (segments, lines, hyperplanes, spheres) there is also a global function *weak_equality* that allows to test for point set equality disregarding the orientation.

12.3.3 Orientation and Relative Position

Geometric objects in CGAL have member functions that test the position of a point relative to the object. Full dimensional objects and their boundaries are represented by the same type, e.g. halfspaces and hyperplanes are not distinguished, neither are balls and spheres. Such objects split the ambient space into two full-dimensional parts, a bounded part and an unbounded part (e.g. spheres), or two unbounded parts (e.g. hyperplanes). By default these objects are oriented, i.e., one of the resulting parts is called the positive side, the other one is called the negative side. Both of these may be unbounded.

For these objects there is a function *oriented_side()* that determines whether a test point is on the positive side, the negative side, or on the oriented boundary. These function returns a value of type *Oriented_side*.

Those objects that split the space in a bounded and an unbounded part, have a member function *bounded_side()* with return type *Bounded_side*.

If an object is lower dimensional, e.g. a segment in d-dimensional space, there is only a test whether a point belongs to the object or not. This member function, which takes a point as an argument and returns a Boolean value, is called *has_on()*

[1] you might call *midpoint(p_1,p_2)* instead

12.4 Predicates and Constructions

12.4.1 Predicates

Predicates are at the heart of a geometry kernel. They are basic units for the composition of geometric algorithms and encapsulate decisions. Hence their correctness is crucial for the control flow and hence for the correctness of an implementation of a geometric algorithm. CGAL uses the term predicate in a generalized sense. Not only components returning a Boolean value are called predicates but also components returning an enumeration type like a *Comparison_result* or an *Orientation*. We say components, because predicates are implemented both as functions and function objects (also called functors and provided by a kernel class).

CGAL provides predicates for the orientation of point sets (*orientation*), for comparing points according to some given order, especially for comparing Cartesian coordinates (e.g. *lexicographically_xy_smaller*), in-sphere tests, and predicates to compare distances.

12.4.2 Constructions

Functions and function objects that generate objects that are neither of type *bool* nor enum types are called constructions. Constructions involve computation of new numerical values and may be imprecise due to rounding errors unless a kernel with an exact number type is used.

Affine transformations (*Aff_transformation_d<R>*) allow to generate new object instances under arbitrary affine transformations. These transformations include translations, rotations (within planes) and scaling. Most of the geometric objects in a kernel have a member function *transform(Aff_transformation t)* which applies the transformation to the object instance.

CGAL also provides a set of functions that detect or compute the intersection between objects and functions to calculate their squared distance. Moreover, some member functions of kernel objects are constructions.

So there are routines that compute the square of the Euclidean distance, but no routines that compute the distance itself. Why? First of all, the two values can be derived from each other quite easily (by taking the square root or taking the square). So, supplying only the one and not the other is only a minor inconvenience for the user. Second, often either value can be used. This is for example the case when (squared) distances are compared. Third, the library wants to stimulate the use of the squared distance instead of the distance. The squared distance can be computed in more cases and the computation is cheaper. We do this by not providing the perhaps more natural routine, The problem of a distance routine is that it needs the *sqrt* operation. This has two drawbacks:

- The *sqrt* operation can be costly. Even if it is not very costly for a specific number type and platform, avoiding it is always cheaper.
- There are number types on which no *sqrt* operation is defined, especially integer types and rationals.

12.4.3 Intersection and Polymorphic Return Values

Intersections on kernel objects currently cover only those objects that are part of flats (*Segment_d<R>*, *Ray_d<R>*, *Line_c<R>*, and *Hyperplane_d<R>*). For any pair of objects $o1$, $o2$ of these types the operation *intersection(o1,o2)* returns a polymorphic object that wraps the result of the intersection operation.

The class *Object* provides the polymorphic abstraction. An object *obj* of type *Object* can represent an arbitrary class. The only operations it provides is to make copies and assignments, so that you can put them in lists or arrays. Note that *Object* is NOT a common base class for the elementary classes. Therefore, there is no automatic conversion from these classes to *Object* Rather this is done with the global function *make_object()*. This encapsulation mechanism requires the use of *object_cast* to unwrap the encapsulated class.

Example

In the following example, the object type is used as a return value for the intersection computation, as there are possibly different return values.

```
typedef Point_d< Cartesian_d<double> >    Point;
typedef Segment_d< Cartesian_d<double> >  Segment;
Segment s1, s2;
std::cin >> s1 >> s2;
Object obj = intersection(s1, s2);
if (const Point *p = object_cast<Point>(&obj) ) {
  /* do something with *p */
} else if (const Segment *s = object_cast&lt;Segment&gt;(&obj) ) {
  /* do something with *s */
}
/* there was no intersection */
```

12.4.4 Constructive Predicates

For testing where a point p lies with respect to a hyperplane defined by an array P of points $p_1, \dots, p_d$, one may be tempted to construct the hyperplane *Hyperplane_d<R>(d,P,P+d)* and use the method *oriented_side(p)*. This may pay off if many tests with respect to the plane are made. Nevertheless, unless the number type is exact, the constructed plane is only approximated, and round-off errors may lead *oriented_side(p)* to return an orientation which is different from the orientation of $p_1, \dots, p_d, p$.

In CGAL, we provide predicates in which such geometric decisions are made directly with a reference to the input points in P without an intermediary object like a plane. For the above test, the recommended way to get the result is to use *orientation(P',P'+d)*, where P' is an array containing the points $p_1, \dots, p_d, p$.

For exact number types like *leda_real*, the situation is different. If several tests are to be made with the same plane, it pays off to construct the plane and to use *oriented_side(p)*.

12.5 Design and Implementation History

This higher-dimensional kernel is the result of a long evolving development. A first version of the kernel was offered as a LEDA extension package ddgeo by Kurt Mehlhorn and Michael Seel. The original design was driven by the realization of a d-dimensional convex hull data type developed at the Max-Planck Institut für Informatik.

The code base was discussed and reviewed within the CGAL kernel group (of the low-dimensional kernel). This led to the identification of the concept interfaces and in parallel to adaptations according to the evolution of the low-dimensional kernel. The kernel was revised based on suggestions by Hervé Brönnimann, Michael Hoffmann, and Stefan Schirra.

12.6 Linear Algebra Concepts and Classes

LinearAlgebraTraits_d

Concept

Definition

The data type *LinearAlgebraTraits_d* encapsulates two classes *Matrix*, *Vector* and many functions of basic linear algebra. An instance of data type *Matrix* is a matrix of variables of type *NT*. Accordingly, *Vector* implements vectors of variables of type *NT*. Most functions of linear algebra are *checkable*, i.e., the programs can be asked for a proof that their output is correct. For example, if the linear system solver declares a linear system $Ax = b$ unsolvable it also returns a vector c such that $c^T A = 0$ and $c^T b \neq 0$.

Types

LinearAlgebraTraits_d:: NT — the number type of the components.

LinearAlgebraTraits_d:: Vector — the vector type.

LinearAlgebraTraits_d:: Matrix — the matrix type.

Operations

static Matrix *LA.transpose(Matrix M)*

returns M^T (a *M.column_dimension()* $\times$ *M.column_dimension()* - matrix).

static bool *LA.inverse(Matrix M, Matrix& I, NT& D, Vector& c)*

determines whether M has an inverse. It also computes either the inverse as $(1/D) \cdot I$ or when no inverse exists, a vector c such that $c^T \cdot M = 0$.
Precondition: M is square.

static Matrix *LA.inverse(Matrix M, NT& D)*

returns the inverse matrix of M. More precisely, $1/D$ times the matrix returned is the inverse of M.

Precondition: *determinant(M) != 0*.
Precondition: M is square.

static NT *LA.determinant(Matrix M, Matrix& L, Matrix& U, std::vector<int>& q, Vector& c)*

returns the determinant D of M and sufficient information to verify that the value of the determinant is correct. If the determinant is zero then c is a vector such that $c^T \cdot M = 0$. If the determinant is non-zero then L and U are lower and upper diagonal matrices respectively and q encodes a permutation matrix Q with $Q(i,j) = 1$ iff $i = q(j)$ such that $L \cdot M \cdot Q = U$, $L(0,0) = 1$, $L(i,i) = U(i-1,i-1)$ for all i, $1 \leq i < n$, and $D = s \cdot U(n-1,n-1)$ where s is the determinant of Q.
Precondition: M is square.

static bool *LA.verify_determinant(Matrix M,*
NT D,
Matrix& L,
Matrix& U,
std::vector<int> q,
Vector& c)

verifies the conditions stated above.

static NT *LA.determinant(Matrix M)*

returns the determinant of M.
Precondition: M is square.

static int *LA.sign_of_determinant(Matrix M)*

returns the sign of the determinant of M.
Precondition: M is square.

static bool *LA.linear_solver(Matrix M,*
Vector b,
Vector& x,
NT& D,
Matrix& spanning_vectors,
Vector& c)

determines the complete solution space of the linear system $M \cdot x = b$. If the system is unsolvable then $c^T \cdot M = 0$ and $c^T \cdot b \neq 0$. If the system is solvable then $(1/D)x$ is a solution, and the columns of *spanning_vectors* are a maximal set of linearly independent solutions to the corresponding homogeneous system.
Precondition: *M.row_dimension() = b.dimension()*.

static bool *LA.linear_solver(Matrix M, Vector b, Vector& x, NT& D, Vector& c)*

determines whether the linear system $M \cdot x = b$ is solvable. If yes, then $(1/D)x$ is a solution, if not then $c^T \cdot M = 0$ and $c^T \cdot b \neq 0$.
Precondition: *M.row_dimension() = b.dimension()*.

static bool *LA.linear_solver(Matrix M, Vector b, Vector& x, NT& D)*

as above, but without the witness c
Precondition: *M.row_dimension() = b.dimension()*.

static bool *LA.is_solvable(Matrix M, Vector b)*

determines whether the system $M \cdot x = b$ is solvable

Precondition: *M.row_dimension() = b.dimension()*.

static bool *LA.homogeneous_linear_solver(Matrix M, Vector& x)*

determines whether the homogeneous linear system $M \cdot x = 0$ has a non - trivial solution. If yes, then x is such a solution.

static int *LA.homogeneous_linear_solver(Matrix M, Matrix& spanning_vecs)*

determines the solution space of the homogeneous linear system $M \cdot x = 0$. It returns the dimension of the solution space. Moreover the columns of *spanning_vecs* span the solution space.

static int *LA.independent_columns(Matrix M, std::vector<int>& columns)*

returns the indices of a maximal subset of independent columns of M.

static int *LA.rank(Matrix M)*

returns the rank of matrix M

Concept

Vector

Definition

An instance of data type *Vector* is a vector of variables of number type *NT*. Together with the type *Matrix* it realizes the basic operations of linear algebra.

Types

Vector:: NT	the ring type of the components.
Vector:: iterator	the iterator type for accessing components.
Vector:: const_iterator	the const iterator type for accessing components.

Creation

Vector v;	creates an instance *v* of type *Vector*.
Vector v(int d);	creates an instance *v* of type *Vector*. *v* is initialized to a vector of dimension *d*.
Vector v(int d, NT x);	creates an instance *v* of type *Vector*. *v* is initialized to a vector of dimension *d* with entries *x*.

template <class Forward_iterator>
Vector v(Forward_iterator first, Forward_iterator last);

creates an instance *v* of type *Vector*; *v* is initialized to the vector with entries *set [first,last)*.
Requirement: *Forward_iterator* has value type *NT*.

Operations

int	*v.dimension()*	returns the dimension of *v*.
bool	*v.is_zero()*	returns true iff *v* is the zero vector.
NT&	*v*[*int i*]	returns the *i*-th component of *v*. *Precondition*: $0 \leq i \leq v.dimension() - 1$.
iterator	*v.begin()*	iterator to the first component.
iterator	*v.end()*	iterator beyond the last component.

The same operations *begin()*, *end()* exist for *const_iterator*.

Vector	$v + v1$	Addition. *Precondition*: *v.dimension() == v1.dimension()*.
Vector	$v - v1$	Subtraction. *Precondition*: *v.dimension() = v1.dimension()*.
NT	$v * v1$	Inner Product. *Precondition*: *v.dimension() = v1.dimension()*.
Vector	$-v$	Negation.
Vector&	$v += v1$	Addition plus assignment. *Precondition*: *v.dimension() == v1.dimension()*.
Vector&	$v -= v1$	Subtraction plus assignment. *Precondition*: *v.dimension() == v1.dimension()*.
Vector&	$v *= NT\ s$	Scalar multiplication plus assignment.
Vector&	$v /= NT\ s$	Scalar division plus assignment.
Vector	$NT\ r * v$	Component-wise multiplication with number *r*.
Vector	$v * NT\ r$	Component-wise multiplication with number *r*.

Matrix

Definition

An instance of data type *Matrix* is a matrix of variables of number type *NT*. The types *Matrix* and *Vector* together realize many functions of basic linear algebra.

Types

Matrix:: NT	the ring type of the components.
Matrix:: iterator	bidirectional iterator for accessing all components row-wise.
Matrix:: row_iterator	random access iterator for accessing row entries.
Matrix:: column_iterator	random access iterator for accessing column entries.

There also constant versions of the above iterators: *const_iterator*, *row_const_iterator*, and *column_const_iterator*.

Matrix:: Identity	a tag class for identity initialization
Matrix:: Vector	the vector type used.

Creation

Matrix M;	creates an instance M of type *Matrix*.
Matrix M(int n);	creates an instance M of type *Matrix* of dimension $n \times n$ initialized to the zero matrix.
Matrix M(int m, int n);	creates an instance M of type *Matrix* of dimension $m \times n$ initialized to the zero matrix.
Matrix M(std::pair<int,int> p);	creates an instance M of type *Matrix* of dimension *p.first*$\times$*p.second* initialized to the zero matrix.

Matrix M(int n, Identity, NT x = NT(1));

creates an instance M of type *Matrix* of dimension $n \times n$ initialized to the identity matrix (times x).

Matrix M(int m, int n, NT x);	creates an instance M of type *Matrix* of dimension $m \times n$ initialized to the matrix with x entries.

template <class Forward_iterator>
Matrix M(Forward_iterator first, Forward_iterator last);

creates an instance M of type *Matrix*. Let S be the ordered set of n column-vectors of common dimension m as given by the iterator range *[first,last)*. M is initialized to an $m \times n$ matrix with the columns as specified by S.
Precondition: *Forward_iterator* has a value type V from which we require to provide a iterator type *V::const_iterator*, to have *V::value_type* $== NT$.
Note that *Vector* or *std::vector<NT>* fulfill these requirements.

Matrix M(std::vector< Vector > A);

creates an instance M of type *Matrix*. Let A be an array of n column-vectors of common dimension m. M is initialized to an $m \times n$ matrix with the columns as specified by A.

Operations

int	*M.row_dimension()*	returns n, the number of rows of M.
int	*M.column_dimension()*	returns m, the number of columns of M.
std::pair<int,int>	*M.dimension()*	returns (m,n), the dimension pair of M.
Vector	*M.row(int i)*	returns the i-th row of M (an m - vector). *Precondition*: $0 \leq i \leq m-1$.
Vector	*M.column(int i)*	returns the i-th column of M (an n - vector). *Precondition*: $0 \leq i \leq n-1$.
NT&	*M(int i, int j)*	returns $M_{i,j}$. *Precondition*: $0 \leq i \leq m-1$ and $0 \leq j \leq n-1$.
void	*M.swap_rows(int i, int j)*	swaps rows i and j. *Precondition*: $0 \leq i \leq m-1$ and $0 \leq j \leq m-1$.
void	*M.swap_columns(int i, int j)*	swaps columns i and j. *Precondition*: $0 \leq i \leq n-1$ and $0 \leq j \leq n-1$.
row_iterator	*M.row_begin(int i)*	an iterator pointing to the first entry of the ith row. *Precondition*: $0 \leq i \leq m-1$.
row_iterator	*M.row_end(int i)*	an iterator pointing beyond the last entry of the ith row. *Precondition*: $0 \leq i \leq m-1$.

column_iterator	*M.column_begin(int i)*	an iterator pointing to the first entry of the ith column. *Precondition*: $0 \leq i \leq n-1$.
column_iterator	*M.column_end(int i)*	an iterator pointing beyond the last entry of the ith column. *Precondition*: $0 \leq i \leq n-1$.
iterator	*M.begin()*	an iterator pointing to the first entry of M.
terator	*M.end()*	an iterator pointing beyond the last entry of M.

The same operations exist for *row_const_iterator*, *column_const_iterator* and *const_iterator*.

bool	$M == M1$	Test for equality.
bool	$M \,!= M1$	Test for inequality.

Arithmetic Operators

Matrix	$M + M1$	Addition. *Precondition*: *M.row_dimension() == M1.row_dimension()* and *M.column_dimension() == M1.column_dimension()*.
Matrix	$M - M1$	Subtraction. *Precondition*: *M.row_dimension() == M1.row_dimension()* and *M.column_dimension() == M1.column_dimension()*.
Matrix	$-M$	Negation.
Matrix	$M * M1$	Multiplication. *Precondition*: *M.column_dimension() = M1.row_dimension()*.
Vector	$M *$ *Vector vec*	Multiplication with vector. *Precondition*: *M.column_dimension() = vec.dimension()*.
Matrix	*NT* $x * M$	Multiplication of every entry with x.
Matrix	$M *$ *NT* x	Multiplication of every entry with x.

CGAL::Linear_algebraCd<FT>

Definition

The class *Linear_algebraCd<FT>* serves as the default traits class for the LA parameter of *CGAL::Cartesian_d<FT,LA>*. It implements linear algebra for field number types *FT*.

#include <CGAL/Linear_algebraCd.h>

Is Model for the Concepts

LinearAlgebraTraits_d . . . . page 1059

Requirements

FT must be a field number type.

Operations

Fits all operation requirements of the concept.

Class

CGAL::Linear_algebraHd<RT>

Definition

The class *Linear_algebraHd<RT>* serves as the default traits class for the LA parameter of *CGAL::Homogeneous_d<RT,LA>*. It implements linear algebra for Euclidean ring number types *RT*.

#include <CGAL/Linear_algebraHd.h>

Is Model for the Concepts

LinearAlgebraTraits_d . . . . page 1059

Requirements

To make a ring number type *RT* work with this class it has to provide a division *operator/* with remainder.

Operations

Fits all operation requirements of the concept.

12.7 Kernels

CGAL::Cartesian_d<FieldNumberType>

#include <CGAL/Cartesian_d.h>

Definition

A model for *Kernel_d* that uses Cartesian coordinates to represent the geometric objects. In order for *Cartesian_d<FieldNumberType>* to model Euclidean geometry in E^d , for some mathematical field E (*e.g.*, the rationals $\mathbb{Q}$ or the reals $\mathbb{R}$), the template parameter *FieldNumberType* must model the mathematical field E. That is, the field operations on this number type must compute the mathematically correct results. If the number type provided as a model for *FieldNumberType* is only an approximation of a field (such as the built-in type *double*), then the geometry provided by the kernel is only an approximation of Euclidean geometry.

Is Model for the Concepts

12.8 Kernel Objects

CGAL::Point_d<Kernel>

Definition

An instance of data type *Point_d<Kernel>* is a point of Euclidean space in dimension d. A point $p = (p_0, \ldots, p_{d-1})$ in d-dimensional space can be represented by homogeneous coordinates $(h_0, h_1, \ldots, h_d)$ of number type RT such that $p_i = h_i/h_d$, which is of type FT. The homogenizing coordinate h_d is positive.

We call p_i, $0 \leq i < d$ the i-th Cartesian coordinate and h_i, $0 \leq i \leq d$, the i-th homogeneous coordinate. We call d the dimension of the point.

Types

Point_d<Kernel>:: LA the linear algebra layer.

Point_d<Kernel>:: Cartesian_const_iterator

a read-only iterator for the Cartesian coordinates.

Point_d<Kernel>:: Homogeneous_const_iterator

a read-only iterator for the homogeneous coordinates.

Creation

Point_d<Kernel> p; introduces a variable p of type *Point_d<Kernel>*.

Point_d<Kernel> p(int d, Origin);

introduces a variable p of type *Point_d<Kernel>* in d-dimensional space, initialized to the origin.

template <class InputIterator>
Point_d<Kernel> p(int d, InputIterator first, InputIterator last);

introduces a variable p of type *Point_d<Kernel>* in dimension d. If *size [first,last) == d* this creates a point with Cartesian coordinates *set [first,last)*. If *size [first,last) == d+1* the range specifies the homogeneous coordinates $H = set\,[first, last) = (\pm h_0, \pm h_1, \ldots, \pm h_d)$ where the sign chosen is the sign of h_d.
Precondition: d is nonnegative, *[first,last)* has d or *d+1* elements where the last has to be non-zero.
Requirement: The value type of *InputIterator* is RT.

template <class InputIterator>
Point_d<Kernel> p(int d, InputIterator first, InputIterator last, RT D);

introduces a variable *p* of type *Point_d<Kernel>* in dimension *d* initialized to the point with homogeneous coordinates as defined by *H = set [first,last)* and *D*: $(\pm H[0], \pm H[1], \ldots, \pm H[d-1], \pm D)$. The sign chosen is the sign of *D*.
Precondition: *D* is non-zero, the iterator range defines a *d*-tuple of *RT*.
Requirement: The value type of *InputIterator* is *RT*.

Point_d<Kernel> p(RT x, RT y, RT w = 1);

introduces a variable *p* of type *Point_d<Kernel>* in 2-dimensional space.
Precondition: $w \neq 0$.

Point_d<Kernel> p(RT x, RT y, RT z, RT w);

introduces a variable *p* of type *Point_d<Kernel>* in 3-dimensional space.
Precondition: $w \neq 0$.

Operations

int	*p.dimension()*	returns the dimension of *p*.
FT	*p.cartesian(int i)*	returns the *i*-th Cartesian coordinate of *p*. *Precondition*: $0 \leq i < d$.
FT	*p*[*int i*]	returns the *i*-th Cartesian coordinate of *p*. *Precondition*: $0 \leq i < d$.
RT	*p.homogeneous(int i)*	returns the *i*-th homogeneous coordinate of *p*. *Precondition*: $0 \leq i \leq d$.
Cartesian_const_iterator	*p.cartesian_begin()*	returns an iterator pointing to the zeroth Cartesian coordinate p_0 of *p*.
Cartesian_const_iterator	*p.cartesian_end()*	returns an iterator pointing beyond the last Cartesian coordinate of *p*.
Homogeneous_const_iterator	*p.homogeneous_begin()*	returns an iterator pointing to the zeroth homogeneous coordinate h_0 of *p*.

Homogeneous_const_iterator

p.homogeneous_end()

returns an iterator pointing beyond the last homogeneous coordinate of *p*.

Point_d<Kernel> *p.transform(Aff_transformation_d<Kernel> t)*

returns $t(p)$.

Arithmetic Operators, Tests and IO

Vector_d<Kernel> $p -$ *Origin o* returns the vector $p - O$.

Vector_d<Kernel> $p - q$ returns $p - q$.
Precondition: *p.dimension()* == *q.dimension()*.

Point_d<Kernel> $p +$ *Vector_d<Kernel> v*

returns $p + v$.
Precondition: *p.dimension()* == *v.dimension()*.

Point_d<Kernel> $p -$ *Vector_d<Kernel> v*

returns $p - v$.
Precondition: *p.dimension()* == *v.dimension()*.

Point_d<Kernel>& $p +=$ *Vector_d<Kernel> v*

adds *v* to *p*.

Precondition: *p.dimension()* == *v.dimension()*.

Point_d<Kernel>& $p -=$ *Vector_d<Kernel> v*

subtracts *v* from *p*.

Precondition: *p.dimension()* == *v.dimension()*.

bool $p ==$ *Origin* returns true if *p* is the origin.

Downward compatibility

We provide operations of the lower dimensional interface *x()*, *y()*, *z()*, *hx()*, *hy()*, *hz()*, *hw()*.

Implementation

Points are implemented by arrays of *RT* items. All operations like creation, initialization, tests, point - vector arithmetic, input and output on a point p take time $O(p.dimension())$. *dimension()*, coordinate access and conversions take constant time. The space requirement for points is $O(p.dimension())$.

CGAL::Vector_d<Kernel>

Class

Definition

An instance of data type *Vector_d<Kernel>* is a vector of Euclidean space in dimension d. A vector $r = (r_0, \ldots, r_{d-1})$ can be represented in homogeneous coordinates $(h_0, \ldots, h_d)$ of number type RT, such that $r_i = h_i / h_d$ which is of type FT. We call the r_i's the Cartesian coordinates of the vector. The homogenizing coordinate h_d is positive.

This data type is meant for use in computational geometry. It realizes free vectors as opposed to position vectors (type *Point_d*). The main difference between position vectors and free vectors is their behavior under affine transformations, e.g., free vectors are invariant under translations.

Types

Vector_d<Kernel>:: LA — the linear algebra layer.

Vector_d<Kernel>:: Cartesian_const_iterator

a read-only iterator for the Cartesian coordinates.

Vector_d<Kernel>:: Homogeneous_const_iterator

a read-only iterator for the homogeneous coordinates.

Vector_d<Kernel>:: Base_vector

construction tag.

Creation

Vector_d<Kernel> v; — introduces a variable v of type *Vector_d<Kernel>*.

Vector_d<Kernel> v(int d, Null_vector);

introduces the zero vector v of type *Vector_d<Kernel>* in d-dimensional space. For the creation flag *CGAL::NULL_VECTOR* can be used.

template <class InputIterator>
Vector_d<Kernel> v(int d, InputIterator first, InputIterator last);

introduces a variable v of type *Vector_d<Kernel>* in dimension d. If *size [first,last) == d* this creates a vector with Cartesian coordinates *set [first,last)*. If *size [first,last) == p+1* the range specifies the homogeneous coordinates $H = set\ [first, last) = (\pm h_0, \pm h_1, \ldots, \pm h_d)$ where the sign chosen is the sign of h_d.
Precondition: d is nonnegative, *[first,last)* has d or d*+1* elements where the last has to be non-zero.
Requirement: The value type of *InputIterator* is RT.

template <class InputIterator>
Vector_d<Kernel> v(int d, InputIterator first, InputIterator last, RT D);

introduces a variable v of type *Vector_d<Kernel>* in dimension d initialized to the vector with homogeneous coordinates as defined by H = *set [first,last)* and D: $(\pm H[0], \pm H[1], \ldots, \pm H[d-1], \pm D)$. The sign chosen is the sign of D.
Precondition: D is non-zero, the iterator range defines a d-tuple of RT.
Requirement: The value type of *InputIterator* is RT.

Vector_d<Kernel> v(int d, Base_vector, int i);

returns a variable v of type *Vector_d<Kernel>* initialized to the i-th base vector of dimension d.
Precondition: $0 \leq i < d$.

Vector_d<Kernel> v(RT x, RT y, RT w = 1);

introduces a variable v of type *Vector_d<Kernel>* in 2-dimensional space.
Precondition: $w \neq 0$.

Vector_d<Kernel> v(RT x, RT y, RT z, RT w);

introduces a variable v of type *Vector_d<Kernel>* in 3-dimensional space.
Precondition: $w \neq 0$.

Operations

int	*v.dimension()*	returns the dimension of v.
FT	*v.cartesian(int i)*	returns the i-th Cartesian coordinate of v. *Precondition*: $0 \leq i < d$.
FT	*v*[*int i*]	returns the i-th Cartesian coordinate of v. *Precondition*: $0 \leq i < d$.
RT	*v.homogeneous(int i)*	returns the i-th homogeneous coordinate of v. *Precondition*: $0 \leq i \leq d$.

FT	*v.squared_length()*	returns the square of the length of v.
Cartesian_const_iterator	*v.cartesian_begin()*	returns an iterator pointing to the zeroth Cartesian coordinate of v.
Cartesian_const_iterator	*v.cartesian_end()*	returns an iterator pointing beyond the last Cartesian coordinate of v.
Homogeneous_const_iterator	*v.homogeneous_begin()*	returns an iterator pointing to the zeroth homogeneous coordinate of v.
Homogeneous_const_iterator	*v.homogeneous_end()*	returns an iterator pointing beyond the last homogeneous coordinate of v.
Direction_d<Kernel>	*v.direction()*	returns the direction of v.
Vector_d<Kernel>	*v.transform(Aff_transformation_d<Kernel> t)*	returns $t(v)$.

Arithmetic Operators, Tests and IO

Vector_d<Kernel>&	$v *= RT\ n$	multiplies all Cartesian coordinates by n.
Vector_d<Kernel>&	$v *= FT\ r$	multiplies all Cartesian coordinates by r.
Vector_d<Kernel>	$v\,/RT\ n$	returns the vector with Cartesian coordinates $v_i/n, 0 \leq i < d$.
Vector_d<Kernel>	$v\,/FT\ r$	returns the vector with Cartesian coordinates $v_i/r, 0 \leq i < d$.
Vector_d<Kernel>&	$v\,/= RT\ n$	divides all Cartesian coordinates by n.
Vector_d<Kernel>&	$v\,/= FT\ r$	divides all Cartesian coordinates by r.
FT	$v * w$	inner product, i.e., $\sum_{0 \leq i < d} v_i w_i$, where v_i and w_i are the Cartesian coordinates of v and w respectively.
Vector_d<Kernel>	$v + w$	returns the vector with Cartesian coordinates $v_i + w_i, 0 \leq i < d$.
Vector_d<Kernel>&	$v += w$	addition plus assignment.

Vector_d<Kernel>	$v - w$	returns the vector with Cartesian coordinates $v_i - w_i, 0 \leq i < d$.
Vector_d<Kernel>&	$v -= w$	subtraction plus assignment.
Vector_d<Kernel>	$-v$	returns the vector in opposite direction.
bool	*v.is_zero()*	returns true if v is the zero vector.

Downward compatibility

We provide all operations of the lower dimensional interface *x()*, *y()*, *z()*, *hx()*, *hy()*, *hz()*, *hw()*.

Vector_d<Kernel>	*RT* $n * v$	returns the vector with Cartesian coordinates nv_i.
Vector_d<Kernel>	*FT* $r * v$	returns the vector with Cartesian coordinates $rv_i, 0 \leq i < d$.

Implementation

Vectors are implemented by arrays of variables of type RT. All operations like creation, initialization, tests, vector arithmetic, input and output on a vector v take time $O(v.dimension())$. coordinate access, *dimension()* and conversions take constant time. The space requirement of a vector is $O(v.dimension())$.

CGAL::Direction_d<Kernel>

Definition

A *Direction_d* is a vector in the d-dimensional vector space where we forget about its length. We represent directions in d-dimensional space as a tuple $(h_0, \ldots, h_d)$ of variables of type *RT* which we call the homogeneous coordinates of the direction. The coordinate h_d must be positive. The Cartesian coordinates of a direction are $c_i = h_i/h_d$ for $0 \leq i < d$, which are of type *FT*. Two directions are equal if their Cartesian coordinates are positive multiples of each other. Directions are in one-to-one correspondence to points on the unit sphere.

Types

Direction_d<Kernel>:: LA the linear algebra layer.

Direction_d<Kernel>:: Delta_const_iterator

a read-only iterator for the deltas of *dir*.

Direction_d<Kernel>:: Base_direction

construction tag.

Creation

Direction_d<Kernel> dir; introduces a variable *dir* of type *Direction_d<Kernel>*.

Direction_d<Kernel> dir(Vector_d<Kernel> v);

introduces a variable *dir* of type *Direction_d<Kernel>* initialized to the direction of v.

template <class InputIterator>
Direction_d<Kernel> dir(int d, InputIterator first, InputIterator last);

introduces a variable *dir* of type *Direction_d<Kernel>* in dimension d with representation tuple *set [first,last)*.
Precondition: d is nonnegative, *[first,last)* has d elements.
Requirement: The value type of *InputIterator* is *RT*.

Direction_d<Kernel> dir(int d, Base_direction, int i);

returns a variable *dir* of type *Direction_d<Kernel>* initialized to the direction of the i-th base vector of dimension d.
Precondition: $0 \leq i < d$.

Direction_d<Kernel> dir(RT x, RT y);

introduces a variable *dir* of type *Direction_d<Kernel>* in 2-dimensional space.

Direction_d<Kernel> dir(RT x, RT y, RT z);

introduces a variable *dir* of type *Direction_d<Kernel>* in 3-dimensional space.

Operations

int	*dir.dimension()*	returns the dimension of *dir*.
RT	*dir.delta(int i)*	returns the i-th component of *dir*. *Precondition*: $0 \leq i < d$.
RT	*dir*[*int i*]	returns the i-th delta of *dir*. *Precondition*: $0 \leq i < d$.
Delta_const_iterator	*dir.deltas_begin()*	returns an iterator pointing to the first delta of *dir*.
Delta_const_iterator	*dir.deltas_end()*	returns an iterator pointing beyond the last delta of *dir*.
Vector_d<Kernel>	*dir.vector()*	returns a vector pointing in direction *dir*.
bool	*dir.is_degenerate()*	returns true iff *dir.delta(i)==0* for all $0 \leq i < d$.
Direction_d<Kernel>	*dir.transform(Aff_transformation_d<Kernel> t)*	returns $t(p)$.
Direction_d<Kernel>	*dir.opposite()*	returns the direction opposite to *dir*.
Direction_d<Kernel>	$-dir$	returns the direction opposite to *dir*.

Downward compatibility

We provide the operations of the lower dimensional interface *dx()*, *dy()*, *dz()*.

Implementation

Directions are implemented by arrays of integers as an item type. All operations like creation, initialization, tests, inversion, input and output on a direction d take time $O(d.dimension())$. *dimension()*, coordinate access and conversion take constant time. The space requirement is $O(d.dimension())$.

CGAL::Line_d<Kernel>

Definition

An instance of data type *Line_d* is an oriented line in d-dimensional Euclidean space.

Types

Line_d<Kernel>:: LA	the linear algebra layer.

Creation

Line_d<Kernel> l; introduces a variable *l* of type *Line_d<Kernel>*.

Line_d<Kernel> l(Point_d<Kernel> p, Point_d<Kernel> q);

introduces a line through p and q and oriented from p to q.
Precondition: p and q are distinct and have the same dimension.

Line_d<Kernel> l(Point_d<Kernel> p, Direction_d<Kernel> dir);

introduces a line through p with direction *dir*.
Precondition: *p.dimension()==dir.dimension()*, *dir* is not degenerate.

Line_d<Kernel> l(Segment_d<Kernel> s);

introduces a variable *l* of type *Line_d<Kernel>* and initializes it to the line through *s.source()* and *s.target()* with direction from *s.source()* to *s.target()*.
Precondition: *s* is not degenerate.

Line_d<Kernel> l(Ray_d<Kernel> r);

introduces a variable *l* of type *Line_d<Kernel>* and initializes it to the line through *r.point(1)* and *r.point(2)*.

Operations

int	*l.dimension()*	returns the dimension of the ambient space.
Point_d<Kernel>	*l.point(int i)*	returns an arbitrary point on *l*. It holds that *point(i) == point(j)*, iff *i==j*. Furthermore, *l* is directed from *point(i)* to *point(j)*, for all $i < j$.
Line_d<Kernel>	*l.opposite()*	returns the line *(point(2),point(1))* of opposite direction.

Direction_d<Kernel>	*l.direction()*	returns the direction of *l*.
Line_d<Kernel>	*l.transform(Aff_transformation_d<Kernel> t)*	
		returns $t(l)$. *Precondition*: *l.dimension()==t.dimension()*.
Line_d<Kernel>	$l +$ *Vector_d<Kernel> v*	
		returns *l*+*v*, i.e., *l* translated by vector *v*. *Precondition*: *l.dimension()==v.dimension()*.
Point_d<Kernel>	*l.projection(Point_d<Kernel> p)*	
		returns the point of intersection of *l* with the hyperplane that is orthogonal to *l* and that contains *p*. *Precondition*: *l.dimension()==p.dimension()*.
bool	*l.has_on(Point_d<Kernel> p)*	
		returns true if *p* lies on *l* and false otherwise. *Precondition*: *l.dimension()==p.dimension()*.

Non-Member Functions

bool	*weak_equality(l1, l2)*	
		Test for equality as unoriented lines. *Precondition*: *l1.dimension()==l2.dimension()*.
bool	*parallel(l1, l2)*	returns true if *l1* and *l2* are parallel as unoriented lines and false otherwise. *Precondition*: *l1.dimension()==l2.dimension()*.

Implementation

Lines are implemented by a pair of points as an item type. All operations like creation, initialization, tests, direction calculation, input and output on a line *l* take time $O(l.dimension())$. *dimension()*, coordinate and point access, and identity test take constant time. The operations for intersection calculation also take time $O(l.dimension())$. The space requirement is $O(l.dimension())$.

CGAL::Ray_d<Kernel>

Class

Definition

An instance of data type *Ray_d* is a ray in d-dimensional Euclidean space. It starts in a point called the source of r and it goes to infinity.

Types

Ray_d<Kernel>:: LA — the linear algebra layer.

Creation

Ray_d<Kernel> r; — introduces some ray in d-dimensional space.

Ray_d<Kernel> r(Point_d<Kernel> p, Point_d<Kernel> q);

introduces a ray through p and q and starting at p.
Precondition: p and q are distinct and have the same dimension.
Precondition: *p.dimension()==q.dimension()*.

Ray_d<Kernel> r(Point_d<Kernel> p, Direction_d<Kernel> dir);

introduces a ray starting in p with direction *dir*.
Precondition: p and *dir* have the same dimension and *dir* is not degenerate.
Precondition: *p.dimension()==dir.dimension()*.

Ray_d<Kernel> r(Segment_d<Kernel> s);

introduces a ray through *s.source()* and *s.target()* and starting at *s.source()*.
Precondition: s is not degenerate.

Operations

int	*r.dimension()*	returns the dimension of the ambient space.
Point_d<Kernel>	*r.source()*	returns the source point of r.
Point_d<Kernel>	*r.point(int i)*	returns a point on r. *point(0)* is the source. *point(i)*, with $i > 0$, is different from the source. *Precondition*: $i \geq 0$.
Direction_d<Kernel>	*r.direction()*	returns the direction of r.

Line_d<Kernel>	*r.supporting_line()*	returns the supporting line of r.
Ray_d<Kernel>	*r.opposite()*	returns the ray with direction opposite to r and starting in *source*.
Ray_d<Kernel>	*r.transform(Aff_transformation_d<Kernel> t)*	returns $t(r)$. *Precondition*: *r.dimension()==t.dimension()*.
Ray_d<Kernel>	$r +$ *Vector_d<Kernel> v*	returns *r+v*, i.e., r translated by vector v. *Precondition*: *r.dimension()==v.dimension()*.
bool	*r.has_on(Point_d<Kernel> p)*	A point is on r, iff it is equal to the source of r, or if it is in the interior of r. *Precondition*: *r.dimension()==p.dimension()*.

Non-Member Functions

bool	*parallel(r1, r2)*	returns true if the unoriented supporting lines of *r1* and *r2* are parallel and false otherwise. *Precondition*: *r1.dimension()==r2.dimension()*.

Implementation

Rays are implemented by a pair of points as an item type. All operations like creation, initialization, tests, direction calculation, input and output on a ray r take time $O(r.dimension())$. *dimension()*, coordinate and point access, and identity test take constant time. The space requirement is $O(r.dimension())$.

CGAL::Segment_d<Kernel>

Class

Definition

An instance s of the data type *Segment_d* is a directed straight line segment in d-dimensional Euclidean space connecting two points p and q. p is called the source point and q is called the target point of s, both points are called endpoints of s. A segment whose endpoints are equal is called *degenerate*.

Types

Segment_d<Kernel>:: LA — the linear algebra layer.

Creation

Segment_d<Kernel> s;

introduces a variable s of type *Segment_d<Kernel>*.

Segment_d<Kernel> s(Point_d<Kernel> p, Point_d<Kernel> q);

introduces a variable s of type *Segment_d<Kernel>* which is initialized to the segment (p,q).
Precondition: *p.dimension()==q.dimension()*.

Segment_d<Kernel> s(Point_d<Kernel> p, Vector_d<Kernel> v);

introduces a variable s of type *Segment_d<Kernel>* which is initialized to the segment *(p,p+v)*.
Precondition: *p.dimension()==v.dimension()*.

Operations

int	*s.dimension()*	returns the dimension of the ambient space.
Point_d<Kernel>	*s.source()*	returns the source point of segment s.
Point_d<Kernel>	*s.target()*	returns the target point of segment s.
Point_d<Kernel>	*s.vertex(int i)*	returns source or target of s: *vertex(0)* returns the source, *vertex(1)* returns the target. The parameter i is taken modulo 2, which gives easy access to the other vertex. *Precondition*: $i \geq 0$.
Point_d<Kernel>	*s.point(int i)*	returns *vertex(i)*.

Point_d<Kernel>	s[*int i*]	returns *vertex(i)*.
Point_d<Kernel>	*s.min()*	returns the lexicographically smaller vertex.
Point_d<Kernel>	*s.max()*	returns the lexicographically larger vertex.
Segment_d<Kernel>	*s.opposite()*	returns the segment *(target(),source())*.
Direction_d<Kernel>	*s.direction()*	returns the direction from source to target. *Precondition*: *s* is non-degenerate.
Vector_d<Kernel>	*s.vector()*	returns the vector from source to target.
FT	*s.squared_length()*	returns the square of the length of *s*.
bool	*s.has_on(Point_d<Kernel> p)*	
		returns true if *p* lies on *s* and false otherwise. *Precondition*: *s.dimension()==p.dimension()*.
Line_d<Kernel>	*s.supporting_line()*	returns the supporting line of *s*. *Precondition*: *s* is non-degenerate.
Segment_d<Kernel>	*s.transform(Aff_transformation_d<Kernel> t)*	
		returns $t(s)$. *Precondition*: *s.dimension()==t.dimension()*.
Segment_d<Kernel>	$s +$ *Vector_d<Kernel> v*	
		returns $s + v$, i.e., *s* translated by vector *v*. *Precondition*: *s.dimension()==v.dimension()*.
bool	*s.is_degenerate()*	returns true if *s* is degenerate i.e. *s.source()=s.target()*.

Non-Member Functions

bool	*weak_equality(s1, s2)*	
		Test for equality as unoriented segments. *Precondition*: *s1.dimension()==s2.dimension()*.
bool	*parallel(s1, s2)*	return true if one of the segments is degenerate or if the unoriented supporting lines are parallel. *Precondition*: *s1.dimension()==s2.dimension()*.

bool *common_endpoint(s1, s2, Point_d<Kernel>& common)*

if *s1* and *s2* touch in a common end point, this point is assigned to *common* and the result is *true*, otherwise the result is *false*. If *s1==s2* then one of the endpoints is returned.
Precondition: *s1.dimension()==s2.dimension()*.

Implementation

Segments are implemented by a pair of points as an item type. All operations like creation, initialization, tests, the calculation of the direction and source - target vector, input and output on a segment *s* take time $O(s.dimension())$. *dimension()*, coordinate and end point access, and identity test take constant time. The operations for intersection calculation also take time $O(s.dimension())$. The space requirement is $O(s.dimension())$.

CGAL::Hyperplane_d<Kernel>

Definition

An instance of data type *Hyperplane_d* is an oriented hyperplane in d - dimensional space. A hyperplane h is represented by coefficients $(c_0, c_1, \ldots, c_d)$ of type RT. At least one of c_0 to c_{d-1} must be non-zero. The plane equation is $\sum_{0 \leq i < d} c_i x_i + c_d = 0$, where x_0 to x_{d-1} are Cartesian point coordinates. For a particular x the sign of $\sum_{0 \leq i < d} c_i x_i + c_d$ determines the position of a point x with respect to the hyperplane (on the hyperplane, on the negative side, or on the positive side).

There are two equality predicates for hyperplanes. The (weak) equality predicate (*weak_equality*) declares two hyperplanes equal if they consist of the same set of points, the strong equality predicate (*operator==*) requires in addition that the negative halfspaces agree. In other words, two hyperplanes are strongly equal if their coefficient vectors are positive multiples of each other and they are (weakly) equal if their coefficient vectors are multiples of each other.

Types

Hyperplane_d<Kernel>:: LA

the linear algebra layer.

Hyperplane_d<Kernel>:: Coefficient_const_iterator

a read-only iterator for the coefficients.

Creation

Hyperplane_d<Kernel> h;

introduces a variable h of type *Hyperplane_d<Kernel>*.

template <class InputIterator>
Hyperplane_d<Kernel> h(int d, InputIterator first, InputIterator last, RT D);

introduces a variable h of type *Hyperplane_d<Kernel>* initialized to the hyperplane with coefficients *set [first,last)* and D.
Precondition: *size [first,last) == d*.
Requirement: The value type of InputIterator is RT.

template <class InputIterator>
Hyperplane_d<Kernel> h(int d, InputIterator first, InputIterator last);

introduces a variable h of type *Hyperplane_d<Kernel>* initialized to the hyperplane with coefficients *set [first,last)*.
Precondition: *size [first,last) == d+1*.
Requirement: The value type of InputIterator is RT.

template <class ForwardIterator>
Hyperplane_d<Kernel> h(ForwardIterator first, ForwardIterator last, Point_d<Kernel> o, Oriented_side side = ON_ORIENTED_BOUNDARY)

constructs some hyperplane that passes through the points in *set [first,last)*. If *side* is *ON_POSITIVE_SIDE* or *ON_NEGATIVE_SIDE* then *o* is on that side of the constructed hyperplane.
Precondition: A hyperplane with the stated properties must exist.
Requirement: The value type of *ForwardIterator* is *Point_d<Kernel>*.

Hyperplane_d<Kernel> h(Point_d<Kernel> p, Direction_d<Kernel> dir);

constructs the hyperplane with normal direction *dir* that passes through p. The direction *dir* points into the positive side.
Precondition: *p.dimension()==dir.dimension()* and *dir* is not degenerate.

Hyperplane_d<Kernel> h(RT a, RT b, RT c);

introduces a variable *h* of type *Hyperplane_d<Kernel>* in 2-dimensional space with equation $ax+by+c=0$.

Hyperplane_d<Kernel> h(RT a, RT b, RT c, RT d);

introduces a variable *h* of type *Hyperplane_d<Kernel>* in 3-dimensional space with equation $ax+by+cz+d=0$.

Operations

int *h.dimension()* returns the dimension of *h*.

RT *h*[*int i*] returns the *i*-th coefficient of *h*.
Precondition: $0 \leq i \leq d$.

RT *h.coefficient(int i)*

returns the *i*-th coefficient of *h*.
Precondition: $0 \leq i \leq d$.

Coefficient_const_iterator *h.coefficients_begin()*

returns an iterator pointing to the first coefficient.

Coefficient_const_iterator *h.coefficients_end()*

returns an iterator pointing beyond the last coefficient.

Vector_d<Kernel> *h.orthogonal_vector()*

returns the orthogonal vector of h. It points from the negative halfspace into the positive halfspace and its homogeneous coordinates are $(c_0, \ldots, c_{d-1}, 1)$.

Direction_d<Kernel> *h.orthogonal_direction()*

returns the orthogonal direction of h. It points from the negative halfspace into the positive halfspace.

Oriented_side *h.oriented_side(Point_d<Kernel> p)*

returns the side of the hyperplane h containing p.
Precondition: *h.dimension() == p.dimension()*.

bool *h.has_on(Point_d<Kernel> p)*

returns true iff point p lies on the hyperplane h.
Precondition: *h.dimension() == p.dimension()*.

bool *h.has_on_boundary(Point_d<Kernel> p)*

returns true iff point p lies on the boundary of hyperplane h.
Precondition: *h.dimension() == p.dimension()*.

bool *h.has_on_positive_side(Point_d<Kernel> p)*

returns true iff point p lies on the positive side of hyperplane h.
Precondition: *h.dimension() == p.dimension()*.

bool *h.has_on_negative_side(Point_d<Kernel> p)*

returns true iff point p lies on the negative side of hyperplane h.
Precondition: *h.dimension() == p.dimension()*.

Hyperplane_d<Kernel> *h.transform(Aff_transformation_d<Kernel> t)*

returns $t(h)$.
Precondition: *h.dimension() == t.dimension()*.

Non-Member Functions

bool *weak_equality(h1, h2)*

test for weak equality.
Precondition: *h1.dimension() == h2.dimension()*.

Implementation

Hyperplanes are implemented by arrays of integers as an item type. All operations like creation, initialization, tests, vector arithmetic, input and output on a hyperplane h take time $O(h.dimension())$. coordinate access and *dimension()* take constant time. The space requirement is $O(h.dimension())$.

Class

CGAL::Sphere_d<Kernel>

Definition

An instance S of the data type *Sphere_d* is an oriented sphere in some d-dimensional space. A sphere is defined by $d+1$ points (class *Point_d<Kernel>*). We use A to denote the array of the defining points. A set A of defining points is *legal* if either the points are affinely independent or if the points are all equal. Only a legal set of points defines a sphere in the geometric sense and hence many operations on spheres require the set of defining points to be legal. The orientation of S is equal to the orientation of the defining points, i.e., *orientation(A)*.

Types

Sphere_d<Kernel>:: LA — the linear algebra layer.

Sphere_d<Kernel>:: point_iterator

a read-only iterator for points defining the sphere.

Creation

Sphere_d<Kernel> S; — introduces a variable S of type *Sphere_d<Kernel>*.

template <class ForwardIterator>
Sphere_d<Kernel> *S(int d, ForwardIterator first, ForwardIterator last);*

introduces a variable S of type *Sphere_d<Kernel>*. S is initialized to the sphere through the points in A = *tuple [first,last)*.
Precondition: A consists of $d+1$ d-dimensional points.
Requirement: The value type of ForwardIterator is *Point_d<Kernel>*.

Operations

int *S.dimension()* — returns the dimension of the ambient space.

Point_d<Kernel> *S.point(int i)* — returns the ith defining point.
Precondition: $0 \leq i \leq dim$.

point_iterator *S.points_begin()*

returns an iterator pointing to the first defining point.

point_iterator *S.points_end()*

returns an iterator pointing beyond the last defining point.

bool *S.is_degenerate()*

returns true iff the defining points are not full dimensional.

bool *S.is_legal()* returns true iff the set of defining points is legal. A set of defining points is legal iff their orientation is non-zero or if they are all equal.

Point_d<Kernel> *S.center()* returns the center of *S*.
Precondition: *S* is legal.

FT *S.squared_radius()*

returns the squared radius of the sphere.
Precondition: *S* is legal.

Orientation *S.orientation()*

returns the orientation of *S*.

Oriented_side *S.oriented_side(Point_d<Kernel> p)*

returns either the constant *ON_ORIENTED_BOUNDARY*, *ON_POSITIVE_SIDE*, or *ON_NEGATIVE_SIDE*, iff p lies on the boundary, properly on the positive side, or properly on the negative side of sphere, resp.
Precondition: *S.dimension()==p.dimension()*.

Bounded_side *S.bounded_side(Point_d<Kernel> p)*

returns *ON_BOUNDED_SIDE*, *ON_BOUNDARY*, or *ON_UNBOUNDED_SIDE* iff p lies properly inside, on the boundary, or properly outside of sphere, resp.
Precondition: *S.dimension()==p.dimension()*.

bool *S.has_on_positive_side(Point_d<Kernel> p)*

returns *S.oriented_side(p)==ON_POSITIVE_SIDE*.
Precondition: *S.dimension()==p.dimension()*.

bool *S.has_on_negative_side(Point_d<Kernel> p)*

returns *S.oriented_side(p)==ON_NEGATIVE_SIDE*.
Precondition: *S.dimension()==p.dimension()*.

bool *S.has_on_boundary(Point_d<Kernel> p)*

returns *S.oriented_side(p)==ON_ORIENTED_BOUNDARY*, which is the same as *S.bounded_side(p)==ON_BOUNDARY*.
Precondition: *S.dimension()==p.dimension()*.

bool *S.has_on_bounded_side(Point_d<Kernel> p)*

returns *S.bounded_side(p)==ON_BOUNDED_SIDE*.
Precondition: *S.dimension()==p.dimension()*.

bool *S.has_on_unbounded_side(Point_d<Kernel> p)*

returns *S.bounded_side(p)==ON_UNBOUNDED_SIDE*.
Precondition: *S.dimension()==p.dimension()*.

Sphere_d<Kernel>

S.opposite() returns the sphere with the same center and squared radius as *S* but with opposite orientation.

Sphere_d<Kernel>

$S +$ *Vector_d<Kernel> v*

returns the sphere translated by v.
Precondition: *S.dimension()==v.dimension()*.

Non-Member Functions

bool *weak_equality(S1, S2)*

Test for equality as unoriented spheres.
Precondition: *S1.dimension()==S2.dimension()*.

Implementation

Spheres are implemented by a vector of points as a handle type. All operations like creation, initialization, tests, input and output of a sphere s take time $O(s.dimension())$. *dimension()*, point access take constant time. The *center()*-operation takes time $O(d^3)$ on its first call and constant time thereafter. The sidedness and orientation tests take time $O(d^3)$. The space requirement for spheres is $O(s.dimension())$ neglecting the storage room of the points.

CGAL::Iso_box_d<Kernel>

Class

Definition

An object b of the data type *Iso_box_d<Kernel>* is an iso-box in the Euclidean space $\mathbb{E}^d$ with edges parallel to the axes of the coordinate system.

Creation

Iso_box_d<Kernel> b(const Point_d<Kernel>& p, const Point_d<Kernel> &q);

introduces an iso-oriented iso-box b with diagonal opposite vertices p and q.

Operations

bool	*b.operator==(const Iso_box_d<Kernel>& b2) const*	
		Test for equality: two iso-oriented cuboid are equal, iff their lower left and their upper right vertices are equal.
bool	*b.operator!=(const Iso_box_d<Kernel>& b2) const*	
		Test for inequality.
const Point_d<Kernel>&	*b.min() const*	returns the smallest vertex of b.
const Point_d<Kernel>&	*b.max() const*	returns the largest vertex of b.

Predicates

bool	*b.is_degenerate() const*	
		b is degenerate, if all vertices are collinear.
Bounded_side	*b.bounded_side(const Point_d<Kernel>& p) const*	
		returns either *ON_UNBOUNDED_SIDE*, *ON_BOUNDED_SIDE*, or the constant *ON_BOUNDARY*, depending on where point p is.
bool	*b.has_on_boundary(const Point_d<Kernel>& p) const*	
bool	*b.has_on_bounded_side(const Point_d<Kernel>& p) const*	
bool	*b.has_on_unbounded_side(const Point_d<Kernel>& p) const*	

Miscellaneous

Kernel::FT	*b.volume() const*	returns the volume of *b*.

CGAL::Aff_transformation_d<Kernel>

Class

Definition

An instance of the data type *Aff_transformation_d<Kernel>* is an affine transformation of d-dimensional space. It is specified by a square matrix M of dimension $d+1$. All entries in the last row of M except the diagonal entry must be zero; the diagonal entry must be non-zero. A point p with homogeneous coordinates $(p[0],\ldots,p[d])$ can be transformed into the point *p.transform(A)* $= Mp$, where A is an affine transformation created from M by the constructors below.

Types

Aff_transformation_d<Kernel>:: LA

the linear algebra layer.

Aff_transformation_d<Kernel>:: Matrix

the matrix type.

Creation

Aff_transformation_d<Kernel> t;

introduces some transformation.

Aff_transformation_d<Kernel> t(int d, Identity_transformation);

introduces the identity transformation in d-dimensional space.

Aff_transformation_d<Kernel> t(Matrix M);

introduces the transformation of d-space specified by matrix M.
Precondition: M is a square matrix of dimension $d+1$ where entries in the last row of M except the diagonal entry must be zero; the diagonal entry must be non-zero.

template <typename Forward_iterator>
Aff_transformation_d<Kernel> t(Scaling, Forward_iterator start, Forward_iterator end);

introduces the transformation of d-space specified by a diagonal matrix with entries *set [start,end)* on the diagonal (a scaling of the space).
Precondition: *set [start,end)* is a vector of dimension $d+1$.

Aff_transformation_d<Kernel> t(Translation, Vector_d<Kernel> v);

introduces the translation by vector v.

Aff_transformation_d<Kernel> t(int d, Scaling, RT num, RT den);

returns a scaling by a scale factor *num/den*.
Precondition: *den !=0*.

Aff_transformation_d<Kernel> t(int d, Rotation, RT sin_num, RT cos_num, RT den, int e1 = 0, int e2 = 1);

returns a planar rotation with sine and cosine values *sin_num/den* and *cos_num/den* in the plane spanned by the base vectors b_{e1} and b_{e2} in d-space. Thus the default use delivers a planar rotation in the x-y plane.
Precondition: $sin\_num^2 + cos\_num^2 = den^2$ and $0 \leq e_1 < e_2 < d$.
Precondition: *den != 0*

Aff_transformation_d<Kernel> t(int d,
Rotation,
Direction_d<Kernel> dir,
RT num,
RT den,
int e1 = 0,
int e2 = 1)

returns a planar rotation within a two-dimensional linear subspace. The subspace is spanned by the base vectors b_{e1} and b_{e2} in d-space. The rotation parameters are given by the 2-dimensional direction *dir*, such that the difference between the sines and cosines of the rotation given by *dir* and the approximated rotation are at most *num/den* each.

Precondition: *dir.dimension()==2*, *!dir.is_degenerate()* and *num* < *den* is positive, *den != 0*, $0 \leq e_1 < e_2 < d$.

Operations

int	*t.dimension()*	the dimension of the underlying space
Matrix	*t.matrix()*	returns the transformation matrix
Aff_transformation_d<Kernel>	*t.inverse()*	returns the inverse transformation. *Precondition*: *t.matrix()* is invertible.
Aff_transformation_d<Kernel>	$t * s$	composition of transformations. Note that transformations are not necessarily commutative. *t*s* is the transformation which transforms first by *t* and then by *s*.

Implementation

Affine Transformations are implemented by matrices of number type *RT* as a handle type. All operations like creation, initialization, input and output on a transformation *t* take time $O(t.dimension()^2)$. *dimension()* takes constant time. The operations for inversion and composition have the cubic costs of the used matrix operations. The space requirement is $O(t.dimension()^2)$.

12.9 Global Kernel Functions

CGAL::affinely_independent

#include <CGAL/predicates_d.h>

template <class ForwardIterator>
bool *affinely_independent(ForwardIterator first, ForwardIterator last)*

returns true iff the points in A = *tuple [first,last)* are affinely independent.
Precondition: The objects are of the same dimension.
Requirement: The value type of *ForwardIterator* is *Point_d<R>*

Function

Function

CGAL::affine_rank

#include <CGAL/predicates_d.h>

template <class ForwardIterator>
int *affine_rank(ForwardIterator first, ForwardIterator last)*

computes the affine rank of the points in *A* = *tuple [first,last)*.
Precondition: The objects in *A* are of the same dimension.
Requirement: The value type of *ForwardIterator* is *Point_d<R>*.

CGAL::center_of_sphere

#include <CGAL/constructions_d.h>

template <class ForwardIterator>
Point_d<R> *center_of_sphere(ForwardIterator first, ForwardIterator last)*

returns the center of the sphere spanned by the points in A = *tuple[first,last)*.
Precondition: A contains $d+1$ affinely independent points of dimension d.
Requirement: The value type of *ForwardIterator* is *Point_d<R>*.

Function

Function

CGAL::compare_lexicographically

#include <CGAL/predicates_d.h>

Comparison_result *compare_lexicographically(Point_d<R> p, Point_d<R> q)*

Compares the Cartesian coordinates of points p and q lexicographically in ascending order of its Cartesian components *p[i]* and *q[i]* for $i = 0, \ldots, d-1$.
Precondition: *p.dimension() == q.dimension()*

CGAL::contained_in_affine_hull

Function

#include <CGAL/predicates_d.h>

template <class ForwardIterator>

bool	*contained_in_affine_hull(*	*ForwardIterator first,* *ForwardIterator last,* *Point_d<R> p)*

determines whether p is contained in the affine hull of the points in A = *tuple [first,last)*.
Precondition: The objects in A are of the same dimension.
Requirement: The value type of *ForwardIterator* is *Point_d<R>*.

Function

CGAL::contained_in_linear_hull

#include <CGAL/predicates_d.h>

template <class ForwardIterator>
bool contained_in_linear_hull(ForwardIterator first, ForwardIterator last, Vector_d<R> v)

determines whether *v* is contained in the linear hull of the vectors in *A* = *tuple [first,last)*.
Precondition: The objects in *A* are of the same dimension.
Requirement: The value type of *ForwardIterator* is *Vector_d<R>*.

CGAL::contained_in_simplex

#include <CGAL/predicates_d.h>

template <class ForwardIterator>
bool *contained_in_simplex(ForwardIterator first, ForwardIterator last, Point_d<R> p)*

determines whether p is contained in the simplex of the points in A = *tuple [first,last)*.
Precondition: The objects in A are of the same dimension and affinely independent.
Requirement: The value type of *ForwardIterator* is *Point_d<R>*.

Function

CGAL::do_intersect

#include <CGAL/intersections_d.h>

bool *do_intersect(Type1<R> obj1, Type2<R> obj2)*

checks whether *obj1* and *obj2* intersect. Two objects *obj1* and *obj2* intersect if there is a point p that is part of both *obj1* and *obj2*. The intersection region of those two objects is defined as the set of all points p that are part of both *obj1* and *obj2*.
Precondition: the objects are of the same dimension.

The types *Type1* and *Type2* can be any of the following:

- *Point_d<R>*
- *Line_d<R>*
- *Ray_d<R>*
- *Segment_d<R>*
- *Hyperplane_d<R>*

See Also

intersection

CGAL::intersection

Function

#include <CGAL/intersections_d.h>

Object *intersection(Type1<R> f1, Type2<R> f2)*

returns the intersection result of $f1$ and $f2$ by means of the polymorphic wrapper type *Object*. The returned object can be tested for the intersection result and assigned by means of the *object_cast* function.
Precondition: The objects are of the same dimension.

The possible value for types *Type1* and *Type2* and the possible return values wrapped in *Object* are the following:

Type1	Type2	Return Type
Line_d	*Line_d*	*Point_d*, *Line_d*
Segment_d	*Line_d*	*Point_d*, *Segment_d*
Segment_d	*Segment_d*	*Point_d*, *Segment_d*
Ray_d	*Line_d*	*Point_d*, *Ray_d*
Ray_d	*Segment_d*	*Point_d*, *Segment_d*
Ray_d	*Ray_d*	*Point_d*, *Segment_d*, *Ray_d*
Hyperplane_d	*Line_d*	*Point_3*, *Line_3*
Hyperplane_d	*Ray_d*	*Point_d*, *Ray_d*
Hyperplane_d	*Segment_d*	*Point_d*, *Segment_d*

Example

The following example demonstrates the most common use of *intersection* routines.

```
#include <CGAL/intersections_d.h>

template <class R>
void foo(Segment_d<R> seg, Line_d<R> lin)
{
  Object result = intersection(seg, lin);
  if (const Point_d<R> *ipnt = object_cast<Point_d<R> >(&result) ) {
    // handle the point intersection case with *ipnt.
  } else if (const Segment_d<R> *iseg = object_cast<Segment_d<R> >(&result) ) {
    // handle the segment intersection case with *iseg.
  } else {
    // handle the no intersection case.
  }
}
```

See Also

do_intersect, *Kernel::Intersect_d*

CGAL::lexicographically_smaller

#include <CGAL/predicates_d.h>

bool	*lexicographically_smaller(Point_d<R> p, Point_d<R> q)*
	returns *true* iff *p* is lexicographically smaller than *q* with respect to Cartesian lexicographic order of points. *Precondition*: *p.dimension() == q.dimension()*.

Function

Function

CGAL::lexicographically_smaller_or_equal

#include <CGAL/predicates_d.h>

bool	*lexicographically_smaller_or_equal(Point_d<R> p, Point_d<R> q)*	
		returns *true* iff p is lexicographically smaller than q with respect to Cartesian lexicographic order of points or equal to q. *Precondition*: *p.dimension() == q.dimension()*.

CGAL::lift_to_paraboloid

#include <CGAL/constructions_d.h>

Point_d<R> *lift_to_paraboloid(Point_d<R> p)*

returns the projection of $p = (x_0, \ldots, x_{d-1})$ onto the paraboloid of revolution which is the point $(p_0, \ldots, p_{d-1}, \sum_{0 \leq i < d} p_i^2)$ in $(d+1)$-space.

Function

Function

CGAL::linearly_independent

#include <CGAL/predicates_d.h>

template <class ForwardIterator>
bool *linearly_independent(ForwardIterator first, ForwardIterator last)*

decides whether the vectors in A = *tuple [first,last)* are linearly independent.
Precondition: The objects in A are of the same dimension.
Requirement: The value type of *ForwardIterator* is *Vector_d<R>*.

CGAL::linear_base

#include <CGAL/constructions_d.h>

template <class ForwardIterator, class OutputIterator>
OutputIterator *linear_base(ForwardIterator first, ForwardIterator last, OutputIterator result)*

computes a basis of the linear space spanned by the vectors in A = *tuple [first,last)* and returns it via an iterator range starting in *result*. The returned iterator marks the end of the output.
Precondition: A contains vectors of the same dimension d.
Requirement: The value type of *ForwardIterator* and *OutputIterator* is *Vector_d<R>*.

Function

Function

CGAL::linear_rank

#include <CGAL/predicates_d.h>

template <class ForwardIterator>
int *linear_rank(ForwardIterator first, ForwardIterator last)*

computes the linear rank of the vectors in A = *tuple [first,last)*.
Precondition: The objects are of the same dimension.
Requirement: The value type of *ForwardIterator* is *Vector_d<R>*.

CGAL::midpoint

#include <CGAL/constructions_d.h>

Point_d<R>	*midpoint(Point_d<R> p, Point_d<R> q)*
	computes the midpoint of the segment *pq*. *Precondition*: *Precondition*: *p.dimension() == q.dimension()*.

Function

Function

CGAL::orientation

#include <CGAL/predicates_d.h>

template <class ForwardIterator>
Orientation *orientation(ForwardIterator first, ForwardIterator last)*

determines the orientation of the points of the tuple A = *tuple [first,last)* where A consists of $d+1$ points in d-space. This is the sign of the determinant

$$\begin{vmatrix} 1 & 1 & 1 & 1 \\ A[0] & A[1] & \dots & A[d] \end{vmatrix}$$

where $A[i]$ denotes the Cartesian coordinate vector of the i-th point in A.
Precondition: *size [first,last)* == *d+1* and $A[i]$*.dimension()* == d $\forall 0 \le i \le d$.
Requirement: The value type of *ForwardIterator* is *Point_d<R>*.

CGAL::project_along_d_axis

#include <CGAL/constructions_d.h>

Point_d<R>	*project_along_d_axis(Point_d<R> p)*	
		returns p projected along the d-axis onto the hyperspace spanned by the first $d-1$ standard base vectors.

Function

Function

CGAL::side_of_bounded_sphere

#include <CGAL/predicates_d.h>

template <class ForwardIterator>
Bounded_side *side_of_bounded_sphere(ForwardIterator first, ForwardIterator last, Point_d<R> p)*

returns the relative position of point p to the sphere defined by A = *tuple [first,last)*. The order of the points of A does not matter.
Precondition: *orientation(first,last)* is not *ZERO*.
Requirement: The value type of *ForwardIterator* is *Point_d<R>*.

CGAL::side_of_oriented_sphere

#include <CGAL/predicates_d.h>

template <class ForwardIterator>
Oriented_side *side_of_oriented_sphere(ForwardIterator first, ForwardIterator last, Point_d<R> p)*

returns the relative position of point p to the oriented sphere defined by the points in A = *tuple [first,last)* The order of the points in A is important, since it determines the orientation of the implicitly constructed sphere. If the points in A are positively oriented, the positive side is the bounded interior of the sphere.
Precondition: A contains $d+1$ points in d-space.
Requirement: The value type of *ForwardIterator* is *Point_d<R>*.

Function

CGAL::squared_distance

#include <CGAL/constructions_d.h>

FT	*squared_distance(Point_d<R> p, Point_d<R> q)*	
		computes the square of the Euclidean distance between the two points p and q. *Precondition*: The dimensions of p and q are the same.

12.10 Kernel Concept

Kernel_d

The concept of a *kernel* is defined by a set of requirements on the provision of certain types and access member functions to create objects of these types. The types are function object classes to be used within the algorithms and data structures in the basic library of CGAL. This allows you to use any model of a kernel as a traits class in the CGAL algorithms and data structures, unless they require types beyond those provided by a kernel.

Kernel_d subsumes the concept of a *d-dimensional kernel*.

A kernel provides types, construction objects, and generalized predicates. The former replace constructors of the kernel classes and constructive procedures in the kernel. There are also function objects replacing operators, especially for equality testing.

Concept

Types

Kernel_d:: FT	a number type that is a model for *FieldNumberType*
Kernel_d:: RT	a number type that is a model for *RingNumberType*

Coordinate Access

Kernel_d:: Cartesian_const_iterator_d	a type that allows to iterate over the Cartesian coordinates

Geometric Objects

Kernel_d:: Point_d
Kernel_d:: Vector_d
Kernel_d:: Direction_d
Kernel_d:: Hyperplane_d
Kernel_d:: Line_d
Kernel_d:: Ray_d
Kernel_d:: Segment_d
Kernel_d:: Iso_box_d
Kernel_d:: Sphere_d
Kernel_d:: Aff_transformation_d

Constructions

Kernel_d:: Barycentric_coordinates_d	
Kernel_d:: Center_of_sphere_d	a model of *Kernel::Center_of_sphere_d*
Kernel_d:: Compute_coordinate_d	a model of *Kernel::Compute_coordinate_d*
Kernel_d:: Construct_point_d	
Kernel_d:: Construct_vector_d	
Kernel_d:: Construct_direction_d	
Kernel_d:: Construct_hyperplane_d	

Kernel_d:: Construct_segment_d	
Kernel_d:: Construct_iso_box_d	
Kernel_d:: Construct_line_d	
Kernel_d:: Construct_ray_d	
Kernel_d:: Construct_sphere_d	
Kernel_d:: Construct_aff_transformation_d	
Kernel_d:: Construct_cartesian_const_iterator_d	a model of *Kernel::ConstructCartesianConstIterator_d*
Kernel_d:: Intersect_d	a model of *Kernel::Intersect_d*
Kernel_d:: Lift_to_paraboloid_d	a model of *Kernel::Lift_to_paraboloid_d*
Kernel_d:: Linear_base_d	a model of *Kernel::Linear_base_d*
Kernel_d:: Midpoint_d	a model of *Kernel::Midpoint_d*
Kernel_d:: Orthogonal_vector_d	a model of *Kernel::Orthogonal_vector_d*
Kernel_d:: Point_of_sphere_d	a model of *Kernel::Point_of_sphere_d*
Kernel_d:: Point_to_vector_d	a model of *Kernel::Point_to_vector_d*
Kernel_d:: Project_along_d_axis_d	a model of *Kernel::Project_along_d_axis_d*
Kernel_d:: Squared_distance_d	a model of *Kernel::Squared_distance_d*
Kernel_d:: Value_at_d	a model of *Kernel::Value_at_d*
Kernel_d:: Vector_to_point_d	a model of *Kernel::Vector_to_point_d*

Generalized Predicates

Kernel_d:: Affine_rank_d	a model of *Kernel::Affine_rank_d*
Kernel_d:: Affinely_independent_d	a model of *Kernel::Affinely_independent_d*
Kernel_d:: Compare_lexicographically_d	a model of *Kernel::Compare_lexicographically_d*
Kernel_d:: Component_accessor_d	a model of *Kernel::Component_accessor_d*
Kernel_d:: Contained_in_affine_hull_d	a model of *Kernel::Contained_in_affine_hull_d*
Kernel_d:: Contained_in_linear_hull_d	a model of *Kernel::Contained_in_linear_hull_d*
Kernel_d:: Contained_in_simplex_d	a model of *Kernel::Contained_in_simplex_d*
Kernel_d:: Equal_d	a model of *Kernel::Equal_d*
Kernel_d:: Has_on_positive_side_d	a model of *Kernel::Has_on_positive_side_d*
Kernel_d:: Less_coordinate_d	a model of *Kernel::Less_coordinate_d*
Kernel_d:: Less_lexicographically_d	a model of *Kernel::Less_lexicographically_d*
Kernel_d:: Less_or_equal_lexicographically_d	a model of *Kernel::Less_or_equal_lexicographically_d*
Kernel_d:: Linear_rank_d	a model of *Kernel::Linear_rank_d*
Kernel_d:: Linearly_independent_d	a model of *Kernel::Linearly_independent_d*
Kernel_d:: Orientation_d	a model of *Kernel::Orientation_d*
Kernel_d:: Oriented_side_d	a model of *Kernel::Oriented_side_d*
Kernel_d:: Point_dimension_d	a model of *Kernel::Point_dimension_d*
Kernel_d:: Position_on_line_d	
Kernel_d:: Side_of_bounded_sphere_d	a model of *Kernel::Side_of_bounded_sphere_d*
Kernel_d:: Side_of_oriented_sphere_d	a model of *Kernel::Side_of_oriented_sphere_d*

Operations

The following member functions return function objects of the types listed above. The name of the access function is the name of the type returned with an *_object* suffix and no capital letter at the beginning. We only give two examples to show the scheme. For the functors *Construct_point_d* and *Orientation_d* the corresponding functions are:

Kernel::Construct_point_d	*kernel.construct_point_d_object() const*
Kernel::Orientation_d	*kernel.orientation_d_object() const*

Has Models

Cartesian_d<FieldNumberType>, *Homogeneous_d<RingNumberType>*

Kernel::Affinely_independent_d

A model for this must provide:

template <class ForwardIterator>
bool *fo(ForwardIterator first, ForwardIterator last)*

returns true iff the points in A = *tuple [first,last)* are affinely independent.
Precondition: The objects are of the same dimension.
Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Kernel::Affine_rank_d

A model for this must provide:

template <class ForwardIterator>
int *fo(ForwardIterator first, ForwardIterator last)*

computes the affine rank of the points in A = *tuple [first,last)*.
Precondition: The objects are of the same dimension.
Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Kernel::CartesianConstIterator_d

A type representing an iterator to the Cartesian coordinates of a point in d dimensions.

Refines

CopyConstructible, Assignable, DefaultConstructible

Is Model for the Concepts

BidirectionalIterator

See Also

Kernel::ConstructCartesianConstIterator_d . . . . page 1130

Kernel::Center_of_sphere_d

A model for this must provide:

template <class ForwardIterator>
Kernel::Point_d *fo(ForwardIterator first, ForwardIterator last)*

returns the center of the sphere spanned by the points in A = *tuple [first,last)*.
Precondition: A contains $d+1$ affinely independent points of dimension d.
Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Kernel::Compare_lexicographically_d

A model for this must provide:

Comparison_result *fo(Kernel::Point_d p, Kernel::Point_d q)*

Compares the Cartesian coordinates of points p and q lexicographically in ascending order of its Cartesian components *p[i]* and *q[i]* for $i = 0, \ldots, d-1$.
Precondition: The objects are of the same dimension.

Kernel::Component_accessor_d

A model for this must provide:

int *fo.dimension(Kernel::Point_d p)*

returns the dimension of p.

Kernel::RT *fo.homogeneous(Kernel::Point_d p, int i)*

returns the ith homogeneous coordinate of p.
Precondition: *0 <= i <= dimension(p)*.

Kernel::FT *fo.cartesian(Kernel::Point_d p, int i)*

returns the ith Cartesian coordinate of p.
Precondition: *0 <= i < dimension(p)*.

Kernel::Compute_coordinate_d

A model for this must provide:

Kernel::FT *fo(Kernel::Point_d p, int i)*

returns the ith cartesian coordinate of p

Kernel::ConstructCartesianConstIterator_d

A model for this must provide:

Kernel::Cartesian_const_iterator_d

fo(Kernel::Point_d p)

returns an iterator on the 0'th Cartesian coordinate of p.

Kernel::Cartesian_const_iterator_d

fo(Kernel::Point_d p, int)

returns the past the end iterator of the Cartesian coordinates of p.

Refines

AdaptableFunctor (with one argument)

See Also

Kernel::CartesianConstIterator_d . . . . page 1125

Kernel::Contained_in_affine_hull_d

A model for this must provide:

template <class ForwardIterator>
Bounded_side *fo(ForwardIterator first, ForwardIterator last, Kernel::Point_d p)*

determines whether p is contained in the affine hull of the points in A = *tuple [first,last)*.
Precondition: The objects are of the same dimension.
Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Kernel::Contained_in_linear_hull_d

A model for this must provide:

template <class ForwardIterator>
Bounded_side *fo(ForwardIterator first, ForwardIterator last, Kernel::Vector_d v)*

determines whether v is contained in the linear hull of the vectors in A = *tuple [first,last)*.
Precondition: The objects are of the same dimension.
Requirement: The value type of *ForwardIterator* is *Kernel::Vector_d*.

Kernel::Contained_in_simplex_d

A model for this must provide:

template <class ForwardIterator>
Bounded_side *fo(ForwardIterator first, ForwardIterator last, Kernel::Point_d p)*

determines whether p is contained in the simplex of the points in A = *tuple [first,last)*.
Precondition: The objects in A are of the same dimension and affinely independent.
Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Functor
Concept

Kernel::Equal_d

A model for this must provide:

bool *fo(Kernel::Point_d p, Kernel::Point_d q)*

returns true iff p and q are equal (as d-dimensional points).
Precondition: p and q have the same dimension.

Kernel::Has_on_positive_side_d

A model for this must provide:

template <class Kernel_object>
bool *fo(Kernel_object o, Kernel::Point_d p)*

returns true iff p is on the positive side of o. *Kernel_object* may be any of *Kernel::Sphere_d*, *Kernel::Hyperplane_d*.
Precondition: p and o have the same dimension.

Functor
Concept

Kernel::Intersect_d

A model for this must provide:

template <class Kernel_object>
Object *fo(Kernel_object p, Kernel_object q)*

returns the result of the intersection of p and q in form of a polymorphic object. *Kernel_object* may be any of *Kernel::Segment_d*, *Kernel::Ray_d*, *Kernel::Line_d*, *Kernel::Hyperplane_d*.
Precondition: p and q have the same dimension.

Kernel::Less_lexicographically_d

A model for this must provide:

bool *fo(Kernel::Point_d p, Kernel::Point_d q)*

returns *true* iff p is lexicographically smaller than q with respect to Cartesian lexicographic order of points.
Precondition: p and q have the same dimension.

Kernel::Less_or_equal_lexicographically_d

A model for this must provide:

bool	*fo(Kernel::Point_d p, Kernel::Point_d q)*	
		returns *true* iff p is lexicographically smaller than q with respect to Cartesian lexicographic order of points or equal to q. *Precondition*: p and q have the same dimension.

Kernel::Less_coordinate_d

A model for this must provide:

bool	*fo(Kernel::Point_d p, Kernel::Point_d q, int i)*	
		returns *true* iff the ith cartesian coordinate of p is smaller than the ith cartesian coordinate of q. *Precondition*: p and q have the same dimension.

Functor
Concept

Kernel::Lift_to_paraboloid_d

A model for this must provide:

Kernel::Point_d *fo(Kernel::Point_d p)*

returns $p = (x_0, \ldots, x_{d-1})$ lifted to the paraboloid of revolution which is the point $(p_0, \ldots, p_{d-1}, \sum_{0 \le i < d} p_i^2)$ in $(d+1)$-space.

Kernel::Linearly_independent_d

A model for this must provide:

template <class ForwardIterator>
bool *fo(ForwardIterator first, ForwardIterator last)*

decides whether the vectors in A = *tuple [first,last)* are linearly independent.
Precondition: The objects in A are of the same dimension.
Requirement: The value type of *ForwardIterator* is *Kernel_d::Vector_d*.

Functor
Concept

Kernel::Linear_base_d

A model for this must provide:

template <class ForwardIterator, class OutputIterator>
int *fo(ForwardIterator first, ForwardIterator last, OutputIterator result)*

computes a basis of the linear space spanned by the vectors in A = *tuple [first,last)* and returns it via an iterator range starting in *result*. The returned iterator marks the end of the output.
Precondition: A contains vectors of the same dimension d.
Requirement: The value type of *ForwardIterator* and *OutputIterator* is *Kernel::Vector_d*.

Kernel::Linear_rank_d

A model for this must provide:

template <class ForwardIterator>
int *fo(ForwardIterator first, ForwardIterator last)*

computes the linear rank of the vectors in A = *tuple [first,last)*.
Precondition:
Precondition: A contains vectors of the same dimension d.
Requirement: The value type of *ForwardIterator* is *Kernel::Vector_d*.

Functor
Concept

Functor
Concept

Kernel::Midpoint_d

A model for this must provide:

Kernel::Point_d *fo(Kernel::Point_d p, Kernel::Point_d q)*

computes the midpoint of the segment pq.
Precondition: p and q have the same dimension.

Kernel::Orientation_d

A model for this must provide:

template <class ForwardIterator>
Orientation *fo(ForwardIterator first, ForwardIterator last)*

determines the orientation of the points of the tuple A = *tuple [first,last)* where A consists of $d+1$ points in d-space. This is the sign of the determinant

$$\begin{vmatrix} 1 & 1 & 1 & 1 \\ A[0] & A[1] & \ldots & A[d] \end{vmatrix}$$

where *A[i]* denotes the Cartesian coordinate vector of the i-th point in A.
Precondition: *size [first,last)* == *d+1* and *A[i].dimension()* == d $\forall 0 \le i \le d$.
Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Functor
Concept

Kernel::Oriented_side_d

A model for this must provide:

template <class Kernel_object>
Oriented_side *fo(Kernel_object o, Kernel::Point_d p)*

returns the side of *p* with respect to *o*. *Kernel_object* may be any of *Kernel::Sphere_d* or *Kernel::Hyperplane_d*.
Precondition: *p* and *o* have the same dimension.

Kernel::Orthogonal_vector_d

A model for this must provide:

Kernel::Vector_d *fo(Kernel::Hyperplane_d h)*

computes an orthogonal vector to *h*.

Functor
Concept

Kernel::Point_dimension_d

A model for this must provide:

int *fo(Kernel::Point_d p)*

returns the dimension of p

Kernel::Point_of_sphere_d

A model for this must provide:

bool *fo(Kernel::Sphere_d s, int i)*

returns the ith point defining the sphere s.

Functor
Concept

Kernel::Point_to_vector_d

A model for this must provide:

Kernel::Vector_d *fo(Kernel::Point_d p)*

converts p to its geometric vector.

Kernel::Project_along_d_axis_d

A model for this must provide:

Kernel::Point_d *fo(Kernel::Point_d p)*

returns p projected along the d-axis onto the hyperspace spanned by the first $d-1$ standard base vectors.

Kernel::Side_of_bounded_sphere_d

A model for this must provide:

template <class ForwardIterator>
Bounded_side *fo(ForwardIterator first, ForwardIterator last, Kernel::Point_d p)*

returns the relative position of point p to the sphere defined by A = *tuple [first,last)*. The order of the points of A does not matter.
Precondition: *orientation(first,last)* is not *ZERO*.
Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Kernel::Side_of_oriented_sphere_d

A model for this must provide:

template <class ForwardIterator>
Bounded_side *fo(ForwardIterator first, ForwardIterator last, Kernel::Point_d p)*

returns the relative position of point p to the oriented sphere defined by the points in A = *tuple [first,last)* The order of the points in A is important, since it determines the orientation of the implicitly constructed sphere. If the points in A are positively oriented, the positive side is the bounded interior of the sphere.
Precondition: A contains $d+1$ points in d-space.
Requirement: The value type of *ForwardIterator* is *Kernel::Point_d*.

Functor
Concept

Kernel::Squared_distance_d

A model for this must provide:

Kernel::FT *fo(Kernel::Point_d p, Kernel::Point_d q)*

computes the square of the Euclidean distance between the two points p and q.
Precondition: The dimensions of p and q are the same.

Kernel::Value_at_d

A model for this must provide:

Kernel::FT *fo(Kernel::Hyperplane_d h, Kernel::Point_d p)*

computes the value of h evaluated at p.
Precondition: p and h have the same dimension.

Kernel::Vector_to_point_d

A model for this must provide:

Kernel::Point_d *fo(Kernel::Vector_d v)*

converts v to the affine point $0 + v$.

Chapter 13

2D Circular Geometry Kernel

Pedro Machado Manhães de Castro, Sylvain Pion, and Monique Teillaud

Contents

13.1 Introduction

The goal of the circular kernel is to offer to the user a large set of functionalities on circles and circular arcs in the plane. All the choices (interface, robustness, representation, and so on) made here are consistent with the choices made in the CGAL kernel, for which we refer the user to the 2D kernel manual.

In this first release, all functionalities necessary for computing an arrangement of circular arcs and these line segments are defined. Three traits classes are provided for the CGAL arrangement package.

13.2 Software Design

The design is done in such a way that the algebraic concepts and the geometric concepts are clearly separated. *Circular_kernel_2* has therefore two template parameters:

- the first parameter must model the CGAL three dimensional *Kernel* concept. The circular kernel derives from it, and it provides all elementary geometric objects like points, lines, circles, and elementary functionality on them.

- the second parameter is the algebraic kernel, which is responsible for computations on polynomials and algebraic numbers. It has to be a model of concept *AlgebraicKernelForCircles*. The robustness of the package relies on the fact that the algebraic kernel provides exact computations on algebraic objects.

The circular kernel uses the extensibility scheme presented in the 2D kernel manual (see Section 11.5). The types of *Kernel* are inherited by the circular kernel and some types are taken from the *AlgebraicKernelForCircles* parameter. Three new main geometric objects are introduced by *Circular_kernel_2*: circular arcs, points of circular arcs (used in particular for endpoints of arcs and intersection points between arcs) and line segments whose endpoints are points of this new type.

In fact, the circular kernel is documented as a concept, *CircularKernel*, and two models are provided:

- *Circular_kernel_2<Kernel,AlgebraicKernelForCircles>*, the basic kernel,

- and a predefined filtered kernel *Exact_circular_kernel_2*, that is based on similar techniques as *Exact_predicates_exact_constructions_kernel*.

13.3 Examples

The first example shows how to construct circles or circular arcs from points, and how to compute intersections between them using the global function.

```
#include <CGAL/Exact_circular_kernel_2.h>
#include <CGAL/point_generators_2.h>

typedef CGAL::Exact_circular_kernel_2             Circular_k;

typedef CGAL::Point_2<Circular_k>                 Point_2;
typedef CGAL::Circle_2<Circular_k>                Circle_2;
typedef CGAL::Circular_arc_2<Circular_k>          Circular_arc_2;

template <typename T>
double prob_2() {
  CGAL::Random_points_in_square_2<Point_2> g(1.0);
  double prob = 0.0;
  for (int i = 0; i < 10000; i++) {

    Point_2 p1, p2, p3, p4, p5, p6;
    p1 = *g++; p2 = *g++; p3 = *g++;
    p4 = *g++; p5 = *g++; p6 = *g++;

    // the pi's are points inherited from the Cartesian kernel Point_2,
   so,
    // the orientation predicate can be called on them
    if(CGAL::orientation(p1, p2, p3) != CGAL::COUNTERCLOCKWISE)
   std::swap(p1, p3);
    T o1 = T(p1, p2, p3);
    if(CGAL::orientation(p4, p5, p6) != CGAL::COUNTERCLOCKWISE)
   std::swap(p4, p6);
```

```
    T o2 = T(p4, p5, p6);

    std::vector< CGAL::Object > res;
    CGAL::intersection(o1, o2, std::back_inserter(res));

    prob += (res.size() != 0) ? 1.0 : 0.0;
  }
  return prob/10000.0;
}

int main()
{
  std::cout << "What is the probability that two arcs formed by" <<
   std::endl;
  std::cout << "three random counterclockwise-oriented points on" <<
   std::endl;
  std::cout << "an unit square intersect? (wait a second please)" <<
   std::endl;
  std::cout << "The probability is: " << prob_2<Circular_arc_2>() <<
    std::endl << std::endl;

  std::cout << "And what about the probability that two circles formed
   by"
    << std::endl;
  std::cout << "three random counterclockwise-oriented points on" <<
   std::endl;
  std::cout << "an unit square intersect? (wait a second please)" <<
   std::endl;
  std::cout << "The probability is: " << prob_2<Circle_2>() << std::endl;
  return 0;
}
```

File: examples/Circular_kernel_2/intersecting_arcs.cpp

The following example shows how to use a functor of the kernel.

```
#include <CGAL/Exact_circular_kernel_2.h>
#include <CGAL/point_generators_2.h>

typedef CGAL::Exact_circular_kernel_2             Circular_k;

typedef CGAL::Point_2<Circular_k>                 Point_2;
typedef CGAL::Circular_arc_2<Circular_k>          Circular_arc_2;

int main()
{
  int n = 0;
  Circular_arc_2 c = Circular_arc_2(Point_2(10,0), Point_2(5,5),
   Point_2(0, 0));

  for(int i = 0; i <= 10; i++) {
    for(int j = 0; j <= 10; j++) {
      Point_2 p = Point_2(i, j);
```

```
      if(Circular_k().has_on_2_object()(c,p)) {
        n++;
        std::cout << "(" << i << "," << j << ")" << std::endl;
      }
    }
  }
  std::cout << "There are " << n << " points in the [0,..,10]x[0,..,10] "
            << "grid on the circular" << std::endl
            << " arc defined counterclockwisely by the points (0,0),
   (5,5), (10,0)"
            << std::endl << "See the points above." << std::endl;
  return 0;
}
```

File: examples/Circular_kernel_2/functor_has_on_2.cpp

13.4 Design and Implementation History

The first pieces of prototype code were comparisons of algebraic numbers of degree 2, written by Olivier Devillers [DFMT00, DFMT02], and that are still used in the current implementation of *CGAL::Root_of_2*.

Some work was then done in the direction of a "kernel" for CGAL.[1] and the first design emerged in [EKP+04].

The code of this package was initially written by Sylvain Pion and Monique Teillaud who also wrote the manual. Athanasios Kakargias had worked on a prototype version of this kernel in 2003. Julien Hazebrouck participated in the implementation in July and August 2005. The contribution of Pedro Machado Manhães de Castro in summer 2006 improved significantly the efficiency of this kernel. He also added more functionality in 2008.

This work was partially supported by the IST Programme of the EU as a Shared-cost RTD (FET Open) Project under Contract No IST-2000-26473 (ECG - Effective Computational Geometry for Curves and Surfaces) and by the IST Programme of the 6th Framework Programme of the EU as a STREP (FET Open Scheme) Project under Contract No IST-006413 (ACS - Algorithms for Complex Shapes).

Kernel

Has Models

CGAL::Circular_kernel_2<Kernel,AlgebraicKernelForCircles>
CGAL::Exact_circular_kernel_2

Types

A model of *CircularKernel* is supposed to provide some basic types

CircularKernel:: Linear_kernel	Model of *LinearKernel*.
CircularKernel:: Algebraic_kernel	Model of *AlgebraicKernelForCircles*.
CircularKernel:: RT	Model of *RingNumberType*.
CircularKernel:: FT	Model of *FieldNumberType*.
CircularKernel:: Root_of_2	Model of *RootOf_2*.
CircularKernel:: Root_for_circles_2_2	Model of *AlgebraicKernelForCircles::RootForCircles_2_2*.
CircularKernel:: Polynomial_1_2	Model of *AlgebraicKernelForCircles::Polynomial_1_2*.
CircularKernel:: Polynomial_for_circles_2_2	Model of *AlgebraicKernelForCircles::PolynomialForCircles_2_2*.

and to define the following geometric objects

CircularKernel:: Point_2	Model of *Kernel::Point_2*.
CircularKernel:: Circle_2	Model of *Kernel::Circle_2*.
CircularKernel:: Line_arc_2	Model of *CircularKernel::LineArc_2*.
CircularKernel:: Circular_arc_2	Model of *CircularKernel::CircularArc_2*.
CircularKernel:: Circular_arc_point_2	Model of *CircularKernel::CircularArcPoint_2*.

Moreover, a model of *CircularKernel* must provide predicates, constructions and other functionalities.

Predicates

CircularKernel:: Compare_x_2	Model of *CircularKernel::CompareX_2*.
CircularKernel:: Compare_y_2	Model of *CircularKernel::CompareY_2*.
CircularKernel:: Compare_xy_2	Model of *CircularKernel::CompareXY_2*.
CircularKernel:: Equal_2	Model of *CircularKernel::Equal_2*.
CircularKernel:: Compare_y_at_x_2	Model of *CircularKernel::CompareYatX_2*.

CircularKernel:: Compare_y_to_right_2	Model of *CircularKernel::CompareYtoRight_2*.
CircularKernel:: Has_on_2	Model of *CircularKernel::HasOn_2*.
CircularKernel:: Do_overlap_2	Model of *CircularKernel::DoOverlap_2*.
CircularKernel:: Do_intersect_2	Model of *CircularKernel::DoIntersect_2*.
CircularKernel:: Bounded_side_2	Model of *CircularKernel::BoundedSide_2*.
CircularKernel:: Has_on_bounded_side_2	Model of *CircularKernel::HasOnBoundedSide_2*.
CircularKernel:: Has_on_unbounded_side_2	Model of *CircularKernel::HasOnUnboundedSide_2*.
CircularKernel:: In_x_range_2	Model of *CircularKernel::InXRange_2*.
CircularKernel:: Is_vertical_2	Model of *CircularKernel::IsVertical_2*.
CircularKernel:: Is_x_monotone_2	Model of *CircularKernel::IsXMonotone_2*.
CircularKernel:: Is_y_monotone_2	Model of *CircularKernel::IsYMonotone_2*.

Constructions

CircularKernel:: Construct_line_2	Model of *CircularKernel::ConstructLine_2*.
CircularKernel:: Construct_circle_2	Model of *CircularKernel::ConstructCircle_2*.
CircularKernel:: Construct_circular_arc_point_2	Model of *CircularKernel::ConstructCircularArcPoint_2*.
CircularKernel:: Construct_line_arc_2	Model of *CircularKernel::ConstructLineArc_2*.
CircularKernel:: Construct_circular_arc_2	Model of *CircularKernel::ConstructCircularArc_2*.
CircularKernel:: Compute_circular_x_2	Model of *CircularKernel::ComputeCircularX_2*
CircularKernel:: Compute_circular_y_2	Model of *CircularKernel::ComputeCircularY_2*
CircularKernel:: Construct_circular_min_vertex_2	Model of *CircularKernel::ConstructCircularMinVertex_2*.
CircularKernel:: Construct_circular_max_vertex_2	Model of *CircularKernel::ConstructCircularMaxVertex_2*.
CircularKernel:: Construct_circular_source_vertex_2	Model of *CircularKernel::ConstructCircularSourceVertex_2*.

CircularKernel:: Construct_circular_target_vertex_2

Model of *CircularKernel::ConstructCircularTargetVertex_2*.

CircularKernel:: Intersect_2	Model of *CircularKernel::Intersect_2*.
CircularKernel:: Split_2	Model of *CircularKernel::Split_2*.
CircularKernel:: Make_x_monotone_2	Model of *CircularKernel::MakeXMonotone_2*.
CircularKernel:: Make_xy_monotone_2	Model of *CircularKernel::MakeXYMonotone_2*.

Link with the algebraic kernel

CircularKernel:: Get_equation	Model of *CircularKernel::GetEquation*.

Operations

As in the *Kernel* concept, for each of the function objects above, there must exist a member function that requires no arguments and returns an instance of that function object. The name of the member function is the uncapitalized name of the type returned with the suffix *_object* appended. For example, for the function object *CircularKernel::Construct_circular_arc_2* the following member function must exist:

Construct_circular_arc_2

ck.construct_circular_arc_2_object() const

CGAL::Circular_kernel_2<Kernel,AlgebraicKernelForCircles>

Class

#include <CGAL/Circular_kernel_2.h>

Is Model for the Concepts

CircularKernel

Parameters

The first parameter of the circular kernel must be instantiated with a model of the *Kernel* concept. The *Circular_kernel_2* class template derives from this first parameter, in order to reuse all needed functionalities on basic objects provided by a model of the Kernel concept.

The second parameter, *AlgebraicKernelForCircles*, is meant to provide the circular kernel with all the algebraic functionalities required for the manipulation of algebraic curves.

Inherits From

Kernel

Types

The circular kernel uses basic number types of the algebraic kernel:

typedef AlgebraicKernelForCircles::RT	*RT;*	Ring number type.
typedef AlgebraicKernelForCircles::FT	*FT;*	Field number type.

In fact, the two number types *AlgebraicKernelForCircles::RT* and *Kernel::RT* must coincide, as well as *AlgebraicKernelForCircles::FT* and *Kernel::FT*.

The following types are available, as well as all the functionality on them described in the *CircularKernel* concept.

typedef Line_arc_2<Circular_kernel_2>	*Line_arc_2;*
typedef Circular_arc_2<Circular_kernel_2>	*Circular_arc_2;*
typedef Circular_arc_point_2<Circular_kernel_2>	*Circular_arc_point_2;*

CGAL::Circular_arc_point_2<CircularKernel>

Class

CGAL::Circular_arc_2<CircularKernel>

#include <CGAL/Circular_arc_2.h>

Is Model for the Concepts

CircularKernel::CircularArc_2

Creation

Circular_arc_2<CircularKernel> ca(Circle_2<CircularKernel> c);

Constructs an arc from a full circle.

Circular_arc_2<CircularKernel> ca(Circle_2<CircularKernel> c,
Circular_arc_point_2<CircularKernel> p,
Circular_arc_point_2<CircularKernel> q)

Constructs the circular arc supported by c, whose source is p and whose target is q when traversing the circle in counterclockwise direction.
Precondition: p and q lie on c.

Circular_arc_2<CircularKernel> ca(Point_2<CircularKernel> p,
Point_2<CircularKernel> q,
Point_2<CircularKernel> r)

Constructs an arc that is supported by the circle of type *Circle_2<CircularKernel>* passing through the points p, q and r. The source and target are respectively p and r, when traversing the supporting circle in the counterclockwise direction. Note that, depending on the orientation of the point triple (p,q,r), q may not lie on the arc.
Precondition: p, q, and r are not collinear.

Access Functions

Circle_2<CircularKernel>	*ca.supporting_circle()*	
Point_2<CircularKernel>	*ca.center() const*	returns the center of the supporting circle.
CircularKernel::FT	*ca.squared_radius() const*	returns the squared radius of the supporting circle.

A circular arc is not oriented. Still, its source and target endpoints can be defined, supposing that its supporting circle in traversed the counterclockwise direction from *source* to *target*.

Circular_arc_point_2<CircularKernel>	*ca.source()*	
Circular_arc_point_2<CircularKernel>	*ca.target()*	

When the methods *source* and *target* return the same point, then the arc is in fact a full circle.

When an arc is x-monotone, its left and right points can be accessed directly:

Circular_arc_point_2<CircularKernel>	*ca.left()*	*Precondition*: *ca.is_x_monotone()*.
Circular_arc_point_2<CircularKernel>	*ca.right()*	*Precondition*: *ca.is_x_monotone()*.
Bbox_2	*ca.bbox() const*	Returns a bounding box containing the arc.

Query Functions

bool	*ca.is_x_monotone()*	Tests whether the arc is x-monotone.
bool	*ca.is_y_monotone()*	Tests whether the arc is y-monotone.

Operations

bool	*ca1 == ca2*	Test for equality. Two arcs are equal, iff their non-oriented supporting circles are equal (i.e. they have same center and same squared radius) and their endpoints are equal.
bool	*ca1 != ca2*	Test for non-equality

I/O

istream&	*std::istream& is >> Circular_arc_2 & ca*
ostream&	*std::ostream& os << Circular_arc_2 ca*

CGAL::Line_arc_2<CircularKernel>

#include <CGAL/Line_arc_2.h>

Is Model for the Concepts

CircularKernel::LineArc_2

Creation

Line_arc_2<CircularKernel> la(Line_2<CircularKernel> l, Circular_arc_point_2<CircularKernel> p1, Circular_arc_point_2<CircularKernel> p2)

Construct the line segment supported by l, whose source is $p1$ and whose target is $p2$.
Precondition: $p1$ and $p2$ lie on l.

Line_arc_2<CircularKernel> la(Line_2<CircularKernel> l, Point_2<CircularKernel> p1, Point_2<CircularKernel> p2)

Same.

Line_arc_2<CircularKernel> la(Segment_2<CircularKernel> s);

Access Functions

Line_2<CircularKernel>	*la.supporting_line()*	
Circular_arc_point_2<CircularKernel>	*la.source()*	
Circular_arc_point_2<CircularKernel>	*la.target()*	
Circular_arc_point_2<CircularKernel>	*la.left()*	
Circular_arc_point_2<CircularKernel>	*la.right()*	
Bbox_2	*la.bbox() const*	Returns a bounding box containing the line segment.

Query Functions

bool	*la.is_vertical()*	

Operations

bool	*la1* == *la2*	Test for equality. Two arcs are equal, iff their non-oriented supporting lines are equal (i.e. they contain the same set of points) and their endpoints are equal.
bool	*la1* != *la2*	Test for non-equality.

I/O

istream&	*std::istream& is >> Line_arc_2 & ca*
ostream&	*std::ostream& os << Line_arc_2 ca*

The format for input/output is, for each line arc: a *Line_2* (the supporting line) and two *Circular_arc_point_2* (the two endpoints), under the condition that the endpoints are actually lying on the line.

CircularKernel::CircularArcPoint_2

Creation

Circular_arc_point_2<CircularKernel> p(CircularKernel::Point_2 q);

Circular_arc_point_2<CircularKernel> p(CircularKernel::Root_for_circles_2_2 r);

Access Functions

CircularKernel::Root_of_2	*p.x()*	x-coordinate of the point.
CircularKernel::Root_of_2	*p.y()*	y-coordinate of the point.
Bbox_2	*p.bbox() const*	Returns a bounding box around the point.

Operations

bool	$p == q$	Test for equality. Two points are equal, iff their x and y coordinates are equal.
bool	$p \,!= q$	Test for nonequality.
bool	$p < q$	Returns true iff p is lexicographically smaller than q, i.e. either if $p.x() < q.x()$ or if $p.x() == q.x()$ and $p.y() < q.y()$.
bool	$p > q$	Returns true iff p is lexicographically greater than q.
bool	$p <= q$	Returns true iff p is lexicographically smaller than or equal to q.
bool	$p >= q$	Returns true iff p is lexicographically greater than or equal to q.

I/O

CircularKernel::Line_arc_2

fo.operator()(CircularKernel::Line_2 l,
CircularKernel::Circle_2 c1,
bool b1,
CircularKernel::Circle_2 c2,
bool b2)

Constructs the line segment whose supporting line is *l*, whose source endpoint is the b_1^{th} intersection of *l* with *c1*, and whose target endpoint is the b_2^{th} intersection of *l* and *c2*, where intersections are ordered lexicographically.
Precondition: *l* intersects both *c1* and *c2*, and the arc defined by the intersections has non-zero length.

CircularKernel::Line_arc_2

fo.operator()(CircularKernel::Line_2 l,
CircularKernel::Line_2 l1,
CircularKernel::Line_2 l2)

Same, for intersections defined by lines instead of circles.

CircularKernel::ConstructCircularArc_2

A model *fo* of this type must provide:

CircularKernel::Circular_arc_2

fo(CircularKernel::Circle_2 c)

Constructs an arc from a full circle.

CircularKernel::Circular_arc_2

*fo.operator()(CircularKernel::Circle_2 c,
CircularKernel::Circular_arc_point_2 p1,
CircularKernel::Circular_arc_point_2 p2)*

Construct the circular arc supported by *c*, whose source is *p1* and whose target is *p2* when traversing the circle in counterclockwise direction.
Precondition: *p1* and *p2* lie on *c*.

CircularKernel::Circular_arc_2

*fo.operator()(CircularKernel::Circle_2 c,
CircularKernel::Circle_2 c1,
bool b1,
CircularKernel::Circle_2 c2,
bool b2)*

Constructs the unique circular arc whose supporting circle is *c*, and whose source is the intersection of *c* and *c1* with index b_1, and whose target is the intersection of *c* and *c2* of index b_2, where intersections are ordered lexicographically, and when traversing the circle in counterclockwise direction.
Precondition: *c* intersects both *c1* and *c2*, and the arc defined by the intersections has non-zero length.

CircularKernel::Circular_arc_2

*fo.operator()(CircularKernel::Circle_2 c,
CircularKernel::Line_2 l1,
bool b1,
CircularKernel::Line_2 l2,
bool b2)*

Same, for intersections defined by lines instead of circles.

CircularKernel::Circular_arc_2

fo.operator()(CircularKernel::Point_2 p,
CircularKernel::Point_2 q,
CircularKernel::Point_2 r)

Constructs an arc that is supported by the circle of type *CircularKernel::Circle_2* passing through the points p, q and r. The source and target are respectively p and r, when traversing the supporting circle in the counterclockwise direction. Note that, depending on the orientation of the point triple (p,q,r), q may not lie on the arc.
Precondition: p, q, and r are not collinear.

Functor
Concept

CircularKernel::ConstructCircularMinVertex_2

A model *fo* of this type must provide:

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Circular_arc_2 c)

Constructs the x-minimal vertex of c.
Precondition: The arc c is x-monotone.

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Line_arc_2 l)

Same, for a line segment.

CircularKernel::ConstructCircularMaxVertex_2

A model *fo* of this type must provide:

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Circular_arc_2 c)

Constructs the x-maximal vertex of c.
Precondition: The arc c is x-monotone.

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Line_arc_2 l)

Same, for a line segment.

Functor
Concept

CircularKernel::ConstructCircularSourceVertex_2

A model *fo* of this type must provide:

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Circular_arc_2 c)

Constructs the source vertex of *c*.

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Line_arc_2 l)

Same, for a line segment.

CircularKernel::ConstructCircularTargetVertex_2

A model *fo* of this type must provide:

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Circular_arc_2 c)

Constructs the target vertex of *c*.

CircularKernel::Circular_arc_point_2

fo(CircularKernel::Line_arc_2 l)

Same, for a line segment.

Functor
Concept

CircularKernel::ConstructBbox_2

A model *fo* of this type must provide operators to construct a bounding box of geometric objects:

CGAL::Bbox_2 *fo(CircularKernel::Circular_arc_point_2 p)*

CGAL::Bbox_2 *fo(CircularKernel::Line_arc_2 l)*

CGAL::Bbox_2 *fo(CircularKernel::Circular_arc_2 c)*

CircularKernel::CompareX_2

Refines

Kernel::CompareX_2

An object *fo* of this type must provide in addition:

Comparison_result	*fo.operator()(CircularKernel::Circular_arc_point_2 p, CircularKernel::Circular_arc_point_2 q)*	
		Compares the x-coordinates of p and q.

See Also

CircularKernel::CompareXY_2

Functor Concept

Refines

Kernel::CompareXY_2

An object *fo* of this type must provide in addition:

Comparison_result	*fo.operator()(CircularKernel::Circular_arc_point_2 p, CircularKernel::Circular_arc_point_2 q)*	
		Compares p and q according to the lexicographic ordering on x- and y-coordinates.

See Also

CircularKernel::CompareX_2 . . . . page 1191
CircularKernel::CompareY_2 . . . . page 1192
CircularKernel::Equal_2 . . . . page 1200

Functor
Concept

CircularKernel::CompareYatX_2

An object *fo* of this type must provide two operators that compare a point p and an arc a on the vertical line passing through p.

Comparison_result *fo(CircularKernel::Circular_arc_point_2 p, CircularKernel::Circular_arc_2 a)*

For a circular arc.
Precondition: The arc a must be monotone and p must be in the vertical range of a.

Comparison_result *fo(CircularKernel::Circular_arc_point_2 p, CircularKernel::Line_arc_2 a)*

Same for a segment.

CircularKernel::CompareYtoRight_2

An object *fo* of this type must provide operators that compare vertically two arcs on the right side of a common point p:

Comparison_result *fo.operator()(Circular_kernel_2::Circular_arc_2 a1, Circular_kernel_2::Circular_arc_2 a2, Circular_kernel_2::Circular_arc_point_2 p)*

For two circular arcs.
Precondition: p must be a common point to a_1 and a_2, and a_1 and a_2 must be defined to the right of p.

Comparison_result *fo.operator()(Circular_kernel_2::Line_arc_2 a1, Circular_kernel_2::Line_arc_2 a2, Circular_kernel_2::Circular_arc_point_2 p)*

Same for two segments.

Comparison_result *fo.operator()(Circular_kernel_2::Line_arc_2 a1, Circular_kernel_2::Circular_arc_2 a2, Circular_kernel_2::Circular_arc_point_2 p)*

For a segment and an arc.

Comparison_result *fo.operator()(Circular_kernel_2::Circular_arc_2 a1, Circular_kernel_2::Line_arc_2 a2, Circular_kernel_2::Circular_arc_point_2 p)*

Same as previous.

Functor
Concept

CircularKernel::MakeXMonotone_2

A model *fo* of this type must provide:

template < class OutputIterator >
OutputIterator *fo(CircularKernel::Circular_arc_2 ca, OutputIterator oit)*

Splits the arc *ca* into x-monotone arcs that are returned through the output iterator. Note that, to ensure an easy interface with the *Arrangement_2* package, the arcs are returned as *CGAL::Object*'s (see the *ArrangementTraits_2* concept).

For the sake of completeness, the *operator()* must also be defined for a *Line_arc_2*. In this case, the input line arc itself is the only arc returned through the *OutputIterator*.

See Also

CircularKernel::MakeXYMonotone_2 . . . . page 1197

CircularKernel::MakeXYMonotone_2

A model *fo* of this type must provide:

template < class OutputIterator >
OutputIterator *fo(CircularKernel::Circular_arc_2 ca, OutputIterator oit)*

Splits the arc *ca* into *xy*-monotone arcs that are returned through the output iterator. Note that, to ensure an easy interface with the *Arrangement_2* package, the arcs are returned as *CGAL::Object*'s (see the *ArrangementTraits_2* concept).

For the sake of completeness, the *operator()* must also be defined for a *Line_arc_2*. In this case, the input line arc itself is the only arc returned through the *OutputIterator*.

See Also

CircularKernel::MakeXMonotone_2 . . . . page 1196

CircularKernel::Intersect_2

Refines

Kernel::Intersect_2

A model *fo* of this type must provide:

template < class OutputIterator >
OutputIterator *fo(Type1 obj1, Type2 obj2, OutputIterator intersections)*

Copies in the output iterator the intersection elements between the two objects. *intersections* iterates on elements of type *CGAL::Object*, in lexicographic order.

where *Type_1* and *Type_2* can both be either

- *CircularKernel::Line_2* or
- *CircularKernel::Line_arc_2* or
- *CircularKernel::Circle_2* or
- *CircularKernel::Circular_arc_2*.

Depending on the types *Type_1* and *Type_2*, these elements can be assigned to

- *std::pair<CircularKernel::Circular_arc_point_2, unsigned>*, where the unsigned integer is the multiplicity of the corresponding intersection point between *obj_1* and *obj_2*,
- *CircularKernel::Circular_arc_2* in case of an overlap of two circular arcs,
- *CircularKernel::Line_arc_2* in case of an overlap of two line segments or
- *CircularKernel::Line_2* or *CircularKernel::Circle_2* in case of two equal input lines or circles.

See Also

CGAL::intersection . . . . page 1553

CircularKernel::Split_2

A model *fo* of this type must provide:

void *fo.operator()(CircularKernel::Circular_arc_2 a, CircularKernel::Circular_arc_point_2 p, CircularKernel::Circular_arc_2 &a1, CircularKernel::Circular_arc_2 &a2)*

Splits arc a at point p, which creates arcs $a1$ and $a2$.
Precondition: The point lies on the input arc.

void *fo.operator()(CircularKernel::Line_arc_2 l, CircularKernel::Circular_arc_point_2 p, CircularKernel::Line_arc_2 &l1, CircularKernel::Line_arc_2 &l2)*

Same for a line arc.

Functor
Concept

Functor
Concept

CircularKernel::Equal_2

Definition

Testing equality between objects.

Refines

Kernel::Equal_2

An object *fo* of this type must provide in addition:

bool *fo.operator()(CircularKernel::Circular_arc_point_2 p0, CircularKernel::Circular_arc_point_2 p1)*

For two points.

bool *fo(CircularKernel::Circular_arc_2 a0, CircularKernel::Circular_arc_2 a1)*

For two arcs.

bool *fo(CircularKernel::Line_arc_2 a0, CircularKernel::Line_arc_2 a1)*

For two segments.

For the sake of completeness, the *operator()* must also be defined for a *Line_arc_2* and a *Circular_arc_2* as arguments (in any order), and it always returns *false*.

CircularKernel::HasOn_2

Functor
Concept

Definition

To test whether a point lies on a curve.

Refines

Kernel::HasOn_2

An object *fo* of this type must provide:

bool *fo(CircularKernel::Line_2 l, CircularKernel::Circular_arc_point_2 p)*

For a line.

bool *fo(CircularKernel::Circle_2 c, CircularKernel::Circular_arc_point_2 p)*

For a circle.

bool *fo(CircularKernel::Line_arc_2 l, CircularKernel::Circular_arc_point_2 p)*

For a line arc.

bool *fo(CircularKernel::Circular_arc_2 c, CircularKernel::Circular_arc_point_2 p)*

For a circular arc.

CircularKernel::DoOverlap_2

Definition

Testing whether the interiors of two curves overlap.

Refines

Kernel::DoOverlap_2

An object *fo* of this type must provide:

bool	*fo(CircularKernel::Line_arc_2 l0, CircularKernel::Line_arc_2 l1)*
	For two line arcs.
bool	*fo(CircularKernel::Circular_arc_2 a0, CircularKernel::Circular_arc_2 a1)*
	For two circular arcs.

CircularKernel::DoIntersect_2

Functor
Concept

Definition

Testing whether two curves intersect.

Refines

Kernel::DoIntersect_2

An object *fo* of this type must provide:

bool *fo(Type1 obj1, Type2 obj2)*

determines if two geometric objects of type Type1 and Type2 intersect or not.

for all pairs *Type1* and *Type2*, where the types *Type1* and *Type2* can be any of the following:

- *CircularKernel::Line_2*
- *CircularKernel::Line_arc_2*
- *CircularKernel::Circle_2*
- *CircularKernel::Circular_arc_2*

CircularKernel::InXRange_2

Definition

To test whether a point lies in the vertical range of a curve.

An object *fo* of this type must provide:

bool	*fo(CircularKernel::Line_arc_2 l, CircularKernel::Circular_arc_point_2 p)*	
		For a line arc.
bool	*fo(CircularKernel::Circular_arc_2 c, CircularKernel::Circular_arc_point_2 p)*	
		For a circular arc. *Precondition*: c is x-monotone.

CircularKernel::IsVertical_2

Refines

Kernel::IsVertical_2

An object *fo* of this type must provide:

bool	*fo(CircularKernel::Line_arc_2 l)*	
		For a line arc.
bool	*fo(CircularKernel::Circular_arc_2 c)*	
		For a circular arc, always returns *false*.

CircularKernel::IsXMonotone_2

An object *fo* of this type must provide:

bool	*fo(CircularKernel::Circular_arc_2 c)*	
		Tests whether the arc is x-monotone.
bool	*fo(CircularKernel::Line_arc_2 l)*	
		For a line arc, always returns *true*.

Functor
Concept

CircularKernel::IsYMonotone_2

An object *fo* of this type must provide:

bool	*fo(CircularKernel::Circular_arc_2 c)*	
		Tests whether the arc is y-monotone.
bool	*fo(CircularKernel::Line_arc_2 l)*	
		For a line arc, always returns *true*.

CircularKernel::GetEquation

A model *fo* of this type must provide:

CircularKernel::Polynomial_1_2

fo(CircularKernel::Line_2 c)

Returns the equation of the line.

CircularKernel::Polynomial_for_circles_2_2

fo(CircularKernel::Circle_2 c)

Returns the equation of the circle.

See Also

CircularKernel::ConstructLine_2 . . . . page 1180
CircularKernel::ConstructCircle_2 . . . . page 1181

CircularKernel::ComputeCircularX_2

A model *fo* of this type must provide:

CircularKernel::Root_of_2

fo(CircularKernel::Circular_arc_point_2 p)

Computes the x-coordinate of the point.

CircularKernel::ComputeCircularY_2

A model *fo* of this type must provide:

CircularKernel::Root_of_2

fo(CircularKernel::Circular_arc_point_2 p)

Computes the *y*-coordinate of the point.

CGAL::x_extremal_point

#include <CGAL/global_functions_circular_kernel_2.h>

Circular_arc_point_2<CircularKernel>

x_extremal_point(Circle_2<CircularKernel> c, bool b)

Returns the leftmost (resp. rightmost) point of the circle if *b* is *true* (resp. *false*).

CGAL::y_extremal_point

#include <CGAL/global_functions_circular_kernel_2.h>

Circular_arc_point_2<CircularKernel>

y_extremal_point(Circle_2<CircularKernel> c, bool b)

Returns the bottommost (ressp. topmost) point of the circle if *b* is *true* (resp. *false*).

Function

Function

CGAL::x_extremal_points

#include <CGAL/global_functions_circular_kernel_2.h>

template < class OutputIterator >
OutputIterator *x_extremal_points(Circle_2<CircularKernel> c, OutputIterator res)*

Copies in the output iterator the x-extremal points of the circle. *res* iterates on elements of type *Circular_arc_point_2<CircularKernel>*, sorted in x.

CGAL::y_extremal_points

#include <CGAL/global_functions_circular_kernel_2.h>

template < class OutputIterator >
OutputIterator *y_extremal_points(Circle_2<CircularKernel> c, OutputIterator res)*

Copies in the output iterator the *y*-extremal points of the circle. *res* iterates on elements of type *Circular_arc_point_2<CircularKernel>*, sorted in *y*.

Function

Function

CGAL::has_on

#include <CGAL/global_functions_circular_kernel_2.h>

bool	*has_on(Circle_2<CircularKernel> c, Circular_arc_point_2<CircularKernel> p)*
	Checks whether the point lies on the circle.

CGAL::compare_y_to_right

CGAL::Comparison_result

compare_y_to_right(Circular_arc_2<CircularKernel> ca1,
Circular_arc_2<CircularKernel> ca2,
Circular_arc_point_2<CircularKernel> &p)

Compares vertically the two arcs, to the right of the point p,
Precondition: p is an intersection point of the arcs, and the arcs are defined to the right of p.

Function

Function

CGAL::has_in_x_range

#include <CGAL/global_functions_circular_kernel_2.h>

bool *has_in_x_range(Circular_arc_2<CircularKernel> ca, Circular_arc_point_2<CircularKernel> p)*

Checks whether the point lies in the vertical range defined by the arc.

bool *has_in_x_range(Line_arc_2<CircularKernel> ca, Circular_arc_point_2<CircularKernel> p)*

Checks whether the point lies in the vertical range defined by the line segment.

CGAL::make_x_monotone

#include <CGAL/global_functions_circular_kernel_2.h>

template < class OutputIterator >
OutputIterator *make_x_monotone(Circular_arc_2<CircularKernel> ca, OutputIterator res)*

Copies in the output iterator the x-monotone sub-arcs of *ca*.

Function

Function

CGAL::make_xy_monotone

#include <CGAL/global_functions_circular_kernel_2.h>

template < class OutputIterator >
OutputIterator *make_xy_monotone(Circular_arc_2<CircularKernel> ca, OutputIterator res)*

Copies in the output iterator the *xy*-monotone sub-arcs of *ca*.

AlgebraicKernelForCircles

Concept

Definition

The *AlgebraicKernelForCircles* concept is meant to provide the curved kernel with all the algebraic functionalities required for the manipulation of circular arcs.

Has Models

Algebraic_kernel_for_circles_2_2

Types

A model of *AlgebraicKernelForCircles* is supposed to provide

AlgebraicKernelForCircles:: RT	A model of *RingNumberType*.
AlgebraicKernelForCircles:: FT	A model of *FieldNumberType<RT>*.
AlgebraicKernelForCircles:: Polynomial_1_2	A model of *AlgebraicKernelForCircles::Polynomial_1_2*, for bivariate polynomials of degree up to 1.
AlgebraicKernelForCircles:: Polynomial_for_circles_2_2	A model of *AlgebraicKernelForCircles::PolynomialForCircles_2_2*, for bivariate polynomials of degree up to 2 that can store equations of circles.
AlgebraicKernelForCircles:: Root_of_2	A model of *RootOf_2*, for algebraic numbers of degree up to 2.
AlgebraicKernelForCircles:: Root_for_circles_2_2	A model of *AlgebraicKernelForCircles::RootForCircles_2_2*, for solutions of systems of two models of *AlgebraicKernelForCircles::PolynomialForCircles_2_2*.
AlgebraicKernelForCircles:: Construct_polynomial_1_2	A model of *AlgebraicKernelForCircles::ConstructPolynomial_1_2*.
AlgebraicKernelForCircles:: Construct_polynomial_for_circles_2_2	A model of *AlgebraicKernelForCircles::ConstructPolynomialForCircles_2_2*.
AlgebraicKernelForCircles:: Compare_x	A model of the concept *AlgebraicKernelForCircles::CompareX*.

AlgebraicKernelForCircles:: Compare_y	A model of the concept *AlgebraicKernelForCircles::CompareY*.
AlgebraicKernelForCircles:: Compare_xy	A model of the concept *AlgebraicKernelForCircles::CompareXY*.
AlgebraicKernelForCircles:: Sign_at	A model of the concept *AlgebraicKernelForCircles::SignAt*.
AlgebraicKernelForCircles:: X_critical_points	A model of the concept *AlgebraicKernelForCircles::XCriticalPoints*.
AlgebraicKernelForCircles:: Y_critical_points	A model of the concept *AlgebraicKernelForCircles::YCriticalPoints*.
AlgebraicKernelForCircles:: Solve	A model of the concept *AlgebraicKernelForCircles::Solve*.

AlgebraicKernelForCircles::XCriticalPoints

Definition

A model *fo* of this type must provide:

template < class OutputIterator >
OutputIterator *fo.operator()(AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p, OutputIterator res)*

Copies in the output iterator the *x*-critical points of polynomial *p*, as objects of type *AlgebraicKernelForCircles::Root_for_circles_2_2*.

template < class OutputIterator >
AlgebraicKernelForCircles::Root_for_circles_2_2

fo(AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p, bool b)

Computes the *x*-critical point with smallest (resp. largest) *x* of polynomial *p* if *b* is *true* (resp. *false*).

Concept

AlgebraicKernelForCircles::YCriticalPoints

Definition

A model *fo* of this type must provide:

template < class OutputIterator >
OutputIterator *fo.operator()(AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p, OutputIterator res)*

Copies in the output iterator the y-critical points of polynomial p, as objects of type *AlgebraicKernelForCircles::Root_for_circles_2_2*.

template < class OutputIterator >
AlgebraicKernelForCircles::Root_for_circles_2_2

fo(AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p, bool i)

Computes the y-critical point with smallest (resp. largest) y of polynomial p if b is *true* (resp. *false*).

3D Spherical Geometry Kernel

Pedro Machado Manhães de Castro, Frédéric Cazals, Sébastien Loriot, and Monique Teillaud

Contents

14.1 Introduction

The goal of the 3D spherical kernel is to offer to the user a large set of functionalities on spheres, circles and circular arcs, in the 3D space or restricted on a given sphere. These functionalities require computing on algebraic numbers, which motivates the creation of a new kernel concept extending the CGAL *Kernel* concept, that is restricted to objects and functionality in a *FieldNumberType*.

All the choices (interface, robustness, representation, and so on) made here are consistent with the choices made in the CGAL kernel, for which we refer the user to the kernel manual (Chapter 11).

14.2 Spherical Kernel Objects

New main geometric objects are introduced by *Spherical_kernel_3*: circular arcs ((model of *SphericalKernel::CircularArc_3*), points of circular arcs (model of *SphericalKernel::CircularArcPoint_3*), and line segments (model of *SphericalKernel::LineArc_3*) whose endpoints are points of this new type.

SphericalKernel::CircularArcPoint_3 is used in particular for endpoints of arcs and intersection points between spheres, circles or arcs. The coordinates of these points are algebraic numbers of degree two. Therefore, general predicates offered by the *Kernel* on *Point_3*, which have coordinates in a *FieldNumberType*, would require heavy algebraic computations in algebraic extensions of higher degrees and thus are not provided on them, which explains the need for a new point type.

A consistent set of predicates and constructions is offered on these new types.

General functionalities

The spherical kernel currently implements a set of fundamental functionalities like intersection, comparisons, inclusion, etc. More might be provided in the future, as long as only algebraic numbers of degree two are used.

Functionalities relative to a sphere

The interface of the underlying objects is extended by providing additional operations that make sense only if the objects are considered on the same sphere. For example, the result of the comparison of the cylindrical or spherical coordinates of two points is well-defined only when looking at them on a given common sphere. The presentation of these operations requires the following definitions:

Coordinate system. Let consider a sphere with center c and radius r. Using the Cartesian frame centered at c, we define a cylindrical coordinate system (θ, z) on that sphere, with $\theta \in [0, 2\pi)$ and $z \in [-r, r]$. θ is given in radian and measured in the xy-plane around the z-axis, starting from $x > 0$, $y = 0$. The z-extremal points of a sphere are its North and South poles defined as (θ, r) and $(\theta, -r)$ respectively, for any value of θ. Observe that each point on the sphere different from a pole corresponds to a unique pair (θ, z).

Definition of a meridian. Given a sphere and its associated cylindrical coordinate system, a meridian of that sphere is a circular arc consisting of the points having the same theta-coordinate (the poles are the end points). A plane containing the two poles of that sphere defines two meridians, one on each side of the line passing through the poles. A vector M whose direction is different from that of the latter line defines a unique meridian on that sphere. The plane of that meridian is defined by the direction of M and the two poles. The sense of M disambiguates the choice among the pair of meridians thus defined. On Fig. 14.1, the normal vectors n_0 and n_1 define two meridians of S: the circular arcs A_0 and A_1 respectively.

Types of circles on a sphere. Given a sphere, a circle on that sphere is termed *polar* if it goes through only one pole, *bipolar* if it goes through the two poles of that sphere and *threaded* if it separates the sphere into two connected components, each containing one pole. Any other circle is termed *normal*. These definitions are illustrated on Fig. 14.2.

θ-*extremal points.* Given a sphere one has: a θ-*extremal point* of a normal circle is a point of tangency between the circle and a meridian anchored at the poles of that sphere. Each normal circle defines two such points; the θ-extremal point of a polar circle is the pole the circle goes through. No such point is defined on a bipolar or a threaded circle. These definitions are illustrated on Fig. 14.2. Notice that the θ-extremal points should not be confused with the endpoints of an arbitrary arc on a sphere.

The θ-coordinate of a θ-extremal point of a normal circle on a sphere is well defined. For a polar circle on a sphere, the plane containing the two poles and which is tangent to that circle contains two different meridians. The θ-values of these meridians are the two θ-coordinates associated to the same θ-extremal point of a polar circle.

θ-*monotone circular arcs.* An arc on a sphere is said to be θ-*monotone* if any meridian on that sphere intersects that arc in at most one point. With this definition, a circular arc on a threaded circle is always θ-monotone, and an arc on a polar or normal circle is θ-monotone if it does not contain a θ-extremal point, unless it is an

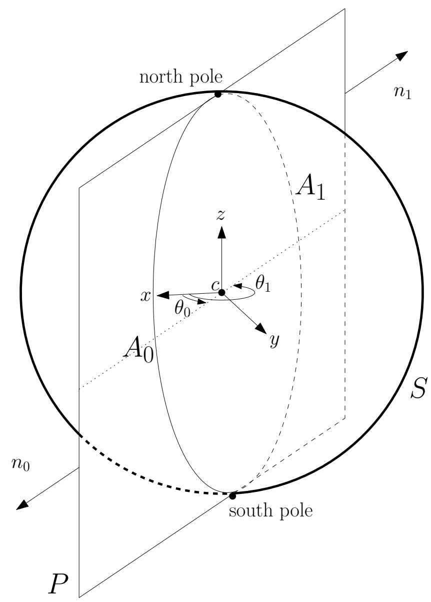

Figure 14.1: Definition of two meridians on S, a sphere of center c. The intersection of the plane P (passing through the two poles of S) and the sphere S is a circle. The two poles of S split that circle into two circular arcs A_0 and A_1, each being a meridian of S. The θ-coordinates of meridians A_0 and A_1 are θ_0 and $\theta_1 = \theta_0 + \pi$ respectively.

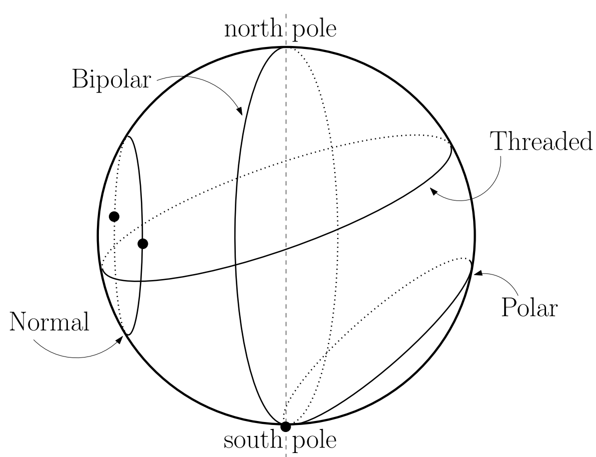

Figure 14.2: The four types of circles on a sphere. Black dots are the θ-extremal points.

endpoint. No such arc is defined on a bipolar circle.

14.3 Software Design

The design of *Spherical_kernel_3* is similar to the design of *Circular_kernel_2* (see Chapter 13). It has two template parameters:

- the first parameter must model the CGAL three dimensional *Kernel* concept. The spherical kernel derives from it, and it provides all elementary geometric objects like points, lines, spheres, circles and elementary functionality on them.
- the second parameter is the algebraic kernel, which is responsible for computations on polynomials and algebraic numbers. It must model the concept *AlgebraicKernelForSpheres*. The robustness of the package relies on the fact that the algebraic kernel provides exact computations on algebraic objects.

The 3D spherical kernel uses the extensibility scheme presented in the kernel manual (see Section 11.5). The types of *Kernel* are inherited by the 3D spherical kernel and some types are taken from the *AlgebraicKernelForSpheres* parameter. *Spherical_kernel_3* introduces new geometric objects as mentioned in Section 14.2.

In fact, the spherical kernel is documented as a concept, *SphericalKernel* and two models are provided:

- *Spherical_kernel_3<Kernel,AlgebraicKernelForSpheres>*, the basic kernel,
- and a predefined kernel *Exact_spherical_kernel_3*.

14.4 Examples

The first example shows how to construct spheres and compute intersections on them using the global function.

```
#include <CGAL/Exact_spherical_kernel_3.h>
#include <CGAL/Random.h>

typedef CGAL::Exact_spherical_kernel_3         Spherical_k;

typedef CGAL::Point_3<Spherical_k>             Point_3;
typedef CGAL::Sphere_3<Spherical_k>            Sphere_3;

int main() {

  CGAL::Random generatorOfgenerator;
  int random_seed = generatorOfgenerator.get_int(0, 123456);
  CGAL::Random theRandom(random_seed);
  int count = 0;

  std::cout << "We will compute the approximate probability that 3
    spheres wit"
  << "h radius 1 intersect on a 5x5x5 box, it might take some time." <<
    std::endl;

  for(int i=0; i<10000; i++) {

    double x1 = theRandom.get_double(0.0,5.0);
    double y1 = theRandom.get_double(0.0,5.0);
```

```
    double z1 = theRandom.get_double(0.0,5.0);
    double r = 1.0;
    double x2 = theRandom.get_double(0.0,5.0);
    double y2 = theRandom.get_double(0.0,5.0);
    double z2 = theRandom.get_double(0.0,5.0);
    double x3 = theRandom.get_double(0.0,5.0);
    double y3 = theRandom.get_double(0.0,5.0);
    double z3 = theRandom.get_double(0.0,5.0);

    Sphere_3 s1 = Sphere_3(Point_3(x1,y1,z1), r);
    Sphere_3 s2 = Sphere_3(Point_3(x2,y2,z2), r);
    Sphere_3 s3 = Sphere_3(Point_3(x3,y3,z3), r);

    std::vector< CGAL::Object > intersecs;
    CGAL::intersection(s1, s2, s3, std::back_inserter(intersecs));
    if(intersecs.size() > 0) count++;
  }

  std::cout << "The approximate probability that 3 spheres with radius 1"
            << std::endl;
  std::cout << "choosen (uniformly) randomly on a 5x5x5 box intersect is:
    "
            << ((double)count)/((double)(10000)) << std::endl;

  return 0;
}
```

File: examples/Circular_kernel_3/intersecting_spheres.cpp

The second example illustrates the use of a functor.

```
#include <CGAL/Exact_spherical_kernel_3.h>
#include <CGAL/Random.h>

typedef CGAL::Exact_spherical_kernel_3         Spherical_k;

typedef CGAL::Point_3<Spherical_k>             Point_3;
typedef CGAL::Circular_arc_3<Spherical_k>      Circular_arc_3;

int main()
{
  int n = 0;
  Circular_arc_3 c = Circular_arc_3(Point_3(10,10,0), Point_3(5,5,5),
   Point_3(0, 0, 0));
  for(int i = 0; i <= 10; i++) {
    for(int j = 0; j <= 10; j++) {
      for(int k = 0; k <= 10; k++) {
        Point_3 p = Point_3(i, j, k);
        if(Spherical_k().has_on_3_object()(c,p)) {
          n++;
          std::cout << "(" << i << "," << j << "," << k << ")" <<
   std::endl;
        }
```

```
      }
    }
  }

  std::cout << "There are " << n << " points in the "
            << "[0,..,10]x[0,..,10]x[0,...,10] "
            << "grid on the circular" << std::endl
            << " arc defined by the points (10,10,0), (5,5,5), (0,0,0)"
            << std::endl << "See the points above." << std::endl;
  return 0;
}
```

File: examples/Circular_kernel_3/functor_has_on_3.cpp

The third example illustrates the use of a functor on objects on the same sphere. The intersection points of two circles on the same sphere are computed and their cylindrical coordinates are then compared.

```
#include <CGAL/Exact_spherical_kernel_3.h>

typedef CGAL::Exact_spherical_kernel_3              SK;

int main(){
  //construction of 3 spheres from their centers and squared radii
  SK::Sphere_3 s1(SK::Point_3(0,0,0),2);
  SK::Sphere_3 s2(SK::Point_3(0,1,0),1);
  SK::Sphere_3 s3(SK::Point_3(1,0,0),3);

  //construct two circles lying on sphere s1
  SK::Circle_3 C1(s1,s2);
  SK::Circle_3 C2(s1,s3);

  SK::Intersect_3 inter;
  //create a functor to compare theta-coordinates on sphere s1
  SK::Compare_theta_z_3 cmp(s1);
  std::vector< CGAL::Object > intersections;
  inter(C1,C2,std::back_inserter(intersections));

  //unsigned integer indicates multiplicity of intersection point
  std::pair<SK::Circular_arc_point_3,unsigned> p1=
    CGAL::object_cast< std::pair<SK::Circular_arc_point_3,unsigned>
   >(intersections[0]);
  std::pair<SK::Circular_arc_point_3,unsigned> p2=
    CGAL::object_cast< std::pair<SK::Circular_arc_point_3,unsigned>
   >(intersections[1]);

  SK::Circular_arc_point_3 t_extreme[2];
  //Compute theta extremal points of circle C1 on sphere s1
  CGAL::theta_extremal_points(C1,s1,t_extreme);

  //The theta coordinates of theta extremal points of C1 enclose that of
   each intersection point.
  assert(cmp(t_extreme[0],p1.first)==CGAL::SMALLER);
```

```
  assert(cmp(t_extreme[0],p2.first)==CGAL::SMALLER);
  assert(cmp(t_extreme[1],p1.first)==CGAL::LARGER);
  assert(cmp(t_extreme[1],p2.first)==CGAL::LARGER);

  return 0;
}
```

File: examples/Circular_kernel_3/functor_compare_theta_3.cpp

14.5 Design and Implementation History

This package follows the 2D circular kernel package (see Chapter 13), which induced the basic choices of design.

Julien Hazebrouck and Damien Leroy participated in a first prototype.

The first version of the package was co-authored by Pedro Machado Manhães de Castro and Monique Teillaud, and integrated in CGAL 3.4. Frédéric Cazals and Sébastien Loriot extended the package by providing functionalities restricted on a given sphere [dCCLT09].

Sylvain Pion is acknowledged for helpful discussions.

This work was partially supported by the IST Programme of the 6th Framework Programme of the EU as a STREP (FET Open Scheme) Project under Contract No IST-006413 (ACS - Algorithms for Complex Shapes).

Refines

Kernel

Has Models

CGAL::Spherical_kernel_3<Kernel,AlgebraicKernelForSpheres>
CGAL::Exact_spherical_kernel_3

Types

A model of *SphericalKernel* is supposed to provide some basic types

SphericalKernel:: Linear_kernel	Model of *Kernel*.
SphericalKernel:: Algebraic_kernel	Model of *AlgebraicKernelForSpheres*.

SphericalKernel:: Root_of_2	Model of *RootOf_2*.
SphericalKernel:: Root_for_spheres_2_3	Model of *AlgebraicKernelForSpheres::RootForSpheres_2_3*.
SphericalKernel:: Polynomial_1_3	Model of *AlgebraicKernelForSpheres::Polynomial_1_3*.
SphericalKernel:: Polynomials_for_line_3	Model of *AlgebraicKernelForSpheres::PolynomialsForLines_3*.
SphericalKernel:: Polynomial_for_spheres_2_3	Model of *AlgebraicKernelForSpheres::PolynomialForSpheres_2_3*.
SphericalKernel:: Polynomials_for_circle_3	Model of *AlgebraicKernelForSpheres::PolynomialsForCircles_3*.

and to define the following geometric objects

SphericalKernel:: Point_3	Model of *Kernel::Point_3*.
SphericalKernel:: Vector_3	Model of *Kernel::Vector_3*.
SphericalKernel:: Line_3	Model of *Kernel::Line_3*.
SphericalKernel:: Plane_3	Model of *Kernel::Plane_3*.
SphericalKernel:: Sphere_3	Model of *Kernel::Sphere_3*.
SphericalKernel:: Circle_3	Model of *Kernel::Circle_3*.

SphericalKernel:: Line_arc_3	Model of *SphericalKernel::LineArc_3*.
SphericalKernel:: Circular_arc_3	Model of *SphericalKernel::CircularArc_3*.
SphericalKernel:: Circular_arc_point_3	Model of *SphericalKernel::CircularArcPoint_3*.

Moreover, a model of *SphericalKernel* must provide predicates, constructions and other functionalities.

Predicates

SphericalKernel:: Compare_x_3	Model of *SphericalKernel::CompareX_3*.

SphericalKernel:: Compare_y_3	Model of *SphericalKernel::CompareY_3*.
SphericalKernel:: Compare_z_3	Model of *SphericalKernel::CompareZ_3*.
SphericalKernel:: Compare_xy_3	Model of *SphericalKernel::CompareXY_3*.
SphericalKernel:: Compare_xyz_3	Model of *SphericalKernel::CompareXYZ_3*.
SphericalKernel:: Compare_theta_3	Model of *SphericalKernel::CompareTheta_3*.
SphericalKernel:: Compare_theta_z_3	Model of *SphericalKernel::CompareThetaZ_3*.
SphericalKernel:: Compare_z_at_theta_3	Model of *SphericalKernel::CompareZAtTheta_3*.
SphericalKernel:: Compare_z_to_right_3	Model of *SphericalKernel::CompareZToRight_3*.
SphericalKernel:: Equal_3	Model of *SphericalKernel::Equal_3*.
SphericalKernel:: Has_on_3	Model of *SphericalKernel::HasOn_3*.
SphericalKernel:: Do_overlap_3	Model of *SphericalKernel::DoOverlap_3*.
SphericalKernel:: Do_intersect_3	Model of *SphericalKernel::DoIntersect_3*.
SphericalKernel:: Bounded_side_3	Model of *SphericalKernel::BoundedSide_3*.
SphericalKernel:: Has_on_bounded_side_3	Model of *SphericalKernel::HasOnBoundedSide_3*.
SphericalKernel:: Has_on_unbounded_side_3	Model of *SphericalKernel::HasOnUnboundedSide_3*.
SphericalKernel:: Is_theta_monotone_3	Model of *SphericalKernel::IsThetaMonotone_3*.

Constructions

SphericalKernel:: Construct_line_3	Model of *SphericalKernel::ConstructLine_3*.
SphericalKernel:: Construct_plane_3	Model of *SphericalKernel::ConstructPlane_3*.
SphericalKernel:: Construct_sphere_3	Model of *SphericalKernel::ConstructSphere_3*.
SphericalKernel:: Construct_circle_3	Model of *SphericalKernel::ConstructCircle_3*.
SphericalKernel:: Construct_line_arc_3	Model of *SphericalKernel::ConstructLineArc_3*.
SphericalKernel:: Construct_circular_arc_3	Model of *SphericalKernel::ConstructCircularArc_3*.
SphericalKernel:: Construct_circular_arc_point_3	Model of *SphericalKernel::ConstructCircularArcPoint_3*.
SphericalKernel:: Construct_circular_min_vertex_3	Model of *SphericalKernel::ConstructCircularMinVertex_3*.
SphericalKernel:: Construct_circular_max_vertex_3	Model of *SphericalKernel::ConstructCircularMaxVertex_3*.
SphericalKernel:: Construct_circular_source_vertex_3	Model of *SphericalKernel::ConstructCircularSourceVertex_3*.
SphericalKernel:: Construct_circular_target_vertex_3	Model of *SphericalKernel::ConstructCircularTargetVertex_3*.

SphericalKernel:: Construct_bbox_3	Model of *SphericalKernel::ConstructBbox_3*.
SphericalKernel:: Intersect_3	Model of *SphericalKernel::Intersect_3*.
SphericalKernel:: Split_3	Model of *SphericalKernel::Split_3*.
SphericalKernel:: Make_theta_monotone_3	Model of *SphericalKernel::MakeThetaMonotone_3*.

Computations

SphericalKernel:: Compute_circular_x_3	Model of *SphericalKernel::ComputeCircularX_3*.
SphericalKernel:: Compute_circular_y_3	Model of *SphericalKernel::ComputeCircularY_3*.
SphericalKernel:: Compute_circular_z_3	Model of *SphericalKernel::ComputeCircularZ_3*.

SphericalKernel:: Compute_approximate_squared_length_3

Model of *SphericalKernel::ComputeApproximateSquaredLength_3*.

SphericalKernel:: Compute_approximate_angle_3	Model of *SphericalKernel::ComputeApproximateAngle_3*.

Link with the algebraic kernel

SphericalKernel:: Get_equation	Model of *SphericalKernel::GetEquation*.

Operations

As in the *Kernel* concept, for each of the function objects above, there must exist a member function that requires no arguments and returns an instance of that function object. The name of the member function is the uncapitalized name of the type returned with the suffix *_object* appended. For example, for the function object *SphericalKernel::Construct_circular_arc_3* the following member function must exist:

Construct_circular_arc_3

sk.construct_circular_arc_3_object() const

For operations on a given sphere, a *context* sphere must be provided to the following functions:

Compare_theta_3	*sk.compare_theta_3_object(Sphere_3 sphere) const*
Compare_theta_z_3	*sk.compare_theta_z_3_object(Sphere_3 sphere) const*
Compare_z_at_theta_3	*sk.compare_z_at_theta_3_object(Sphere_3 sphere) const*
Compare_z_to_right_3	*sk.compare_z_to_right_3_object(Sphere_3 sphere) const*
Make_theta_monotone_3	*sk.make_theta_monotone_3_object(Sphere_3 sphere) const*

Is_theta_monotone_3　　*sk.is_theta_monotone_3_object(Sphere_3 sphere) const*

CGAL::Spherical_kernel_3<Kernel,AlgebraicKernelForSpheres>

Class

#include <CGAL/Spherical_kernel_3.h>

Is Model for the Concepts

SphericalKernel

Parameters

The first parameter of the spherical kernel must be instantiated with a model of the *Kernel* concept. The *Spherical_kernel_3* class template derives from this first parameter, in order to reuse all needed functionalities on basic objects provided by a model of the Kernel concept.

The second parameter, *AlgebraicKernelForSpheres*, is meant to provide the spherical kernel with all the algebraic functionalities required for the manipulation of algebraic curves.

Inherits From

Kernel

Types

The spherical kernel uses basic number types of the algebraic kernel:

typedef AlgebraicKernelForSpheres::RT	*RT;*	Ring number type.
typedef AlgebraicKernelForSpheres::FT	*FT;*	Field number type.

In fact, the two number types *AlgebraicKernelForSpheres::RT* and *Kernel::RT* must refer to the same type, as well as *AlgebraicKernelForSpheres::FT* and *Kernel::FT*.

The following types are available, as well as all the functionality on them described in the *SphericalKernel* concept.

typedef Line_arc_3<Spherical_kernel_3>	*Line_arc_3;*
typedef Circular_arc_3<Spherical_kernel_3>	*Circular_arc_3;*
typedef Circular_arc_point_3<Spherical_kernel_3>	*Circular_arc_point_3;*

Polynomials_for_circle_3 is implemented as a *std::pair< Polynomial_for_spheres_2_3, Polynomial_1_3 >* and is a model of *AlgebraicKernelForSpheres::PolynomialsForCircles_3*.

Class

CGAL::Exact_spherical_kernel_3

#include <CGAL/Exact_spherical_kernel_3.h>

Definition

A typedef to a spherical kernel that provides both exact geometric predicates and exact geometric constructions.

It defines the same types as *CGAL::Spherical_kernel_3*.

Is Model for the Concepts

SphericalKernel

SphericalKernel::CircularArcPoint_3

Definition

Concept for points on spheres, circles, circular arcs or line arcs.

Refines

CopyConstructible, Assignable, DefaultConstructible

Has Models

CGAL::Circular_arc_point_3<SphericalKernel>

Class

CGAL::Circular_arc_point_3<SphericalKernel>

#include <CGAL/Circular_arc_point_3.h>

Is Model for the Concepts

SphericalKernel::CircularArcPoint_3

Creation

Circular_arc_point_3<SphericalKernel> p(Point_3<SphericalKernel> q);

Circular_arc_point_3<SphericalKernel> p(SphericalKernel::Root_for_spheres_2_3 r);

Access Functions

SphericalKernel::Root_of_2	*p.x()*	x-coordinate of the point.
SphericalKernel::Root_of_2	*p.y()*	y-coordinate of the point.
SphericalKernel::Root_of_2	*p.z()*	z-coordinate of the point.
Bbox_3	*p.bbox() const*	Returns a bounding box around the point.

Operations

bool	$p == q$	Test for equality. Two points are equal, iff their x, y and z coordinates are equal.
bool	$p\,!= q$	Test for nonequality.
bool	$p < q$	Returns true iff p is lexicographically smaller than q, i.e. either if $p.x() < q.x()$ or if $p.x() == q.x()$ and $p.y() < q.y()$ or if $p.x() == q.x()$ and $p.y() == q.y()$ and $p.z() < q.z()$.
bool	$p > q$	Returns true iff p is lexicographically greater than q.
bool	$p <= q$	Returns true iff p is lexicographically smaller than or equal to q.
bool	$p >= q$	Returns true iff p is lexicographically greater than or equal to q.

I/O

istream&	*std::istream& is >> Circular_arc_point_3 & p*

Concept

SphericalKernel::LineArc_3

Definition

Concept for line segments supported by a line that is a model of *Kernel::Line_3*, and whose endpoints are models of the *SphericalKernel::CircularArcPoint_3* concept.

Refines

CopyConstructible, Assignable, DefaultConstructible

Has Models

CGAL::Line_arc_3<SphericalKernel>

CGAL::Line_arc_3<SphericalKernel>

#include <CGAL/Line_arc_3.h>

Is Model for the Concepts

SphericalKernel::LineArc_3

Creation

Line_arc_3<SphericalKernel> la(Line_3<SphericalKernel> l,
Circular_arc_point_3<SphericalKernel> p1,
Circular_arc_point_3<SphericalKernel> p2)

Construct the line segment supported by *l*, whose source is *p1*, and whose target is *p2*.
Precondition: *p1* and *p2* lie on *l*. *p1* and *p2* are different.

Line_arc_3<SphericalKernel> la(Line_3<SphericalKernel> l,
Point_3<SphericalKernel> p1,
Point_3<SphericalKernel> p2)

Same.

Line_arc_3<SphericalKernel> la(Segment_3<SphericalKernel> s);

Access Functions

Line_3<SphericalKernel>	*la.supporting_line()*	
Circular_arc_point_3<SphericalKernel>	*la.source()*	
Circular_arc_point_3<SphericalKernel>	*la.target()*	
Circular_arc_point_3<SphericalKernel>	*la.min()*	Constructs the minimum vertex according to the lexicographic ordering of coordinates.
Circular_arc_point_3<SphericalKernel>	*la.max()*	Same for the maximum vertex.

Query Functions

bool	*la.is_vertical()*	Returns true *iff* the segment is vertical.

Operations

bool	*s1 == s2*	Test for equality. Two segments are equal, iff their non-oriented supporting lines are equal (i.e. they define the same set of points), and their endpoints are the same.
bool	*s1 != s2*	Test for nonequality.

I/O

istream&	*std::istream& is >> Line_arc_3 & ca*
ostream&	*std::ostream& os << Line_arc_3 ca*

The format for input/output is, for each line arc: a *Line_3* (the supporting line) and two *Circular_arc_point_3* (the two endpoints), under the condition that the endpoints are actually lying on the line.

SphericalKernel::CircularArc_3

Concept

Concept for arcs of circles.

Refines

CopyConstructible, Assignable, DefaultConstructible

Has Models

CGAL::Circular_arc_3<SphericalKernel>

Class

CGAL::Circular_arc_3<SphericalKernel>

#include <CGAL/Circular_arc_3.h>

Is Model for the Concepts

SphericalKernel::CircularArc_3

Creation

Circular_arc_3<SphericalKernel> ca(Circle_3<SphericalKernel> c);

Constructs an arc from a full circle.

Circular_arc_3<SphericalKernel> ca(Circle_3<SphericalKernel> c, Circular_arc_point_3 pt);

Constructs an arc from a full circle, using pt as source and target.

Circular_arc_3<SphericalKernel> ca(Circle_3<SphericalKernel> c,
Circular_arc_point_3<SphericalKernel> p,
Circular_arc_point_3<SphericalKernel> q)

Constructs the circular arc supported by c, whose source and target are p and q, respectively.
Precondition: p and q lie on c and are different.

The circular arc constructed from a circle, a source, and a target, is defined as the set of points of the circle that lie between the source *p1* and the target *p2*, when traversing the circle counterclockwise seen from the side of the plane of the circle pointed by its *positive* normal vectors.

In this definition, we say that a normal vector (a,b,c) is *positive* if $(a,b,c) > (0,0,0)$ (i.e. $(a > 0)||(a == 0)\&\&(b > 0)||(a == 0)\&\&(b == 0)\&\&(c > 0)$).

Circular_arc_3<SphericalKernel> ca(Point_3<SphericalKernel> p,
Point_3<SphericalKernel> q,
Point_3<SphericalKernel> r)

Constructs an arc that is supported by the circle of type *Circle_3<SphericalKernel>* passing through the points p, q and r. The source and target are respectively p and r, when traversing the supporting circle in the counterclockwise direction seen from the side of the plane containing the circle pointed by its *positive* normal vectors. Note that, depending on the orientation of the point triple *(p,q,r)*, q may not lie on the arc.
Precondition: p, q, and r are not collinear.

Access Functions

Circle_3<SphericalKernel>	*ca.supporting_circle()*	
Point_3<SphericalKernel>	*ca.center() const*	returns the center of the supporting circle.
SphericalKernel::FT	*ca.squared_radius() const*	returns the squared radius of the supporting circle.
Plane_3<SphericalKernel>	*ca.supporting_plane()*	
Sphere_3<SphericalKernel>	*ca.diametral_sphere()*	
Circular_arc_point_3<SphericalKernel>	*ca.source()*	
Circular_arc_point_3<SphericalKernel>	*ca.target()*	

When the methods *source* and *target* return the same point, then the arc is in fact a full circle.

When the arc was constructed from its (full) underlying circle, then source and target both return the smallest x-extremal point of the circle if the circle is not contained in a plane $x = A$, and the smallest y-extremal point otherwise.

Operations

bool	$a1 == a2$	Test for equality. Two arcs are equal, iff their non-oriented supporting planes are equal, and the centers and squared radii of their respective supporting circles are equal, and their sources and targets are equal.
bool	$a1 \,!= a2$	Test for nonequality.

I/O

istream&	*std::istream& is >> Circular_arc_3 & ca*
ostream&	*std::ostream& os << Circular_arc_3 ca*

The input/output format of a circular arc consists of the supporting circle represented as a *Circle_3* object followed by the source and target points of the arc represented as two *Circular_arc_point_3* objects. The defined arc is the unique arc constructed from such three objects.

Enum

CGAL::Circle_type

Definition

The enum *Circle_type* is used to classify an object of type *Circle_3*, so as to specify its type (normal,polar,bipolar or threaded), as defined in section 14.2.

enum type { *NORMAL, THREADED, POLAR, BIPOLAR*}*;*

Functor
Concept

SphericalKernel::ConstructSphere_3

Refines

Kernel::ConstructSphere_3

A model *fo* of this concept must provide:

SphericalKernel::Sphere_3

fo(SphericalKernel::Circular_arc_3 a)

Returns the diametral sphere of the supporting circle of arc *a*.

SphericalKernel::Sphere_3

fo(SphericalKernel::Polynomial_2_3 p)

Constructs a sphere from an equation.

See Also

SphericalKernel::GetEquation . . . . page 1309

SphericalKernel::ConstructLine_3

Refines

Kernel::ConstructLine_3

A model *fo* of this concept must provide:

SphericalKernel::Line_3 *fo(SphericalKernel::Line_arc_3 s)*

Constructs the line containing the segment.

SphericalKernel::Line_3 *fo(SphericalKernel::Polynomials_for_lines_3 p)*

Constructs a line from an equation.

See Also

SphericalKernel::GetEquation . . . . page 1309

SphericalKernel::ConstructCircle_3

A model *fo* of this concept must provide:

SphericalKernel::Circle_3

fo(SphericalKernel::Circular_arc_3 a)

Constructs the circle containing the arc.

SphericalKernel::Circle_3

fo(SphericalKernel::Polynomials_for_circles_3 p)

Constructs a circle from an equation.

SphericalKernel::GetEquation . . . . page 1309

SphericalKernel::ConstructCircularArcPoint_3

A model *fo* of this concept must provide:

SphericalKernel::Circular_arc_point_3

fo(SphericalKernel::Root_for_spheres_2_3 r)

SphericalKernel::Circular_arc_point_3

fo(SphericalKernel::Point_3 p)

SphericalKernel::ConstructLineArc_3

A model *fo* of this concept must provide:

SphericalKernel::Line_arc_3

*fo.operator()(SphericalKernel::Line_3 l,
SphericalKernel::Circular_arc_point_3 p,
SphericalKernel::Circular_arc_point_3 q)*

Constructs the line segment supported by *l*, whose source is *p* and whose target is *q*.
Precondition: *p* and *q* lie on *l* and are different.

SphericalKernel::Line_arc_3

fo(SphericalKernel::Segment_3 s)

SphericalKernel::Line_arc_3

fo(SphericalKernel::Point_3 p, SphericalKernel::Point_3 q)

SphericalKernel::ConstructCircularArc_3

A model *fo* of this concept must provide:

SphericalKernel::Circular_arc_3

fo(SphericalKernel::Circle_3 c)

Constructs an arc from a full circle.

SphericalKernel::Circular_arc_3

fo.operator()(SphericalKernel::Circle_3 c,
SphericalKernel::Circular_arc_point_3 p,
SphericalKernel::Circular_arc_point_3 q)

Constructs the circular arc supported by c, whose source and target are p and q, respectively.
Precondition: p and q lie on c and they are different.

The circular arc constructed from a circle, a source, and a target, is defined as the set of points of the circle that lie between the source *p1* and the target *p2*, when traversing the circle counterclockwise seen from the side of the plane of the circle pointed by its *positive* normal vectors.

In this definition, we say that a normal vector (a,b,c) is *positive* if $(a,b,c) > (0,0,0)$ (i.e. $(a > 0)||(a == 0)\&\&(b > 0)||(a == 0)\&\&(b == 0)\&\&(c > 0)$).

SphericalKernel::Circular_arc_3

fo.operator()(SphericalKernel::Point_3 p,
SphericalKernel::Point_3 q,
SphericalKernel::Point_3 r)

Constructs an arc that is supported by the circle of type *SphericalKernel::Circle_3* passing through the points p, q and r. The source and target are respectively p and r, when traversing the supporting circle in the counterclockwise direction seen from the side of the plane containing the circle pointed by its *positive* normal vectors. the circle. Note that, depending on the orientation of the point triple *(p,q,r)*, q may not lie on the arc.
Precondition: p, q, and r are not collinear.

SphericalKernel::ConstructCircularMinVertex_3

A model *fo* of this concept must provide:

SphericalKernel::Circular_arc_point_3

fo(SphericalKernel::Line_arc_3 l)

Constructs the minimal vertex of *l* with lexicographically smallest coordinates.

SphericalKernel::ConstructCircularMaxVertex_3

A model *fo* of this concept must provide:

SphericalKernel::Circular_arc_point_3

fo(SphericalKernel::Line_arc_3 l)

Constructs the maximal vertex of *l* with lexicographically largest coordinates.

Functor
Concept

SphericalKernel::ConstructCircularSourceVertex_3

A model *fo* of this concept must provide:

SphericalKernel::Circular_arc_point_3

fo(SphericalKernel::Circular_arc_3 a)

Constructs the source vertex of *a*.

SphericalKernel::Circular_arc_point_3

fo(SphericalKernel::Line_arc_3 l)

Same, for a line segment.

SphericalKernel::ConstructCircularTargetVertex_3

A model *fo* of this concept must provide:

SphericalKernel::Circular_arc_point_3

fo(SphericalKernel::Circular_arc_3 a)

Constructs the target vertex of *a*.

SphericalKernel::Circular_arc_point_3

fo(SphericalKernel::Line_arc_3 l)

Same, for a line segment.

SphericalKernel::ConstructBbox_3

A model *fo* of this concept must provide operators to construct a bounding box of geometric objects:

CGAL::Bbox_3	*fo(SphericalKernel::Circular_arc_point_3 p)*
CGAL::Bbox_3	*fo(SphericalKernel::Line_arc_3 l)*
CGAL::Bbox_3	*fo(SphericalKernel::Circular_arc_3 a)*

SphericalKernel::Split_3

A model *fo* of this type must provide:

void *fo.operator()(SphericalKernel::Circular_arc_3 a, SphericalKernel::Circular_arc_point_3 p, SphericalKernel::Circular_arc_3 &a1, SphericalKernel::Circular_arc_3 &a2)*

Splits arc a at point p, which creates arcs $a1$ and $a2$.
Precondition: The point p lies in the interior of the input arc a.

void *fo.operator()(SphericalKernel::Line_arc_3 l, SphericalKernel::Circular_arc_point_3 p, SphericalKernel::Line_arc_3 &l1, SphericalKernel::Line_arc_3 &l2)*

Same for a line arc.

Functor
Concept

SphericalKernel::MakeThetaMonotone_3

A model *fo* of this concept must provide:

template<class OutputIterator>
OutputIterator *fo(SphericalKernel::Circular_arc_3 a, OutputIterator res)*

Copies in the output iterator the results of the split of arc *a* at the θ-extremal point(s) of its supporting circle relatively to the context sphere used by the function *SphericalKernel::make_theta_monotone_3_object* (Refer to section 14.2 for the definition of these points.) The output iterator may contain no arc (if the supporting circle is a bipolar circle), one arc (if *a* is already θ-monotone), two arcs (if only one θ-extremal point is on *a*), or three arcs (if two θ-extremal points are on *a*).
Precondition: *a* lies on the context sphere used by the function *SphericalKernel::make_theta_monotone_3_object*, and the supporting circle of *a* is not bipolar.

template<class OutputIterator>
OutputIterator *fo(SphericalKernel::Circle_3 c, OutputIterator res)*

Copies in the output iterator the results of the split of circle *c* at its θ-extremal point(s) relatively to the context sphere used by the function *SphericalKernel::make_theta_monotone_3_object*. (Refer to section 14.2 for the definition of these points.) The output iterator may contain no arc (if the circle is bipolar), one arc (if the circle is polar or threaded), or two arcs (if the circle is normal). The source and target are such that the circular arc is the set of points of the circle that lie between the source and the target when traversing the circle counterclockwise seen from the positive side of the plane of the circle. In this definition, we say that a normal vector (a,b,c) is *positive* if $(a > 0)||(a == 0)\&\&(b > 0)||(a == 0)\&\&(b == 0)\&\&(c > 0)$.
For a threaded circle, the arc returned the one built using the full circle.
For a polar circle, the arc returned is the full circle, the source and target correspond to the pole the circle goes through.
Precondition: *c* lies on the context sphere used by the function *SphericalKernel::make_theta_monotone_3_object*, and *c* is not bipolar.

Functor
Concept

SphericalKernel::CompareTheta_3

An object *fo* of this type must provide:

Comparison_result *fo.operator()(SphericalKernel::Circular_arc_point_3 p, SphericalKernel::Circular_arc_point_3 q)*

Compares the θ-coordinates of p and q in the cylindrical coordinate system relative to the context sphere used by the function *SphericalKernel::compare_theta_3_object*.
Precondition: p and q lie on the context sphere used by the function *SphericalKernel::compare_theta_3_object*, but do not coincide with its poles.

Comparison_result *fo(SphericalKernel::Circular_arc_point_3 p, SphericalKernel::Vector_3 m)*

Compares the θ-coordinates of p and of the meridian defined by m (see section 14.2) in the cylindrical coordinate system relative to the context sphere used by the function *SphericalKernel::compare_theta_3_object*.
Precondition: p lies on the context sphere used by the function *SphericalKernel::compare_theta_3_object*, but does not coincide with its poles. $m \neq (0,0,0)$ and the z-coordinate of m is 0.

Comparison_result *fo(SphericalKernel::Vector_3 m, SphericalKernel::Circular_arc_point_3 p)*

Same as previous, with opposite result.

Comparison_result *fo(SphericalKernel::Vector_3 m1, SphericalKernel::Vector_3 m2)*

Compares the θ-coordinates of the meridians defined by $m1$ and by $m2$ (see section 14.2) in the cylindrical coordinate system relative to the context sphere used by the function *SphericalKernel::compare_theta_3_object*.
$m1 \neq (0,0,0)$, $m2 \neq (0,0,0)$ and the z-coordinate of $m1$ and $m2$ is 0.

Concept

SphericalKernel::CompareZAtTheta_3

An object *fo* of this type must provide:

Comparison_result *fo.operator()(SphericalKernel::Circular_arc_3 a0, SphericalKernel::Circular_arc_3 a1, SphericalKernel::Vector_3 m)*

compares the z-coordinates of the two intersections points of $a0$ and $a1$ with the meridian defined by m (see section 14.2).
Precondition: *a0* and *a1* lie on the context sphere used by the function *SphericalKernel::compare_z_at_theta_3_object*. $m \neq (0,0,0)$ and the z-coordinate of m is 0. Arcs $a0$ and $a1$ are θ-monotone and both intersected by the meridian defined by m (see section 14.2).

Comparison_result *fo(SphericalKernel::Circular_arc_point_3 p, SphericalKernel::Circular_arc_3 a)*

given a meridian anchored at the poles of the context sphere used by the function *SphericalKernel::compare_z_at_theta_3_object*, and passing through point p, compares the z-coordinate of point p and that of the intersection of the meridian with a.
Precondition: a and p lie on the context sphere used by the function *SphericalKernel::compare_z_at_theta_3_object*, arc a is θ-monotone and the meridian passing through p intersects arc a.

See Also

SphericalKernel::CompareZToRight_3 . . . . page 1293

SphericalKernel::CompareZToRight_3

An object *fo* of this type must provide:

Comparison_result *fo.operator()(SphericalKernel::Circular_arc_3 a0, SphericalKernel::Circular_arc_3 a1, SphericalKernel::Circular_arc_point_3 p)*

Compares the z-coordinates of the intersection points of both arcs with a meridian anchored at the poles of the context sphere used by the function *SphericalKernel::compare_z_to_right_3_object*, at a θ-coordinate infinitesimally greater that the θ-coordinate of point p.
Precondition: *a0* and *a1* lie on the context sphere used by the function *SphericalKernel::compare_z_to_right_3_object*, *a0* and *a1* are θ-monotone, p lies on *a0* and *a1* and is not a θ-extremal point of the supporting circle of *a0* or *a1*.

SphericalKernel::Equal_3

Definition

Testing equality between objects.

Refines

Kernel::Equal_3

An object *fo* of this type must provide in addition:

bool *fo.operator()(SphericalKernel::Circular_arc_point_3 p0, SphericalKernel::Circular_arc_point_3 p1)*

For two points.

bool *fo(SphericalKernel::Circular_arc_3 a0, SphericalKernel::Circular_arc_3 a1)*

For two arcs. Two arcs are equal, iff their non-oriented supporting planes are equal, and the centers and squared radii of their respective supporting circles are equal, and their sources and targets are equal.

bool *fo(SphericalKernel::Line_arc_3 a0, SphericalKernel::Line_arc_3 a1)*

For two segments. Two segments are equal, iff their non-oriented supporting lines are equal (i.e. they define the same set of points), and their endpoints are the same.

SphericalKernel::HasOn_3

Refines

Kernel::HasOn_3

An object *fo* of this type must provide:

bool *fo(Type1 obj1, Type2 obj2)*

Returns *true* when *obj1* contains *obj2*,

where *Type1* and *Type2* can be respectively:

Type1	*Type2*
SphericalKernel::Sphere_3, *SphericalKernel::Plane_3*, *SphericalKernel::Line_3*, *SphericalKernel::Circle_3*, *SphericalKernel::Line_arc_3*, or *SphericalKernel::Circular_arc_3*	*SphericalKernel::Circular_arc_point_3*
SphericalKernel::Plane_3, *SphericalKernel::Line_3*	*SphericalKernel::Line_arc_3*
SphericalKernel::Sphere_3, *SphericalKernel::Circle_3*, or *SphericalKernel::Plane_3*	*SphericalKernel::Circular_arc_3*

SphericalKernel::DoOverlap_3

Refines

Kernel::DoOverlap_3

An object *fo* of this type must provide:

bool	*fo.operator()(*	*SphericalKernel::Line_arc_3 l0, SphericalKernel::Line_arc_3 l1, const bool known_equal_supporting_line = false)*
		For two line arcs.
bool	*fo.operator()(*	*SphericalKernel::Circular_arc_3 a0, SphericalKernel::Circular_arc_3 a1, const bool known_equal_supporting_circle = false)*
		For two circular arcs.

The computation may be faster when the boolean is set to *true*.

SphericalKernel::DoIntersect_3

Definition

Testing whether two curves intersect.

Refines

Kernel::DoIntersect_3

An object *fo* of this type must provide:

bool	*fo(Type1 obj1, Type2 obj2)*	
		determines if two geometric objects of type Type1 and Type2 intersect or not.

for all pairs *Type1* and *Type2*, where the types *Type1* and *Type2* can be either, any of the following:

- *SphericalKernel::Plane_3*
- *SphericalKernel::Line_3*
- *SphericalKernel::Line_arc_3*
- *SphericalKernel::Sphere_3*
- *SphericalKernel::Circle_3*

Functor
Concept

SphericalKernel::Intersect_3

Refines

Kernel::Intersect_3

A model *fo* of this concept must provide:

template < class OutputIterator >
OutputIterator *fo(Type1 obj1, Type2 obj2, OutputIterator intersections)*

Copies in the output iterator the intersection elements between the two objects. *intersections* iterates on elements of type *CGAL::Object*, in lexicographic order when this ordering is defined on the computed objects.

template < class OutputIterator >
OutputIterator *fo(Type1 obj1, Type2 obj2, Type3 obj3, OutputIterator intersections)*

Copies in the output iterator the intersection elements between the three objects. *intersections* iterates on elements of type *CGAL::Object*, in lexicographic order when this ordering is defined on the computed objects.

For the **first operator**, *Type1* and *Type2* can both be either

- *SphericalKernel::Sphere_3*,
- *SphericalKernel::Plane_3*,
- *SphericalKernel::Line_3*,
- *SphericalKernel::Circle_3*,
- *SphericalKernel::Line_arc_3* or
- *SphericalKernel::Circular_arc_3*,

depending on the types *Type1* and *Type2*, the computed *CGAL::Object*s can be assigned to

- *std::pair<SphericalKernel::Circular_arc_point_3, unsigned>*, where the unsigned integer is the multiplicity of the corresponding intersection point between *obj_1* and *obj_2*,
- *Type1*, when *Type1* and *Type2* are equal, and if the two objects *obj1* and *obj2* are equal,
- *SphericalKernel::Line_3* or *SphericalKernel::Circle_3* when *Type1* and *Type2* are two-dimensional objects intersecting along a curve (2 planes, or 2 spheres, or one plane and one sphere),
- *SphericalKernel::Circular_arc_3* in case of an overlap of two circular arcs or
- *SphericalKernel::Line_arc_3* in case of an overlap of two line segments.

For the **second operator**, *Type1*, *Type2* and *Type3* can be either

- *SphericalKernel::Sphere_3* or
- *SphericalKernel::Plane_3*

and depending of these types, the computed *CGAL::Object*s can be assigned to

- *std::pair<SphericalKernel::Circular_arc_point_3, unsigned>*, where the unsigned integer is the multiplicity of the corresponding intersection point,
- *SphericalKernel::Circle_3* or
- *Type1*, when *Type1*, *Type2* and *Type3* are equal, and if the three objects *obj1* and *obj2* and *obj3* are equal.

SphericalKernel::ComputeCircularX_3

SphericalKernel::Root_of_2

fo(SphericalKernel::Circular_arc_point_3 p)

returns the x-coordinate of the point p.

SphericalKernel::ComputeCircularY_3

SphericalKernel::Root_of_2

fo(SphericalKernel::Circular_arc_point_3 p)

returns the y-coordinate of the point p.

SphericalKernel::ComputeCircularZ_3

SphericalKernel::Root_of_2

fo(SphericalKernel::Circular_arc_point_3 p)

returns the z-coordinate of the point p.

SphericalKernel::ComputeApproximateSquaredLength_3

Refines

Kernel::ComputeApproximateSquaredLength_3

In addition, an object *fo* of this type must provide:

double	*fo(SphericalKernel::Circular_arc_3 a)*	
		Computes an approximation of the squared length of the arc *a*.

Functor
Concept

SphericalKernel::ComputeApproximateAngle_3

An object *fo* of this type must provide:

double	*fo(SphericalKernel::Circular_arc_3 a)*	
		Computes an approximation of the angle of the arc in radians *a*.

SphericalKernel::GetEquation

A model *fo* of this concept must provide:

SphericalKernel::Polynomial_1_3

fo(SphericalKernel::Plane_3 p)

Returns the equation of the plane.

SphericalKernel::Polynomial_for_spheres_2_3

fo(SphericalKernel::Sphere_3 p)

Returns the equation of the sphere.

SphericalKernel::Polynomials_for_line_3

fo(SphericalKernel::Line_3 c)

Returns the equations of the line.

SphericalKernel::Polynomials_for_circle_3

fo(SphericalKernel::Circle_3 c)

Returns the equations of the circle.

Function

CGAL::is_theta_monotone

#include <CGAL/global_functions_spherical_kernel_3.h>

bool *is_theta_monotone(Circular_arc_3<SphericalKernel> a, Sphere_3<SphericalKernel> sphere)*

Tests whether the arc *a* is θ-monotone, i.e. the intersection of any meridian anchored at the poles *sphere* and the arc *a* is reduced to at most one point in general, and two points if a pole of *sphere* is an endpoint of the arc. Note that a bipolar circle has no such arcs.
Precondition: *a* lies on *sphere*, and the supporting circle of *a* is not bipolar.

CGAL::compare_theta

#include <CGAL/global_functions_spherical_kernel_3.h>

Comparison_result *compare_theta(Circular_arc_point_3<SphericalKernel> p, Circular_arc_point_3<SphericalKernel> q, Sphere_3<SphericalKernel> sphere)*

Compares the θ-coordinates of p and q relatively to *sphere*.
Precondition: p and q lie on *sphere*, but do not coincide with the poles of *sphere*.

Comparison_result *compare_theta(SphericalKernel::Circular_arc_point_3 p, SphericalKernel::Vector_3 m, SphericalKernel::Sphere_3 sphere)*

Compares the θ-coordinates of p and of the meridian defined by m (see section 14.2) in the cylindrical coordinate system relative to *sphere* .
Precondition: p lies on *sphere*, but does not coincide with its poles. $m \neq (0,0,0)$ and the z-coordinate of m is 0.

Comparison_result *compare_theta(SphericalKernel::Vector_3 m, SphericalKernel::Circular_arc_point_3 p)*

Same as previous, with opposite result.

CGAL::x_extremal_point

#include <CGAL/global_functions_spherical_kernel_3.h>

Circular_arc_point_3<SphericalKernel>

x_extremal_point(Sphere_3<SphericalKernel> c, bool b)

Returns the point on the sphere that is extremal in the x-direction, and that is the smallest (resp. largest) of the two x-extremal points for the lexicographic order if b is *true* (resp. *false*).

Circular_arc_point_3<SphericalKernel>

x_extremal_point(Circle_3<SphericalKernel> c, bool b)

Same for a circle.
Precondition: The circle is not contained in a plane orthogonal to the x-axis.

Function

Function

CGAL::y_extremal_point

#include <CGAL/global_functions_spherical_kernel_3.h>

Circular_arc_point_3<SphericalKernel>

y_extremal_point(Sphere_3<SphericalKernel> c, bool b)

Returns the point on the sphere that is extremal in the y-direction, and that is the smallest (resp. largest) of the two y-extremal points for the lexicographic order if b is *true* (resp. *false*).

Circular_arc_point_3<SphericalKernel>

y_extremal_point(Circle_3<SphericalKernel> c, bool b)

Same for a circle.
Precondition: The circle is not contained in a plane orthogonal to the y-axis.

CGAL::z_extremal_point

#include <CGAL/global_functions_spherical_kernel_3.h>

Circular_arc_point_3<SphericalKernel>

z_extremal_point(Sphere_3<SphericalKernel> c, bool b)

Returns the point on the sphere that is extremal in the z-direction, and that is the smallest (resp. largest) of the two z-extremal points for the lexicographic order if b is *true* (resp. *false*).

Circular_arc_point_3<SphericalKernel>

z_extremal_point(Circle_3<SphericalKernel> c, bool b)

Same for a circle.
Precondition: The circle is not contained in a plane orthogonal to the z-axis.

Function

Function

CGAL::theta_extremal_point

#include <CGAL/global_functions_spherical_kernel_3.h>

Circular_arc_point_3<SphericalKernel>

theta_extremal_point(Circle_3<SphericalKernel> c,
const Sphere_3<SphericalKernel> sphere,
bool b)

Returns the point on the circle that is extremal in θ using the cylindrical coordinate system relative to *sphere*, and that has the smallest (resp. largest) θ-coordinate of the two points if *b* is *true* (resp. *false*). See section 14.2 for definitions.
Precondition: *c* lies on *sphere* and is a normal circle.

CGAL::x_extremal_points

#include <CGAL/global_functions_spherical_kernel_3.h>

template < class OutputIterator >
OutputIterator *x_extremal_points(Sphere_3<SphericalKernel> c, OutputIterator res)*

Copies in the output iterator the x-extremal points of the sphere. *res* iterates on elements of type *Circular_arc_point_3<SphericalKernel>*, lexicographically sorted.

template < class OutputIterator >
OutputIterator *x_extremal_points(Circle_3<SphericalKernel> c, OutputIterator res)*

Copies in the output iterator the x-extremal points of the circle. *res* iterates on elements of type *Circular_arc_point_3<SphericalKernel>*, lexicographically sorted.
Precondition: The circle is not contained in a plane orthogonal to the x-axis.

Function

Function

CGAL::y_extremal_points

#include <CGAL/global_functions_spherical_kernel_3.h>

template < class OutputIterator >
OutputIterator *y_extremal_points(Sphere_3<SphericalKernel> c, OutputIterator res)*

Copies in the output iterator the y-extremal points of the sphere. *res* iterates on elements of type *Circular_arc_point_3<SphericalKernel>*, lexicographically sorted.

template < class OutputIterator >
OutputIterator *y_extremal_points(Circle_3<SphericalKernel> c, OutputIterator res)*

Copies in the output iterator the y-extremal points of the circle. *res* iterates on elements of type *Circular_arc_point_3<SphericalKernel>*, lexicographically sorted.
Precondition: The circle is not contained in a plane orthogonal to the y-axis.

CGAL::z_extremal_points

#include <CGAL/global_functions_spherical_kernel_3.h>

template < class OutputIterator >
OutputIterator *z_extremal_points(Sphere_3<SphericalKernel> c, OutputIterator res)*

Copies in the output iterator the z-extremal points of the sphere. *res* iterates on elements of type *Circular_arc_point_3<SphericalKernel>*, lexicographically sorted.

template < class OutputIterator >
OutputIterator *z_extremal_points(Circle_3<SphericalKernel> c, OutputIterator res)*

Copies in the output iterator the z-extremal points of the circle. *res* iterates on elements of type *Circular_arc_point_3<SphericalKernel>*, lexicographically sorted.
Precondition: The circle is not contained in a plane orthogonal to the z-axis.

Function

CGAL::theta_extremal_points

#include <CGAL/global_functions_spherical_kernel_3.h>

template < class OutputIterator >
OutputIterator *theta_extremal_points(Circle_3<SphericalKernel> c, Sphere_3<SphericalKernel> sphere, OutputIterator res)*

Copies in the output iterator the θ-extremal points of the circle relatively to *sphere*. *res* iterates on elements of type *Circular_arc_point_3<SphericalKernel>*, lexicographically sorted in the cylindrical coordinate system relative to *sphere*. See section 14.2 for definitions.
Precondition: *c* lies on *sphere* and is a normal circle.

CGAL::classify

#include <CGAL/global_functions_spherical_kernel_3.h>

CGAL::Circle_type	*classify(Circle_3<SphericalKernel> c, Sphere_3<SphericalKernel> sphere)*	
		Classify a circle according to *sphere*, as defined in section 14.2. *Precondition*: *c* lies on *sphere*.

Function

CGAL::Circle_type . . . . page 1270

AlgebraicKernelForSpheres

Definition

The *AlgebraicKernelForSpheres* concept is meant to provide the curved kernel with all the algebraic functionalities required for the manipulation of spheres, circles, and circular arcs in 3D.

Has Models

Algebraic_kernel_for_spheres_2_3

Types

A model of *AlgebraicKernelForSpheres* is supposed to provide

AlgebraicKernelForSpheres:: RT	A model of *RingNumberType*.
AlgebraicKernelForSpheres:: FT	A model of *FieldNumberType<RT>*.
AlgebraicKernelForSpheres:: Polynomial_1_3	A model of *AlgebraicKernelForSpheres::Polynomial_1_3*, for trivariate polynomials of degree up to 1.
AlgebraicKernelForSpheres:: Polynomial_for_spheres_2_3	A model of *AlgebraicKernelForSpheres::PolynomialForSpheres_2_3*, for trivariate polynomials of degree up to 2 that can store equations of spheres.
AlgebraicKernelForSpheres:: Polynomials_for_lines_3	A model of *AlgebraicKernelForSpheres::PolynomialsForLines_3*, for systems of polynomials that can store equations of lines in 3D.
AlgebraicKernelForSpheres:: Root_of_2	A model of *RootOf_2*, for algebraic numbers of degree up to 2.
AlgebraicKernelForSpheres:: Root_for_spheres_2_3	A model of *AlgebraicKernelForSpheres::RootForSpheres_2_3*, for solutions of systems of three models of *AlgebraicKernelForSpheres::PolynomialForSpheres_2_3*.
AlgebraicKernelForSpheres:: Construct_polynomial_1_3	A model of *AlgebraicKernelForSpheres::ConstructPolynomial_1_3*.

AlgebraicKernelForSpheres:: Construct_polynomial_for_spheres_2_3

A model of *AlgebraicKernelForSpheres::ConstructPolynomialForSpheres_2_3*.

AlgebraicKernelForSpheres:: Construct_polynomials_for_lines_3

A model of *AlgebraicKernelForSpheres::ConstructPolynomialsForLines_3*.

AlgebraicKernelForSpheres:: Compare_x	A model of the concept *AlgebraicKernelForSpheres::CompareX*.
AlgebraicKernelForSpheres:: Compare_y	A model of the concept *AlgebraicKernelForSpheres::CompareY*.
AlgebraicKernelForSpheres:: Compare_z	A model of the concept *AlgebraicKernelForSpheres::CompareZ*.
AlgebraicKernelForSpheres:: Compare_xy	A model of the concept *AlgebraicKernelForSpheres::CompareXY*.
AlgebraicKernelForSpheres:: Compare_xyz	A model of the concept *AlgebraicKernelForSpheres::CompareXYZ*.
AlgebraicKernelForSpheres:: Sign_at	A model of the concept *AlgebraicKernelForSpheres::SignAt*.
AlgebraicKernelForSpheres:: X_critical_points	A model of the concept *AlgebraicKernelForSpheres::XCriticalPoints*.
AlgebraicKernelForSpheres:: Y_critical_points	A model of the concept *AlgebraicKernelForSpheres::YCriticalPoints*.
AlgebraicKernelForSpheres:: Z_critical_points	A model of the concept *AlgebraicKernelForSpheres::ZCriticalPoints*.
AlgebraicKernelForSpheres:: Solve	A model of the concept *AlgebraicKernelForSpheres::Solve*.

AlgebraicKernelForSpheres::Solve

Definition

A model *fo* of this concept must provide:

template < class OutputIterator >
OutputIterator *fo(Type1 p1, Type2 p2, Type3 p3, OutputIterator res)*

Copies in the output iterator the common roots of *p1*, *p2*, and *p3*, with their multiplicity, as objects of type *std::pair< AlgebraicKernelForSpheres::Root_for_spheres_2_3, int>*.
Precondition: The set of solutions of the system is 0-dimensional.

Here, *Type1*, *Type2*, and *Type3* can all be either *AlgebraicKernelForSpheres::Polynomial_1_3* or *AlgebraicKernelForSpheres::Polynomial_for_spheres_2_3*.

Concept

AlgebraicKernelForSpheres::XCriticalPoints

Definition

A model *fo* of this concept must provide:

template < class OutputIterator >
OutputIterator *fo.operator()(AlgebraicKernelForSpheres::Polynomial_for_spheres_2_3 p, OutputIterator res)*

Copies in the output iterator the x-critical points of polynomial p, as objects of type *AlgebraicKernelForSpheres::Root_for_spheres_2_3*.

template < class OutputIterator >
AlgebraicKernelForSpheres::Root_for_spheres_2_3
fo(AlgebraicKernelForSpheres::Polynomial_for_spheres_2_3 p, bool i)

Computes the ith x-critical point of polynomial p.

Convex Hull Algorithms

Chapter 15

2D Convex Hulls and Extreme Points

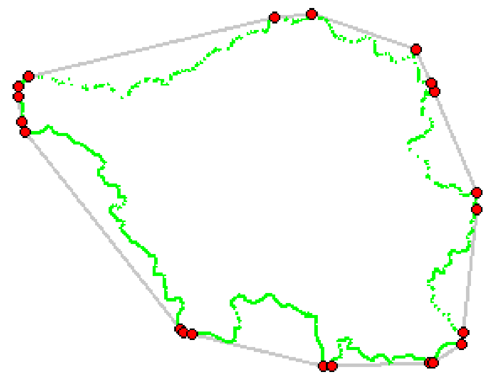
Susan Hert and Stefan Schirra

Contents

15.1 Introduction

A subset $S \subseteq \mathbb{R}^2$ is convex if for any two points p and q in the set the line segment with endpoints p and q is contained in S. The convex hull of a set S is the smallest convex set containing S. The convex hull of a set of points P is a convex polygon with vertices in P. A point in P is an extreme point (with respect to P) if it is a vertex of the convex hull of P. A set of points is said to be strongly convex if it consists of only extreme points.

This chapter describes the functions provided in CGAL for producing convex hulls in two dimensions as well as functions for checking if sets of points are strongly convex are not. There are also a number of functions described for computing particular extreme points and subsequences of hull points, such as the lower and upper hull of a set of points.



15.2 Convex Hull

CGAL provides implementations of several classical algorithms for computing the counterclockwise sequence of extreme points for a set of points in two dimensions (*i.e.*, the counterclockwise sequence of points on the convex hull). The algorithms have different asymptotic running times and require slightly different sets of geometric primitives. Thus you may choose the algorithm that best fits your setting.

Each of the convex hull functions presents the same interface to the user. That is, the user provides a pair of iterators, *first* and *beyond*, an output iterator *result*, and a traits class *traits*. The points in the range [*first*, *beyond*) define the input points whose convex hull is to be computed. The counterclockwise sequence of extreme points is written to the sequence starting at position *result*, and the past-the-end iterator for the resulting set of points is returned. The traits classes for the functions specify the types of the input points and the geometric primitives that are required by the algorithms. All functions provide an interface in which this class need not be specified and defaults to types and operations defined in the kernel in which the input point type is defined.

Given a sequence of n input points with h extreme points, the function *convex_hull_2* uses either the output-sensitive $O(nh)$ algorithm of Bykat [Byk78] (a non-recursive version of the quickhull [BDH96] algorithm) or the algorithm of Akl and Toussaint, which requires $O(n \log n)$ time in the worst case. The algorithm chosen depends on the kind of iterator used to specify the input points. These two algorithms are also available via the functions *ch_bykat* and *ch_akl_toussaint*, respectively. Also available are the $O(n \log n)$ Graham-Andrew scan algorithm [And79, Meh84] (*ch_graham_andrew*), the $O(nh)$ Jarvis march algorithm [Jar73] (*ch_jarvis*), and Eddy's $O(nh)$ algorithm [Edd77] (*ch_eddy*), which corresponds to the two-dimensional version of the quickhull algorithm. The linear-time algorithm of Melkman for producing the convex hull of simple polygonal chains (or polygons) is available through the function *ch_melkman*.

15.3 Example using Graham-Andrew's Algorithm

In the following example a convex hull is constructed from point data read from standard input using *Graham_Andrew* algorithm. The resulting convex polygon is shown at the standard output console. The same results could be achieved by substituting the function *CGAL::ch_graham_andrew* by other function like *CGAL::ch_bykat*.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/ch_graham_andrew.h>
```

```
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point_2;

int main()
{
  CGAL::set_ascii_mode(std::cin);
  CGAL::set_ascii_mode(std::cout);
  std::istream_iterator< Point_2 >  in_start( std::cin );
  std::istream_iterator< Point_2 >  in_end;
  std::ostream_iterator< Point_2 >  out( std::cout, "\n" );
  CGAL::ch_graham_andrew( in_start, in_end, out );

15.4 Extreme Points and Hull Subsequences

In addition to the functions for producing convex hulls, there are a number of functions for computing sets and sequences of points related to the convex hull. The functions *lower_hull_points_2* and *upper_hull_points_2* provide the computation of the counterclockwise sequence of extreme points on the lower hull and upper hull, respectively. The algorithm used in these functions is Andrew's variant of Graham's scan algorithm [And79, Meh84], which has worst-case running time of $O(n \log n)$.

There are also functions available for computing certain subsequences of the sequence of extreme points on the convex hull. The function *ch_jarvis_march* generates the counterclockwise ordered subsequence of extreme points between a given pair of points and *ch_graham_andrew_scan* computes the sorted sequence of extreme points that are not left of the line defined by the first and last input points.

Finally, a set of functions (*ch_nswe_point*, *ch_ns_point*, *ch_we_point*, *ch_n_point*, *ch_s_point*, *ch_w_point*, *ch_e_point*) is provided for computing extreme points of a 2D point set in the coordinate directions.

15.5 Traits Classes

Each of the functions used to compute convex hulls or extreme points is parameterized by a traits class, which specifies the types and geometric primitives to be used in the computation. There are several implementations of 2D traits classes provided in the library. The class *Convex_hull_traits_2<R>* corresponds to the default traits class that provides the types and predicates presented in the 2-dimensional CGAL kernel in which the input points lie. The class *Convex_hull_constructive_traits<R>* is a second traits class based on CGAL primitives but differs from *Convex_hull_traits_2* in that some of its primitives reuse intermediate results to speed up computation.

In addition, the 2D and 3D Linear Geometric Kernel provides three projective traits classes (*Projection_traits_xy_3<K>*, *Projection_traits_zx_3<K*, and *Projection_traits_yz_3<K*),

which may be used to compute the convex hull of a set of three-dimensional points projected into each of the three coordinate planes.

15.6 Convexity Checking

The functions *is_ccw_strongly_convex_2* and *is_cw_strongly_convex_2* check whether a given sequence of 2D points forms a (counter)clockwise strongly convex polygon.. These are used in postcondition testing of the two-dimensional convex hull functions.

2D Convex Hulls and Extreme Points Reference Manual

Susan Hert and Stefan Schirra

A subset $S \subseteq \mathbb{R}^2$ is convex if for any two points p and q in the set the line segment with endpoints p and q is contained in S. The convex hull of a set S is the smallest convex set containing S. The convex hull of a set of points P is a convex polygon with vertices in P. A point in P is an extreme point (with respect to P) if it is a vertex of the convex hull of P.

CGAL provides functions for computing convex hulls in two dimensions as well as functions for testing if a given set of points is strongly convex or not. There are also a number of functions available for computing particular extreme points in 2D and subsequences of the hull points, such as the lower hull or upper hull of a set of points.

15.7 Classified Reference Pages

Assertions

The assertion flags for the convex hull and extreme point algorithms use *CH* in their names (*e.g.*, *CGAL_CH_NO_POSTCONDITIONS*). For the convex hull algorithms, the postcondition check tests only convexity (if not disabled), but not containment of the input points in the polygon or polyhedron defined by the output points. The latter is considered an expensive checking and can be enabled by defining *CGAL_CH_CHECK_EXPENSIVE*.

Function

CGAL::ch_akl_toussaint

Definition

The function *ch_akl_toussaint* generates the counterclockwise sequence of extreme points from a given set of input points.

#include <CGAL/ch_akl_toussaint.h>

```
template <class ForwardIterator, class OutputIterator, class Traits>
OutputIterator    ch_akl_toussaint( ForwardIterator first,
                                    ForwardIterator beyond,
                                    OutputIterator result,
                                    Traits ch_traits = Default_traits())
```

generates the counterclockwise sequence of extreme points of the points in the range [*first*,*beyond*). The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.
Precondition: The source range [*first*,*beyond*) does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

1. *ForwardIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
   - *Traits::Point_2*,
   - *Traits::Less_xy_2*,
   - *Traits::Less_yx_2*,
   - *Traits::Left_turn_2*,
   - *Traits::Equal_2*.

Implementation

This function uses the algorithm of Akl and Toussaint [AT78] that requires $O(n \log n)$ time for n input points.

Function

CGAL::ch_bykat

Definition

The function *ch_bykat* generates the counterclockwise sequence of extreme points from a given set of input points.

#include <CGAL/ch_bykat.h>

template <class InputIterator, class OutputIterator, class Traits>
OutputIterator ch_bykat(InputIterator first, InputIterator beyond, OutputIterator result, Traits ch_traits = Default_traits)

generates the counterclockwise sequence of extreme points of the points in the range [*first*,*beyond*). The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.
Precondition: The source range [*first*,*beyond*) does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
   - *Traits::Point_2*,
   - *Traits::Less_signed_distance_to_line_2*,
   - *Traits::Left_turn_2*,
   - *Traits::Less_xy_2*,
   - *Traits::Equal_2*.

CGAL::convex_hull_2 . . . . . page 1379

Implementation

This function implements the non-recursive variation of Eddy's algorithm [Edd77] described in [Byk78]. This algorithm requires $O(nh)$ time in the worst case for n input points with h extreme points.

CGAL::ch_eddy

Definition

The function *ch_eddy* generates the counterclockwise sequence of extreme points from a given set of input points.

#include <CGAL/ch_eddy.h>

template <class InputIterator, class OutputIterator, class Traits>
OutputIterator ch_eddy(InputIterator first, InputIterator beyond, OutputIterator result, Traits ch_traits = Default_traits)

generates the counterclockwise sequence of extreme points of the points in the range [*first*,*beyond*). The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.
Precondition: The source range [*first*,*beyond*) does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
   - *Traits::Point_2*,
   - *Traits::Equal_2*,
   - *Traits::Less_signed_distance_to_line_2*,
   - *Traits::Left_turn_2*,
   - *Traits::Less_xy_2*.

CGAL::ch_melkman . . . . page 1371
CGAL::convex_hull_2 . . . . page 1379

Implementation

This function implements Eddy's algorithm [Edd77], which is the two-dimensional version of the quickhull algorithm [BDH96] . This algorithm requires $O(nh)$ time in the worst case for n input points with h extreme points.

Function

CGAL::ch_e_point

Definition

The function *ch_e_point* finds a point of a given set of input points with maximal x coordinate.

#include <CGAL/ch_selected_extreme_points_2.h>

template <class ForwardIterator>
void *ch_e_point(ForwardIterator first, ForwardIterator beyond, ForwardIterator& e, Traits ch_traits = Default_traits)*

traverses the range [*first*,*beyond*). After execution, the value of e is an iterator in the range such that $*e \geq_{xy} *it$ for all iterators *it* in the range.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

Traits defines a type *Traits::Less_xy_2* as described in the concept *ConvexHullTraits_2* and the corresponding member function that returns an instance of this type.

CGAL::ch_graham_andrew

Function

Definition

The function *ch_graham_andrew* generates the counterclockwise sequence of extreme points from a given set of input points.

#include <CGAL/ch_graham_andrew.h>

template <class InputIterator, class OutputIterator, class Traits>
OutputIterator ch_graham_andrew(InputIterator first, InputIterator beyond, OutputIterator result, Traits ch_traits = Default_traits)

generates the counterclockwise sequence of extreme points of the points in the range [*first*,*beyond*). The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.
Precondition: The source range [*first*,*beyond*) does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *InputIterator::value_type* is defined.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
   - *Traits::Point_2*,
   - *Traits::Less_xy_2*,
   - *Traits::Left_turn_2*,
   - *Traits::Equal_2*.

CGAL::convex_hull_2 . . . . . . page 1379

Implementation

This function implements Andrew's variant of the Graham scan algorithm [And79] and follows the presentation of Mehlhorn [Meh84]. This algorithm requires $O(n \log n)$ time in the worst case for n input points.

CGAL::ch_graham_andrew_scan

Function

Definition

The function *ch_graham_andrew_scan* generates the counterclockwise sequence of extreme points from a given set of input points that are not left of the line defined by the first and last points in this sequence.

#include <CGAL/ch_graham_andrew.h>

template <class BidirectionalIterator, class OutputIterator, class Traits>
OutputIterator ch_graham_andrew_scan(BidirectionalIterator first, BidirectionalIterator beyond, OutputIterator result, Traits ch_traits = Default_traits)

generates the counterclockwise sequence of extreme points that are not left of pq, where p is the value of *first* and q is the value of *beyond* -1. The resulting sequence is placed starting at *result* with p; point q is omitted. The past-the-end iterator for the sequence is returned.
Precondition: The range [*first*,*beyond*) contains at least two different points. The points in [*first*,*beyond*) are "sorted" with respect to pq, *i.e.*, the sequence of points in [*first*,*beyond*) define a counterclockwise polygon, for which the Graham-Sklansky-procedure [Skl72] works.

The default traits class *Default_traits* is the kernel in which the type *BidirectionalIterator::value_type* is defined.

Requirements

1. *BidirectionalIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* defines the following two types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
   - *Traits::Point_2*,
   - *Traits::Left_turn_2*.

CGAL::ch_graham_andrew . . . . page 1363
CGAL::lower_hull_points_2 . . . . page 1393
CGAL::upper_hull_points_2 . . . . page 1395

Implementation

The function uses Andrew's variant of the Graham scan algorithm [And79] . This algorithm requires $O(n \log n)$ time in the worst case for n input points.

Example

In the following example *ch_graham_andrew_scan()* is used to realize Anderson's variant [And78] of the Graham Scan [Gra72]. The points are sorted counterclockwise around the leftmost point using the *Less_rotate_ccw_2* predicate, as defined in the concept *ConvexHullTraits_2*. According to the definition of *Less_rotate_ccw_2*, the leftmost point is the last point in the sorted sequence and its predecessor on the convex hull is the first point in the sorted sequence. It is not hard to see that the preconditions of *ch_graham_andrew_scan()* are satisfied. Anderson's variant of the Graham scan is usually inferior to Andrew's variant because of its higher arithmetic demand.

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator
ch_graham_anderson( InputIterator  first, InputIterator  beyond,
                    OutputIterator result, const Traits&  ch_traits)
{
  typedef typename Traits::Less_xy_2          Less_xy_2;
  typedef typename Traits::Point_2            Point_2;
  typedef typename Traits::Less_rotate_ccw_2  Less_rotate_ccw_2;

  if (first == beyond) return result;
  std::vector< Point_2 >  V;
  copy( first, beyond, back_inserter(V) );
  typename std::vector< Point_2 >::iterator it =
              std::min_element(V.begin(), V.end(), Less_xy_2());
  std::sort( V.begin(), V.end(), CGAL::bind_1(Less_rotate_ccw_2(), *it) );
  if ( *(V.begin()) == *(V.rbegin()) )
  {
      *result = *(V.begin());  ++result;
      return result;
  }
  return ch_graham_andrew_scan( V.begin(), V.end(), result, ch_traits);
}
```

CGAL::ch_jarvis

Function

Definition

The function *ch_jarvis* generates the counterclockwise sequence of extreme points from a given set of input points.

#include <CGAL/ch_jarvis.h>

template <class InputIterator, class OutputIterator, class Traits>
OutputIterator ch_jarvis(InputIterator first, InputIterator beyond, OutputIterator result, Traits ch_traits = Default_traits)

generates the counterclockwise sequence of extreme points of the points in the range [*first*,*beyond*). The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.
Precondition: The source range [*first*,*beyond*) does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *InputIterator::value_type* is defined.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
   - *Traits::Point_2*,
   - *Traits::Equal_2*,
   - *Traits::Less_rotate_ccw_2*,
   - *Traits::Less_xy_2*.

CGAL::ch_jarvis_march . . . . page 1369
CGAL::ch_melkman . . . . page 1371
CGAL::convex_hull_2 . . . . page 1379

Implementation

This function uses the Jarvis march (gift-wrapping) algorithm [Jar73]. This algorithm requires $O(nh)$ time in the worst case for n input points with h extreme points.

CGAL::ch_jarvis_march

Function

Definition

The function *ch_jarvis_march* generates the counterclockwise sequence of extreme points from a given set of input points that line between two input points.

#include <CGAL/ch_jarvis.h>

template <class ForwardIterator, class OutputIterator, class Traits>
OutputIterator ch_jarvis_march(ForwardIterator first, ForwardIterator beyond, Traits::Point_2 start_p, Traits::Point_2 stop_p, OutputIterator result, Traits ch_traits = Default_traits)

generates the counterclockwise subsequence of extreme points between *start_p* and *stop_p* of the points in the range [*first*,*beyond*), starting at position *result* with point *start_p*. The last point generated is the point preceding *stop_p* in the counterclockwise order of extreme points.

Precondition: *start_p* and *stop_p* are extreme points with respect to the points in the range [*first*,*beyond*) and *stop_p* is an element of range [*first*,*beyond*).

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

1. *ForwardIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
   - *Traits::Point_2*,
   - *Traits::Equal_2*,
   - *Traits::Less_rotate_ccw_2*.

Implementation

The function uses the Jarvis march (gift-wrapping) algorithm [Jar73]. This algorithm requires $O(nh)$ time in the worst case for n input points with h extreme points.

CGAL::ch_melkman

Definition

The function *ch_melkman* computes the counterclockwise sequence of extreme points of a sequence of points that forms a simple polyline or polygon.

#include <CGAL/ch_melkman.h>

template <class InputIterator, class OutputIterator>
OutputIterator ch_melkman(InputIterator first, InputIterator last, OutputIterator result, Traits ch_traits = Default_traits)

generates the counterclockwise sequence of extreme points of the points in the range [*first*, *beyond*). The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned.
Precondition: The source range [*first*,*beyond*) corresponds to a simple polyline. [*first*,*beyond*) does not contain *result*

.

The default traits class *Default_traits* is the kernel in which the type *InputIterator::value_type* is defined.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* contains the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
   - *Traits::Point_2*,
   - *Traits::Equal_2*,
   - *Traits::Less_xy_2*,
   - *Traits::Left_turn_2*.

See Also

Implementation

It uses an implementation of Melkman's algorithm [Mel87]. Running time of this is linear.

CGAL::ch_nswe_point

Definition

The function *ch_nswe_point* finds the four extreme points of a given set of input points using a linear scan of the input points. That is, it determines the points with maximal y, minimal y, minimal x, and maximal x coordinates.

#include <CGAL/ch_selected_extreme_points_2.h>

template <class ForwardIterator>
void *ch_nswe_point(ForwardIterator first, ForwardIterator beyond, ForwardIterator& n, ForwardIterator& s, ForwardIterator& w, ForwardIterator& e, Traits ch_traits = Default_traits)*

traverses the range [*first*,*beyond*). After execution, the value of n is an iterator in the range such that $*n \geq_{yx} *it$ for all iterators it in the range. Similarly, for s, w, and e the inequalities $*s \leq_{yx} *it$, $*w \leq_{xy} *it$, and $*e \geq_{xy} *it$ hold for all iterators it in the range.

Requirements

Traits contains the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:

- *Traits::Less_xy_2*,
- *Traits::Less_yx_2*.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

CGAL::ch_n_point

Definition

The function *ch_n_point* finds a point in a given set of input points with maximal y coordinate.

#include <CGAL/ch_selected_extreme_points_2.h>

template <class ForwardIterator>
void *ch_n_point(ForwardIterator first, ForwardIterator beyond, ForwardIterator& n, Traits ch_traits = Default_traits)*

traverses the range [*first*,*beyond*). After execution, the value of n is an iterator in the range such that $*n \geq_{yx} *it$ for all iterators *it* in the range.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

Traits defines the type *Traits::Less_yx_2* as specified in the concept *ConvexHullTraits_2* and the corresponding member function that returns an instance of this type.

Function

Function

CGAL::ch_s_point

Definition

The function *ch_s_point* finds a points in a given set of input points with minimal y coordinates.

#include <CGAL/ch_selected_extreme_points_2.h>

template <class ForwardIterator>
void *ch_s_point(ForwardIterator first,*
ForwardIterator beyond,
ForwardIterator& s,
Traits ch_traits = Default_traits)

traverses the range [*first*,*beyond*). After execution, the value of s is an iterator in the range such that $*s \leq_{yx} *it$ for all iterators *it* in the range.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

Traits defines the type *Traits::Less_yx_2* as specified in the concept *ConvexHullTraits_2* and the corresponding member function that returns an instance of this type.

CGAL::ch_we_point

Definition

The function *ch_we_point* finds two points of a given set of input points with minimal and maximal x coordinates.

#include <CGAL/ch_selected_extreme_points_2.h>

```
template <class ForwardIterator>
void    ch_we_point( ForwardIterator first,
                     ForwardIterator beyond,
                     ForwardIterator& w,
                     ForwardIterator& e,
                     Traits ch_traits = Default_traits)
```

traverses the range [*first*,*beyond*). After execution, the value of w is an iterator in the range such that $*w \leq_{xy} *it$ for all iterators *it* in the range. Similarly, for e the inequality $*e \geq_{xy} *it$ holds for all iterators in the range.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

Traits defines the type *Traits::Less_xy_2* as specified in the concept *ConvexHullTraits_2* and the corresponding member function that returns an instance of this type.

CGAL::ch_w_point

Definition

The function *ch_w_point* finds a point in a given set of input points with minimal x coordinate.

#include <CGAL/ch_selected_extreme_points_2.h>

template <class ForwardIterator>
void *ch_w_point(ForwardIterator first, ForwardIterator beyond, ForwardIterator& w, Traits ch_traits = Default_traits)*

traverses the range [*first*,*beyond*). After execution, the value of w is an iterator in the range such that $*w \leq_{xy} *it$ for all iterators *it* in the range.

Requirements

Traits defines the type *Traits::Less_xy_2* as specified in the concept *ConvexHullTraits_2* and the corresponding member function that returns an instance of this type.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

CGAL::convex_hull_2

Function

Definition

The function *convex_hull_2* generates the counterclockwise sequence of extreme points from a given set of input points.

#include <CGAL/convex_hull_2.h>

template <class InputIterator, class OutputIterator>
OutputIterator convex_hull_2(InputIterator first,
InputIterator beyond,
OutputIterator result,
Traits ch_traits = Default_traits)

generates the counterclockwise sequence of extreme points of the points in the range [*first*,*beyond*). The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.
Precondition: The source range [*first*,*beyond*) does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *InputIterator::value_type* is defined.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* contains the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
   - *Traits::Point_2*,
   - *Traits::Less_signed_distance_to_line_2*,
   - *Traits::Equal_2*,
   - *Traits::Less_xy_2*,
   - *Traits::Less_yx_2*,
   - *Traits::Left_turn_2*.

CGAL::ch_jarvis . . . . page 1367
CGAL::ch_melkman . . . . page 1371

Implementation

One of two algorithms is used, depending on the type of iterator used to specify the input points. For input iterators, the algorithm used is that of Bykat [Byk78], which has a worst-case running time of $O(nh)$, where n is the number of input points and h is the number of extreme points. For all other types of iterators, the $O(n \log n)$ algorithm of of Akl and Toussaint [AT78] is used.

ConvexHullTraits_2

Definition

All convex hull and extreme point algorithms provided in CGAL are parameterized with a traits class *Traits*, which defines the primitives (objects and predicates) that the convex hull algorithms use. ConvexHullTraits_2 defines the complete set of primitives required in these functions. The specific subset of these primitives required by each function is specified with each function.

Types

ConvexHullTraits_2:: Point_2 — The point type on which the convex hull functions operate.

ConvexHullTraits_2:: Equal_2 — Binary predicate object type comparing *Point_2*s. Must provide *bool operator()(Point_2 p, Point_2 q)* where *true* is returned iff $p ==_{xy} q$, false otherwise.

ConvexHullTraits_2:: Less_xy_2 — Binary predicate object type comparing *Point_2*s lexicographically. Must provide *bool operator()(Point_2 p, Point_2 q)* where *true* is returned iff $p <_{xy} q$. We have $p <_{xy} q$, iff $p_x < q_x$ or $p_x = q_x$ and $p_y < q_y$, where p_x and p_y denote x and y coordinate of point p, respectively.

ConvexHullTraits_2:: Less_yx_2 — Same as *Less_xy_2* with the roles of x and y interchanged.

ConvexHullTraits_2:: Left_turn_2 — Predicate object type that must provide *bool operator()(Point_2 p,Point_2 q,Point_2 r)*, which returns *true* iff r lies to the left of the oriented line through p and q.

ConvexHullTraits_2:: Less_signed_distance_to_line_2

Predicate object type that must provide *bool operator()(Point_2 p, Point_2 q, Point_2 r,Point_2 s)*, which returns *true* iff the signed distance from r to the line l_{pq} through p and q is smaller than the distance from s to l_{pq}. It is used to compute the point right of a line with maximum unsigned distance to the line. The predicate must provide a total order compatible with convexity, *i.e.*, for any line segment s one of the endpoints of s is the smallest point among the points on s, with respect to the order given by *Less_signed_distance_to_line_2*.

ConvexHullTraits_2:: Less_rotate_ccw_2

Predicate object type that must provide *bool operator()(Point_2 e, Point_2 p,Point_2 q)*, where *true* is returned iff a tangent at e to the point set $\{e,p,q\}$ hits p before q when rotated counterclockwise around e. Ties are broken such that the point with larger distance to e is smaller!

Creation

Only a copy constructor is required.

ConvexHullTraits_2 traits(& t);

Operations

The following member functions to create instances of the above predicate object types must exist.

Equal_2	*traits.equal_2_object()*
Less_xy_2	*traits.less_xy_2_object()*
Less_yx_2	*traits.less_yx_2_object()*
Less_signed_distance_to_line_2	
	traits.less_signed_distance_to_line_2_object()
Less_rotate_ccw_2	*traits.less_rotate_ccw_2_object()*
Left_turn_2	*traits.left_turn_2_object()*

CGAL::Convex_hull_constructive_traits_2<R>

Class

Definition

The class *Convex_hull_constructive_traits_2<R>* serves as a traits class for all the two-dimensional convex hull and extreme point calculation function. Unlike the class *CGAL::Convex_hull_traits_2<R>*, this class makes use of previously computed results to avoid redundancy. For example, in the sidedness tests, lines (of type *R::Line_2*) are constructed, which is equivalent to the precomputation of subdeterminants of the orientation-determinant for three points.

#include <CGAL/convex_hull_constructive_traits_2.h>

CGAL::is_ccw_strongly_convex_2

Function

Definition

The function *is_ccw_strongly_convex_2* determines if a given sequence of points defines a counterclockwise-oriented, strongly convex polygon. A set of points is said to be strongly convex if it consists of only extreme points (*i.e.*, vertices of the convex hull).

#include <CGAL/convexity_check_2.h>

template <class ForwardIterator, class Traits>
bool *is_ccw_strongly_convex_2(ForwardIterator first, ForwardIterator beyond, Traits ch_traits = Default_traits)*

returns *true*, iff the point elements in [*first*,*beyond*) form a counterclockwise-oriented strongly convex polygon.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

Traits contains the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:

- *Traits::Less_xy_2*,
- *Traits::Equal_2*,
- *Traits::Left_turn_2*.

See Also

CGAL::is_cw_strongly_convex_2 . . . . page 1392
CGAL::is_strongly_convex_3 . . . . page 1423

Implementation

The algorithm requires $O(n)$ time for a set of n input points.

Function

CGAL::is_cw_strongly_convex_2

Definition

The function *is_cw_strongly_convex_2* determines if a given sequence of points defines a clockwise-oriented, strongly convex polygon. A set of points is said to be strongly convex if it consists of only extreme points (*i.e.*, vertices of the convex hull).

#include <CGAL/convexity_check_2.h>

template <class ForwardIterator, class Traits>
bool *is_cw_strongly_convex_2(ForwardIterator first, ForwardIterator beyond, Traits ch_traits = Default_traits)*

returns *true*, iff the point elements in [*first*,*beyond*) form a clockwise-oriented strongly convex polygon.

The default traits class *Default_traits* is the kernel in which the type *ForwardIterator::value_type* is defined.

Requirements

Traits contains the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:

- *Traits::Equal_2*,
- *Traits::Less_xy_2*,
- *Traits::Left_turn_2*.

See Also

CGAL::is_ccw_strongly_convex_2 . . . . page 1391
CGAL::is_strongly_convex_3 . . . . page 1423

Implementation

The algorithm requires $O(n)$ time for a set of n input points.

CGAL::lower_hull_points_2

Definition

The function *lower_hull_points_2* generates the counterclockwise sequence of extreme points on the lower hull of a given set of input points.

#include <CGAL/convex_hull_2.h>

template <class InputIterator, class OutputIterator>
OutputIterator lower_hull_points_2(InputIterator first, InputIterator beyond, OutputIterator result, Traits ch_traits = Default_traits)

generates the counterclockwise sequence of extreme points on the lower hull of the points in the range [*first*, *beyond*). The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. The sequence starts with the leftmost point; the rightmost point is not included. If there is only one extreme point (*i.e.*, leftmost and rightmost point are equal) the extreme point is reported.
Precondition: The source range [*first*,*beyond*) does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *InputIterator::value_type* is defined.

The different treatment by *CGAL::upper_hull_points_2* of the case that all points are equal ensures that concatenation of lower and upper hull points gives the sequence of extreme points.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* contains the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
   - *Traits::Point_2*,
   - *Traits::Equal_2*,
   - *Traits::Less_xy_2*,
   - *Traits::Less_yx_2*,
   - *Traits::Left_turn_2*.

CGAL::upper_hull_points_2 . . . . page 1395

Implementation

This function uses Andrew's variant of Graham's scan algorithm [And79, Meh84]. The algorithm has worst-case running time of $O(n \log n)$ for n input points.

CGAL::upper_hull_points_2

Function

Definition

The function *upper_hull_points_2* generates the counterclockwise sequence of extreme points on the upper hull of a given set of input points.

#include <CGAL/convex_hull_2.h>

```
template <class InputIterator, class OutputIterator>
OutputIterator     upper_hull_points_2( InputIterator first,
                                        InputIterator beyond,
                                        OutputIterator result,
                                        Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points on the upper hull of the points in the range [*first*, *beyond*). The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. The sequence starts with the rightmost point, the leftmost point is not included. If there is only one extreme point (*i.e.*, the leftmost and rightmost point are equal), the extreme point is not reported.
Precondition: The source range [*first*,*beyond*) does not contain *result*.

The default traits class *Default_traits* is the kernel in which the type *InputIterator::value_type* is defined.

The different treatment by *CGAL::lower_hull_points_2* of the case that all points are equal ensures that concatenation of lower and upper hull points gives the sequence of extreme points.

Requirements

1. *InputIterator::value_type* and *OutputIterator::value_type* are equivalent to *Traits::Point_2*.
2. *Traits* contains the following subset of types from the concept *ConvexHullTraits_2* and their corresponding member functions that return instances of these types:
   - *Traits::Point_2*,
   - *Traits::Equal_2*,
   - *Traits::Less_xy_2*,
   - *Traits::Less_yx_2*,
   - *Traits::Left_turn_2*.

Chapter 16

3D Convex Hulls

Susan Hert and Stefan Schirra

Contents

16.1 Introduction

A subset $S \subseteq \mathbb{R}^3$ is convex if for any two points p and q in the set the line segment with endpoints p and q is contained in S. The convex hull of a set S is the smallest convex set containing S. The convex hull of a set of points $P \in \mathbb{R}^3$ is a convex polytope with vertices in P. A point in P is an extreme point (with respect to P) if it is a vertex of the convex hull of P. A set of points is said to be strongly convex if it consists of only extreme points.

This chapter describes the functions provided in CGAL for producing convex hulls in three dimensions as well as functions for checking if sets of points are strongly convex are not. One can compute the convex hull of a set of points in three dimensions in one of three ways in CGAL: using a static algorithm, using an incremental construction algorithm, or using a triangulation to get a fully dynamic computation.

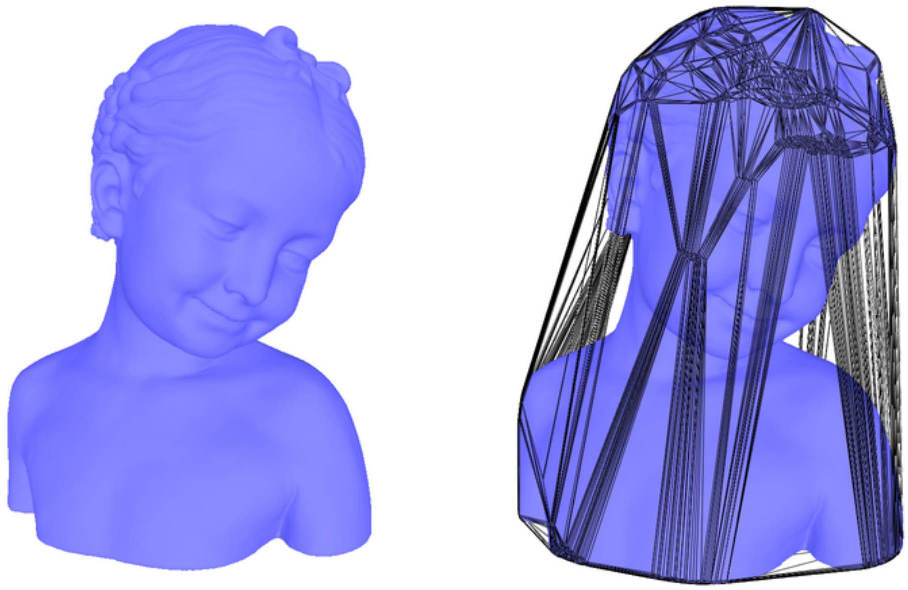

Figure 16.1: The convex hull of a model made of 192135 points.

16.2 Static Convex Hull Construction

The function *convex_hull_3* provides an implementation of the quickhull algorithm [BDH96] for three dimensions. There are two versions of this function available, one that can be used when it is known that the output will be a polyhedron (*i.e.*, there are more than three points and they are not all collinear) and one that handles all degenerate cases and returns a *CGAL::Object*, which may be a point, a segment, a triangle, or a polyhedron. Both versions accept a range of input iterators defining the set of points whose convex hull is to be computed and a traits class defining the geometric types and predicates used in computing the hull.

16.2.1 Traits Class

The function *convex_hull_3* is parameterized by a traits class, which specifies the types and geometric primitives to be used in the computation. If input points from a kernel with exact predicates and non-exact constructions are used, and a certified result is expected, the traits *Convex_hull_traits_3<R>* should be used (*R* being the input kernel). Note that the default traits class takes this into account.

16.2.2 Convexity Checking

The function *is_strongly_convex_3* implements the algorithm of Mehlhorn *et al.* [MNS+96] to determine if the vertices of a given polytope constitute a strongly convex point set or not. This function is used in postcondition testing for *convex_hull_3*.

16.2.3 Example

The following program computes the convex hull of a set of 250 random points chosen from a sphere of radius 100. We assume that the points are not all identical and not all collinear, thus we directly use a polyhedron as output. Note the usage of the functor *Plane_from_facet* together with *std::transform* to compute the equations of the plane of each facet of the convex hull.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/algorithm.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/convex_hull_3.h>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel  K;
typedef CGAL::Polyhedron_3<K>                                Polyhedron_3;
typedef K::Segment_3                                         Segment_3;

// define point creator
typedef K::Point_3                                           Point_3;
typedef CGAL::Creator_uniform_3<double, Point_3>  PointCreator;

//a functor computing the plane containing a triangular facet
struct Plane_from_facet {
  Polyhedron_3::Plane_3 operator()(Polyhedron_3::Facet& f) {
      Polyhedron_3::Halfedge_handle h = f.halfedge();
      return Polyhedron_3::Plane_3( h->vertex()->point(),
                                    h->next()->vertex()->point(),
                                    h->opposite()->vertex()->point());
  }
};

int main()
{
  CGAL::Random_points_in_sphere_3<Point_3, PointCreator> gen(100.0);

  // generate 250 points randomly on a sphere of radius 100.0
  // and copy them to a vector
  std::vector<Point_3> points;
  CGAL::cpp0x::copy_n( gen, 250, std::back_inserter(points) );

  // define polyhedron to hold convex hull

16.3 Incremental Convex Hull Construction

The function *convex_hull_incremental_3* provides an interface similar to *convex_hull_3* for the d-dimensional incremental construction algorithm [CMS93] implemented by the class *CGAL::Convex_hull_d<R>* that is specialized to three dimensions. This function accepts an iterator range over a set of input points and returns a polyhedron, but it does not have a traits class in its interface. It uses the kernel class *Kernel* used in the polyhedron type to define an instance of the adapter traits class *CGAL::Convex_hull_d_traits_3<Kernel>*.

In almost all cases, the static and the dynamic version will be faster than the incremental convex hull algorithm (mainly because of the lack of efficient filtering and the overhead of the general d-dimension). The incremental version is provided for completeness and educational purposes. You should use the dynamic version when you need an efficient incremental convex hull algorithm.

To use the full functionality available with the d-dimensional class *CGAL::Convex_hull_d<R>* in three dimensions (*e.g.*, the ability to insert new points and to query if a point lies in the convex hull or not), you can instantiate the class *CGAL::Convex_hull_d<K>* with the adapter traits class *CGAL::Convex_hull_d_traits_3<K>*, as shown in the following example.

16.3.1 Example

```
#include <CGAL/Cartesian.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Convex_hull_d.h>
#include <CGAL/Convex_hull_d_traits_3.h>
#include <CGAL/Convex_hull_d_to_polyhedron_3.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/algorithm.h>
#include <vector>
#include <cassert>

#ifdef CGAL_USE_GMP
#include <CGAL/Gmpq.h>
typedef CGAL::Gmpq RT;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::Quotient<CGAL::MP_Float> RT;
#endif
```

```
typedef CGAL::Cartesian<RT>                             K;
typedef K::Point_3                                      Point_3;
typedef CGAL::Polyhedron_3< K>                          Polyhedron_3;

typedef CGAL::Convex_hull_d_traits_3<K>                 Hull_traits_3;
typedef CGAL::Convex_hull_d< Hull_traits_3 >            Convex_hull_3;
typedef CGAL::Creator_uniform_3<double, Point_3>        Creator;

int main ()
{
  Convex_hull_3 CH(3);   // create instance of the class with dimension ==
     3

  // generate 250 points randomly on a sphere of radius 100
  // and insert them into the convex hull
  CGAL::Random_points_in_sphere_3<Point_3, Creator> gen(100);

  for (int i = 0; i < 250 ; i++, ++gen)
     CH.insert(*gen);

  assert(CH.is_valid());

  // define polyhedron to hold convex hull and create it
  Polyhedron_3 P;
  CGAL::convex_hull_d_to_polyhedron_3(CH,P);

  std::cout << "The convex hull has " << P.size_of_vertices()
            << " vertices" << std::endl;
  return 0;
}
```

File: examples/Convex_hull_3/incremental_hull_class_3.cpp

16.4 Dynamic Convex Hull Construction

Fully dynamic maintenance of a convex hull can be achieved by using the class *CGAL::Delaunay_triangulation_3*. This class supports insertion and removal of points (*i.e.*, vertices of the triangulation) and the convex hull edges are simply the finite edges of infinite faces. The following example illustrates the dynamic construction of a convex hull. First, random points from a sphere of a certain radius are generated and are inserted into a triangulation. Then the number of points of the convex hull are obtained by counting the number of triangulation vertices incident to the infinite vertex. Some of the points are removed and then the number of points remaining on the hull are determined. Notice that the vertices incident to the infinite vertex of the triangulation are on the convex hull but it may be that not all of them are vertices of the hull.

16.4.1 Example

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Delaunay_triangulation_3.h>
```

```
#include <CGAL/Polyhedron_3.h>
#include <CGAL/convex_hull_3_to_polyhedron_3.h>
#include <CGAL/algorithm.h>

#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel      K;
typedef K::Point_3                                              Point_3;
typedef CGAL::Delaunay_triangulation_3<K>                       Delaunay;
typedef Delaunay::Vertex_handle
    Vertex_handle;
typedef CGAL::Polyhedron_3<K>
    Polyhedron_3;

int main()
{
  CGAL::Random_points_in_sphere_3<Point_3> gen(100.0);
  std::list<Point_3>   points;

  // generate 250 points randomly on a sphere of radius 100.0
  // and insert them into the triangulation
  CGAL::cpp0x::copy_n(gen, 250, std::back_inserter(points) );
  Delaunay T;
  T.insert(points.begin(), points.end());

  std::list<Vertex_handle>  vertices;
  T.incident_vertices(T.infinite_vertex(), std::back_inserter(vertices));
  std::cout << "This convex hull of the 250 points has "
            << vertices.size() << " points on it." << std::endl;

  // remove 25 of the input points
  std::list<Vertex_handle>::iterator v_set_it = vertices.begin();
  for (int i = 0; i < 25; i++)
  {
     T.remove(*v_set_it);
     v_set_it++;
  }

  //copy the convex hull of points into a polyhedron and use it
  //to get the number of points on the convex hull
  Polyhedron_3 chull;
  CGAL::convex_hull_3_to_polyhedron_3(T,chull);

  std::cout << "After removal of 25 points, there are "
            << chull.size_of_vertices() << " points on the convex hull."
   << std::endl;

  return 0;
}
```

File: examples/Convex_hull_3/dynamic_hull_3.cpp

16.5 Performance

In the following, we compare the running times of the three approaches to compute 3D convex hulls. For the static version (using *CGAL::convex_hull_3*) and the dynamic version (using *CGAL::Delaunay_triangulation_3* and *CGAL::convex_hull_3_to_polyhedron_3*), the kernel used was *CGAL::Exact_predicates_inexact_constructions_kernel*. For the incremental version (using *CGAL::convex_hull_incremental_3*), the kernel used was *CGAL::Exact_predicates_exact_constructions_kernel*.

To compute the convex hull of a million of random points in a unit ball the static approach needed 1.63s, while the dynamic and incremental approaches needed 9.50s and 11.54s respectively. To compute the convex hull of the model of Figure 16.1 featuring 192135 points, the static approach needed 0.18s, while the dynamic and incremental approaches needed 1.90s and 6.80s respectively.

The measurements have been performed using CGAL 3.9, using the GNU C++ compiler version 4.3.5, under Linux (Debian distribution), with the compilation options `-O3 -DCGAL_NDEBUG`. The computer used was equipped with a 64bit Intel Xeon 2.27GHz processor and 12GB of RAM.

3D Convex Hulls
Reference Manual

Susan Hert and Stefan Schirra

A subset $S \subseteq \mathbb{R}^3$ is convex if for any two points p and q in the set the line segment with endpoints p and q is contained in S. The convex hull of a set S is the smallest convex set containing S. The convex hull of a set of points P is a convex polytope with vertices in P. A point in P is an extreme point (with respect to P) if it is a vertex of the convex hull of P.

CGAL provides functions for computing convex hulls in two, three and arbitrary dimensions as well as functions for testing if a given set of points in is strongly convex or not. This chapter describes the functions available for three dimensions.

Assertions

The assertion flags for the convex hull and extreme point algorithms use *CH* in their names (*e.g.*, *CGAL_CH_NO_POSTCONDITIONS*). For the convex hull algorithms, the postcondition check tests only convexity (if not disabled), but not containment of the input points in the polygon or polyhedron defined by the output points. The latter is considered an expensive checking and can be enabled by defining *CGAL_CH_CHECK_EXPENSIVE*.

CGAL::convex_hull_3

Definition

The function *convex_hull_3* computes the convex hull of a given set of three-dimensional points Two versions of this function are available. The first can be used when it is known that the result will be a polyhedron and the second when a degenerate hull may also be possible.

#include <CGAL/convex_hull_3.h>

template <class InputIterator, class Polyhedron_3, class Traits>
void convex_hull_3(InputIterator first, InputIterator last, Polyhedron_3& P, Traits ch_traits = Default_traits)

computes the convex hull of the set of points in the range [*first*, *last*). The polyhedron *P* is cleared, then the convex hull is stored in *P* and the plane equations of each face are not computed.
Precondition: : There are at least four points in the range [*first*, *last*) not all of which are collinear.

template <class InputIterator, class Traits>
void convex_hull_3(InputIterator first, InputIterator last, Object& ch_object, Traits ch_traits = Default_traits)

computes the convex hull of the set of points in the range [*first*, *last*). The result, which may be a point, a segment, a triangle, or a polyhedron, is stored in *ch_object*. When the result is a polyhedron, the plane equations of each face are not computed.

Requirements

Both functions require the following:

1. *InputIterator::value_type* is equivalent to *Traits::Point_3*.
2. *Traits* is a model of the concept *ConvexHullTraits_3* . For the purposes of checking the postcondition that the convex hull is valid, *Traits* should also be a model of the concept *IsStronglyConvexTraits_3*.

Both functions have an additional requirement for the polyhedron that is to be constructed. For the first version this is that:

- *Polyhedron_3* is a model of *ConvexHullPolyhedron_3*, and for the second, it is required that

- *Traits* defines a type *Polyhedron_3* that is a model of *ConvexHullPolyhedron_3*.

For both versions, if the kernel *R* of the points determined by *InputIterator::value_type* is a kernel with exact predicates but inexact constructions (in practice we check *R::Has_filtered_predicates_tag* is *Tag_true* and *R::FT* is a floating point type), then the default traits class of *convex_hull_3* is *Convex_hull_traits_3*<*R*>, and *R* otherwise.

Implementation

The algorithm implemented by these functions is the quickhull algorithm of Barnard *et al.* [BDH96].

Example

The following program computes the convex hull of a set of 250 random points chosen from a sphere of radius 100. It then determines if the resulting hull is a segment or a polyhedron. Notice that the traits class is not necessary in the call to *convex_hull_3* but is used in the definition of *Polyhedron_3*.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/algorithm.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/convex_hull_3.h>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel  K;
typedef CGAL::Polyhedron_3<K>                               Polyhedron_3;
typedef K::Segment_3                                        Segment_3;

// define point creator
typedef K::Point_3                                          Point_3;
typedef CGAL::Creator_uniform_3<double, Point_3>  PointCreator;

//a functor computing the plane containing a triangular facet
struct Plane_from_facet {
  Polyhedron_3::Plane_3 operator()(Polyhedron_3::Facet& f) {
      Polyhedron_3::Halfedge_handle h = f.halfedge();
      return Polyhedron_3::Plane_3( h->vertex()->point(),
                                    h->next()->vertex()->point(),
                                    h->opposite()->vertex()->point());
  }
};
```

```
int main()
{
  CGAL::Random_points_in_sphere_3<Point_3, PointCreator> gen(100.0);

  // generate 250 points randomly on a sphere of radius 100.0
  // and copy them to a vector
  std::vector<Point_3> points;
  CGAL::cpp0x::copy_n( gen, 250, std::back_inserter(points) );

  // define polyhedron to hold convex hull
  Polyhedron_3 poly;

  // compute convex hull of non-collinear points
  CGAL::convex_hull_3(points.begin(), points.end(), poly);

  std::cout << "The convex hull contains " << poly.size_of_vertices() <<
   " vertices" << std::endl;

  // assign a plane equation to each polyhedron facet using functor
   Plane_from_facet
  std::transform( poly.facets_begin(), poly.facets_end(),
   poly.planes_begin(),Plane_from_facet());

  return 0;
}
```

File: examples/Convex_hull_3/quickhull_3.cpp

CGAL::convex_hull_incremental_3

Function

Definition

The function *convex_hull_incremental_3* computes the convex hull polyhedron from a set of given three-dimensional points.

This function is provided for completeness and educational purposes. When an efficient incremental implementation is needed, using *CGAL::Delaunay_triangulation_3* together with *CGAL::convex_hull_3_to_polyhedron_3* is highly recommended.

#include <CGAL/convex_hull_incremental_3.h>

```
template <class InputIterator, class Polyhedron>
void convex_hull_incremental_3( InputIterator first,
                                InputIterator beyond,
                                Polyhedron& P,
                                bool test_correctness = false)
```

computes the convex hull polyhedron of the points in the range [*first*,*beyond*) and assigns it to *P*. If *test_correctness* is set to *true*, the tests described in [MNS+96] are used to determine the correctness of the resulting polyhedron.

Requirements

1. *Polyhedron* must provide a type *Polyhedron::Traits* that defines the following types
   - *Polyhedron::Traits::R*, which is a model of the representation class *R* required by *CGAL::Convex_hull_d_traits_3<R>*
   - *Polyhedron::Traits::Point*
2. *InputIterator::value_type* must be the same as *Polyhedron::Traits::Point*

Example

The following example computes the convex hull of a set of 250 random points chosen uniformly in a sphere of radius 100.

```
#include <CGAL/Homogeneous.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/algorithm.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/convex_hull_incremental_3.h>
#include <vector>

#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz RT;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float RT;
#endif

typedef CGAL::Homogeneous<RT>                     K;
typedef K::Point_3                                Point_3;
typedef CGAL::Polyhedron_3< K>                    Polyhedron;
typedef CGAL::Creator_uniform_3<int, Point_3>    Creator;

int main()
{
  CGAL::Random_points_in_sphere_3<Point_3, Creator> gen(100.0);

  std::vector<Point_3> V;
  // generate 250 points randomly on a sphere of radius 100.0 and copy
  // them to a vector
  CGAL::cpp0x::copy_n( gen, 250, std::back_inserter(V) );

  Polyhedron P; // define polyhedron to hold convex hull

  // compute convex hull
  CGAL::convex_hull_incremental_3( V.begin(), V.end(), P, true);

  return 0;
}
```

ConvexHullPolyhedronFacet_3

Definition

The requirements of the facet type of a polyhedron to be built by the function *convex_hull_3*.

Has Models

CGAL::Polyhedron_3<Traits>::Facet . . . . page 1807

Types

ConvexHullPolyhedronFacet_3:: Plane	plane equation type stored in facets.
ConvexHullPolyhedronFacet_3:: Halfedge_handle	handle to halfedge.
ConvexHullPolyhedronFacet_3:: Halfedge_around_facet_circulator	circulator of halfedges around a facet.

Creation

ConvexHullPolyhedronFacet_3 f;	default constructor.

Operations

Plane&	*f.plane()*	
const Plane&	*f.plane() const*	plane equation.
Halfedge_handle	*f.halfedge()*	an incident halfedge that points to *f*.
Halfedge_around_facet_circulator	*f.facet_begin()*	circulator of halfedges around the facet (counterclockwise).

ConvexHullPolyhedronHalfedge_3 . . . . page 1414

ConvexHullPolyhedronHalfedge_3

Definition

The requirements of the halfedge type required for the polyhedron built by the function *convex_hull_3*.

Has Models

CGAL::Polyhedron_3<Traits>::Halfedge . . . . page 1809

Creation

ConvexHullPolyhedronHalfedge_3 h;	default constructor.

Operations

Halfedge_handle	*h.opposite()*	the opposite halfedge.
Halfedge_handle	*h.next()*	the next halfedge around the facet.
Halfedge_handle	*h.prev()*	the previous halfedge around the facet.
bool	*h.is_border() const*	is true if *h* is a border halfedge.
Halfedge_around_facet_circulator		
	h.facet_begin()	circulator of halfedges around the facet (counterclockwise).
Vertex_handle	*h.vertex()*	the incident vertex of *h*.
Facet_handle	*h.facet()*	the incident facet of *h*. If *h* is a border halfedge the result is default construction of the handle.

ConvexHullPolyhedronVertex_3

Definition

The requirements of the vertex type of the polyhedron to be built by the function *convex_hull_3*.

Has Models

CGAL::Polyhedron_3<Traits>::Vertex . . . . page 1812.

Creation

ConvexHullPolyhedronVertex_3 v;	default constructor.

Operations

Point&	*v.point()*	
const Point&	*v.point() const*	the point.

Concept

ConvexHullPolyhedron_3

Definition

The requirements of the polyhedron type to be built by the function *convex_hull_3*.

Has Models

CGAL::Polyhedron_3<Traits> . . . . page 1795

Types

ConvexHullPolyhedron_3:: Point_3	type of point stored in a vertex
ConvexHullPolyhedron_3:: Vertex	a model of *ConvexHullPolyhedronVertex_3*
ConvexHullPolyhedron_3:: Halfedge	a model of *ConvexHullPolyhedronHalfedge_3*
ConvexHullPolyhedron_3:: Facet	a model of *ConvexHullPolyhedronFacet_3*
ConvexHullPolyhedron_3:: Halfedge_data_structure	halfedge data structure
ConvexHullPolyhedron_3:: Halfedge_handle	handle to halfedge
ConvexHullPolyhedron_3:: Halfedge_iterator	iterator for halfedge
ConvexHullPolyhedron_3:: Facet_handle	handle to facet
ConvexHullPolyhedron_3:: Facet_iterator	iterator for facet

Creation

Only a default constructor is required.

ConvexHullPolyhedron_3 p;

Operations

Facet_iterator	*p.facets_begin()*	iterator over all facets (excluding holes).
Facet_iterator	*p.facets_end()*	past-the-end iterator.
Halfedge_iterator	*p.P.halfedges_begin()*	iterator over all halfedges.
Halfedge_iterator	*p.P.halfedges_end()*	past-the-end iterator.
Halfedge_handle	*p.make_tetrahedron(Point_3 p1, Point_3 p2, Point_3 p3, Point_3 p4)*	adds a new tetrahedron to the polyhedral surface with its vertices initialized with *p1*, *p2*, *p3* and *p4*. Returns that halfedge of the tetrahedron which incident vertex is initialized with *p1*, the incident vertex of the next halfedge with *p2*, and the vertex thereafter with *p3*. The remaining fourth vertex is initialized with *p4*.

void *p.erase_facet(Halfedge_handle h)*

removes the incident facet of *h* and changes all halfedges incident to the facet into border edges or removes them from the polyhedral surface if they were already border edges.

Halfedge_handle *p.add_vertex_and_facet_to_border(Halfedge_handle h, Halfedge_handle g)*

creates a new facet within the hole incident to *h* and *g* by connecting the tip of *g* with the tip of *h* with two new halfedges and a new vertex and filling this separated part of the hole with a new facet, such that the new facet is incident to *g*. Returns the halfedge of the new edge that is incident to the new facet and the new vertex.

Halfedge_handle *p.add_facet_to_border(Halfedge_handle h, Halfedge_handle g)*

creates a new facet within the hole incident to *h* and *g* by connecting the tip of *g* with the tip of *h* with a new halfedge and filling this separated part of the hole with a new facet, such that the new facet is incident to *g*. Returns the halfedge of the new edge that is incident to the new facet.

Halfedge_handle *p.fill_hole(Halfedge_handle h)*

fills a hole with a newly created facet. Makes all border halfedges of the hole denoted by h incident to the new facet. Returns *h*.

void *p.delegate(Modifier_base<Halfedge_data_structure>& m)*

calls the *operator()* of the modifier *m*. See *Modifier_base* for a description of modifier design and its usage.

Concept

ConvexHullTraits_3

Definition

Requirements of the traits class to be used with the function *convex_hull_3*.

Types

ConvexHullTraits_3:: Point_3	The point type on which the convex hull algorithm operates
ConvexHullTraits_3:: Plane_3	a 3D plane
ConvexHullTraits_3:: Segment_3	a 3D segment
ConvexHullTraits_3:: Triangle_3	a 3D triangle
ConvexHullTraits_3:: Vector_3	a 3D vector
ConvexHullTraits_3:: Construct_plane_3	Function object type that provides *Plane_3 operator()(Point_3 p, Point_3 q, Point_3 r)*, which constructs and returns a plane passing through *p*, *q*, and *r* and oriented in a positive sense when seen from the positive side of the plane.
ConvexHullTraits_3:: Construct_segment_3	Function object type that provides *Segment_3 operator()(Point_3 p, Point_3 q)*, which constructs and returns the segment with source *p* and target *q*.
ConvexHullTraits_3:: Construct_triangle_3	Function object type that provides *Triangle_3 operator()(Point_3 p, Point_3 q, Point_3 r)*, which constructs and returns the triangle with vertices *p*, *q*, and *r*
ConvexHullTraits_3:: Construct_vector_3	Function object type that provides *Vector_3 operator()(Point_3 p, Point_3 q)*, which constructs and returns the vector *q*-*p*
ConvexHullTraits_3:: Equal_3	Predicate object type that provides *bool operator()(Point_3 p, Point_3 q)*, which determines if points *p* and *q* are equal or not
ConvexHullTraits_3:: Collinear_3	Predicate object type that provides *bool operator()(Point_3 p, Point_3 q, Point_3 r)*, which determines if points *p*, *q* and *r* are collinear or not
ConvexHullTraits_3:: Coplanar_3	Predicate object type that provides *bool operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s)*, which determines if points *p*, *q*, *r*, and *s* are coplanar or not
ConvexHullTraits_3:: Has_on_positive_side_3	Predicate object type that provides *bool operator()(Plane_3 h, Point_3 q)*, which determines of the point *q* is on the positive side of the halfspace *h*

ConvexHullTraits_3:: Less_distance_to_point_3	Predicate object type that provides a constructor taking a single *Point_3* object and *bool operator()(Point_3 q, Point_3 r)*, which returns true iff the distance from *q* to *p* is smaller than the distance from *r* to *p*, where *p* is the point passed to the object at construction.
ConvexHullTraits_3:: Less_signed_distance_to_plane_3	Predicate object type that provides *bool operator()(Plane_3 p, Point_3 q, Point_3 r)*, which returns true iff the signed distance from *q* to *p* is smaller than the signed distance from *r* to *p*

Creation

Only a copy constructor is required.

ConvexHullTraits_3 traits(& ch);

Operations

For each of the above function and predicate object types, *Func_obj_type*, a function must exist with the name *func_obj_type_object* that creates an instance of the function or predicate object type. For example:

Construct_plane_3 *traits.construct_plane_3_object()*

Class

CGAL::Convex_hull_traits_3<R>

Definition

The class *Convex_hull_traits_3<R>* serves as a traits class for the function *convex_hull_3*. This is the default traits class for this function when *R* is a kernel with exact predicates but inexact constructions (note below that the type *Plane_3* is a triple of *Point_3* and not *R::Plane_3*).

#include <CGAL/Convex_hull_traits_3.h>

Is Model for the Concepts

Function

CGAL::convex_hull_3_to_polyhedron_3

Definition

The function *convex_hull_3_to_polyhedron_3* fills a polyhedron with the convex hull of a set of 3D points contained into a 3D triangulation of CGAL.

#include <CGAL/convex_hull_3_to_polyhedron_3.h>

template <class Triangulation_3, class Polyhedron_3>
void *convex_hull_3_to_polyhedron_3(Triangulation_3 T, Polyhedron_3& P)*

The polyhedron *P* is cleared and the convex hull of the set of 3D points is stored in *P*. The plane equations of each face are not computed.
Precondition: *T.dimension()*==3.

Requirements

This function requires the following:

1. *Triangulation_3* is a CGAL 3D triangulation.
2. *Polyhedron_3* is an instantiation of *CGAL::Polyhedron_3<Traits>*.

See Also

CGAL::convex_hull_3 . . . . page 1408

CGAL::is_strongly_convex_3

Function

Definition

The function *is_strongly_convex_3* determines if the vertices of a given polyhedron represents a strongly convex set of points or not. A set of points is said to be strongly convex if it consists of only extreme points (*i.e.*, vertices of the convex hull).

#include <CGAL/convexity_check_3.h>

template<class Polyhedron_3, class Traits>
bool *is_strongly_convex_3(Polyhedron_3& P, Traits traits = Default_traits)*

determines if the set of vertices of the polyhedron *P* represent a strongly convex set of points or not.
Precondition: The equations of the facet planes of the polyhedron must have already been computed.

The default traits class is the kernel in which the type *Polyhedron_3::Point_3* is defined.

Requirements

1. *Polyhedron_3::Point_3* is equivalent to *Traits::Point_3*.
2. *Traits* is a model of the concept *IsStronlyConvexTraits_3*
3. *Polyhedron_3* must define the following types:
   - *Polyhedron_3::Facet_iterator*
   - *Polyhedron_3::Vertex_iterator*

   and the following member functions:

   - *facets_begin()*
   - *facets_end()*
   - *vertices_begin()*
   - *vertices_end()*

   The vertex type of *Polyhedron_3* must be a model of *ConvexHullPolyhedronVertex_3*; the facet type must be *ConvexHullPolyhedronFacet_3*.

CGAL::is_cw_strongly_convex_2 . . . . page 1392

Implementation

This function implements the tests described in [MNS+96] to determine convexity and requires $O(e+f)$ time for a polyhedron with e edges and f faces.

Concept

IsStronglyConvexTraits_3

Definition

Requirements of the traits class used by the function *is_strongly_convex_3*, which is used for postcondition checking by *convex_hull_3*.

Types

IsStronglyConvexTraits_3:: Plane_3	a 3D plane
IsStronglyConvexTraits_3:: Point_3	a 3D point
IsStronglyConvexTraits_3:: Ray_3	a 3D ray
IsStronglyConvexTraits_3:: Triangle_3	a 3D triangle
IsStronglyConvexTraits_3:: Construct_ray_3	Function object type that provides *Ray_3 operator()(Point_3 p, Point_3 q)*, which constructs and returns the ray based at point *p* and passing though *q*
IsStronglyConvexTraits_3:: Construct_triangle_3	Function object type that provides *Triangle_3 operator()(Point_3 p, Point_3 q, Point_3 r)*, which constructs and returns the triangle with vertices *p*, *q*, and *r*
IsStronglyConvexTraits_3:: Coplanar_3	Predicate object type that provides *bool operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s)*, which determines if points *p*, *q*, *r*, and *s* are coplanar or not
IsStronglyConvexTraits_3:: Do_intersect_3	Function object type that provides *CGAL::Object operator()(Triangle_3 t, Ray_3 r)*, which returns *true* iff *t* and *r* intersect.
IsStronglyConvexTraits_3:: Has_on_positive_side_3	Predicate object type that provides *bool operator()(Plane_3 h, Point_3 q)*, which determines of the point *q* is on the positive side of the halfspace *h*
IsStronglyConvexTraits_3:: Oriented_side_3	Predicate object type that provides *Oriented_side operator()(Plane_3 p, Point_3 q)*, which determines the position of point *q* relative to plane *p*

Creation

Only a copy constructor is required.

IsStronglyConvexTraits_3 traits(& t);

Operations

For each of the above function and predicate object types, *Func_obj_type*, a function must exist with the name *func_obj_type_object* that creates an instance of the function or predicate object type. For example:

Construct_ray_3 *traits.construct_ray_3_object()*

Chapter 17

dD Convex Hulls and Delaunay Triangulations

Susan Hert and Michael Seel

Contents

17.1 Introduction

A subset $S \subseteq \mathbb{R}^d$ is convex if for any two points p and q in the set the line segment with endpoints p and q is contained in S. The convex hull of a set S is the smallest convex set containing S. The convex hull of a set of points P is a convex polytope with vertices in P. A point in P is an extreme point (with respect to P) if it is a vertex of the convex hull of P. A set of points is said to be strongly convex if it consist of only extreme points.

This chapter describes the class provided in CGAL for producing convex hull in arbitrary dimensions. There is an intimate relationship between the Delaunay triangulation of a point set S and the convex hull of *lift(S)*: The nearest site Delaunay triangulation is the projection of the lower hull and the furthest site Delaunay triangulation is the upper hull. Here we also describe the companion class to the convex hull class that computes nearest and furthest site Delaunay triangulations.

17.2 dD Convex Hull

The class *CGAL::Convex_hull_d<R>* is used to represent the convex hull of a set of points in d-dimensional space. This class supports incremental construction of hulls, and provides a rich interface for exploration. There are also output routines for hulls of dimension 2 and 3.

The convex hull class is parameterized by a traits class that provides d-dimensional data types and predicates. The class *Convex_hull_d_traits_3* adapts any low-dimensional standard kernel model *e.g.*, *Homogeneous<RT>* or *Cartesian<FT>* for use with *Convex_hull_d*, where the dimension is fixed to three. The validity of the computed convex hull can be checked using the member function *is_valid*, which implements the algorithm of Mehlhorn *et al.*[MNS+96] to determine if the vertices of a given polytope constitute a strongly convex point set or not.

The implementation follows the papers [CMS93] and [BMS94].

17.3 Delaunay Triangulation

There is a class type with a thorough interface providing the construction and exploration of closest and furthest site Delaunay simplicial complexes in arbitrary higher dimension. The class *CGAL::Delaunay_d<R, Lifted_R>* provides an implementation via the lifting map to higher dimensional convex hulls.. The class supports incremental construction of Delaunay triangulations and various kind of query operations (in particular, nearest and furthest neighbor queries and range queries with spheres and simplices).

dD Convex Hulls and Delaunay Triangulations Reference Manual

Susan Hert and Michael Seel

A subset $S \subseteq \mathbb{R}^3$ is convex if for any two points p and q in the set the line segment with endpoints p and q is contained in S. The convex hull of a set S is the smallest convex set containing S. The convex hull of a set of points P is a convex polytope with vertices in P. A point in P is an extreme point (with respect to P) if it is a vertex of the convex hull of P.

CGAL provides functions for computing convex hulls in two, three and arbitrary dimensions as well as functions for testing if a given set of points in is strongly convex or not. This chapter describes the class available for arbitrary dimensions and its companion class for computing the nearest and furthest side Delaunay triangulation.

ConvexHullTraits_d

Definition

Requirements of the traits class to be used with the class *Convex_hull_d*.

Types

ConvexHullTraits_d:: Point_d	the dD point type on which the convex hull algorithm operates
ConvexHullTraits_d:: Hyperplane_d	a dD plane
ConvexHullTraits_d:: Vector_d	a dD vector
ConvexHullTraits_d:: Ray_d	a dD ray
ConvexHullTraits_d:: RT	an arithmetic ring type
ConvexHullTraits_d:: Construct_vector_d	Function object type that provides *Vector_d operator()(int d, CGAL::Null_vector)*, which constructs and returns the null vector.
ConvexHullTraits_d:: Construct_hyperplane_d	Function object type that provides *Hyperplane_d operator()(ForwardIterator first, ForwardIterator last, Point_d p, CGAL::Oriented_side side)*, which constructs and returns a hyperplane passing through the points in *tuple[first,last)* and oriented such that *p* is on the side *side* of the returned hyperplane. When *side==ON_ORIENTED_BOUNDARY* then any hyperplane containing the tuple is returned.
ConvexHullTraits_d:: Vector_to_point_d	Function object type that provides *Point_d operator()(Vector_d v)*, which constructs and returns the point defined by $0+v$.
ConvexHullTraits_d:: Point_to_vector_d	Function object type that provides *Vector_d operator()(Point_d v)*, which constructs and returns the vector defined by $p-0$.
ConvexHullTraits_d:: Orientation_d	Function object type that provides *Orientation operator()(ForwardIterator first, ForwardIterator last)*, which determines the orientation of the points *tuple[first,last)*.
ConvexHullTraits_d:: Orthogonal_vector_d	Function object type that provides *Vector_d operator()(Hyperplane_d h)*, which constructs and returns a vector orthogonal to h and pointing from the boundary into its positive halfspace.
ConvexHullTraits_d:: Oriented_side_d	Predicate object type that provides *Oriented_side operator()(Hyperplane_d h, Point_d p)*, which determines the oriented side of p with respect to h.

ConvexHullTraits_d:: Has_on_positive_side_d	Predicate object type that provides *bool operator()(Hyperplane_d h, Point_d p)*, which return true iff *p* lies in the positive halfspace determined by *h*.
ConvexHullTraits_d:: Affinely_independent_d	Predicate object type that provides *bool operator()(ForwardIterator first, ForwardIterator last)*, which determines if the points *tuple[first,last)* are affinely independent.
ConvexHullTraits_d:: Contained_in_simplex_d	Predicate object type that provides *bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)*, which determines if *p* is contained in the closed simplex defined by the points in *tuple[first,last)*.
ConvexHullTraits_d:: Contained_in_affined_hull_d	
	Predicate object type that provides *bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)*, which determines if *p* is contained in the affine hull of the points in *tuple[first,last)*.
ConvexHullTraits_d:: Intersect_d	Predicate object type that provides *Object operator()(Ray_d r, Hyperplane_d h)*, which determines if *r* and *h* intersect and returns the corresponding polymorphic object.

Creation

A default constructor and copy constructor is required.

Operations

For each of the above function and predicate object types, *Func_obj_type*, a function must exist with the name *func_obj_type_object* that creates an instance of the function or predicate object type. For example:

Construct_vector_d *traits.construct_vector_d_object()*

Has Models

CGAL::Cartesian_d<FT,LA>
CGAL::Homogeneous_d<RT,LA>
CGAL::Convex_hull_d_traits_3<R> . . . . page 1440

CGAL::Convex_hull_d<R>

Definition

An instance *C* of type *Convex_hull_d<R>* is the convex hull of a multi-set *S* of points in *d*-dimensional space. We call *S* the underlying point set and *d* or *dim* the dimension of the underlying space. We use *dcur* to denote the affine dimension of *S*. The data type supports incremental construction of hulls.

The closure of the hull is maintained as a simplicial complex, i.e., as a collection of simplices. The intersection of any two is a face of both[1]. In the sequel we reserve the word simplex for the simplices of dimension *dcur*. For each simplex there is a handle of type *Simplex_handle* and for each vertex there is a handle of type *Vertex_handle*. Each simplex has $1+dcur$ vertices indexed from 0 to *dcur*; for a simplex *s* and an index *i*, *C.vertex(s,i)* returns the *i*-th vertex of *s*. For any simplex *s* and any index *i* of *s* there may or may not be a simplex *t* opposite to the *i*-th vertex of *s*. The function *C.opposite_simplex(s,i)* returns *t* if it exists and returns *Simplex_handle()* (the undefined handle) otherwise. If *t* exists then *s* and *t* share *dcur* vertices, namely all but the vertex with index *i* of *s* and the vertex with index *C.index_of_vertex_in_opposite_simplex(s,i)* of *t*. Assume that *t* exists and let *j* = *C.index_of_vertex_in_opposite_simplex(s,i)*. Then *s* = *C.opposite_simplex(t,j)* and *i* = *C.index_of_vertex_in_opposite_simplex(t,j)*.

The boundary of the hull is also a simplicial complex. All simplices in this complex have dimension $dcur-1$. For each boundary simplex there is a handle of type *Facet_handle*. Each facet has *dcur* vertices indexed from 0 to $dcur-1$. If *dcur* > *1* then for each facet *f* and each index *i*, $0 \leq i < dcur$, there is a facet *g* opposite to the *i*-th vertex of *f*. The function *C.opposite_facet(f,i)* returns *g*. Two neighboring facets *f* and *g* share *dcur - 1* vertices, namely all but the vertex with index *i* of *f* and the vertex with index *C.index_of_vertex_in_opposite_facet(f,i)* of *g*. Let *j* = *C.index_of_vertex_in_opposite_facet(f,i)*. Then *f* = *C.opposite_facet(g,j)* and *i* = *C.index_of_vertex_in_opposite_facet(g,j)*.

Types

Convex_hull_d<R>:: R	the representation class.
Convex_hull_d<R>:: Point_d	the point type.
Convex_hull_d<R>:: Hyperplane_d	the hyperplane type.
Convex_hull_d<R>:: Simplex_handle	handle for simplices.
Convex_hull_d<R>:: Facet_handle	handle for facets.
Convex_hull_d<R>:: Vertex_handle	handle for vertices.
Convex_hull_d<R>:: Simplex_iterator	iterator for simplices.
Convex_hull_d<R>:: Facet_iterator	iterator for facets.
Convex_hull_d<R>:: Vertex_iterator	iterator for vertices.

[1] The empty set if a facet of every simplex.

Convex_hull_d<R>:: Hull_vertex_iterator iterator for vertices that are part of the convex hull.

Note that each iterator fits the handle concept, i.e. iterators can be used as handles. Note also that all iterator and handle types come also in a const flavor, e.g., *Vertex_const_iterator* is the constant version of *Vertex_iterator*. Const correctness requires to use the const version whenever the convex hull object is referenced as constant. The *Hull_vertex_iterator* is convertible to *Vertex_iterator* and *Vertex_handle*.

Convex_hull_d<R>:: Point_const_iterator const iterator for all inserted points.

Convex_hull_d<R>:: Hull_point_const_iterator

const iterator for all points that are part of the convex hull.

Creation

Convex_hull_d<R> C(int d, R Kernel = R());

creates an instance C of type *Convex_hull_d*. The dimension of the underlying space is d and S is initialized to the empty point set. The traits class R specifies the models of all types and the implementations of all geometric primitives used by the convex hull class. The default model is one of the d-dimensional representation classes (e.g., *Homogeneous_d*).

The data type *Convex_hull_d* offers neither copy constructor nor assignment operator.

Requirements

R is a model of the concept *ConvexHullTraits_d* .

Operations

All operations below that take a point x as argument have the common precondition that x is a point of ambient space.

int *C.dimension()*

returns the dimension of ambient space

int *C.current_dimension()*

returns the affine dimension $dcur$ of S.

Point_d *C.associated_point(Vertex_handle v)*

returns the point associated with vertex v.

Vertex_handle *C.vertex_of_simplex(Simplex_handle s, int i)*

returns the vertex corresponding to the i-th vertex of s.

Precondition: $0 \leq i \leq dcur$.

Point_d *C.point_of_simplex(Simplex_handle s, int i)*

same as *C.associated_point(C.vertex_of_simplex(s,i))*.

Simplex_handle *C.opposite_simplex(Simplex_handle s, int i)*

returns the simplex opposite to the i-th vertex of s (*Simplex_handle()* if there is no such simplex).
Precondition: $0 \leq i \leq dcur$.

int *C.index_of_vertex_in_opposite_simplex(Simplex_handle s, int i)*

returns the index of the vertex opposite to the i-th vertex of s.
Precondition: $0 \leq i \leq dcur$ and there is a simplex opposite to the i-th vertex of s.

Simplex_handle *C.simplex(Vertex_handle v)*

returns a simplex of which v is a node. Note that this simplex is not unique.

int *C.index(Vertex_handle v)*

returns the index of v in *simplex(v)*.

Vertex_handle *C.vertex_of_facet(Facet_handle f, int i)*

returns the vertex corresponding to the i-th vertex of f.
Precondition: $0 \leq i < dcur$.

Point_d *C.point_of_facet(Facet_handle f, int i)*

same as *C.associated_point(C.vertex_of_facet(f,i))*.

Facet_handle *C.opposite_facet(Facet_handle f, int i)*

returns the facet opposite to the i-th vertex of f (*Facet_handle()* if there is no such facet).
Precondition: $0 \leq i < dcur$ and $dcur > 1$.

int *C.index_of_vertex_in_opposite_facet(Facet_handle f, int i)*

returns the index of the vertex opposite to the i-th vertex of f.
Precondition: $0 \leq i < dcur$ and *dcur > 1*.

Hyperplane_d *C.hyperplane_supporting(Facet_handle f)*

returns a hyperplane supporting facet f. The hyperplane is oriented such that the interior of C is on the negative side of it.
Precondition: f is a facet of C and *dcur > 1*.

Vertex_handle *C.insert(Point_d x)*

adds point x to the underlying set of points. If x is equal to (the point associated with) a vertex of the current hull this vertex is returned and its associated point is changed to x. If x lies outside the current hull, a new vertex v with associated point x is added to the hull and returned. In all other cases, i.e., if x lies in the interior of the hull or on the boundary but not on a vertex, the current hull is not changed and *Vertex_handle()* is returned. If *CGAL_CHECK_EXPENSIVE* is defined then the validity check *is_valid(true)* is executed as a post condition.

template <typename Forward_iterator>
void *C.insert(Forward_iterator first, Forward_iterator last)*

adds S = *set [first,last)* to the underlying set of points. If any point *S[i]* is equal to (the point associated with) a vertex of the current hull its associated point is changed to *S[i]*.

bool *C.is_dimension_jump(Point_d x)*

returns true if x is not contained in the affine hull of S.

std::list<Facet_handle>

C.facets_visible_from(Point_d x)

returns the list of all facets that are visible from x.

Precondition: x is contained in the affine hull of S.

Bounded_side *C.bounded_side(Point_d x)*

returns *ON_BOUNDED_SIDE* (*ON_BOUNDARY*,*ON_UNBOUNDED_SIDE*) if x is contained in the interior (lies on the boundary, is contained in the exterior) of C.
Precondition: x is contained in the affine hull of S.

void *C.clear(int d)*

re-initializes C to an empty hull in d-dimensional space.

int *C.number_of_vertices()*

returns the number of vertices of C.

int *C.number_of_facets()*

returns the number of facets of C.

int *C.number_of_simplices()*

returns the number of bounded simplices of C.

void *C.print_statistics()*

gives information about the size of the current hull and the number of visibility tests performed.

bool *C.is_valid(bool throw_exceptions = false)*

checks the validity of the data structure. If *throw_exceptions* == *thrue* then the program throws the following exceptions to inform about the problem.
chull_has_center_on_wrong_side_of_hull_facet the hyperplane supporting a facet has the wrong orientation.
chull_has_local_non_convexity a ridge is locally non convex.
chull_has_double_coverage the hull has a winding number larger than 1.

Lists and Iterators

Vertex_iterator	*C.vertices_begin()*	an iterator of C to start the iteration over all vertices of the complex.
Vertex_iterator	*C.vertices_end()*	the past the end iterator for vertices.
Simplex_iterator	*C.simplices_begin()*	an iterator of C to start the iteration over all simplices of the complex.
Simplex_iterator	*C.simplices_end()*	the past the end iterator for simplices.
Facet_iterator	*C.facets_begin()*	an iterator of C to start the iteration over all facets of the complex.

Facet_iterator	*C.facets_end()*	the past the end iterator for facets.
Hull_vertex_iterator	*C.hull_vertices_begin()*	an iterator to start the iteration over all vertices of C that are part of the convex hull.
Hull_vertex_iterator	*C.hull_vertices_end()*	the past the end iterator for hull vertices.
Point_const_iterator	*C.points_begin()*	returns the start iterator for all points that have been inserted to construct C.
Point_const_iterator	*C.points_end()*	returns the past the end iterator for points.
Hull_point_const_iterator	*C.hull_points_begin()*	returns an iterator to start the iteration over all points in the convex hull C. Included are points in the interior of facets.
Hull_point_const_iterator	*C.hull_points_end()*	returns the past the end iterator for points in the convex hull.
template <typename Visitor> *void*	*C.visit_all_facets(Visitor V)*	each facet of C is visited by the visitor object V. V has to have a function call operator: *void operator()(Facet_handle) const*
std::list<Point_d>	*C.all_points()*	returns a list of all points that have been inserted to construct C.
std::list<Vertex_handle>	*C.all_vertices()*	returns a list of all vertices of C (also interior ones).
std::list<Simplex_handle>	*C.all_simplices()*	returns a list of all simplices in C.
std::list<Facet_handle>	*C.all_facets()*	returns a list of all facets of C.

Iteration Statements

forall_ch_vertices(v, C) { "the vertices of C are successively assigned to v" }

forall_ch_simplices(s, C) { "the simplices of C are successively assigned to s" }

forall_ch_facets(f, C) { "the facets of C are successively assigned to f" }

Implementation

The implementation of type *Convex_hull_d* is based on [CMS93] and [BMS94]. The details of the implementation can be found in the implementation document available at the download site of this package.

The time and space requirements are input dependent. Let C_1, C_2, C_3, ... be the sequence of hulls constructed and for a point x let k_i be the number of facets of C_i that are visible from x and that are not already facets of C_{i-1}. Then the time for inserting x is $O(dim \sum_i k_i)$ and the number of new simplices constructed during the insertion of x is the number of facets of the hull which were not already facets of the hull before the insertion.

The data type *Convex_hull_d* is derived from *Regular_complex_d*. The space requirement of regular complexes is essentially $12(dim+2)$ bytes times the number of simplices plus the space for the points. *Convex_hull_d* needs an additional $8+(4+x)dim$ bytes per simplex where x is the space requirement of the underlying number type and an additional 12 bytes per point. The total is therefore $(16+x)dim+32$ bytes times the number of simplices plus $28+x \cdot dim$ bytes times the number of points.

Low Dimensional Conversion Routine

include <*CGAL/Convex_hull_d_to_polyhedron_3.h*>

template <class R, class T, class HDS>
void *convex_hull_d_to_polyhedron_3(C, Polyhedron_3<T,HDS>& P)*

converts the convex hull C to polyhedral surface stored in P.

Precondition: *dim == 3* and *dcur == 3*.

Low Dimensional Output Routines

template <class R>
void *d3_surface_map(C, GRAPH< typename ::Point_d ,int>& G)*

constructs the representation of the surface of C as a bidirected LEDA graph G.

Precondition: *dim == 3*.

Class

CGAL::Convex_hull_d_traits_3<R>

Definition

The class *Convex_hull_d_traits_3<R>* serves as a traits class for the class *Convex_hull_d*. This is a traits class that adapts any low-dimensional standard kernel model, e.g. *Homogeneous<RT>* or *Cartesian<FT>* for the fixed 3-dimensional usage of *Convex_hull_d*.

#include <CGAL/Convex_hull_d_traits_3.h>

Is Model for the Concepts

ConvexHullTraits_d

Creation

Convex_hull_d_traits_3<R> traits;	default constructor.

DelaunayLiftedTraits_d

Definition

Requirements of the second traits class to be used with the class *Delaunay_d*.

Types

DelaunayLiftedTraits_d:: Point_d	the dD point type on which the Delaunay algorithm operates
DelaunayLiftedTraits_d:: Hyperplane_d	a dD plane
DelaunayLiftedTraits_d:: Vector_d	a dD vector
DelaunayLiftedTraits_d:: Ray_d	a dD ray
DelaunayLiftedTraits_d:: RT	a arithmetic ring type
DelaunayLiftedTraits_d:: Construct_vector_d	Function object type that provides *Vector_d operator()(int d, CGAL::Null_vector)*, which constructs and returns the null vector.
DelaunayLiftedTraits_d:: Construct_hyperplane_d	Function object type that provides *Hyperplane_d operator()(ForwardIterator first, ForwardIterator last, Point_d p, CGAL::Oriented_side side)*, which constructs and returns a hyperplane passing through the points in *tuple[first,last)* and oriented such that *p* is on the side *side* of the returned hyperplane. When *side==ON_ORIENTED_BOUNDARY* then any hyperplane containing the tuple is returned.
DelaunayLiftedTraits_d:: Vector_to_point_d	Function object type that provides *Point_d operator()(Vector_d v)*, which constructs and returns the point defined by $0+v$.
DelaunayLiftedTraits_d:: Point_to_vector_d	Function object type that provides *Vector_d operator()(Point_d v)*, which constructs and returns the vector defined by $p-0$.
DelaunayLiftedTraits_d:: Orientation_d	Function object type that provides *Orientation operator()(ForwardIterator first, ForwardIterator last)*, which determines the orientation of the points *tuple[first,last)*.
DelaunayLiftedTraits_d:: Orthogonal_vector_d	Function object type that provides *Vector_d operator()(Hyperplane_d h)*, which constructs and returns a vector orthogonal to *h* and pointing from the boundary into its positive halfspace.
DelaunayLiftedTraits_d:: Oriented_side_d	Predicate object type that provides *Oriented_side operator()(Hyperplane_d h, Point_d p)*, which determines the oriented side of *p* with respect to *h*.

DelaunayLiftedTraits_d:: Has_on_positive_side_d — Predicate object type that provides *bool operator()(Hyperplane_d h, Point_d p)*, which return true iff p lies in the positive halfspace determined by h.

DelaunayLiftedTraits_d:: Affinely_independent_d — Predicate object type that provides *bool operator()(ForwardIterator first, ForwardIterator last)*, which determines if the points *tuple[first,last)* are affinely independent.

DelaunayLiftedTraits_d:: Contained_in_simplex_d — Predicate object type that provides *bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)*, which determines if p is contained in the closed simplex defined by the points in *tuple[first,last)*.

DelaunayLiftedTraits_d:: Contained_in_affined_hull_d

Predicate object type that provides *bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)*, which determines if p is contained in the affine hull of the points in *tuple[first,last)*.

DelaunayLiftedTraits_d:: Intersect_d — Predicate object type that provides *Object operator()(Ray_d r, Hyperplane_d h)*, which determines if r and h intersect and returns the corresponding polymorphic object.

The previous requirements are all identical to the concept *ConvexHullTraits_d*. The Delaunay class adds the following requirements.

DelaunayLiftedTraits_d:: Project_along_d_axis_d — Predicate object type that provides *DelaunayTraits_d::Point_d operator()(Point_d p)*, which determines the $d-1$-dimensional point from the d-dimensional point p while discarding the last coordinate.

DelaunayLiftedTraits_d:: Lift_to_paraboloid_d — Predicate object type that provides *Point_d operator()(DelaunayTraits_d::Point_d p)*, which determines the d-dimensional point from the $d-1$-dimensional point p while lifting it to the paraboloid of revolution.

DelaunayLiftedTraits_d:: Component_accessor_d — Predicate object type that provides *RT homogeneous(Vector_d v,int i)* and *int dimension(Vector_d v)*, where the former determines the ith coordinate of v and the latter the dimension of v.

Creation

A default constructor and copy constructor is required.

Operations

For each of the above function and predicate object types, *Func_obj_type*, a function must exist with the name *func_obj_type_object* that creates an instance of the function or predicate object type. For example:

Construct_vector_d *traits.construct_vector_d_object()*

Has Models

CGAL::Cartesian_d<FT,LA>
CGAL::Homogeneous_d<RT,LA>

Concept

DelaunayTraits_d

Definition

Requirements of the first traits class to be used with the class *Delaunay_d*.

Types

DelaunayTraits_d:: Point_d	the dD point type on which the Delaunay algorithm operates
DelaunayTraits_d:: Sphere_d	a dD sphere
DelaunayTraits_d:: FT	an arithmetic field type
DelaunayTraits_d:: Point_of_sphere_d	Predicate object type that provides *Point_d operator()(Sphere_d s, int i)*, which returns the *i*th point defining sphere *s*.
DelaunayTraits_d:: Construct_sphere_d	Predicate object type that provides *Sphere_d operator()(int d, ForwardIterator first, ForwardIterator last)*, which returns a dD sphere through the points in *tuple[first,last)*.
DelaunayTraits_d:: Contained_in_simplex_d	Predicate object type that provides *bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)*, which determines if *p* is contained in the closed simplex defined by the points in *tuple[first,last)*.
DelaunayTraits_d:: Squared_distance_d	Predicate object type that provides *FT operator()(Point_d p,Point_d q)*, which determines the squared distance from *p* to *q*.
DelaunayTraits_d:: Affinely_independent_d	Predicate object type that provides *bool operator()(ForwardIterator first, ForwardIterator last)*, which determines if the points in *tuple[first,last)* are affinely independent.

Creation

A default constructor and copy constructor is required.

Operations

For each of the above function and predicate object types, *Func_obj_type*, a function must exist with the name *func_obj_type_object* that creates an instance of the function or predicate object type. For example:

Construct_sphere_d	*traits.construct_sphere_d_object()*

Has Models

CGAL::Cartesian_d<FT,LA>
CGAL::Homogeneous_d<RT,LA>

Class

CGAL::Delaunay_d< R, Lifted_R >

Definition

An instance *DT* of type *Delaunay_d< R, Lifted_R >* is the nearest and furthest site Delaunay triangulation of a set *S* of points in some *d*-dimensional space. We call *S* the underlying point set and *d* or *dim* the dimension of the underlying space. We use *dcur* to denote the affine dimension of *S*. The data type supports incremental construction of Delaunay triangulations and various kind of query operations (in particular, nearest and furthest neighbor queries and range queries with spheres and simplices).

A Delaunay triangulation is a simplicial complex. All simplices in the Delaunay triangulation have dimension *dcur*. In the nearest site Delaunay triangulation the circumsphere of any simplex in the triangulation contains no point of *S* in its interior. In the furthest site Delaunay triangulation the circumsphere of any simplex contains no point of *S* in its exterior. If the points in *S* are co-circular then any triangulation of *S* is a nearest as well as a furthest site Delaunay triangulation of *S*. If the points in *S* are not co-circular then no simplex can be a simplex of both triangulations. Accordingly, we view *DT* as either one or two collection(s) of simplices. If the points in *S* are co-circular there is just one collection: the set of simplices of some triangulation. If the points in *S* are not co-circular there are two collections. One collection consists of the simplices of a nearest site Delaunay triangulation and the other collection consists of the simplices of a furthest site Delaunay triangulation.

For each simplex of maximal dimension there is a handle of type *Simplex_handle* and for each vertex of the triangulation there is a handle of type *Vertex_handle*. Each simplex has *1 + dcur* vertices indexed from 0 to *dcur*. For any simplex *s* and any index *i*, *DT.vertex_of(s,i)* returns the *i*-th vertex of *s*. There may or may not be a simplex *t* opposite to the vertex of *s* with index *i*. The function *DT.opposite_simplex(s,i)* returns *t* if it exists and returns *Simplex_handle()* otherwise. If *t* exists then *s* and *t* share *dcur* vertices, namely all but the vertex with index *i* of *s* and the vertex with index *DT.index_of_vertex_in_opposite_simplex(s,i)* of *t*. Assume that $t = DT.opposite\_simplex(s,i)$ exists and let $j = DT.index\_of\_vertex\_in\_opposite\_simplex(s,i)$. Then *s* = *DT.opposite_simplex(t,j)* and *i* = *DT.index_of_vertex_in_opposite_simplex(t,j)*. In general, a vertex belongs to many simplices.

Any simplex of *DT* belongs either to the nearest or to the furthest site Delaunay triangulation or both. The test *DT.simplex_of_nearest(dt_simplex s)* returns true if *s* belongs to the nearest site triangulation and the test *DT.simplex_of_furthest(dt_simplex s)* returns true if *s* belongs to the furthest site triangulation.

Inherits From

Convex_hull_d<Lifted_R>

Types

Delaunay_d< R, Lifted_R >:: Simplex_handle	handles to the simplices of the complex.
Delaunay_d< R, Lifted_R >:: Vertex_handle	handles to vertices of the complex.
Delaunay_d< R, Lifted_R >:: Point_d	the point type
Delaunay_d< R, Lifted_R >:: Sphere_d	the sphere type

enum Delaunay_voronoi_kind { *NEAREST, FURTHEST*};

interface flags

To use these types you can typedef them into the global scope after instantiation of the class. We use *Vertex_handle* instead of *Delaunay_d< R, Lifted_R >::Vertex_handle* from now on. Similarly we use *Simplex_handle*.

Delaunay_d< R, Lifted_R >:: Point_const_iterator	the iterator for points.
Delaunay_d< R, Lifted_R >:: Vertex_iterator	the iterator for vertices.
Delaunay_d< R, Lifted_R >:: Simplex_iterator	the iterator for simplices.

Creation

Delaunay_d< R, Lifted_R > DT(int d, R k1 = R(), Lifted_R k2 = Lifted_R());

creates an instance *DT* of type *Delaunay_d*. The dimension of the underlying space is *d* and *S* is initialized to the empty point set. The traits class *R* specifies the models of all types and the implementations of all geometric primitives used by the Delaunay class. The traits class *Lifted_R* specifies the models of all types and the implementations of all geometric primitives used by the base class of *Delaunay_d< R, Lifted_R >*. The second template parameter defaults to the first: *Delaunay_d<R> = Delaunay_d<R, Lifted_R = R >*.

The data type *Delaunay_d* offers neither copy constructor nor assignment operator.

Requirements

R is a model of the concept *DelaunayTraits_d* . *Lifted_R* is a model of the concept *DelaunayLiftedTraits_d* .

Operations

All operations below that take a point x as an argument have the common precondition that $x.dimension() = DT.dimension()$.

int *DT.dimension()* returns the dimension of ambient space

int *DT.current_dimension()*

returns the affine dimension of the current point set, i.e., -1 is *S* is empty, 0 if *S* consists of a single point, 1 if all points of *S* lie on a common line, etc.

bool *DT.is_simplex_of_nearest(Simplex_handle s)*

returns true if *s* is a simplex of the nearest site triangulation.

bool *DT.is_simplex_of_furthest(Simplex_handle s)*

returns true if *s* is a simplex of the furthest site triangulation.

Vertex_handle *DT.vertex_of_simplex(Simplex_handle s, int i)*

returns the vertex associated with the *i*-th node of *s*.
Precondition: $0 \leq i \leq dcur$.

Point_d *DT.associated_point(Vertex_handle v)*

returns the point associated with vertex *v*.

Point_d *DT.point_of_simplex(Simplex_handle s, int i)*

returns the point associated with the *i*-th vertex of *s*.
Precondition: $0 \leq i \leq dcur$.

Simplex_handle *DT.opposite_simplex(Simplex_handle s, int i)*

returns the simplex opposite to the *i*-th vertex of *s* (*Simplex_handle()* if there is no such simplex).
Precondition: $0 \leq i \leq dcur$.

int *DT.index_of_vertex_in_opposite_simplex(Simplex_handle s, int i)*

returns the index of the vertex opposite to the *i*-th vertex of *s*.
Precondition: $0 \leq i \leq dcur$.

Simplex_handle *DT.simplex(Vertex_handle v)*

returns a simplex of the nearest site triangulation incident to *v*.

int *DT.index(Vertex_handle v)*

returns the index of *v* in *DT.simplex(v)*.

bool *DT.contains(Simplex_handle s, Point_d x)*

returns true if *x* is contained in the closure of simplex *s*.

bool *DT.empty()* decides whether *DT* is empty.

void *DT.clear()* re-initializes *DT* to the empty Delaunay triangulation.

Vertex_handle *DT.insert(Point_d x)*

inserts point x into DT and returns the corresponding *Vertex_handle*. More precisely, if there is already a vertex v in DT positioned at x (i.e., *associated_point(v)* is equal to x) then *associated_point(v)* is changed to x (i.e., *associated_point(v)* is made identical to x) and if there is no such vertex then a new vertex v with *associated_point(v)* = x is added to DT. In either case, v is returned.

Simplex_handle *DT.locate(Point_d x)*

returns a simplex of the nearest site triangulation containing x in its closure (returns *Simplex_handle()* if x lies outside the convex hull of S).

Vertex_handle *DT.lookup(Point_d x)*

if DT contains a vertex v with *associated_point(v)* = x the result is v otherwise the result is *Vertex_handle()*.

Vertex_handle *DT.nearest_neighbor(Point_d x)*

computes a vertex v of DT that is closest to x, i.e., $dist(x, associated\_point(v)) = \min\{dist(x,\ associated\_point(u)) \mid u \in S\ \}$.

std::list<Vertex_handle>

DT.range_search(Sphere_d C)

returns the list of all vertices contained in the closure of sphere C.

std::list<Vertex_handle>

DT.range_search(std::vector<Point_d> A)

returns the list of all vertices contained in the closure of the simplex whose corners are given by A.
Precondition: A must consist of $d+1$ affinely independent points in base space.

std::list<Simplex_handle>

DT.all_simplices(Delaunay_voronoi_kind k = NEAREST)

returns a list of all simplices of either the nearest or the furthest site Delaunay triangulation of S.

std::list<Vertex_handle>

DT.all_vertices(Delaunay_voronoi_kind k = NEAREST)

returns a list of all vertices of either the nearest or the furthest site Delaunay triangulation of *S*.

std::list<Point_d>	*DT.all_points()*	returns *S*.
Point_const_iterator	*DT.points_begin()*	returns the start iterator for points in *DT*.
Point_const_iterator	*DT.points_end()*	returns the past the end iterator for points in *DT*.

Simplex_iterator *DT.simplices_begin(Delaunay_voronoi_kind k = NEAREST)*

returns the start iterator for simplices of *DT*.

Simplex_iterator	*DT.simplices_end()*	returns the past the end iterator for simplices of *DT*.

Implementation

The data type is derived from *Convex_hull_d* via the lifting map. For a point *x* in *d*-dimensional space let *lift(x)* be its lifting to the unit paraboloid of revolution. There is an intimate relationship between the Delaunay triangulation of a point set *S* and the convex hull of *lift(S)*: The nearest site Delaunay triangulation is the projection of the lower hull and the furthest site Delaunay triangulation is the upper hull. For implementation details we refer the reader to the implementation report available from the CGAL server.

The space requirement is the same as for convex hulls. The time requirement for an insert is the time to insert the lifted point into the convex hull of the lifted points.

Example

The abstract data type *Delaunay_d* has a default instantiation by means of the *d*-dimensional geometric kernel.

```
#include <CGAL/Homogeneous_d.h>
#include <CGAL/leda_integer.h>
#include <CGAL/Delaunay_d.h>

typedef leda_integer RT;
typedef CGAL::Homogeneous_d<RT> Kernel;
typedef CGAL::Delaunay_d<Kernel> Delaunay_d;
typedef Delaunay_d::Point_d Point;
typedef Delaunay_d::Simplex_handle Simplex_handle;
typedef Delaunay_d::Vertex_handle Vertex_handle;

int main()
{
  Delaunay_d T(2);
  Vertex_handle v1 = T.insert(Point_d(2,11));
  ...
}
```

Traits requirements

Delaunay_d< R, Lifted_R > requires the following types from the kernel traits *Lifted_R*:

```
RT Point_d Vector_d Ray_d Hyperplane_d
```

and uses the following function objects from the kernel traits:

```
Construct_hyperplane_d
Construct_vector_d
Vector_to_point_d / Point_to_vector_d
Orientation_d
Orthogonal_vector_d
Oriented_side_d / Has_on_positive_side_d
Affinely_independent_d
Contained_in_simplex_d
Contained_in_affine_hull_d
Intersect_d
Lift_to_paraboloid_d / Project_along_d_axis_d
Component_accessor_d
```

Delaunay_d< R, Lifted_R > requires the following types from the kernel traits *R*:

```
FT Point_d Sphere_d
```

and uses the following function objects from the kernel traits *R*:

```
Construct_sphere_d
Squared_distance_d
Point_of_sphere_d
Affinely_independent_d
Contained_in_simplex_d
```

Low Dimensional Output Routines

template <typename R, typename Lifted_R>
template <typename R, typename Lifted_R> void

d2_map(Delaunay_d<R,Lifted_R> D,
GRAPH< typename Delaunay_d<R,Lifted_R>::Point_d, int >& DTG,
typename Delaunay_d<R,Lifted_R>::Delaunay_voronoi_kind k = Delaunay_d<R,Lifted_R>::NEAREST)

constructs a LEDA graph representation of the nearest (*kind = NEAREST* or the furthest (*kind = FURTHEST*) site Delaunay triangulation.

Precondition: *dim() == 2*.

Part VI

Polygons

Chapter 18

2D Polygons

Geert-Jan Giezeman and Wieger Wesselink

Contents

18.1 Introduction

A polygon is a closed chain of edges. Several algorithms are available for polygons. For some of those algorithms, it is necessary that the polygon is simple. A polygon is simple if edges don't intersect, except consecutive edges, which intersect in their common vertex.

The following algorithms are available:

- find the leftmost, rightmost, topmost and bottommost vertex.
- compute the (signed) area.
- check if a polygon is simple.
- check if a polygon is convex.
- find the orientation (clockwise or counterclockwise)
- check if a point lies inside a polygon.

All those operations take two forward iterators as parameters in order to describe the polygon. These parameters have a point type as value type.

The type *Polygon_2* can be used to represent polygons. Polygons are dynamic. Vertices can be modified, inserted and erased. They provide the algorithms described above as member functions. Moreover, they provide ways of iterating over the vertices and edges.

Currently, the *Polygon_2* class is a nice wrapper around a container of points, but little more. Especially, computed values are not cached. That is, when the *is_simple()* member function is called twice or more, the result is computed each time anew.

18.2 Examples

18.2.1 The Polygon Class

The following example creates a polygon and illustrates the usage of some member functions.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Polygon_2.h>
#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point;
typedef CGAL::Polygon_2<K> Polygon_2;
using std::cout; using std::endl;

int main()
{
  Point points[] = { Point(0,0), Point(5.1,0), Point(1,1), Point(0.5,6)};
  Polygon_2 pgn(points, points+4);

  // check if the polygon is simple.
  cout << "The polygon is " <<
    (pgn.is_simple() ? "" : "not ") << "simple." << endl;

  // check if the polygon is convex
  cout << "The polygon is " <<
    (pgn.is_convex() ? "" : "not ") << "convex." << endl;

  return 0;
}
```

File: `examples/Polygon/Polygon.cpp`

18.2.2 Algorithms Operating on Sequences of Points

The following example creates a polygon and illustrates the usage of some global functions that operate on sequences of points.

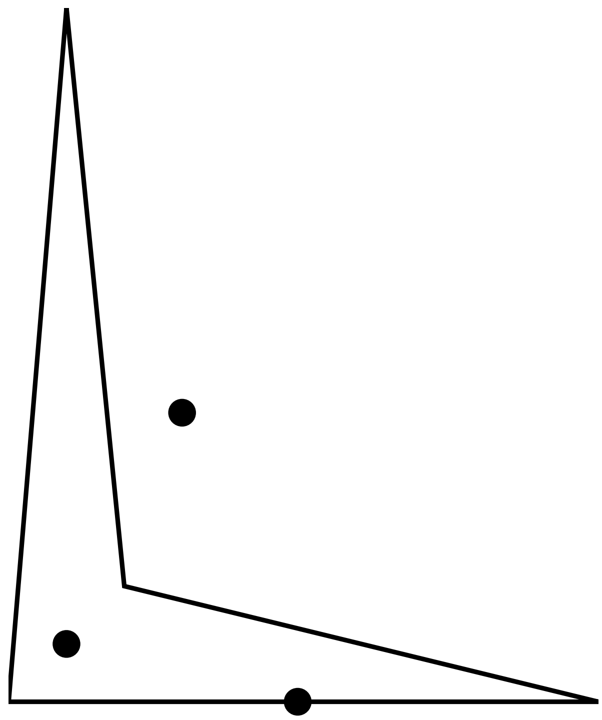

Figure 18.1: A polygon and some points

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Polygon_2_algorithms.h>
#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point;
using std::cout; using std::endl;

void check_inside(Point pt, Point *pgn_begin, Point *pgn_end, K traits)
{
  cout << "The point " << pt;
  switch(CGAL::bounded_side_2(pgn_begin, pgn_end,pt, traits)) {
    case CGAL::ON_BOUNDED_SIDE :
      cout << " is inside the polygon.\n";
      break;
    case CGAL::ON_BOUNDARY:
      cout << " is on the polygon boundary.\n";
      break;
    case CGAL::ON_UNBOUNDED_SIDE:
      cout << " is outside the polygon.\n";
      break;
  }
}

int main()
{
  Point points[] = { Point(0,0), Point(5.1,0), Point(1,1), Point(0.5,6)};
```

```
  // check if the polygon is simple.
  cout << "The polygon is "
    << (CGAL::is_simple_2(points, points+4, K()) ? "" : "not ")
    << "simple." << endl;

  check_inside(Point(0.5, 0.5), points, points+4, K());
  check_inside(Point(1.5, 2.5), points, points+4, K());
  check_inside(Point(2.5, 0), points, points+4, K());

  return 0;
}
```

File: examples/Polygon/polygon_algorithms.cpp

18.2.3 Polygons in 3D Space

Sometimes it is useful to run a 2D algorithm on 3D data. Polygons may be contours of a 3D object, where the contours are organized in parallel slices, generated by segmentation of image data from a scanner.

In order to avoid an explixit projection on the *xy* plane, one can use the traits class *Projection_traits_xy_3<K>* which is part of the 2D and 3D Linear Geometric Kernel,

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Projection_traits_yz_3.h>
#include <CGAL/Polygon_2_algorithms.h>
#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_3 Point_3;

int main()
{
  Point_3 points[4] = { Point_3(0,1,1), Point_3(0,2,1), Point_3(0,2,2),
   Point_3(0,1,2) };
  bool b =  CGAL::is_simple_2(points,
                              points+4,
                              CGAL::Projection_traits_yz_3<K>());
  if (!b){
    std::cerr << "Error polygon is not simple" << std::endl;
    return 1;
  }
  return 0;
}
```

File: examples/Polygon/projected_polygon.cpp

2D Polygons
Reference Manual

Geert-Jan Giezeman and Wieger Wesselink

Assertions

The assertion flags for the polygons and polygon operations use *POLYGON* in their names (*e.g.*, *CGAL_POLYGON_NO_ASSERTIONS*).

Concepts

Classes

Global Functions

18.4 Alphabetical List of Reference Pages

CGAL::area_2

Function

Definition

The function *area_2* computes the signed area of a polygon.

#include <CGAL/Polygon_2_algorithms.h>

```
template <class ForwardIterator, class Traits>
void                area_2( ForwardIterator first,
                            ForwardIterator last,
                            typename Traits::FT &result,
                            Traits traits)
```

Computes the signed area of the polygon defined by the range of points *first* ... *last*. The area is returned in the parameter *result*. The sign is positive for counterclockwise polygons, negative for clockwise polygons. If the polygon is not simple, the area is not well defined. The functionality is also available by the *polygon_area_2* function, which returns the area instead of taking it as a parameter.

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. Only the following members of this traits class are used:
   - *Compute_area_2* : Computes the signed area of the oriented triangle defined by 3 *Point_2* passed as arguments.
   - *FT*
   - *compute_area_2_object()*
2. The value type of *ForwardIterator* must be *Traits::Point_2*,

Function

CGAL::bbox_2

Definition

#include <CGAL/Polygon_2_algorithms.h>

template <class InputIterator, class Traits>
Bbox_2 *bbox_2(InputIterator first, InputIterator last, Traits traits)*

Returns the bounding box of the range *[first,last)*.

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. In fact, only the members *Construct_bbox_2* and *construct_bbox_2_object()* are used.
2. The value type of *InputIterator* must be *Traits::Point_2*,

See Also

CGAL::Polygon_2<PolygonTraits_2, Container> . . . . page 1472

CGAL::bottom_vertex_2

Function

Definition

#include <CGAL/Polygon_2_algorithms.h>

template <class ForwardIterator, class Traits>
ForwardIterator *bottom_vertex_2(ForwardIterator first, ForwardIterator last, Traits traits)*

Returns an iterator to the bottommost point from the range *[first,last)*. In case of a tie, the point with the smallest x-coordinate is taken.

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. In fact, only the members *Less_yx_2* and *less_yx_2_object()* are used.
2. The value type of *ForwardIterator* must be *Traits::Point_2*,

PolygonTraits_2 . . . . page 1470

Example

CGAL::bounded_side_2

Definition

The function *bounded_side_2* computes if a point lies inside a polygon.

#include <CGAL/Polygon_2_algorithms.h>

```
template <class ForwardIterator, class Traits>
Bounded_side        bounded_side_2( ForwardIterator first,
                                    ForwardIterator last,
                                    Traits::Point_2 point,
                                    Traits traits)
```

The function *bounded_side_2* computes if a point lies inside a polygon. The polygon is defined by the sequence of points *first*...*last*. Being inside is defined by the odd-even rule. If we take a ray starting at the point and extending to infinity (in any direction), we count the number of intersections. If this number is odd, the point is inside, otherwise it is outside. If the point is on a polygon edge, a special value is returned. A simple polygon divides the plane in an unbounded and a bounded region. According to the definition points in the bounded region are inside the polygon.

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. Only the following members of this traits class are used:
   - *Compare_x_2*
   - *Compare_y_2*
   - *Orientation_2*
   - *compare_x_2_object()*
   - *compare_y_2_object()*
   - *orientation_2_object()*
2. The value type of *ForwardIterator* must be *Traits::Point_2*,

Implementation

The running time is linear in the number of vertices of the polygon. A horizontal ray is taken to count the number of intersections. Special care is taken that the result is correct even if there are degeneracies (if the ray passes through a vertex).

CGAL::is_convex_2

Definition

The function *is_convex_2* computes if a polygon is convex.

#include <CGAL/Polygon_2_algorithms.h>

template <class ForwardIterator, class Traits>
bool *is_convex_2(ForwardIterator first, ForwardIterator last, Traits traits)*

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. Only the following members of this traits class are used:
   - *Less_xy_2*
   - *Orientation_2*
   - *less_xy_2_object*
   - *orientation_2_object*
2. *ForwardIterator::value_type* should be *Traits::Point_2*,

See Also

PolygonTraits_2 . . . . page 1470
CGAL::Polygon_2<PolygonTraits_2, Container> . . . . page 1472

Function

CGAL::is_simple_2

Definition

The function *is_simple_2* computes if a polygon is simple, that is, if the edges do not intersect, except consecutive edges in their common vertex.

#include <CGAL/Polygon_2_algorithms.h>

template <class ForwardIterator, class Traits>
inline bool *is_simple_2(ForwardIterator first, ForwardIterator last, Traits traits)*

Checks if the polygon defined by the iterator range *first* ... *last* is simple.

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. Only the following members of this traits class are used:
   - *Point_2*
   - *Less_xy_2*
   - *Orientation_2*
   - *less_xy_2_object()*
   - *orientation_2_object()*
2. The value type of *ForwardIterator* must be *Traits::Point_2*,

Implementation

The simplicity test is implemented by means of a plane sweep algorithm. The algorithm is quite robust when used with inexact number types. The running time is O(n log n), where n is the number of vertices of the polygon.

CGAL::left_vertex_2

Function

Definition

#include <CGAL/Polygon_2_algorithms.h>

template <class ForwardIterator, class Traits>
ForwardIterator *left_vertex_2(ForwardIterator first, ForwardIterator last, Traits traits)*

Returns an iterator to the leftmost point from the range *[first,last)*. In case of a tie, the point with the smallest y-coordinate is taken.

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. In fact, only the members *Less_xy_2* and *less_xy_2_object()* are used.
2. The value type of *ForwardIterator* must be *Traits::Point_2*,

Function

CGAL::orientation_2

Definition

The function *orientation_2* computes if a polygon is clockwise or counterclockwise oriented.

#include <CGAL/Polygon_2_algorithms.h>

template <class ForwardIterator, class Traits>
Orientation *orientation_2(ForwardIterator first, ForwardIterator last, Traits traits)*

Precondition: *is_simple_2(first, last, traits);*

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. Only the following members of this traits class are used:
   - *Less_xy_2*
   - *less_xy_2_object()*
   - *orientation_2_object()*
2. The value type of *ForwardIterator* must be *Traits::Point_2*,

CGAL::oriented_side_2

Definition

The function *oriented_side_2* computes on which side of a polygon a point lies.

#include <CGAL/Polygon_2_algorithms.h>

```
template <class ForwardIterator, class Traits>
Oriented_side        oriented_side_2( ForwardIterator first,
                                      ForwardIterator last,
                                      Traits::Point_2 point,
                                      Traits traits)
```

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. Only the following members of this traits class are used:
   - *Less_xy_2*
   - *Compare_x_2*
   - *Compare_y_2*
   - *Orientation_2*
   - *less_xy_2_object()*
   - *compare_x_2_object()*
   - *compare_y_2_object()*
   - *orientation_2_object()*
2. The value type of *ForwardIterator* must be *Traits::Point_2*,

Concept

PolygonTraits_2

Definition

The *Polygon_2* class and the functions that implement the functionality found in that class each are parameterized by a traits class that defines the primitives used in the algorithms. The concept PolygonTraits_2 defines this common set of requirements.

The requirements of PolygonTraits_2 are a subset of the kernel requirements. We only list the types and methods which are required and refer to the description of the kernel concept for details.

Types

PolygonTraits_2:: FT	
PolygonTraits_2:: Point_2	The point type.
PolygonTraits_2:: Segment_2	The segment type.
PolygonTraits_2:: Construct_segment_2	
PolygonTraits_2:: Equal_2	
PolygonTraits_2:: Less_xy_2	
PolygonTraits_2:: Less_yx_2	
PolygonTraits_2:: Compare_x_2	
PolygonTraits_2:: Compare_y_2	
PolygonTraits_2:: Orientation_2	
PolygonTraits_2:: Compute_area_2	Computes the signed area of the oriented triangle defined by 3 *Point_2* passed as arguments.

Creation

A default constructor and copy constructor are required.

Operations

The following functions that create instances of the above predicate object types must exist.

Equal_2	*traits.equal_2_object()*

Less_xy_2	*traits.less_xy_2_object()*
Less_yx_2	*traits.less_yx_2_object()*
Compare_y_2	*traits.compare_y_2_object()*
Compare_x_2	*traits.compare_x_2_object()*
Orientation_2	*traits.orientation_2_object()*
Compute_area_2	*traits.compute_area_2_object()*
Construct_segment_2	*traits.construct_segment_2_object()*

Has Models

The kernels supplied by CGAL are models of PolygonTraits_2.

Class

CGAL::Polygon_2<PolygonTraits_2, Container>

Definition

The class *Polygon_2<PolygonTraits_2, Container>* implements polygons. The *Polygon_2<PolygonTraits_2, Container>* is parameterized by a traits class and a container class. The latter can be any class that fulfills the requirements for an STL container. It defaults to the vector class.

#include <CGAL/Polygon_2.h>

Types

Polygon_2<PolygonTraits_2, Container>:: Traits The traits type.

Polygon_2<PolygonTraits_2, Container>:: Container

The container type.

typedef Traits::FT	*FT;*	The number type, which is the *field type* of the points of the polygon.
typedef Traits::Point_2	*Point_2;*	The point type of the polygon.
typedef Traits::Segment_2	*Segment_2;*	The type of a segment between two points of the polygon.

The following types denote iterators that allow to traverse the vertices and edges of a polygon. Since it is questionable whether a polygon should be viewed as a circular or as a linear data structure both circulators and iterators are defined. The circulators and iterators are non-mutable.[1] The iterator category is in all cases bidirectional, except for *Vertex_iterator*, which has the same iterator category as *Container::iterator*. **N.B.** In fact all of them should have the same iterator category as *Container::iterator*. However, due to compiler problems this is currently not possible.

For vertices we define

Polygon_2<PolygonTraits_2, Container>:: Vertex_iterator
Polygon_2<PolygonTraits_2, Container>:: Vertex_circulator

Their value type is *Point_2*.

For edges we define

Polygon_2<PolygonTraits_2, Container>:: Edge_const_circulator
Polygon_2<PolygonTraits_2, Container>:: Edge_const_iterator

Their value type is *Segment_2*.

[1] At least conceptually. The enforcement depends on preprocessor flags.

Creation

Polygon_2<PolygonTraits_2, Container> pgn(Traits p_traits = Traits());

Creates an empty polygon *pgn*.

template <class InputIterator>
Polygon_2<PolygonTraits_2, Container> pgn(InputIterator first, InputIterator last, Traits p_traits = Traits())

Introduces a polygon *pgn* with vertices from the sequence defined by the range *[first,last)*. The value type of *InputIterator* must be *Point_2*.

Modifiers

void *pgn.set(Vertex_iterator pos, Point_2 x)*

Acts as **pos* = *x*, except that that would be illegal because the iterator is not mutable.

Vertex_iterator *pgn.insert(Vertex_iterator i, Point_2 q)*

Inserts the vertex *q* before *i*. The return value points to the inserted vertex.

template <class InputIterator>
void *pgn.insert(Vertex_iterator i, InputIterator first, InputIterator last)*

Inserts the vertices in the range *[first, last)* before *i*. The value type of points in the range *[first,last)* must be *Point_2*.

void *pgn.push_back(Point_2 q)*

Has the same semantics as *p.insert(p.vertices_end(), q)*.

void *pgn.erase(Vertex_iterator i)*

Erases the vertex pointed to by *i*.

void *pgn.erase(Vertex_iterator first, Vertex_iterator last)*

Erases the vertices in the range *[first, last)*.

void *pgn.clear()* Erases all vertices.

void *pgn.reverse_orientation()*

Reverses the orientation of the polygon. The vertex pointed to by *p.vertices_begin()* remains the same.

Access Functions

The following methods of the class return circulators and iterators that allow to traverse the vertices and edges.

Vertex_iterator *pgn.vertices_begin() const*

Returns a constant iterator that allows to traverse the vertices of the polygon *pgn*.

Vertex_iterator *pgn.vertices_end() const*

Returns the corresponding past-the-end iterator.

Vertex_circulator *pgn.vertices_circulator() const*

Returns a mutable circulator that allows to traverse the vertices of the polygon *pgn*.

Edge_const_iterator *pgn.edges_begin() const*

Returns a non-mutable iterator that allows to traverse the edges of the polygon *pgn*.

Edge_const_iterator	*pgn.edges_end() const*	
		Returns the corresponding past-the-end iterator.
Edge_const_circulator	*pgn.edges_circulator() const*	
		Returns a non-mutable circulator that allows to traverse the edges of the polygon *pgn*.

Predicates

bool	*pgn.is_simple() const*	Returns whether *pgn* is a simple polygon.
bool	*pgn.is_convex() const*	Returns whether *pgn* is convex.
Orientation	*pgn.orientation() const*	
		Returns the orientation of *pgn*. If the number of vertices $p.size() < 3$ then *COLLINEAR* is returned. *Precondition*: *p.is_simple()*.
Oriented_side	*pgn.oriented_side(Point_2 q) const*	
		Returns *POSITIVE_SIDE*, or *NEGATIVE_SIDE*, or *ON_ORIENTED_BOUNDARY*, depending on where point *q* is. *Precondition*: *p.is_simple()*.
Bounded_side	*pgn.bounded_side(Point_2 q) const*	
		Returns the symbolic constant *ON_BOUNDED_SIDE*, *ON_BOUNDARY* or *ON_UNBOUNDED_SIDE*, depending on where point *q* is. *Precondition*: *p.is_simple()*.
Bbox_2	*pgn.bbox() const*	Returns the smallest bounding box containing *pgn*.
Traits::FT	*pgn.area() const*	Returns the signed area of the polygon *pgn*. This means that the area is positive for counter clockwise polygons and negative for clockwise polygons.
Vertex_iterator	*pgn.left_vertex()*	Returns the leftmost vertex of the polygon *pgn* with the smallest *x*-coordinate.
Vertex_iterator	*pgn.right_vertex()*	Returns the rightmost vertex of the polygon *pgn* with the largest *x*-coordinate.

Vertex_iterator	*pgn.top_vertex()*	Returns topmost vertex of the polygon *pgn* with the largest *y*-coordinate.
Vertex_iterator	*pgn.bottom_vertex()*	Returns the bottommost vertex of the polygon *pgn* with the smallest *y*-coordinate.

For convenience we provide the following Boolean functions:

bool *pgn.is_counterclockwise_oriented() const*
bool *pgn.is_clockwise_oriented() const*

bool *pgn.is_collinear_oriented() const*
bool *pgn.has_on_positive_side(Point_2 q) const*
bool *pgn.has_on_negative_side(Point_2 q) const*
bool *pgn.has_on_boundary(Point_2 q) const*
bool *pgn.has_on_bounded_side(Point_2 q) const*
bool *pgn.has_on_unbounded_side(Point_2 q) const*

Random access methods

These methods are only available for random access containers.

Point_2 *pgn.vertex(std::size_t i) const*

Returns a (const) reference to the *i*-th vertex.

Point_2 *pgn*[*std::size_t i*] Returns a (const) reference to the *i*-th vertex.

Segment_2 *pgn.edge(std::size_t i) const*

Returns the *i*-th edge.

Miscellaneous

std::size_t	*pgn.size() const*	Returns the number of vertices of the polygon *pgn*.
bool	*pgn.is_empty() const*	Returns $p.size() == 0$.
Container	*pgn.container() const*	Returns a const reference to the sequence of vertices of the polygon *pgn*.

Globally defined operators

template <class Traits, class Container1, class Container2>

bool *Polygon_2<Traits,Container1> p1 == Polygon_2<Traits,Container2> p2*

Test for equality: two polygons are equal iff there exists a cyclic permutation of the vertices of *p2* such that they are equal to the vertices of *p1*. Note that the template argument *Container* of *p1* and *p2* may be different.

template <class Traits, class Container1, class Container2>

bool *Polygon_2<Traits,Container1> p1* $!=$ *Polygon_2<Traits,Container2> p2*

Test for inequality.

template <class Transformation, class Traits, class Container>

Polygon_2<Traits,Container>

transform(Transformation t, Polygon_2<Traits,Container> p)

Returns the image of the polygon p under the transformation t.

I/O

The I/O operators are defined for *iostream*. The format for the iostream is an internal format.

ostream& *ostream& os* $<<$ *Polygon_2<Traits,Container> p*

Inserts the polygon *pgn* into the stream *os*.
Precondition: The insert operator must be defined for *Point_2*.

istream& *istream& is* $>>$ *Polygon_2<Traits,Container> p*

Reads a polygon from stream *is* and assigns it to *pgn*.
Precondition: The extract operator must be defined for *Point_2*.

The information output in the *iostream* is the number of points followed by the output of the coordinates of the vertices.

Implementation

The methods *is_simple*, *is_convex*, *orientation*, *oriented_side*, *bounded_side*, *bbox*, *area*, *left_vertex*, *right_vertex*, *top_vertex* and *bottom_vertex* are all implemented using the algorithms on sequences of 2D points. See the corresponding global functions for information about which algorithms were used and what complexity they have.

Example

The following code fragment creates a polygon and checks if it is convex.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Polygon_2.h>
#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point;
typedef CGAL::Polygon_2<K> Polygon_2;
```

```
using std::cout; using std::endl;

int main()
{
  Point points[] = { Point(0,0), Point(5.1,0), Point(1,1), Point(0.5,6)};
  Polygon_2 pgn(points, points+4);

  // check if the polygon is simple.
  cout << "The polygon is " <<
    (pgn.is_simple() ? "" : "not ") << "simple." << endl;

  // check if the polygon is convex
  cout << "The polygon is " <<
    (pgn.is_convex() ? "" : "not ") << "convex." << endl;

  return 0;
}
```

File: examples/Polygon/Polygon.cpp

CGAL::polygon_area_2

Function

Definition

The function *polygon_area_2* computes the signed area of a polygon.

#include <CGAL/Polygon_2_algorithms.h>

template <class ForwardIterator, class Traits>
typename Traits::FT *polygon_area_2(ForwardIterator first, ForwardIterator last, Traits traits)*

Computes the signed area of the polygon defined by the range of points *first* ... *last*. The sign is positive for counterclockwise polygons, negative for clockwise polygons. If the polygon is not simple, the area is not well defined.

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. Only the following members of this traits class are used:
   - *Compute_area_2* : Computes the signed area of the oriented triangle defined by 3 *Point_2* passed as arguments.
   - *FT*
   - *compute_area_2_object*
2. *ForwardIterator::value_type* should be *Traits::Point_2*,

Function

CGAL::right_vertex_2

Definition

#include <CGAL/Polygon_2_algorithms.h>

template <class ForwardIterator, class Traits>
ForwardIterator *right_vertex_2(ForwardIterator first, ForwardIterator last, Traits traits)*

Returns an iterator to the rightmost point from the range *[first,last)*. In case of a tie, the point with the largest y-coordinate is taken.

Requirements

1. *Traits* is a model of the concept *PolygonTraits_2*. In fact, only the members *Less_xy_2* and *less_xy_2_object()* are used.
2. The value type of *ForwardIterator* must be *Traits::Point_2*,

Chapter 19

2D Regularized Boolean Set-Operations

Efi Fogel, Ophir Setter, Ron Wein, Guy Zucker, Baruch Zukerman, and Dan Halperin

Contents

19.1 Introduction

This package consists of the implementation of Boolean set-operations on point sets bounded by weakly x-monotone curves[1] in 2-dimensional Euclidean space. In particular, it contains the implementation of *regularized* Boolean set-operations, intersection predicates, and point containment predicates. Figure 35 shows simple examples of such operations.

Ordinary Boolean set-operations, which distinguish between the interior and the boundary of a polygon, are not implemented within this package. The *Nef_2* package supports these operations for (linear) polygons; see Chapter 20.

[1] A continuous planar curve C is *weakly x-monotone* if every vertical line intersects it at most once, or if it is vertical. Hereafter we refer to weakly x-monotone curves as x-monotone curves.

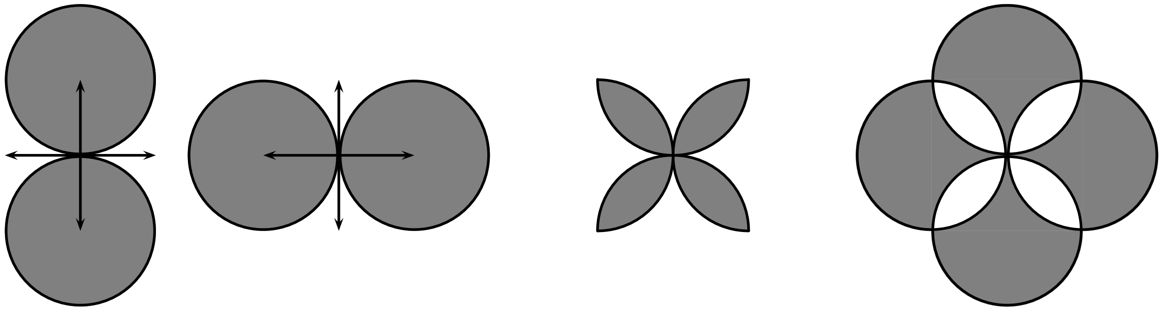

Figure 19.1: Examples of Boolean set-operations on general polygons.

In the rest of this chapter we use, unless otherwise stated, the traditional notation to denote regularized operations; e.g., $P \cap Q$ means the *regularized* intersection of P and Q.

Our package supports the following Boolean set-operations on two point sets P and Q that each is the union of one or more general polygons:

Intersection computes the intersection $R = P \cap Q$.

Join computes the union $R = P \cup Q$.

Difference computes the difference $R = P \setminus Q$.

Symmetric Difference computes the symmetric difference $P = P \oplus Q = (P \setminus Q) \cup (Q \setminus P)$.

Complement computes the complement $R = \overline{P}$.

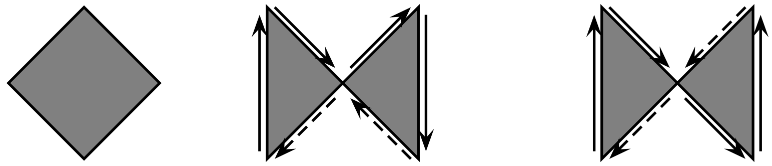
Intersection predicate tests whether the two sets P and Q overlap, distinguishing three possible scenarios: (i) the two sets intersect on their interior (that is, their regularized intersection is not empty $P \cap Q \neq \emptyset$); (ii) the boundaries of two sets intersect but their interiors are disjoint; namely they have a finite number of common points or even share a boundary curve (still in this case $P \cap Q = \emptyset$; and (iii) the two sets are disjoint.

In general, the set R, resulting from a regularized Boolean set-operation, is considered as being a closed point-set; see definition of regularized boolean set operations below.

In the rest of this chapter we review the Boolean set-operations package in more depth. In Section 19.3 we focus on Boolean set-operations on linear polygons, introducing the notion of polygons with holes and of a general polygon set. Section 19.4 introduces general polygons. We first discuss polygons whose edges are either line segments or circular arcs and then explain how to construct and use general polygons whose edges can be arbitrary weakly x-monotone curves.

19.2 Terms and Definitions

- The counterclockwise cyclic sequence of alternating polygon edges and polygon vertices is referred to as the polygon **(outer) boundary**.



A *B* *C*

Figure 19.2: Examples of polygons. (a) A simple polygon. (b) A relatively simple polygon (c) A polygon that is neither simple nor relatively simple

- A polygon whose curves are pairwise disjoint in their interior, and whose vertices' degree equals two is defined as a **Simple polygon**. Such a polygon has a well-defined interior and exterior and is topologically equivalent to a disk. Note that while traversing the edges of the relatively simple polygon illustrated above (B), no curve is crossed over.
- A **Relatively simple** polygon allows vertices with a degree>2, but all of its edges are disjoint in their interior. Furthermore, it must be an orientable polygon. Namely when it is inserted into an arrangement and its outer boundary is traversed, the same face is adjacent to all of the halfedges (no crossing over any curve during the traversal). Note that while polygon C has the same curves as polygon B, traversal of the curves leads to crossing over a previously traversed curve, and is therefore neither simple nor relatively simple.
- A polygon in our context must be relatively simple and its outer boundary vertices must be ordered in a counterclockwise direction around the interior of the polygon. We extend the notion of a polygon to a **point set** in IR^2 that has a topology of a polygon and its boundary edges must map to x-monotone curves, and refer to it as a **general polygon**. We sometimes use the term *polygon* instead of general polygon for simplicity hereafter.
- A **polygon with holes** represents a point set that may be bounded or unbounded. In case of a bounded set, its *outer boundary* is represented as a *relatively simple* (but not necessarily simple) polygon, whose vertices are oriented in a *counterclockwise* order around the interior of the set. In addition, the set may contain *holes*, where each hole is represented as a *simple* polygon, whose vertices are oriented in a *clockwise* order around the interior of the hole. Note that an unbounded polygon without holes spans the entire plane. Vertices of holes may coincide with vertices of the boundary.
- A **regularized Boolean set-operation** op* can be obtained by first taking the interior of the resultant point set of an *ordinary* Boolean set-operation (P op Q) and then by taking the closure [Hof04]. That is, P op* Q = closure(interior(P op Q)). Regularized Boolean set-operations appear in Constructive Solid Geometry (CSG), because regular sets are closed under regularized Boolean set-operations, and because regularization eliminates lower dimensional features, namely isolated vertices and antennas, thus simplifying and restricting the representation to physically meaningful solids. Our package provides regularized operations on polygons and general polygons, where the edges of a general polygon may be general x-monotone curves, rather than being simple line segments.

19.2.1 Conditions for Valid Polygons

In our context, a polygon must uphold the following conditions:

1. *Closed Boundary* - the polygon's outer boundary must be a connected sequence of curves, that start and end at the same vertex.

2. *Simplicity* - the polygon must be simple.
3. *Orientation* - the polygon's outer boundary must be *counter-clockwise oriented*.

19.2.2 Conditions for Valid Polygons with Holes

In our context, a polygon with holes must uphold the following conditions:

1. *Closed Boundary* - both the outer boundary and the holes must be closed polygons as defined above.
2. *Simplicity* - the outer boundary must be a ***relatively*** *simple* polygon (as defined above). Every hole must be a *simple* polygon.
3. *Orientation* - The polygon with holes must have an outer boundary with *counter clockwise orientation*. Every hole's outer boundary should have *clockwise orientation*.
4. *The holes and the outer boundary must be pairwise disjoint,except maybe on vertices*.
   - *All holes are contained in the outer boundary* - holes must be contained inside the outer boundary and must be disjoint from it (except on vertices).
   - *Pairwise disjoint holes (on interior)* - the polygon's holes must be *pairwise disjoint*, except for intersection on a joint vertex/vertices.

19.3 Boolean Set-Operations on Linear Polygons

The basic library of CGAL includes the *Polygon_2<Kernel,Container>* class-template that represents a linear polygon in the plane. The polygon is represented by its vertices stored in a container of objects of type *Kernel::Point_2*. The polygon edges are line segments (*Kernel::Segment_2* objects) between adjacent points in the container. By default, the *Container* is a vector of *Kernel::Point_2* objects.

The following function demonstrates how to use the basic access functions of the *Polygon_2* class. It accepts a polygon *P* and prints it in a readable format:

```
template<class Kernel, class Container>
void print_polygon (const CGAL::Polygon_2<Kernel, Container>& P)
{
  typename CGAL::Polygon_2<Kernel, Container>::Vertex_const_iterator  vit;

  std::cout << "[ " << P.size() << " vertices:";
  for (vit = P.vertices_begin(); vit != P.vertices_end(); ++vit)
    std::cout << " (" << *vit << ')';
  std::cout << " ]" << std::endl;
}
```

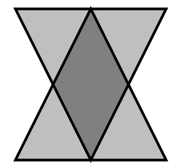
In this section we use the term *polygon* to indicate a *Polygon_2* instance, namely, a polygon having linear edges. General polygons are only discussed in Section 19.4.

The basic components of our package are the free (global) functions *complement()* that accepts a single *Polygon_2* object, and *intersection()*, *join()*,[2] *difference()*, *symmetric_difference()* and the predicate *do_intersect()* that

[2]The function that computes the union of two polygons is called *join()*, since the word *union* is reserved in C++.

accept two *Polygon_2* objects as their input. We explain how these functions should be used through several examples in the following sections.

A Simple Example



Testing whether two polygons intersect results with a Boolean value, and does not require any additional data beyond the provision of the two input polygons. The example listed below tests whether the two triangles depicted on the right intersect. It uses, as do the other example programs in this chapter, the auxiliary header file *bso_rational_nt.h*, which defines the type *Number_type* as GMP's rational number-type (*CGAL::Gmpq*), or as the number type *Quotient*<*MP_Float*> that is included in the support library of CGAL, based on whether the GMP library is installed or not. It also uses the function *print_polygon.h* listed above, which is located in the header file *print_utils.h*.

```
/*! \file do_intersect.cpp
 * Determining whether two triangles intersect.
 */

#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Boolean_set_operations_2.h>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef Kernel::Point_2                                   Point_2;
typedef CGAL::Polygon_2<Kernel>                           Polygon_2;

#include "print_utils.h"

int main ()
{
  Polygon_2 P;
  P.push_back (Point_2 (-1,1));
  P.push_back (Point_2 (0,-1));
  P.push_back (Point_2 (1,1));
  std::cout << "P = "; print_polygon (P);

  Polygon_2 Q;
  Q.push_back(Point_2 (-1,-1));
  Q.push_back(Point_2 (1,-1));
  Q.push_back(Point_2 (0,1));
  std::cout << "Q = "; print_polygon (Q);

  if ((CGAL::do_intersect (P, Q)))
    std::cout << "The two polygons intersect in their interior." <<
   std::endl;
  else
    std::cout << "The two polygons do not intersect." << std::endl;

  return 0;
}
```

19.3.1 Polygons with Holes

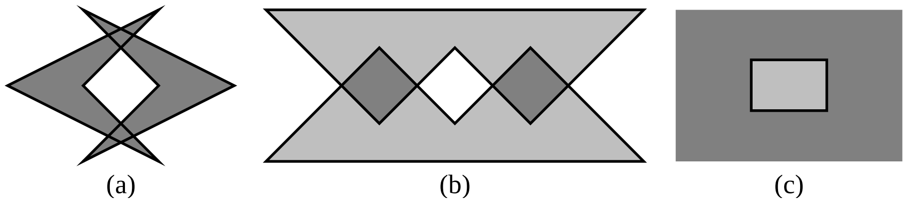

Figure 19.3: Operations on simple polygons. (a) The union of two polygons, resulting in a point set whose outer boundary is defined by a simple polygon and contains a polygonal hole in its interior. (b) The intersection (darkly shaded) of two polygons (lightly shaded), resulting in two disjoint polygons. (c) The complement (darkly shaded) of a simple polygon (lightly shaded).

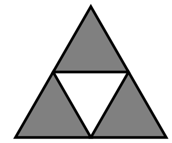
In many cases a binary operation that operates on two simple polygons that have no holes may result in a set of polygons that contain holes in their interior (see Figure 19.3.1 (a)), or a set of disjoint polygons (see Figure 19.3.1 (b); a similar set may result from the union, or the symmetric difference, of two disjoint polygons). Moreover, the complement of a simple polygon is an unbounded set that contains a hole; see Figure 19.3.1 (c).

Regular sets are closed under regularized Boolean set-operations. These operations accept as input, and may result as output, polygons with holes. A *polygon with holes* represents a point set that may be bounded or unbounded. In case of a bounded set, its *outer boundary* is represented as a relatively simple (but not necessarily simple) polygon, whose vertices are oriented in a counterclockwise order around the interior of the set. In addition, the set may contain *holes*, where each hole is represented as a simple polygon, whose vertices are oriented in a clockwise order around the interior of the hole. Note that an unbounded polygon without holes spans the entire plane. Vertices of holes may coincide with vertices of the boundary; see below for an example.

A point set represented by a polygon with holes is considered to be closed. Therefore, the boundaries of the holes are parts of the set (and not part of the holes). The exact definition of the obtained polygon with holes as a result of a Boolean set-operation or a sequence of such operations is closely related to the definition of regularized Boolean set-operations, being the closure of the interior of the corresponding ordinary operation as explained next.

Consider, for example, the regular set depicted on the right, which is the result of the union of three small triangles translated appropriately. Alternatively, the same set can be reached by taking the difference between a large triangle and a small upside-down triangle. In general, there are many ways to arrive at a particular point set. However, the set of polygons with holes obtained through the application of any sequence of operations is unique. The set depicted on the right is represented as a single polygon having a triangular outer boundary with a single triangular hole in its interior — and not as three triangles that have no holes at all. As a general rule, if two point sets are connected, then they belong to the same polygon with holes.



The class template *Polygon_with_holes_2<Kernel,Container>* represents polygons with holes as described above, where the outer boundary and the hole boundaries are realized as *Polygon_2<Kernel,Container>* objects. Given an instance *P* of the *Polygon_with_holes_2* class, you can use the predicate *is_unbounded()* to check whether *P* is a unbounded set. If it is bounded, you can obtain the counterclockwise-oriented polygon that represents its outer boundary through the member function *outer_boundary()*. You can also traverse the holes of *P* through *holes_begin()* and *holes_end()*. The two functions return iterators of the nested type *Polygon_with_holes_2::Hole_const_iterator* that defines the valid range of *P*'s holes. The value type of this iterator is *Polygon_2*.

The following function demonstrates how to traverse a polygon with holes. It accepts a *Polygon_with_holes_2* object and uses the auxiliary function *print_polygon()* to prints all its components in a readable format:

```
template<class Kernel, class Container>
void print_polygon_with_holes(const CGAL::Polygon_with_holes_2<Kernel, Container> & pwh)
{
  if (! pwh.is_unbounded()) {
    std::cout << "{ Outer boundary = ";
    print_polygon (pwh.outer_boundary());
  }
  else
    std::cout << "{ Unbounded polygon." << std::endl;

  typename CGAL::Polygon_with_holes_2<Kernel,Container>::Hole_const_iterator hit;
  unsigned int k = 1;

  std::cout << "  " << pwh.number_of_holes() << " holes:" << std::endl;
  for (hit = pwh.holes_begin(); hit != pwh.holes_end(); ++hit, ++k) {
    std::cout << "    Hole #" << k << " = ";
    print_polygon (*hit);
  }
  std::cout << " }" << std::endl;
}
```

The simple versions of the free functions mentioned therefore accept two *Polygon_2* object *P* and *Q* as their input, while their output is given using polygon with holes instances:

- The complement of a simple polygon *P* is always an unbounded set with a single polygonal hole. The function *complement(P)* therefore returns a polygon-with-holes object that represents the complement of *P*.
- The union of two polygons *P* and *Q* is always a single connected set, unless of course the two input polygons are completely disjoint. In the latter case $P \cup Q$ trivially consists of the two input polygons. The free function *join(P, Q, R)* therefore returns a Boolean value indicating whether $P \cap Q \neq \emptyset$. If the two polygons are not disjoint, it assigns the polygon with holes object *R* (which it accepts by reference) with the union of the regularized union operation $P \cup Q$.

- The other three functions, namely *intersection(P, Q, oi)*, *difference(P, Q, oi)* and *symmetric_difference(P, Q, oi)*, all have a similar interface. As the result of these operation may consist of several disconnected components, they all accept an output iterator *oi*, whose value type is *Polygon_with_holes_2*, and adds the output polygons to its associated container.

Example — Joining and Intersecting Simple Polygons

The following example demonstrates the usage of the free functions *join()* and *intersect()* for computing the union and the intersection of the two simple polygons depicted in Figure 19.3.1 (b). The example uses the auxiliary function *print_polygon_with_holes()* listed above, which is located in the header file *print_utils.h* under the examples folder.

```
/*! \file simple_join_intersect.cpp
 * Computing the union and the intersection of two simple polygons.
 */

#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Boolean_set_operations_2.h>
#include <list>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef Kernel::Point_2                                   Point_2;
typedef CGAL::Polygon_2<Kernel>                           Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel>
   Polygon_with_holes_2;
typedef std::list<Polygon_with_holes_2>                   Pwh_list_2;

#include "print_utils.h"

int main ()
{
  // Construct the two input polygons.
  Polygon_2 P;
  P.push_back (Point_2 (0, 0));
  P.push_back (Point_2 (5, 0));
  P.push_back (Point_2 (3.5, 1.5));
  P.push_back (Point_2 (2.5, 0.5));
  P.push_back (Point_2 (1.5, 1.5));

  std::cout << "P = "; print_polygon (P);

  Polygon_2 Q;
  Q.push_back (Point_2 (0, 2));
  Q.push_back (Point_2 (1.5, 0.5));
  Q.push_back (Point_2 (2.5, 1.5));
  Q.push_back (Point_2 (3.5, 0.5));
  Q.push_back (Point_2 (5, 2));

  std::cout << "Q = "; print_polygon (Q);

  // Compute the union of P and Q.
  Polygon_with_holes_2 unionR;
```

```
  if (CGAL::join (P, Q, unionR)) {
    std::cout << "The union: ";
    print_polygon_with_holes (unionR);
  } else
    std::cout << "P and Q are disjoint and their union is trivial."
              << std::endl;
  std::cout << std::endl;

  // Compute the intersection of P and Q.
  Pwh_list_2                  intR;
  Pwh_list_2::const_iterator  it;

  CGAL::intersection (P, Q, std::back_inserter(intR));

  std::cout << "The intersection:" << std::endl;
  for (it = intR.begin(); it != intR.end(); ++it) {
    std::cout << "--> ";
    print_polygon_with_holes (*it);
  }

  return 0;
}
```

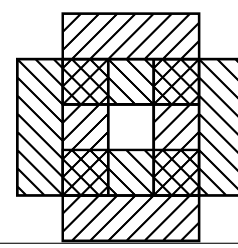
Operations on Polygons with Holes

We have demonstrated that free functions that perform boolean set operations on simple polygons may output polygons with holes. In addition to these functions, the Boolean set-operations package provides the following overridden free functions that accept *General_polygon_with_holes_2* objects as their input - *complement()*, *intersection()*, *join()*, *difference()*, *symmetric_difference()* and *do_intersect()* The prototypes of most functions is the same as of their simpler counterparts that operate on simple polygons. The only exception is *complement(P, oi)*, which outputs a range of polygons with holes that represents the complement of the polygon with holes *P*.

The following example demonstrates how to compute the symmetric difference between two sets that contain holes. Each set is a rectangle that contains a rectangular hole in its interior, such that the symmetric difference between the two sets is a single polygon that contains of five holes:



```
/*! \file symmetric_difference.cpp
 * Computing the symmetric difference of two polygons with holes.
 */

#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Boolean_set_operations_2.h>
#include <list>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
```

```
typedef Kernel::Point_2                                     Point_2;
typedef CGAL::Polygon_2<Kernel>                             Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel>
   Polygon_with_holes_2;
typedef std::list<Polygon_with_holes_2>                     Pwh_list_2;

#include "print_utils.h"

int main ()
{
  // Construct P - a bounded rectangle that contains a rectangular hole.
  Polygon_2 outP;
  Polygon_2 holesP[1];

  outP.push_back (Point_2 (-3, -5));  outP.push_back (Point_2 (3, -5));
  outP.push_back (Point_2 (3, 5));    outP.push_back (Point_2 (-3, 5));
  holesP[0].push_back (Point_2 (-1, -3));
  holesP[0].push_back (Point_2 (-1, 3));
  holesP[0].push_back (Point_2 (1, 3));
  holesP[0].push_back (Point_2 (1, -3));

  Polygon_with_holes_2  P (outP, holesP, holesP + 1);
  std::cout << "P = "; print_polygon_with_holes (P);

  // Construct Q - a bounded rectangle that contains a rectangular hole.
  Polygon_2 outQ;
  Polygon_2 holesQ[1];

  outQ.push_back (Point_2 (-5, -3));  outQ.push_back (Point_2 (5, -3));
  outQ.push_back (Point_2 (5, 3));    outQ.push_back (Point_2 (-5, 3));
  holesQ[0].push_back (Point_2 (-3, -1));
  holesQ[0].push_back (Point_2 (-3, 1));
  holesQ[0].push_back (Point_2 (3, 1));
  holesQ[0].push_back (Point_2 (3, -1));

  Polygon_with_holes_2  Q (outQ, holesQ, holesQ + 1);
  std::cout << "Q = "; print_polygon_with_holes (Q);

  // Compute the symmetric difference of P and Q.
  Pwh_list_2 symmR;
  Pwh_list_2::const_iterator it;

  CGAL::symmetric_difference (P, Q, std::back_inserter(symmR));

  std::cout << "The symmetric difference:" << std::endl;
  for (it = symmR.begin(); it != symmR.end(); ++it) {
    std::cout << "--> ";
    print_polygon_with_holes (*it);
  }

  return 0;
}
```

File: examples/Boolean_set_operations_2/symmetric_difference.cpp

In some cases it is convenient to connect the outer boundary of a polygon with holes with the holes inside it. The function *connect_holes()* accepts a polygon with holes, and connects the topmost vertex in each hole with the polygon feature located directly above it (a vertex or an edge of the outer boundary, or of another hole). It produces an output sequence of points that match the traversal of all vertices in the connected polygon (note that there are additional vertices, induced by the vertical walls).

```
/*! \file connect_polygon.cpp
 * Connecting a polygon with holes.
 */

#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/connect_holes.h>
#include <list>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef Kernel::Point_2                                   Point_2;
typedef CGAL::Polygon_2<Kernel>                           Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel>
   Polygon_with_holes_2;

int main (int argc, char* argv[])
{

  // Get the name of the input file from the command line, or use the
    default
  // pgn_holes.dat file if no command-line parameters are given.
  //more data files can be found under test data
  //boundary no other connections are made.
  const char* filename = (argc > 1) ? argv[1] : "pgn_holes.dat";
  std::ifstream input_file (filename);
  if (! input_file.is_open())
  {
    std::cerr << "Failed to open the " << filename <<std::endl;
    return -1;
  }

  // Read a polygon with holes from a file.
  Polygon_2               outerP;
  unsigned int            num_holes;

  input_file >> outerP;
  input_file >> num_holes;

  std::vector<Polygon_2>  holes (num_holes);
  unsigned int            k;

  for (k = 0; k < num_holes; k++)
    input_file >> holes[k];

  Polygon_with_holes_2    P (outerP, holes.begin(), holes.end());

  // Connect the outer boundary of the polygon with its holes.
```

```
  std::list<Point_2>            pts;
  std::list<Point_2>::iterator  pit;

  connect_holes (P, std::back_inserter (pts));

  for (pit = pts.begin(); pit != pts.end(); ++pit)
    std::cout << '(' << *pit << ")  ";
  std::cout << std::endl;

  return (0);
}
```

File: examples/Boolean_set_operations_2/connect_polygon.cpp

19.3.2 Operating on Polygon Sets

We argue that the result of a regularized operations on two polygons (or polygons with holes) P and Q is typically a collection of several disconnected polygons with holes. It is only natural to represent such a collection in terms of a class, making it possible to operate on the set resulting from computing, for example, $P \setminus Q$.

A central component in the Boolean set-operations package is the *Polygon_set_2<Kernel, Container, Dcel>* class-template. An instance of this class represents a point set formed by the collection of several disconnected polygons with holes. It employs the *Arrangement_2* class to represent this point set in the plane as a planar arrangement; see Chapter 32. The instantiated *Dcel* type is used to represent the underlying internal arrangement. It must model the concept *GeneralPolygonSetDcel*, and defaults to *Gps_default_dcel*. You can override this default, with a different DCEL class, typically an extension of the default. Overriding the default is necessary only if you intend to obtain the underlying internal arrangement and process it further.

An instance S of a *Polygon_set_2* class usually represents the result of a sequence of operations that were applied on some input polygons. The representation of S is unique, regardless of the particular sequence of operations that were applied in order to arrive at it.

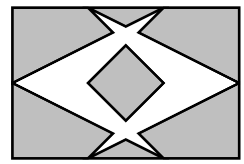
In addition, a polygon-set object can be constructed from a single polygon object or from a polygon-with-holes object. Once constructed, it is possible to insert new polygons (or polygons with holes) into the set using the *insert()* method, as long as the inserted polygons and the existing polygons in the set are disjoint. The *Polygon_set_2* class also provides access functions for accessing the polygons with holes it contains, and a few queries. The most important query is *S.oriented_side(q)*, which determined whether the query point q is contained in the interior of the set S, lies on the boundary of the set, or neither.

The *General_polygon_set_2* class defines the predicate *do_intersect()* and the methods *complement()*, *intersection()*, *join()*, *difference()* and *symmetric_difference()* as member functions. The operands to these functions may be simple polygons (*Polygon_2* object), polygons with holes (*General_polygon_with_holes_2* objects), or polygon sets (*General_polygon_set_2* objects). Thus, each of the function mentioned above is actually realized by a set overriding member functions.

Member functions of the *General_polygon_set_2* that perform Boolean set-operations come in two flavors: for example, *S.join(P, Q)* computes the union of P and Q and assigned the result to S, while *S.join(P)* performs the operation $S \longleftarrow S \cup P$. Similarly, *S.complement(P)* sets S to be the complement of P, while $S.complement()$ simply negates the set S.

A Sequence of Set Operations

The free functions reviewed in Section 19.3.1 serve as a wrapper for the polygon-set class, and are only provided for convenience. A typical such function constructs a pair of *General_polygon_set_2* objects, invokes the appropriate method to apply the desired Boolean operation, and transforms the resulting polygon set to the required output format. Thus, when several operations are performed in a sequence, it is much more efficient to use the member functions of the *General_polygon_set_2* type directly, as the extraction of the polygons from the internal representation for some operation, and the reconstruction of the internal representation for the succeeding operation could be time consuming.



The next example performs a sequence of three Boolean set-operations. First, it computes the union of two simple polygons depicted in Figure 19.3.1 (a). It then computes the complement of the result of the union operation. Finally, it computes the intersection of the result of the complement operation with a rectangle, confining the final result to the area of the rectangle. The resulting set S is comprised of two components: a polygon with a hole, and a simple polygon contained in the interior of this hole.

```
/*! \file sequence.cpp
 * Performing a sequence of Boolean set-operations.
 */

#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/Polygon_with_holes_2.h>
#include <CGAL/Polygon_set_2.h>

#include <list>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef Kernel::Point_2                                   Point_2;
typedef CGAL::Polygon_2<Kernel>                           Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel>
    Polygon_with_holes_2;
typedef CGAL::Polygon_set_2<Kernel>                       Polygon_set_2;

#include "print_utils.h"

int main ()
{
  // Construct the two initial polygons and the clipping rectangle.
  Polygon_2 P;
  P.push_back (Point_2 (0, 1));
  P.push_back (Point_2 (2, 0));
  P.push_back (Point_2 (1, 1));
  P.push_back (Point_2 (2, 2));

  Polygon_2 Q;
  Q.push_back (Point_2 (3, 1));
  Q.push_back (Point_2 (1, 2));
  Q.push_back (Point_2 (2, 1));
  Q.push_back (Point_2 (1, 0));

  Polygon_2 rect;
  rect.push_back (Point_2 (0, 0));
  rect.push_back (Point_2 (3, 0));
```

```
  rect.push_back (Point_2 (3, 2));
  rect.push_back (Point_2 (0, 2));

  // Perform a sequence of operations.
  Polygon_set_2 S;
  S.insert (P);
  S.join (Q);                    // Compute the union of P and Q.
  S.complement();                // Compute the complement.
  S.intersection (rect);         // Intersect with the clipping rectangle.

  // Print the result.
  std::list<Polygon_with_holes_2> res;
  std::list<Polygon_with_holes_2>::const_iterator it;

  std::cout << "The result contains " <<
   S.number_of_polygons_with_holes()
            << " components:" << std::endl;

  S.polygons_with_holes (std::back_inserter (res));
  for (it = res.begin(); it != res.end(); ++it) {
    std::cout << "--> ";
    print_polygon_with_holes (*it);
  }

  return 0;
}
```

File: examples/Boolean_set_operations_2/sequence.cpp

Inserting Non Intersecting Polygons

If you want to compute the union of a polygon P (P may be a simple polygon or a polygon-with-holes object) with a general-polygon set R, and store the result in R, you can construct a polygon set $S(P)$, and apply the *union* operation as follows:

```
General_polygon_2 S (P);
R.join (S);
```

As a matter of fact, you can apply the union operation directly:

```
R.join (P);
```

However, if you know that the polygon does not intersect any one of the polygons represented by R, you can use the more efficient method *insert()*:

```
R.insert (P);
```

As *insert()* assumes that $P \cap R = \emptyset$, it does not try to compute intersections between the boundaries of P and of R. This fact significantly speeds up the insertion process in comparison with the insertion of a non-disjoint polygon that intersects R.

The *insert()* function is also overloaded, so it can also accept a range of polygons. When a range of polygons are inserted into a polygon set S, all the polygons in the range and the polygons represented by S must be pairwise disjoint in their interiors.

19.3.3 Performing Aggregated Operations

There are a few options to compute the union of a set of polygons $P_1, \ldots P_m$. You can do it incrementally as follows. At each step compute the union of $S_{k-1} = \bigcup_{i=1}^{k-1} P_i$ with P_k and obtain S_k. Namely, if the polygon set is given as a pair of iterator *[begin, end)*, the following loop computes their union in S.

```
InputIterator iter = begin;
Polygon_set_2 S (*iter);

while (++iter != end) {
  S.join (*iter);
  ++iter;
}
```

A second option is to use a divide-and-conquer approach. You bisect the set of polygons into two sets. Compute the union of each set recursively and obtain the partial results in S_1 and S_2, and finally, you compute the union $S_1 \cup S_2$. However, the union operation can be done more efficiently for sparse polygons, having a relatively small number of intersections, using a third option that simultaneously computes the union of all polygons. This is done by constructing a planar arrangement of all input polygons, utilizing the sweep-line algorithm, then extracting the result from the arrangement. Similarly, it is also possible to aggregately compute the intersection $\bigcap_{i=1}^{m} P_i$ of a set of input polygons.

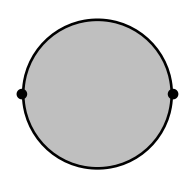
Our package provides the free overloaded functions *join()* and *intersect()* that aggregately compute the union and the intersection of a range of input polygons. There is no restriction on the polygons in the range — naturally, they may intersect each other. The package provides the overloaded free function *do_intersect(begin, end)* that determines whether the polygons in the range defined by the two input iterators *[begin, end)* intersect.

The class *General_polygon_set_2* also provides equivalent member functions that aggragately operate on a range of input polygons or polygons with holes. When such a member function is called, the general polygons represented by the current object are considered operands as well. Thus, you can easily compute the union of our polygon range as follows:

```
Polygon_set_2 S;
S.join (begin, end);
```

19.4 Boolean Set-Operations on General Polygons

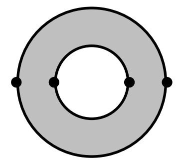
In previous sections only ordinary (linear) polygons were dealt with. Namely, closed point sets bounded by piecewise linear curves. The Boolean set-operations package allows a more general geometric mapping of the polygon edges. The operations provided by the package operate on point sets bounded by x-monotone segments of general curves (e.g., conic arcs and segments of polynomial functions). For example, the point set depicted on the right is a general polygon bounded by two x-monotone circular arcs that correspond to the lower half and the upper half of a circle, respectively.



Using the topological terminology, a general polygon can represent any simply-connected point set whose boundary is a strictly simple curve. Such a polygon is a model of the *GeneralPolygon_2* concept. A model of this concept must fulfill the following requirements:

- A general polygon is constructible from a range of pairwise interior disjoint x-monotone curves $c_1, \ldots, c_n$. The target point of the kth curve c_k and the source point of the next curve in the range (in a cyclic order) must coincide, such that this point defines the kth polygon vertex.
- It is possible to traverse the x-monotone curves that form the edges of a general polygon.

The concept *GeneralPolygonWithHoles_2* is defined in an analogous way to the definition of linear polygons with holes. A model of this concept represent a bounded or an unbounded set that may not be simply connected, and must provide the following operations:



- Construction for a general polygon that represent the outer boundary and a range of general polygons that represent the holes.
- Accessing the general polygons that represents the outer boundary (in case of a bounded set).
- Traversing the holes.

In Section 19.3 we introduce the classes *Polygon_2* and *Polygon_with_holes_2* that model the concepts *GeneralPolygon_2* and *GeneralPolygonWithHoles_2* respectively. In this section we introduce other models of these two concepts.

The central class-template *General_polygon_set_2<Traits,Dcel>* is used to represent point sets that are comprised of a finite number of pairwise disjoint general polygons with holes, and provides various Boolean set-operations on such sets. It is parameterized by a *traits* class and a DCEL class. The former defines the type of points used to represent polygon vertices and the type of x-monotone curves that represent the polygon edges. The traits class also provides primitive geometric operations that operate on objects of these types. The DCEL class is used to represent the underlying internal *Arrangement_2* data structure. The instantiated *Dcel* type is used to represent the underlying internal arrangement. It must model the concept *GeneralPolygonSetDcel*, and defaults to *Gps_default_dcel*. You can override this default, with a different DCEL class, typically an extension of the default. Overriding the default is necessary only if you intend to obtain the underlying internal arrangement and process it further.

An instantiated *General_polygon_set_2* class defines the nested types *General_polygon_set_2<Traits,Dcel> ::Polygon_2* and *General_polygon_set_2<Traits,Dcel>::Polygon_with_holes_2*, which model the concepts *GeneralPolygon_2* and *GeneralPolygonWithHoles_2* respectively.

19.4.1 The Traits-Class Concepts

The traits class used to instantiate the *General_polygon_set_2* class template must model the concept *GeneralPolygonSetTraits_2*, and is tailored to handle a specific family of curves. The concept *GeneralPolygonSetTraits_2* refines the concept *ArrangementDirectionalXMonotoneTraits_2* specified next.

The concept *ArrangementDirectionalXMonotoneTraits_2* refines the concept *ArrangementXMonotoneTraits_2* (see Section 32.4.1 in the 2D Arrangements chapter). Thus, a model of this concept must define the type *X_monotone_curve_2*, which represents an x-monotone curve, and the type *Point_2*, with represents a planar point. Such a point may be an endpoint of an x-monotone curve or an intersection point between two curves.

It must also provide various geometric predicates and operations on these types listed by the base concept, such as determining whether a point lies above or below an x-monotone curve, computing the intersections between two curves, etc. Note that the base concept does not assume that x-monotone curves are directed: an x-monotone curve is not required to have a designated *source* and *target*, it is only required to determine the left (lexicographically smaller) and the right (lexicographically larger) endpoints of a given curve.

The *ArrangementDirectionalXMonotoneTraits_2* concept treats its x-monotone curves as directed objects. It thus requires two additional operations on x-monotone curves:

- Given an x-monotone curve, compare its source and target points lexicographically.
- Given an x-monotone curve, construct its opposite curve (namely, swap its source and target points).

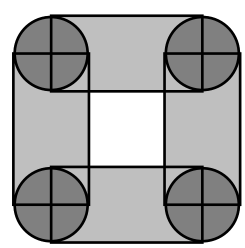
The traits classes *Arr_segment_traits_2*, *Arr_non_caching_segment_traits*, *Arr_circle_segment_traits_2*, *Arr_conic_traits_2* and *Arr_rational_arc_traits_2*, which are bundled in the *Arrangement_2* package and distributed with CGAL, are all models of the refined concept *ArrangementDirectionalXMonotoneTraits_2*.[3]

Just as with the case of computations using models of the *ArrangementXMonotoneTraits_2* concept, operations are robust only when exact arithmetic is used. When inexact arithmetic is used, (nearly) degenerate configurations may result in abnormal termination of the program or even incorrect results.

19.4.2 Operating on Polygons with Circular Arcs

Two traits classes are distributed with CGAL. The first one is named *Gps_segment_traits_2*, and it is used to perform Boolean set-operations on ordinary polygons and polygons with holes. In fact, the class *Polygon_set_2* introduced in Section 19.3.2 is a specialization of *General_polygon_set_2*<*Gps_segment_traits_2*>. This class defined its polygon and polygon with holes types, such that the usage of this traits class is encapsulated in the polygon-set class.

The other predefined traits class is named *Gps_circle_segment_traits_2*<*Kernel*> and is parameterized by a geometric CGAL kernel. By instantiating the *General_polygon_set_2* with this traits class, we obtain the representation of a polygon whose boundary may be comprised of line segments and circular arcs. The circle–segment traits class provides predicates and constructions on non-linear objects; yet, it uses only rational arithmetic and is very efficient as a consequence.



The following example uses the *Gps_circle_segment_traits_2* class to compute the union of four rectangles and four circles. Each circle is represented as a general polygon having two x-monotone circular arcs. The union is computed incrementally, resulting with a single polygon with a single hole, as depicted on the right. Note that as the four circles are disjoint, their union is computed with the *insert* method, while the union with the rectangles is computed with the *join* operator.

```
/*! \file circle_segment.cpp
 * Handling circles and linear segments concurrently.
 */

#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Gps_circle_segment_traits_2.h>
```

[3] The *Arr_polyline_traits_2* class is *not* a model of the, *ArrangementDirectionalXMonotoneTraits_2* concept, as the x-monotone curve it defines is always directed from left to right. Thus, an opposite curve cannot be constructed. However, it is not very useful to construct a polygon whose edges are polylines, as an ordinary polygon with linear edges can represent the same entity.

```
#include <CGAL/General_polygon_set_2.h>
#include <CGAL/Lazy_exact_nt.h>

#include <list>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef Kernel::Point_2                                   Point_2;

19.4.3 General Polygon Set Traits Adapter

The concept *GeneralPolygon_2* and its generic model *General_polygon_2<ArrDirectionalXMonotoneTraits>* facilitate the production of general-polygon set traits classes. A model of the concept *GeneralPolygon_2* represents a simple point-set in the plane bounded by x-monotone curves. As opposed to the plain *Traits::Polygon_2* type defined by any traits class, it must define the type *X_monotone_curve_2*, which represents an x-monotone curve of the point-set boundary. It must provide a constructor from a range of such curves, and a pair of methods, namely *curves_begin()* and *curves_end()*, that can be used to iterate over the point-set boundary curves.

The class-template *General_polygon_2<ArrDirectionalXMonotoneTraits>* models the concept *GeneralPolygon_2*. Its sole template parameter must be instantiated with a model of the concept *ArrangementDirectionalXMonotoneTraits_2* from which it obtains the *X_monotone_curve_2* type. It uses the geometric operations on this type provided by such a model to maintain a container of directed curves of type *X_monotone_curve_2*, which represents a boundary of the general polygon.

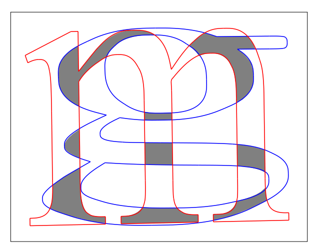
The class-template *Gps_traits_2<ArrDirectionalXMonotoneTraits,GeneralPolygon>* models the concept *GeneralPolygonSetTraits_2*, and can be used to instantiate the class template *General_polygon_set_2*. It serves as an adapter for a geometric traits class, which models the concept *ArrangementDirectionalXMonotoneTraits_2*. It can be used for performing set-operations on general polygons. The implementation of the adapter is rather simple, as it is derived from the instantiated template-parameter *ArrXMonotoneTraits_2* inheriting its necessary types and methods. It further exploits the methods provided by the instantiated parameter *GeneralPolygon*, which is a model of the concept *GeneralPolygon_2*. By default, the *GeneralPolygon* parameter is defined as *General_polygon_2<ArrangementDirectionalXMonotoneTraits_2>*.

The code excerpt listed below defines a general-polygon set type that can be used to perform Boolean set-operations on point sets bounded by the x-monotone curve type defined by the arrangement-traits class *Arr_traits_2*, which is some representative model of the concept *ArrangementDirectionalXMonotoneTraits_2*.

```
#include <CGAL/General_polygon_2.h>
#include <CGAL/Gps_traits_2.h>

typedef CGAL::General_polygon_2<Arr_traits_2>               General_polygon_2;
typedef CGAL::Gps_traits_2<Arr_traits_2, General_polygon_2> Traits_2;
typedef CGAL::General_polygon_set_2<Traits_2>               General_polygon_set_2;
```

Instantiating the arrangement-traits *Arr_traits_2* above with the traits class that handle Bézier curves *Arr_bezier_traits_2*, results with the definition of a general-polygon set type that can be used to perform Boolean set-operations on point sets bounded by Bézier curves.
The next example computes the intersection of two general polygons bounded by Bézier curves read from two input files respectively. The default input files our example uses (*char_g.dat* and *char_m.dat*) define two general polygons shaped in the form of the characters **g** and **m** in the Times New Roman font respectively. Their intersection comprises nine simple polygons, as depicted to the right.



Recall that every Bézier curve is defined by a sequence of control points that form chains (see Section 32.6.7. The last control point of every curve must be identical to the first control point of its successor. The function *read_Bezier_polygon()* included in the example reads the curves from an input file until they form a closed chain, which is assumed to be the outer boundary of the polygon. If more curves are available, its starts constructing polygons that correspond to holes in the area bounded by the outer boundary. Note that this function is also responsible for subdividing the input Bézier curves into x-monotone subcurves, as required by the *Gps_traits_2* adapter.

```

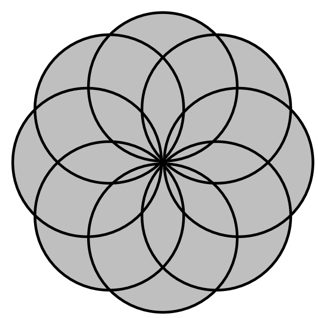
19.4.4 Example - Aggregated Operations

In Section 19.3.3 we describe how aggregated union and intersection operations can be applied to a collection of ordinary polygons or polygons with holes. Naturally, the aggregated operations can be applied also to collections of general polygons. As was the case with ordinary polygons, using aggregated operations is recommended when the number of intersections of the input polygons is of the same order of magnitude as the complexity of the result. If this is not the case, computing the result incrementally may prove faster.

The next example computes the union of eight unit discs whose centers are placed a unit distance from the origin, as depicted to the right. The example also allows users to provide a different number of discs through the command line.



```
/*! \file set_union.cpp

2D Regularized Boolean Set-Operations Reference Manual

Efi Fogel, Ophir Setter, Ron Wein, Guy Zucker, Baruch Zukerman, and Dan Halperin

Introduction

This package consists of the implementation of Boolean set-operations on point sets bounded by x-monotone curves in 2-dimensional Euclidean space. In particular, it contains the implementation of regularized Boolean set-operations, intersection predicates, and point containment predicates.

CGAL::General_polygon_set_2<Traits,Dcel>

Class

Definition

An object of the *General_polygon_set_2<Traits,Dcel>* class-template represents a point set in the plane bounded by x monotone curves. Points in the set lie on the boundary or on the positive side of the curves. This class template provides methods to apply regularized Boolean set-operations and few other utility methods. An *Arrangement_2* data structure is internally used to represent the point set. The arrangement is represented as a doubly-connected edge-list (DCEL).

The *Traits* template-parameter should be instantiated with a model of the concept *GeneralPolygonSetTraits_2*. The traits class defines the types of points, x-monotone curves, general polygons, and general polygons with holes, that is *Traits::Point_2*, *Traits::X_monotone_curve_2*, *Traits::Polygon_2*, and *Traits::Polygon_with_holes_2*, respectively. *Traits::Point_2* must be the type of the endpoints of *Traits::X_monotone_curve_2*, and *Traits::X_monotone_curve_2* must be the type of the curves that comprise the boundaries of the general polygons. The traits class supports geometric operations on the types above. We sometimes use the term *polygon* instead of general polygon for simplicity hereafter.

The template parameter *Dcel* should be instantiated with a model of the concept *GeneralPolygonSetDcel*. It is instantiated by default with the type *Gps_default_dcel<Traits>*. You can override this default, with a different DCEL class, typically an extension of the *Gps_default_dcel* class template. Overriding the default is necessary only if you intend to obtain the underlying internal arrangement and process it further.

The input and output of the Boolean set-operations methods consist of one or more general polygons, some of which may have holes. In particular, these methods operate on pairs of objects of type *General_polygon_set_2<Traits,Dcel>*, or directly on objects of type *Traits::Polygon_2* or *Traits::Polygon_with_holes_2*. An object of type *Traits::Polygon_2* is a valid operand, only if it is simple and its boundary is oriented counterclockwise. An object of type *Traits::Polygon_with_holes_2* is valid, only if its outer boundary bounds a relatively simple general polygon oriented counterclockwise, and each one of its holes is a simple polygon oriented clockwise. The holes are pairwise disjoint, except perhaps at the vertices, and are contained in the polygon bounded by the outer boundary. The outer boundary and the holes are also pairwise disjoint, except perhaps at the vertices.

Types

General_polygon_set_2<Traits,Dcel>:: Traits_2	the traits class in use.
General_polygon_set_2<Traits,Dcel>:: Polygon_2	the general polygon type. Must model the *GpsTraitsGeneralPolygon_2* Concept.
General_polygon_set_2<Traits,Dcel>:: Polygon_with_holes_2	the general polygon with holes type. Must model the *GpsTraitsGeneralPolygonWithHoles_2* Concept.
General_polygon_set_2<Traits,Dcel>:: Size	number of polygons with holes size type.
General_polygon_set_2<Traits,Dcel>:: Arrangement_2	the arrangement type used internally.

Creation

General_polygon_set_2<Traits,Dcel> gps;	constructs an empty set of polygons represented by an empty arrangement.
General_polygon_set_2<Traits,Dcel> gps(Self other);	copy constructor.
General_polygon_set_2<Traits,Dcel> gps(Traits & traits);	constructs an empty set of polygons that uses the given *traits* instance for performing the geometric operations.
General_polygon_set_2<Traits,Dcel> gps(Polygon_2 pgn);	constructs a set of polygons that consists of the single polygon *pgn*.
General_polygon_set_2<Traits,Dcel> gps(Polygon_with_holes_2 pgn_with_holes);	constructs a set of polygons that consists of the single polygon with holes *pgn_with_holes*.

Access Functions

template <class OutputIterator>

OutputIterator	*gps.polygons_with_holes(OutputIterator out)*	obtains the polygons with holes represented by *gps*.
Size	*gps.number_of_polygons_with_holes() const*	returns the total number of general polygons represented by *gps*.
bool	*gps.is_empty() const*	returns *true* if *gps* represents an empty set.
bool	*gps.is_plane() const*	returns *true* if *gps* represents the entire plane.
Traits&	*gps.traits() const*	obtains an instance of the traits. If the traits was passed as a parameter to the constructor of *gps*, it is returned. Otherwise, a newly created instance is returned.
Arrangement_2	*gps.arrangement() const*	obtains the arrangement data structure that internally represents the general-polygon set.

Modifiers

void *gps.clear()*

clears *gps*.

void *gps.insert(Polygon_2 & pgn)*

inserts *pgn* into *gps*.
Precondition: *pgn* and the point set represented by *gps* are disjoint. This precondition enables the use of very efficient insertion methods. Use the respective overloaded method that inserts a polygon of type *Polygon_with_holes_2*, if only a relaxed precondition can be guaranteed. If even the relaxed precondition cannot be guaranteed, use the *join* method.

void *gps.insert(Polygon_with_holes_2 & pgn_with_holes)*

inserts *pgn_with_holes* into *gps*.
Precondition: *pgn_with_holes* does not intersect with the point set represented by *gps*, except maybe at the vertices. If this relaxed precondition cannot be guaranteed, use the *join* method.

template <class InputIterator>
void *gps.insert(InputIterator begin, InputIterator end)*

inserts the range of polygons (or polygons with holes) into *gps*. (The value type of the input iterator is used to distinguish between the two.)
Precondition: If the given range contains objects of type *Polygon_with_holes_2*, then these polygons and the point set represented by *gps* are pairwise disjoint, except maybe at the vertices. If the given range contains objects of type *Polygon_2*, then these polygons and the point set represented by *gps* are pairwise disjoint without any exceptions.

template <class InputIterator1, class InputIterator2>
void *gps.insert(InputIterator1 pgn_begin,*
InputIterator1 pgn_end,
InputIterator2 pgn_with_holes_begin,
InputIterator2 pgn_with_holes_end)

inserts the two ranges of polygons and polygons with holes into *gps*.
Precondition: All polygons in the first range, all polygon with holes in the second range, and the point set represented by *gps* are pairwise disjoint, except maybe at the vertices

void *gps.complement()*

computes the complement of *gps*.

void *gps.complement(Polygon_set_2 other)*

computes the complement of *other*. *gps* is overridden by the result.

Univariate Operations

In the following univariate and bivariate methods the result is placed in *gps* after it is cleared.

void gps.intersection(General_polygon_set_2 other)

computes the intersection of *gps* and *other*.

void gps.intersection(Polygon_2 pgn)

computes the intersection of *gps* and *pgn*.

void gps.intersection(Polygon_with_holes_2 pgn)

computes the intersection of *gps* and *pgn*.

template <class InputIterator>
void gps.intersection(InputIterator begin, InputIterator end)

computes the intersection of a collection of point sets. The collection consists of the polygons (or polygons with holes) in the given range and the point set represented by *gps*. (The value type of the input iterator is used to distinguish between the two options.)

template <class InputIterator1, class InputIterator2>
void gps.intersection(InputIterator1 pgn_begin, InputIterator1 pgn_end, InputIterator2 pgn_with_holes_begin, InputIterator2 pgn_with_holes_end)

computes the intersection of a collection of point sets. The collection consists of the polygons and polygons with holes in the given two ranges and the point set represented by *gps*.

void gps.join(General_polygon_set_2 other)

computes the union of *gps* and *other*.

void gps.join(Polygon_2 pgn)

computes the union of *gps* and *pgn*.

void gps.join(Polygon_with_holes_2 pgn)

computes the union of *gps* and *pgn*.

template <class InputIterator>
void gps.join(InputIterator begin, InputIterator end)

computes the union of the polygons (or polygons with holes) in the given range and the point set represented by *gps*. (The value type of the input iterator is used to distinguish between the two options.)

template <class InputIterator1, class InputIterator2>
void gps.join(InputIterator1 pgn_begin, InputIterator1 pgn_end, InputIterator2 pgn_with_holes_begin, InputIterator2 pgn_with_holes_end)

computes the union of the polygons and polygons with holes in the given two ranges and the point set represented by *gps*.

void *gps.difference(General_polygon_set_2 other)*

computes the difference between *gps* and *other*.

void *gps.difference(Polygon_2 pgn)* computes the difference between *gps* and *pgn*.

void *gps.difference(Polygon_with_holes_2 pgn)* computes the difference between *gps* and *pgn*.

void *gps.symmetric_difference(General_polygon_set_2 other)*

computes the symmetric difference between *gps* and *other*.

void *gps.symmetric_difference(Polygon_2 pgn)* computes the symmetric difference between *gps* and *pgn*.

void *gps.symmetric_difference(Polygon_with_holes_2 pgn)*

computes the symmetric difference between *gps* and *pgn*.

template <class InputIterator>
void *gps.symmetric_difference(InputIterator begin, InputIterator end)*

computes the symmetric difference (xor) of a collection of point sets. The collection consists of the polygons (or polygons with holes) in the given range and the point set represented by *gps*. (The value type of the input iterator is used to distinguish between the two options.)

template <class InputIterator1, class InputIterator2>
void *gps.symmetric_difference(InputIterator1 pgn_begin,*
InputIterator1 pgn_end,
InputIterator2 pgn_with_holes_begin,
InputIterator2 pgn_with_holes_end)

computes the symmetric difference (xor) of a collection of point sets. The collection consists of the polygons and polygons with holes in the given two ranges and the point set represented by *gps*.

Bivariate Operations

The following bivariate function replace *gps* with the result.

void *gps.intersection(General_polygon_set_2 gps1, General_polygon_set_2 gps2)*

computes the intersection of *gps1* and *gps2*.

void *gps.join(General_polygon_set_2 gps1, General_polygon_set_2 gps2)*

computes the union of *gps1* and *gps2*.

void *gps.difference(General_polygon_set_2 gps1, General_polygon_set_2 gps2)*

computes the difference between *gps1* and *gps2*.

void *gps.symmetric_difference(General_polygon_set_2 gps1, General_polygon_set_2 gps2)*

computes the symmetric difference between *gps1* and *gps2*.

Query Functions

bool	*gps.do_intersect(General_polygon_set_2 other)*	returns *true* if *gps* and *other* intersect in their interior, and *false* otherwise.
bool	*gps.do_intersect(Polygon_2 pgn)*	returns *true* if *gps* and *pgn* intersect in their interior, and *false* otherwise.
bool	*gps.do_intersect(Polygon_with_holes_2 pgn)*	returns *true* if *gps* and *pgn* intersect in their interior, and *false* otherwise.

template <class InputIterator>
void *gps.do_intersect(InputIterator begin, InputIterator end)*

returns *true* if the interior of the point sets in a collection intersect, and *false* otherwise. The collection consists of the polygons (or polygons with holes) in the given range and the point set represented by *gps*. (The value type of the input iterator is used to distinguish between the two options.)

template <class InputIterator1, class InputIterator2>
void *gps.do_intersect(InputIterator1 pgn_begin, InputIterator1 pgn_end, InputIterator2 pgn_with_holes_begin, InputIterator2 pgn_with_holes_end)*

returns *true* if the interior of the point sets in a collection intersect, and *false* otherwise. The collection consists of the polygons and polygons with holes in the given two ranges and the point set represented by *gps*.

bool *gps.locate(Point_2 p, Polygon_with_holes_2 & pgn)*

obtains a polygon with holes that contains the query point *p*, if exists, through *pgn*, and returns *true*. Otherwise, returns *false*.

Oriented_side	*gps.oriented_side(Point_2 q)*	returns either the constant *ON_ORIENTED_BOUNDARY*, *ON_POSITIVE_SIDE*, or *ON_NEGATIVE_SIDE*, iff *p* lies on the boundary, properly on the positive side, or properly on the negative side of *gps* respectively.
Oriented_side	*gps.oriented_side(General_polygon_set_2 other)*	
		returns either the constant *ON_NEGATIVE_SIDE*, *ON_ORIENTED_BOUNDARY*, or *ON_POSITIVE_SIDE*, iff *other* and *gps* are completely disjoint, in contact, or intersect in their interior, respectively.
Oriented_side	*gps.oriented_side(Polygon_2 pgn)*	returns either the constant *ON_NEGATIVE_SIDE*, *ON_ORIENTED_BOUNDARY*, or *ON_POSITIVE_SIDE*, iff *pgn* and *gps* are completely disjoint, in contact, or intersect in their interior, respectively.
Oriented_side	*gps.oriented_side(Polygon_with_holes_2 pgn)*	returns either the constant *ON_NEGATIVE_SIDE*, *ON_ORIENTED_BOUNDARY*, or *ON_POSITIVE_SIDE*, iff *pgn* and *gps* are completely disjoint, in contact, or intersect in their interior, respectively.

Miscellaneous

bool	*gps.is_valid() const*	returns *true* if *gps* represents a valid point set.

Concept

GeneralPolygon_2

Refines

GpsTraitsGeneralPolygon_2

Types

GeneralPolygon_2:: X_monotone_curve_2	represents a planar (weakly) x-monotone curve. The type of the geometric mapping of the polygonal edges. It must model the concept ArrTraits::XMonotoneCurve_2.
GeneralPolygon_2:: Curve_iterator	an iterator over the geometric mapping of the polygon edges. Its value type is *X_monotone_curve_2*.
GeneralPolygon_2:: Curve_const_iterator	a const iterator over the geometric mapping of the polygon edges. Its value type is *X_monotone_curve_2*.

Definition

A model of this concept represents a simple general-polygon. The geometric mapping of the edges of the polygon must be x-monotone curves. The concept requires the ability to access these curves. The general polygon represented must be simple. That is, the only points of the plane belonging to two curves are the geometric mapping of the polygon vertices. In addition, the vertices of the represented polygon must be ordered consistently, and the curved must be directed accordingly. Only counterclockwise oriented polygons are valid operands of Boolean set-operations. General polygon that represent holes must be clockwise oriented.

Creation

GeneralPolygon_2	*polygon*;	default constructor.
GeneralPolygon_2	*polygon(other);*	copy constructor.
GeneralPolygon_2	*polygon = other*	assignment operator.

template <class InputIterator>
GeneralPolygon_2 polygon(InputIterator begin, InputIterator end);

constructs a general polygon from a given range of curves.

Access Functions

Curve_iterator	*polygon.curves_begin()*	returns the begin iterator of the curves.
Curve_iterator	*polygon.curves_end()*	returns the past-the-end iterator of the curves.
Curve_const_iterator	*polygon.curves_begin()*	returns the begin const iterator of the curves.
Curve_const_iterator	*polygon.curves_end()*	returns the past-the-end const iterator of the curves.

Modifiers

template <class Iterator>
void *polygon.init(Iterator begin, Iterator end)*

initializes the polygon with the polygonal chain given by the range. The value type of *Iterator* must be *X_monotone_curve_2*.
Precondition: The curves in the range must define a simple polygon.

Has Models

CGAL::General_polygon_2<ArrTraits>

Concept

GeneralPolygonWithHoles_2

Refines

GpsTraitsGeneralPolygonWithHoles_2

Types

GeneralPolygonWithHoles_2:: General_polygon_2	the general-polygon type used to represent the outer boundary and each hole. Must Model the *GeneralPolygon_2* Concept.
GeneralPolygonWithHoles_2:: Hole_const_iterator	a bidirectional iterator over the polygonal holes. Its value type is *General_polygon_2*.

Definition

A model of this concept represents a general polygon with holes. The concept requires the ability to access the general polygon that represents the outer boundary and the general polygons that represent the holes.

Creation

GeneralPolygonWithHoles_2 polygon;	default constructor.
GeneralPolygonWithHoles_2 polygon(other);	copy constructor.
GeneralPolygonWithHoles_2 polygon = other	assignment operator.

GeneralPolygonWithHoles_2 polygon(General_polygon_2 & outer);

constructs a general polygon with holes that has no holes using a given general polygon *outer* as the outer boundary.

template <class InputIterator>
GeneralPolygonWithHoles_2 polygon(General_polygon_2 & outer, InputIterator begin, InputIterator end);

constructs a general polygon with holes using a given general polygon *outer* as the outer boundary and a given range of holes. If *outer* is an empty general polygon, then an unbounded polygon with holes will be created. The holes must be contained inside the outer boundary, and the polygons representing the holes must be simple and pairwise disjoint, except perhaps at the vertices.

Predicates

bool	*polygon.is_unbounded()*	returns *true* if the outer boundary is empty, and *false* otherwise.

Access Functions

General_polygon_2	*polygon.outer_boundary() const*	
		returns the general polygon that represents the outer boundary. Note that this polygon is not necessarily a valid (simple) general polygon because it may be relatively simple.
Hole_const_iterator	*polygon.holes_begin() const*	returns the begin iterator of the holes.
Hole_const_iterator	*polygon.holes_end() const*	returns the past-the-end iterator of the holes.

Has Models

CGAL::General_polygon_with_holes_2<General_polygon>
CGAL::Polygon_with_holes_2<Kernel,Container>
CGAL::Gps_circle_segment_traits_2<Kernel>::Polygon_with_holes_2
CGAL::Gps_traits_2<ArrTraits,GeneralPolygon>::Polygon_with_holes_2

Concept

ArrangementDirectionalXMonotoneTraits_2

Definition

This concept refines the basic arrangement x-monotone traits concept. A model of this concept is able to handle *directed* x-monotone curves that intersect in their interior. Namely, an instance of the *X_monotone_curve_2* type defined by a model of the concept *ArrangementXMonotoneTraits_2* is only required to have a *left* (lexicographically smaller) endpoint and a *right* endpoint. If the traits class is also a model of *ArrangementDirectionalXMonotoneTraits_2*, the x-monotone curve is also required to have a direction, namely one of these two endpoint serves as its *source* and the other as its *target*.

Refines

ArrangementXMonotoneTraits_2

Functor Types

ArrangementDirectionalXMonotoneTraits_2:: Compare_endpoints_xy_2

models the concept *ArrDirectionalTraits::CompareEndpointsXy_2*.

ArrangementDirectionalXMonotoneTraits_2:: Construct_opposite_2

models the concept *ArrDirectionalTraits::ConstructOpposite_2*.

ArrangementDirectionalXMonotoneTraits_2:: Intersect_2

models the concept *ArrDirectionalTraits::Intersect_2*.

ArrangementDirectionalXMonotoneTraits_2:: Split_2

models the concept *ArrDirectionalTraits::Split_2*.

ArrangementDirectionalXMonotoneTraits_2:: Are_mergeable_2

models the concept *ArrDirectionalTraits::AreMergeable_2*.

ArrangementDirectionalXMonotoneTraits_2:: Merge_2

models the concept *ArrDirectionalTraits::Merge_2*.

Creation

ArrangementDirectionalXMonotoneTraits_2	*traits*;	default constructor.
ArrangementDirectionalXMonotoneTraits_2	*traits(other);*	copy constructor
ArrangementDirectionalXMonotoneTraits_2	$traits = other$	assignment operator.

ArrangementXMonotoneTraits_2 (page 2273)

Concept

ArrDirectionalTraits::Intersect_2

Refines

Functor

Has Models

ArrangementDirectionalXMonotoneTraits_2::Intersect_2

Output_iterator *fo.operator()(ArrDirectionalTraits::X_monotone_curve_2 xc1, ArrDirectionalTraits::X_monotone_curve_2 xc2, Output_iterator& oi)*

computes the intersections of *xc1* and *xc2* and inserts them *in an ascending lexicographic xy-order* into the output iterator *oi*. The value-type of *Output_iterator* is *CGAL::Object*, where each *Object* wraps either a *pair<ArrDirectionalTraits::Point_2, ArrDirectionalTraits::Multiplicity>* object, which represents an intersection point with its multiplicity (in case the multiplicity is undefined or unknown, it is set to 0) or an *ArrDirectionalTraits::X_monotone_curve_2* object, representing an overlapping subcurve of *xc1* and *xc2*. In the latter case, the overlapping subcurves are given the direction of *xc1* and *xc2* if their directions are identical. Otherwise, the overlapping subcurves are given an arbitrary direction. The operator returns a past-the-end iterator for the output sequence.

ArrDirectionalTraits::Split_2

Refines

Functor

Has Models

ArrangementDirectionalXMonotoneTraits_2::Split_2

void *fo.operator()(ArrDirectionalTraits::X_monotone_curve_2 xc,*
ArrDirectionalTraits::Point_2 p,
ArrDirectionalTraits::X_monotone_curve_2& xc1,
ArrDirectionalTraits::X_monotone_curve_2& xc2)

accepts an input curve *xc* and a split point *p* in its interior. It splits *xc* at the split point into two subcurves *xc1* and *xc2*, such that *p* is *xc1*'s *right* endpoint and *xc2*'s *left* endpoint. The direction of *xc* is preserved. That is, in case *xc* is directed from left to right, *p* becomes *xc1*'s target and *c2*'s source; otherwise, *p* becomes *xc2*'s target and *xc1*'s source.

Concept

ArrDirectionalTraits::AreMergeable_2

Refines

Functor

Has Models

ArrangementDirectionalXMonotoneTraits_2::Are_mergeable_2

bool *fo.operator()(ArrDirectionalTraits::X_monotone_curve_2 xc1, ArrDirectionalTraits::X_monotone_curve_2 xc2)*

accepts two x-monotone curves *xc1* and *xc2* and determines whether they can be merged to form a single x-monotone curve. *xc1* and *xc2* are mergeable if their underlying curves are identical, they share a common endpoint, and they do not bend to form a non-x-monotone curve.
Precondition: The target point of *xc1* and the source point *xc2* coincide or the source point of *xc2* and the target point *xc2* coincide.

ArrDirectionalTraits::Merge_2

Refines

Functor

Has Models

ArrangementDirectionalXMonotoneTraits_2::Merge_2

void *fo.operator()(ArrDirectionalTraits::X_monotone_curve_2 xc1, ArrDirectionalTraits::X_monotone_curve_2 xc2, ArrDirectionalTraits::X_monotone_curve_2& xc)*

accepts two *mergeable* *x*-monotone curves *xc1* and *xc2* and asigns *xc* with the merged curve. If the target point of *xc1* and the source point of *xc2* coincide; then the source point of *xc1* and the target point of *xc2* become the source and target points of *xc*, respectively. If the target point of *xc2* and the source point of *xc1* coincide; then the source point of *xc2* and the target point of *xc1* become the source and target points of *xc*, respectively.
Precondition: *are_mergeable_2*(*xc1*, *xc2*) is true.

Concept

ArrDirectionalTraits::CompareEndpointsXy_2

Refines

Functor

Has Models

ArrangementDirectionalXMonotoneTraits_2::CompareEndpointsXy_2

Comparison_result *fo(ArrDirectionalTraits::X_monotone_curve_2 xc)*

accepts an input curve *xc* and compares its source and target points. It returns *SMALLER* if the curve is directed from lexicographically left to right, and *LARGER* if it is directed from lexicographically right to left.

ArrDirectionalTraits::ConstructOpposite_2

Concept

Refines

Functor

Has Models

ArrangementDirectionalXMonotoneTraits_2::ConstructOpposite_2

ArrDirectionalTraits::X_monotone_curve_2

fo(ArrDirectionalTraits::X_monotone_curve_2 xc)

accepts an x-monotone curve *xc* and returns its opposite curve, namely a curve whose graph is the same as *xc*'s, and whose source and target are swapped with respect to *xc*'s source and target.

Concept

GeneralPolygonSetTraits_2

Definition

This concept defines the minimal set of geometric predicates needed to perform the Boolean-set operations. It refines the directional x-monotone arrangement-traits concept. In addition to the *Point_2* and *X_monotone_curve_2* types defined in the generalized concept, it defines a type that represents a general polygon and another one that represents general polygon with holes. It also requires operations that operate on these types.

Refines

ArrangementDirectionalXMonotoneTraits_2

Types

GeneralPolygonSetTraits_2:: Polygon_2	represents a general polygon. Must be a model of the *GpsTraitsGeneralPolygon_2* concept.
GeneralPolygonSetTraits_2:: Polygon_with_holes_2	represents a general polygon with holes. Must be a model of the *GpsTraitsGeneralPolygonWithHoles_2* concept.
GeneralPolygonSetTraits_2:: Curve_const_iterator	A const iterator of curves. Its value type is const *X_monotone_curve_2*.

Functor Types

GeneralPolygonSetTraits_2:: Construct_polygon_2

a functor that constructs a general polygon from a range of x-monotone curves. It uses the operator
void operator() (InputIterator begin, Input iterator end, Polygon_2 & pgn),
parameterized by the *InputIterator* type.

GeneralPolygonSetTraits_2:: Construct_general_polygon_with_holes_2

a functor that constructs a general polygon with holes from a general polygon and, optionally, a range of holes. It uses the operator
void operator() (const General_polygon_2& pgn_boundary) or
void operator() (const General_polygon_2& pgn_boundary, HolesInputIterator h_begin, HolesInputIterator h_end) parameterized by the *HolesInputIterator* type.

GeneralPolygonSetTraits_2:: Construct_outer_boundary

A functor for constructing the outer boundary of a polygon with holes. It uses the operator
General_polygon_2 operator()(const General_polygon_with_holes_2& pol_wh).

GeneralPolygonSetTraits_2:: Construct_holes	A functor for constructing the container of holes of a polygon with holes. It returns the begin/end iterators for the holes It uses the operator *std::pair<Hole_const_iterator, Hole_const_iterator> operator()(const General_polygon_with_holes_2& pol_wh).*
GeneralPolygonSetTraits_2:: Is_unbounded	A functor for checking if polygon with holes has no outer boundary. It uses the operator *bool operator()(const General_polygon_with_holes_2& pol_wh).*

Creation

GeneralPolygonSetTraits_2 traits; — default constructor.

GeneralPolygonSetTraits_2 traits(other); — copy constructor

GeneralPolygonSetTraits_2

traits = other — assignment operator.

Accessing Functor Objects

Construct_polygon_2 *traits.construct_polygon_2_object()*

returns a functor that constructs a polygon.

Construct_curves_2 *traits.construct_curves_2_object()*

returns a functor that obtains the curves of a polygon.

Construct_general_polygon_with_holes_2

traits.construct_polygon_with_holes_2_object() const

returns a functor that constructs a polygon with holes.

Construct_outer_boundary

traits.construct_outer_boundary_object() const

returns a functor that obtains the outer boundary of a polygon with holes.

Construct_holes *traits.construct_holes_object() const*

returns a functor that obtains begin/end iterators over a container of holes.

Is_unbounded	*traits.construct_is_unbounded_object()*	
		returns a functor that determines if the polygon with holes is unbounded

CGAL::General_polygon_2<ArrTraits>

Class

Definition

The class *General_polygon_2<ArrTraits>* models the concept *GeneralPolygon_2*. It represents a simple general-polygon. It is parameterized with the type *ArrTraits* that models the concept *ArrangementDirectionalXMonotoneTraits*. The latter is a refinement of the concept *ArrangementXMonotoneTraits_2*. In addition to the requirements of the concept *ArrangementXMonotoneTraits_2*, a model of the concept *ArrangementDirectionalXMonotoneTraits* must support the following functions:

- Given an x-monotone curve, construct its opposite curve.
- Given an x-monotone curve, compare its two endpoints lexicographically.

This class supports a few convenient operations in addition to the requirements that the concept *GeneralPolygon_2* lists.

#include <CGAL/General_polygon_2.h>

Types

General_polygon_2<ArrTraits>:: Size	number of edges size type.

Creation

Operations

Size	*polygon.size()*	returns the number of edges of *polygon*.

Modifiers

void	*polygon.clear()*	clears *polygon*.
void	*polygon.reverse_orientation()*	reverses the orientation of the polygon. *Precondition*: *is_simple()*.

Predicates

bool	*polygon.is_empty()*	returns *true* if *polygon* is empty, and *false* otherwise.
Orientation	*polygon.orientation()*	returns the orientation of *polygon*. *Precondition*: *is_simple()*.

Is Model for the Concepts

GeneralPolygon_2

Class

CGAL::Polygon_with_holes_2<Kernel,Container>

Definition

The class *Polygon_with_holes_2<Kernel,Container>* models the concept *GeneralPolygonWithHoles_2*. It represents a linear polygon with holes. It is parameterized with two types (*Kernel* and *Container*) that are used to instantiate the type *CGAL::Polygon_2<Kernel,Container>*. The latter is used to represents the outer boundary and the boundary of the holes (if any exist).

#include <CGAL/Polygon_with_holes_2.h>

Is Model for the Concepts

GeneralPolygonWithHoles_2

CGAL::Polygon_set_2<Kernel,Container,Dcel>

Definition

The class *Polygon_set_2<Kernel,Container,Dcel>* represents sets of linear polygons with holes. The first two template parameters (*Kernel* and *Container*) are used to instantiate the type *CGAL::Polygon_2< Kernel,Container>*. This type is used to represents the outer boundary of every set member and the boundaries of all holes of every set member.

The third template parameter *Dcel* should be instantiated with a model of the concept *GeneralPolygonSetDcel*. It is instantiated by default with the type *Gps_default_dcel<Traits>*. You can override this default, with a different DCEL class, typically an extension of the *Gps_default_dcel* class template. Overriding the default is necessary only if you intend to obtain the underlying internal arrangement and process it further.

#include <CGAL/Polygon_set_2.h>

Class

CGAL::General_polygon_with_holes_2<Polygon>

Definition

The class *General_polygon_with_holes_2<Polygon>* models the concept *GeneralPolygonWithHoles_2*. It represents a general polygon with holes. It is parameterized with a type *Polygon* used to define the exposed type *General_polygon_2*. This type represents the outer boundary of the general polygon and the outer boundaries of each hole.

#include <CGAL/General_polygon_with_holes_2.h>

typedef Polygon	*General_polygon_2;*

Is Model for the Concepts

GeneralPolygonWithHoles_2

CGAL::Gps_segment_traits_2<Kernel,Container,ArrSegmentTraits>

Class

Definition

The traits class *Gps_segment_traits_2<Kernel,Container,ArrSegmentTraits>* models the concept *GeneralPolygonSetTraits_2*. It enables Boolean set-operations on (linear) polygons. It defines the exposed type *Polygon_2* to be *CGAL::Polygon_2<Kernel,Container>*. By default, the template parameter *Container* is instantiated by *std::vector<Kernel::Point_2>* and the template parameter *ArrSegmentTraits* is instantiated by *CGAL::Arr_segment_traits_2<Kernel>*.

#include <CGAL/Gps_segment_traits_2.h>

typedef CGAL::Polygon_2<Kernel,Container>

Polygon_2;

CGAL::Arr_circle_segment_traits_2<Kernel>(page **??**)

CGAL::Gps_traits_2<ArrTraits,GeneralPolygon_t>

Class

Definition

The traits class *Gps_traits_2<ArrTraits,GeneralPolygon_t>* models the concept *GeneralPolygonSetTraits_2*. It inherits from the instantiated type of the template parameter *ArrTraits*, which must model the concept *ArrangementDirectionalXMonotoneTraits*, (which in turn refines the concept *ArrangementXMonotoneTraits*). The template parameter *GeneralPolygon_t* must be instantiated with a model of the concept of *GpsTraitsGeneralPolygon_2*. By default, the latter is instantiated by *CGAL::General_polygon_2<ArrTraits>* .

#include <CGAL/Gps_traits_2.h>

Is Model for the Concepts

GeneralPolygonSetTraits_2

Class

CGAL::Gps_default_dcel<Traits>

Definition

The class *Gps_default_dcel<Traits>* is the default DCEL class used by the *General_polygon_set_2* and *Polygon_set_2* class-templates to represent the underlying internal *Arrangement_2* data structure.

#include <CGAL/Boolean_set_operations_2/Gps_default_dcel.h>

Is Model for the Concepts

GeneralPolygonSetDcel

Inherits From

Arr_dcel_base<Arr_vertex_base<typename Traits_::Point_2>,
Arr_halfedge_base<typename Traits_::X_monotone_curve_2>,
Gps_face_base>

Types

Gps_default_dcel<Traits>:: template <class T> rebind

allows the rebinding of the DCEL with a different traits class T.

GeneralPolygonSetDcel

Concept

Definition

A doubly-connected edge-list (DCEL for short) data-structure. It consists of three containers of records: vertices V, halfedges E, and faces F. It maintains the incidence relation among them. The halfedges are ordered in pairs sometimes referred to as twins, such that each halfedge pair represent an edge.

A model of the GeneralPolygonSetDcel concept must provide the following types and operations. (In addition to the requirements here, the local types *Vertex*,*Halfedge*, *Face Hole* and *Isolated_vertex* must be models of the concepts *ArrangementDcelVertex*(page 2236), *ArrangementDcelHalfedge*(page 2238), *GeneralPolygonSetDcelFace* (page 1544), *ArrangementDcelHole*(page 2243), and *ArrangementDcelIsolatedVertex* (page 2244) respectively.) Notice that this concept differs from the concept *ArrangemenDcel* only in the type *Face*.

Types

GeneralPolygonSetDcel:: Vertex	the vertex type.
GeneralPolygonSetDcel:: Halfedge	the halfedge type.
GeneralPolygonSetDcel:: Face	the face type.
GeneralPolygonSetDcel:: Hole	the hole type.
GeneralPolygonSetDcel:: Isolated_vertex	the isolated vertex type.
GeneralPolygonSetDcel:: Size	used to represent size values (e.g., *size_t*).
GeneralPolygonSetDcel:: Vertex_iterator	a bidirectional iterator over the vertices. Its value-type is *Vertex*.
GeneralPolygonSetDcel:: Halfedge_iterator	a bidirectional iterator over the halfedges. Its value-type is *Halfedge*.
GeneralPolygonSetDcel:: Face_iterator	a bidirectional iterator over the faces. Its value-type is *Face*.

The non-mutable iterators *Vertex_const_iterator*, *Halfedge_const_iterator* and *Face_const_iterator* are also defined.

Creation

GeneralPolygonSetDcel dcel; — constructs an empty DCEL with one unbounded face.

*Face** *dcel.assign(Self other, const Face *uf)*

assigns the contents of the *other* DCEL whose unbounded face is given by *uf*, to *dcel*. The function returns a pointer to the unbounded face of *dcel* after the assignment.

Access Functions

Size *dcel.size_of_vertices() const*

returns the number of vertices.

Size *dcel.size_of_halfedges() const*

returns the number of halfedges (always even).

Size *dcel.size_of_faces() const*

returns the number of faces.

Size *dcel.size_of_holes() const*

returns the number of holes (the number of connected components).

Size *dcel.size_of_isolated_vertices() const*

returns the number of isolated vertices.

The following operations have an equivalent *const* operations that return the corresponding non-mutable iterators:

Vertex_iterator *dcel.vertices_begin()* returns a begin-iterator of the vertices in *dcel*.
Vertex_iterator *dcel.vertices_end()* returns a past-the-end iterator of the vertices in *dcel*.

Halfedge_iterator *dcel.halfedges_begin()*

returns a begin-iterator of the halfedges in *dcel*.

Halfedge_iterator *dcel.halfedges_end()* returns a past-the-end iterator of the halfedges in *dcel*.

Vertex_iterator *dcel.faces_begin()* returns a begin-iterator of the faces in *dcel*.
Vertex_iterator *dcel.faces_end()* returns a past-the-end iterator of the faces in *dcel*.

Modifiers

The following operations allocate a new element of the respective type. Halfedges are always allocated in pairs of opposite halfedges. The halfedges and their opposite pointers are automatically set.

*Vertex** *dcel.new_vertex()* creates a new vertex.
*Halfedge** *dcel.new_edge()* creates a new pair of twin halfedges.
*Face** *dcel.new_face()* creates a new face.
*Hole** *dcel.new_hole()* creates a new hole record.
*Isolated_vertex** *dcel.new_isolated_vertex()*

creates a new isolated vertex record.

void *dcel.delete_vertex(Vertex* v)*

deletes the vertex *v*.

void	*dcel.delete_edge(Halfedge* e)*	
		deletes the halfedge *e* as well as its twin.
void	*dcel.delete_face(Face* f)*	
		deletes the face *f*.
void	*dcel.delete_hole(Hole* ho)*	
		deletes the hole *ho*.
void	*dcel.delete_isolated_vertex(Isolated_vertex* iv)*	
		deletes the isolated vertex *iv*.

Concept

GeneralPolygonSetDcelFace

Definition

A face record in a DCEL data structure used by the *General_polygon_set_2* and *Polygon_set_2* class-templates to represent the underlying internal *Arrangement_2* data structure.

Refines

ArrangementDcelFace

Creation

GeneralPolygonSetDcelFace f;		default constructor.
void	*f.assign(Self other)*	assigns *f* with the contents of the *other* face.

Access Functions

bool	*f.contained() const*	returns *true* if the face is contained in the general-polygon set, and *false* otherwise.
bool	*f.visited()*	returns *true* if the face has been visited, and *false* otherwise. This is used internally by the some of the operations of the *General_polygon_set_2* class that traverse the arrangement faces.

Modifiers

void	*f.set_contained(bool flag)*	marks the face as contained (if *flag* is *true*), or as a hole (if it is *false*).
void	*f.set_visited(bool flag)*	marks the face as visited (if *flag* is *true*), or as not visited (if it is *false*). This is used internally by the some of the operations of the *General_polygon_set_2* class that traverse the arrangement faces.

CGAL::complement

Definition

#include <CGAL/Boolean_set_operations_2.h>

void *complement(Type pgn, Type & res)*

Each one of these functions computes the complement of a given polygon *pgn*, and stores the resulting polygon with holes in *res*.

Arg Type
Polygon_2
General_polygon_2

OutputIterator *complement(Type pgn, OutputIterator oi)*

Each one of these functions computes the complement of a given polygon *pgn*, inserts the resulting polygons with holes into an output container through a given output iterator *oi*, and returns the output iterator. The value type of the *OutputIterator* is either *Polygon_with_holes_2* or *General_polygon_with_holes_2*.

Arg Type
Polygon_with_holes_2
General_polygon_with_holes_2

```
template <class Kernel, class Container>
void            complement( Polygon_2<Kernel, Container> pgn,
                            Polygon_with_holes_2<Kernel, Container> & res)

template <class Traits>
void            complement( General_polygon_2<Traits> pgn,
                            General_polygon_with_holes_2<Traits> & res)

template <class Traits, class OutputIterator>
OutputIterator  complement( Polygon_with_holes_2<Kernel, Container> pgn, OutputIterator oi)
template <class Traits, class OutputIterator>
OutputIterator  complement( General_polygon_with_holes_2<General_polygon_2<Traits> > pgn,
                            OutputIterator oi)
```

CGAL::difference

Definition

```
#include <CGAL/Boolean_set_operations_2.h>
```

```
OutputIterator    difference( Type1 p1, Type2 p2, OutputIterator oi)
```

Each one of these functions computes the difference between two given polygons *p1* and *p2*, and inserts the resulting polygons with holes into an output container through the output iterator *oi*. The value type of the *OutputIterator* is either *Polygon_with_holes_2* or *General_polygon_with_holes_2*.

Arg 1 Type	Arg 2 Type

CGAL::do_intersect

Definition

#include <CGAL/Boolean_set_operations_2.h>

bool *do_intersect(Type1 p1, Type2 p2)*

Each one of these functions return *true*, if the two given polygons *p1* and *p2* intersect in their interior, and *false* otherwise.

Arg 1 Type	**Arg 2 Type**
Polygon_2	*Polygon_2*
Polygon_2	*Polygon_with_holes_2*
Polygon_with_holes_2	*Polygon_2*
Polygon_with_holes_2	*Polygon_with_holes_2*
General_polygon_2	*General_polygon_2*
General_polygon_2	*General_polygon_with_holes_2*
General_polygon_with_holes_2	*General_polygon_2*
General_polygon_with_holes_2	*General_polygon_with_holes_2*

template <class Kernel, class Container>
bool *do_intersect(Polygon_2<Kernel, Container> p1, Polygon_2<Kernel, Container> p2)*
template <class Kernel, class Container>
bool *do_intersect(Polygon_2<Kernel, Container> p1, Polygon_with_holes_2<Kernel, Container> p2)*
template <class Kernel, class Container>

bool *do_intersect(General_polygon_with_holes_2<Polygon> p1,*
General_polygon_with_holes_2<Polygon> p2)

template <class InputIterator>
bool *do_intersect(InputIterator begin, InputIterator end)*

Returns *true*, if the set of general polygons (or general polygons with holes) in the given range intersect in their interior, and *false* otherwise. (The value type of the input iterator is used to distinguish between the two).

template <class InputIterator1, class InputIterator2>
bool do_intersect(InputIterator1 pgn_begin1,
InputIterator1 pgn_end1,
InputIterator2 pgn_begin2,
InputIterator2 pgn_end2)

Returns *true*, if the set of general polygons and general polygons with holes in the given two ranges respectively intersect in their interior, and *false* otherwise.

General_polygon_with_holes_2<Polygon> p2,
OutputIterator oi)

template <class InputIterator, class OutputIterator>
OutputIterator intersection(InputIterator begin, InputIterator end, OutputIterator oi)

Computes the intersection of the general polygons (or general polygons with holes) in the given range. (The value type of the input iterator is used to distinguish between the two.) The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon_with_holes_2*.

template <class InputIterator1, class InputIterator2, class OutputIterator>
OutputIterator intersection(InputIterator1 pgn_begin1,
InputIterator1 pgn_end1,
InputIterator2 pgn_begin2,
InputIterator2 pgn_end2,
OutputIterator oi)

Computes the intersection of the general polygons and general polygons with holes in the given two ranges. The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon_with_holes_2*.

template <class Kernel, class Container>
bool        join( Polygon_with_holes_2<Kernel, Container> p2,
                  Polygon_with_holes_2<Kernel, Container> p1,
                  General_polygon_with_holes_2<Polygon_2<Kernel, Container> > & p)

template <class Traits>
bool        join( General_polygon_2<Traits> p1,
                  General_polygon_2<Traits> p2,
                  General_polygon_with_holes_2<General_polygon_2<Traits> > & p)

template <class Traits>
bool        join( General_polygon_2<Traits> p1,
                  General_polygon_with_holes_2<General_polygon_2<Traits> > p2,
                  General_polygon_with_holes_2<General_polygon_2<Traits> > & p)
```

template <class Traits>
bool *join(General_polygon_with_holes_2<General_polygon_2<Traits> > p2, General_polygon_2<Traits> p1, General_polygon_with_holes_2<General_polygon_2<Traits> > & p)*

template <class Polygon>
bool *join(General_polygon_with_holes_2<Polygon> p1, General_polygon_with_holes_2<Polygon> p2, Traits::Polygon_with_holes_2 & p)*

template <class InputIterator, class OutputIterator>
OutputIterator *join(InputIterator begin, InputIterator end, OutputIterator oi)*

Computes the union of the general polygons (or general polygons with holes) in the given range. (The value type of the input iterator is used to distinguish between the two.) The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon_with_holes_2*.

template <class InputIterator1, class InputIterator2, class OutputIterator>
OutputIterator *join(InputIterator1 pgn_begin1, InputIterator1 pgn_end1, InputIterator2 pgn_begin2, InputIterator2 pgn_end2, OutputIterator oi)*

Computes the union of the general polygons and general polygons with holes in the given two ranges. The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon_with_holes_2*.

CGAL::symmetric_difference

Definition

#include <CGAL/Boolean_set_operations_2.h>

OutputIterator intersection(Type1 p1, Type2 p2, OutputIterator oi)

Each one of these functions computes the symmetric difference between two given polygons *p1* and *p2*, and inserts the resulting polygons with holes into an output container through the output iterator *oi*. The value type of the *OutputIterator* is either *Polygon_with_holes_2* or *General_polygon_with_holes_2*.

CGAL::connect_holes

Function

Definition

#include <CGAL/connect_holes.h>

template <class Kernel, class Container, class OutputIterator>
OutputIterator *connect_holes(Polygon_with_holes_2<Kernel,Container> pwh, OutputIterator oi)*

Connects the holes of *pwh* with its outer boundary. This is done by locating the topmost vertex in each hole in the polygon with holes *pwh*, and connecting it by a vertical segment to the polygon feature located directly above it (a vertex or an edge of the outer boundary, or of another hole). The function produces an output sequence of points, which corresponds to the traversal of the vertices of the input polygon; this traversal starts from the outer boundary and moves to the holes using the auxiliary vertical segments that were added to connect the polygon with its holes. The value-type of *oi* is *Kernel::Point_2*.

Precondition: The input polygon with holes *pwh* is bounded (namely it has a valid outer boundary).

Function

CGAL::operator<<

Definition

This operator exports a polygon with holes, a general polygon, or a general polygon with holes *P* to the output stream *out*. The output is in ASCII format.

An ASCII and a binary format exist. The format can be selected with the CGAL modifiers for streams, *set_ascii_mode* and *set_binary_mode* respectively. The modifier *set_pretty_mode* can be used to allow for (a few) structuring comments in the output. Otherwise, the output would be free of comments. The default for writing is ASCII without comments.

#include <CGAL/Polygon_with_holes_2.h> *template <class Kernel, class Container>*

ostream& *ostream& out << CGAL::Polygon_with_holes_2<Kernel,Container> P*

The number of points of the outer boundary is exported followed by the points themselves in counterclockwise order. Then, the number of holes is exported, and for each hole, the number of points on its outer boundary is exported followed by the points themselves in clockwise order.

#include <CGAL/General_polygon_2.h> *template <class ArrTraits>*

ostream& *ostream& out << CGAL::General_polygon_2<ArrTraits> P*

The number of curves of the outer boundary is exported followed by the curves themselves in counterclockwise order.

#include <CGAL/General_polygon_with_holes_2.h> *template <class Polygon>*

ostream& *ostream& out << CGAL::General_polygon_with_holes_2<Polygon> P*

The number of curves of the outer boundary is exported followed by the curves themselves in counterclockwise order. Then, the number of holes is exported, and for each hole, the number of curves on its outer boundary is exported followed by the curves themselves in clockwise order.

CGAL::operator>>

Function

Definition

This operator imports a polygon with holes, a general polygon, or a general polygon with holes from the input stream *in*.

An ASCII and a binary format exist. The stream detects the format automatically and can read both.

#include <CGAL/Polygon_with_holes_2.h> *template <class Kernel, Class Container>*

istream& *istream& in >> CGAL::Polygon_with_holes_2<Kernel, Container>& P*

The format consists of the number of points of the outer boundary followed by the points themselves in counterclockwise order, followed by the number of holes, and for each hole, the number of points of the outer boundary is followed by the points themselves in clockwise order.

#include <CGAL/General_polygon_2.h> *template <class ArrTraits>*

istream& *istream& in >> CGAL::General_polygon_2<ArrTraits>& P*

The format consists of the number of curves of the outer boundary followed by the curves themselves in counterclockwise order.

#include <CGAL/General_polygon_with_holes_2.h> *template <class Polygon>*

istream& *istream& in >> CGAL::General_polygon_with_holes_2<Polygon>& P*

The format consists of the number of curves of the outer boundary followed by the curves themselves in counterclockwise order, followed by the number of holes, and for each hole, the number of curves on its outer boundary is followed by the curves themselves in clockwise order.

Chapter 20

2D Boolean Operations on Nef Polygons

Michael Seel

Contents

20.1 Introduction

When working with polygonal and polyhedral sets, the mathematical model determines the kind of point set that can be represented. Nef polyhedra are the most general rectilinear polyhedral model.

Topological simpler models that are contained in the domain of Nef polyhedra are:

- *convex polytopes* normally defined as the convex hull of a nonempty finite set of points. Convex polytopes are compact closed and manifold sets.
- *elementary polyhedra* normally defined as the union of a finite number of convex polytopes.
- *polyhedral sets* nomally defined as the intersection of a finite number of closed halfspaces. Such sets are closed and convex but need not to be compact.
- *linear polyhedra* normally defined as the set of all points belonging to the simplices of a *simplicial complex*.

A planar *Nef polyhedron* is any set that can be obtained from a finite set of open halfspaces by set complement and set intersection operations. Due to the fact that all other binary set operations like union, difference and symmetric difference can be reduced to intersection and complement calculations, Nef polyhedra are also closed under those operations. Apart from the set complement operation there are more topological unary set operations that are closed in the domain of Nef polyhedra. Given a Nef polyhedron one can determine its interior, its boundary, and its closure, and also composed operations like regularization (defined to be the closure of the interior or a point set).

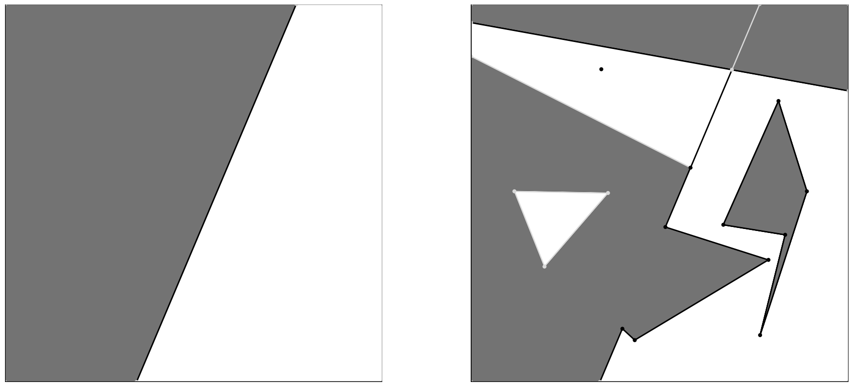

Figure 20.1: Two Nef polyhedra in the plane. A closed halfspace on the left and a complex polyhedron on the right. Note that the points on the squared boundary are at infinity.

20.2 Construction and Composition

Following the above definition, the data type *Nef_polyhedron_2<T>* allows construction of elementary Nef polyhedra and the binary and unary composition by the mentioned set operations.

In the following examples skip the typedefs at the beginning at first and take the types *Point* and *Line* to be models of the standard two-dimensional CGAL kernel (*CGAL::Point_2<K>* and *CGAL::Line_2<K>*). Their user interface is thus defined in the corresponding reference pages.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Filtered_extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_2.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Filtered_extended_homogeneous<RT> Extended_kernel;
typedef CGAL::Nef_polyhedron_2<Extended_kernel> Nef_polyhedron;
typedef Nef_polyhedron::Point Point;
typedef Nef_polyhedron::Line  Line;

int main() {

  Nef_polyhedron N1(Nef_polyhedron::COMPLETE);

  Line l(2,4,2); // l : 2x + 4y + 2 = 0
  Nef_polyhedron N2(l,Nef_polyhedron::INCLUDED);
  Nef_polyhedron N3 = N2.complement();
  CGAL_assertion(N1 == N2.join(N3));

  Point p1(0,0), p2(10,10), p3(-20,15);
  Point triangle[3] = { p1, p2, p3 };
  Nef_polyhedron N4(triangle, triangle+3);
  Nef_polyhedron N5 = N2.intersection(N4);
```

```
  CGAL_assertion(N5 <= N2 && N5 <= N4);

  return 0;
}
```

File: examples/Nef_2/nef_2_construction.cpp

Planar halfspaces (as used in the definition) are modelled by oriented lines. In the previous example *N1* is the Nef polyhedron representing the full plane, *N2* is the closed halfspace left of the oriented line with equation $2x+4y+2=0$ including the line, *N3* is the complement of *N2* and therefore it must hold that $N2 \cup N3 = N1$.

Additionally one can construct Nef polyhedra from iterator ranges that hold simple polygonal chains. In the example *N4* is the triangle spanned by the vertices $(0,0)$, $(10,10)$, $(-20,15)$. Note that the construction from a simple polygonal chain has several cases and preconditions that are described in the reference manual page of *Nef_polyhedron_2<T>*. The *operator<=* in the last assertion is a subset-or-equal comparison of two polyhedra.

Nef polyhedra have input and output operators that allows one to output them via streams and read them from streams. Graphical output is currently possible. For an elaborate example see the demo programs in the directory *demo/Nef_2*.

20.3 Exploration

By recursively composing binary and unary operations one can end with a very complex rectilinear structure. To explore that structure there is a data type *Nef_polyhedron_2<T>::Explorer* that allows read-only exploration of the rectilinear structure. To understand its usability we need more knowledge about the representation of Nef polyhedra.

The rectilinear structure underlying a Nef polyhedron is stored in a selective plane map. Plane map here means a straightline embedded bidirected graph with face objects such that each point in the plane can be uniquely assigned to an object (vertex, edge, face) of the planar subdivision defined by the graph. Selective means that each object (vertex, edge, face) has a Boolean value associated with it to indicate set inclusion or exclusion.

The plane map is defined by the interface data type *Nef_polyhedron_2<T>::Topological_explorer*. Embedding the vertices by standard affine points does not suffice to model the unboundedness of halfspaces and ray-like structures. Therefore the planar subdivision is bounded symbolically by an axis-parallel square box of infimaximal size centered at the origin of our coordinate system. All structures extending to infinity are pruned by the box. Lines and rays have symbolic endpoints on the box. Faces are circularly closed. Infimaximal here means that its geometric extend is always large enough (but finite for our intuition). Assume you approach the box with an affine point, then this point is always inside the box. The same holds for straight lines; they always intersect the box. There are more accurate notions of “large enough”, but the previous propositions are enough at this point. Due to the fact that the infimaximal box is included in the plane map, the vertices and edges are partitioned with respect to this box.

Vertices inside the box are called standard vertices and they are embedded by affine points of type *Explorer::Point*. Vertices on the box are called non-standard vertices and they get their embedding where a ray intersects the box (their embedding is defined by an object of type *Explorer::Ray*). By their straightline embedding, edges represent either segments, rays, lines, or box segments depending on the character of their source and target vertices.

During exploration, box objects can be tracked down by the interface of *Nef_polyhedron_2<T>::Explorer* that is derived from *Nef_polyhedron_2<T>::Topological_explorer* and adds just the box exploration functionality to the interface of the latter. In the following code fragment we iterate over all vertices of a Nef polyhedron and check whether their embedding is an affine point or a point on the infimaximal frame.

```
typedef Nef_polyhedron::Explorer Explorer;
Explorer E = N4.explorer();
Explorer::Vertex_const_iterator v;
for (v = E.vertices_begin(); v != E.vertices_end(); ++v)
  if ( E.is_standard(v) )
    Explorer::Point p = E.point(v) // affine embedding of v
  else /* non-standard */
    Explorer::Ray r = E.ray(v) // extended embedding of v
```

Note that box edges only serve as boundary edges (combinatorically) to close the faces that extend to infinity (geometrically). Their status can be queried by the following operation:

```
typedef Nef_polyhedron::Explorer Explorer;
Explorer E = N4.explorer();
Explorer::Halfedge_const_iterator e;
for (e = E.halfedges_begin(); e != E.halfedges_end(); ++e)
  if ( E.is_frame_edge(e) ) // e is part of square box.
```

20.4 Traits Classes

Now finally we clarify what the template parameter of class *Nef_polyhedron_2<T>* actually models. *T* carries the implementation of a so-called extended geometric kernel.

Currently there are three kernel models: *CGAL::Extended_cartesian<FT>*, *CGAL::Extended_homogeneous<RT>*, and *CGAL::Filtered_extended_homogeneous<RT>*. The latter is the most optimized one. The former two are simpler versions corresponding to the simple planar affine kernels. Actually, it holds that (type equality in pseudo-code notation):

```
CGAL::Nef_polyhedron_2< CGAL::Extended_cartesian<FT> >::Point
  == CGAL::Cartesian<FT>::Point_2

CGAL::Nef_polyhedron_2< CGAL::Extended_homogeneous<RT> >::Point
   == CGAL::Homogeneous<RT>::Point_2

CGAL::Nef_polyhedron_2< CGAL::Filtered_extended_homogeneous<RT> >::Point
   == CGAL::Homogeneous<RT>::Point_2
```

Similar equations hold for the types *Line* and *Direction* in the local scope of *Nef_polyhedron_2<...>*.

advanced

For its notions and requirements see the desciption of the concept *ExtendedKernelTraits_2* in the reference manual.

advanced

20.5 Implementation

The underlying set operations are realized by an efficient and complete algorithm for the overlay of two plane maps. The algorithm is efficient in the sense that its running time is bounded by the size of the inputs plus the size of the output times a logarithmic factor. The algorithm is complete in the sense that it can handle all inputs and requires no general position assumption.

2D Boolean Operations on Nef Polygons Reference Manual

Michael Seel

Planar Nef Polyhedra are whatever can be constructed with a finite number of Boolean operations on halfspaces. See the user manual pages for a detailed introduction.

Classes

20.7 Alphabetical List of Reference Pages

Class

CGAL::Nef_polyhedron_2<T>

Definition

An instance of data type *Nef_polyhedron_2<T>* is a subset of the plane that is the result of forming complements and intersections starting from a finite set *H* of halfspaces. *Nef_polyhedron_2* is closed under all binary set operations *intersection*, *union*, *difference*, *complement* and under the topological operations *boundary*, *closure*, and *interior*.

The template parameter *T* is specified via an extended kernel concept. *T* must be a model of the concept *ExtendedKernelTraits_2*.

#include <CGAL/Nef_polyhedron_2.h>

Types

Nef_polyhedron_2<T>:: Line	the oriented lines modeling halfplanes
Nef_polyhedron_2<T>:: Point	the affine points of the plane.
Nef_polyhedron_2<T>:: Direction	directions in our plane.
Nef_polyhedron_2<T>:: Polygons_tag	tag for calling polygon constructor.
Nef_polyhedron_2<T>:: Polylines_tag	tag for calling polyline constructor.
enum Boundary { EXCLUDED, INCLUDED};	construction selection.
enum Content { EMPTY, COMPLETE};	construction selection

Creation

Nef_polyhedron_2<T> N(Content plane = EMPTY);

creates an instance *N* of type *Nef_polyhedron_2<T>* and initializes it to the empty set if *plane == EMPTY* and to the whole plane if *plane == COMPLETE*.

Nef_polyhedron_2<T> N(Line l, Boundary line = INCLUDED);

creates a Nef polyhedron *N* containing the halfplane left of *l* including *l* if *line==INCLUDED*, excluding *l* if *line==EXCLUDED*.

template <class Forward_iterator>
Nef_polyhedron_2<T> N(Forward_iterator it, Forward_iterator end, Boundary b = INCLUDED);

creates a Nef polyhedron *N* from the simple polygon *P* spanned by the list of points in the iterator range *[it,end)* and including its boundary if *b = INCLUDED* excluding the boundary otherwise. *Forward_iterator* has to be an iterator with value type *Point*. This construction expects that *P* is simple. The degenerate cases where *P* contains no point, one point or spans just one segment (two points) are correctly handled. In all degenerate cases there's only one unbounded face adjacent to the degenerate polygon. If *b == INCLUDED* then *N* is just the boundary. If *b == EXCLUDED* then *N* is the whole plane without the boundary.

template <class Forward_iterator>
Nef_polyhedron_2<T> N(Forward_iterator it, Forward_iterator end, Polygons_tag);

The iterator range [it, end) defines a set point ranges, each of which defines the boundary of simple polygon.

template <class Forward_iterator>
Nef_polyhedron_2<T> N(Forward_iterator it, Forward_iterator end, Polylines_tag);

The iterator range [it, end) defines a set point ranges, each of which defines a polyline.

Operations

void	*N.clear(Content plane = EMPTY)*	makes *N* the empty set if *plane == EMPTY* and the full plane if *plane == COMPLETE*.
bool	*N.is_empty()*	returns true if *N* is empty, false otherwise.
bool	*N.is_plane()*	returns true if *N* is the whole plane, false otherwise.

Constructive Operations

Nef_polyhedron_2<T>	*N.complement()*	returns the complement of *N* in the plane.
Nef_polyhedron_2<T>	*N.interior()*	returns the interior of *N*.
Nef_polyhedron_2<T>	*N.closure()*	returns the closure of *N*.
Nef_polyhedron_2<T>	*N.boundary()*	returns the boundary of *N*.
Nef_polyhedron_2<T>	*N.regularization()*	returns the regularized polyhedron (closure of interior).

Nef_polyhedron_2<T>	*N.intersection(N1)*	returns $N \cap N1$.
Nef_polyhedron_2<T>	*N.join(N1)*	returns $N \cup N1$. Note that "union" is a keyword of C++ and cannot be used for this operation.
Nef_polyhedron_2<T>	*N.difference(N1)*	returns $N - N1$.
Nef_polyhedron_2<T>	*N.symmetric_difference(N1)*	returns the symmectric difference *N - T* $\cup$ *T - N*.

Additionally there are operators **,+,-,^,!* which implement the binary operations *intersection*, *join*, *difference*, *symmetric difference*, and the unary operation *complement*, respectively. There are also the corresponding modification operations **=,+=,-=,^=*.

There are also comparison operations like *<,<=,>,>=,==,!=* which implement the relations subset, subset or equal, superset, superset or equal, equality, inequality, respectively.

Exploration - Point location - Ray shooting

As Nef polyhedra are the result of forming complements and intersections starting from a set H of halfspaces that are defined by oriented lines in the plane, they can be represented by an attributed plane map $M = (V,E,F)$. For topological queries within M the following types and operations allow exploration access to this structure.

Types

Nef_polyhedron_2<T>:: Explorer

a decorator to examine the underlying plane map. See the manual page of *Explorer*.

Nef_polyhedron_2<T>:: Object_handle

a generic handle to an object of the underlying plane map. The kind of object *(vertex, halfedge, face)* can be determined and the object can be assigned to a corresponding handle by the three functions:
bool assign(Vertex_const_handle& h, Object_handle)
bool assign(Halfedge_const_handle& h, Object_handle)
bool assign(Face_const_handle& h, Object_handle)
where each function returns *true* iff the assignment to *h* was done.

enum Location_mode { *DEFAULT, NAIVE, LMWT*}*;*

selection flagfor the point location mode. LMWT stands for Locally Minimum Weight Triangulation, a locally optimized constrained triangulation where the weight corresponds to the length of the edges of the triangulation.

Operations

bool *N.contains(Object_handle h)*

returns true iff the object h is contained in the set represented by N.

bool *N.contained_in_boundary(Object_handle h)*

returns true iff the object h is contained in the 1-skeleton of N.

Object_handle *N.locate(Point p, Location_mode m = DEFAULT)*

returns a generic handle h to an object (face, halfedge, vertex) of the underlying plane map that contains the point p in its relative interior. The point p is contained in the set represented by N if *N.contains(h)* is true. The location mode flag m allows one to choose between different point location strategies.

Object_handle *N.ray_shoot(Point p, Direction d, Location_mode m = DEFAULT)*

returns a handle h with *N.contains(h)*, that can be converted to a *Vertex_/Halfedge_/Face_const_handle* as described above. The object returned is intersected by the ray starting in p with direction d and has minimal distance to p. The operation returns an empty *Object_handle* if the ray shoot along d does not hit any object h of N with *N.contains(h)*. The location mode flag m allows one to choose between different point location strategies.

Object_handle *N.ray_shoot_to_boundary(Point p, Direction d, Location_mode m = DEFAULT)*

returns a handle h, that can be converted to a *Vertex_/Halfedge_const_handle* as described above. The object returned is part of the 1-skeleton of N, intersected by the ray starting in p with direction d and has minimal distance to p. The operation returns an empty *Object_handle* if the ray shoot along d does not hit any 1-skeleton object h of N. The location mode flag m allows one to choose between different point location strategies.

Explorer *N.explorer()*

returns a decorator object that allows read-only access of the underlying plane map. See the manual page *Explorer* for its usage.

Implementation

Nef polyhedra are implemented on top of a halfedge data structure and use linear space in the number of vertices, edges and facets. Operations like *empty* take constant time. The operations *clear*, *complement*, *interior*, *closure*, *boundary*, *regularization*, input and output take linear time. All binary set operations and comparison operations take time $O(n \log n)$ where n is the size of the output plus the size of the input.

The point location and ray shooting operations are implemented in two flavors. The *NAIVE* operations run in linear query time without any preprocessing, the *DEFAULT* operations (equals *LMWT*) run in sub-linear query time, but preprocessing is triggered with the first operation. Preprocessing takes time $O(N^2)$, the sub-linear point location time is either logarithmic when LEDA's persistent dictionaries are present or if not then the point location time is worst-case linear, but experiments show often sublinear runtimes. Ray shooting equals point location plus a walk in the constrained triangulation overlayed on the plane map representation. The cost of the walk is proportional to the number of triangles passed in direction d until an obstacle is met. In a minimum weight triangulation of the obstacles (the plane map representing the polyhedron) the theory provides a $O(\sqrt{n})$ bound for the number of steps. Our locally minimum weight triangulation approximates the minimum weight triangulation only heuristically (the calculation of the minimum weight triangulation is conjectured to be NP hard). Thus we have no runtime guarantee but a strong experimental motivation for its approximation.

Example

Nef polyhedra are parameterized by a so-called extended geometric kernel. There are three kernels, one based on a homogeneous representation of extended points called *Extended_homogeneous<RT>* where *RT* is a ring type providing additionally a *gcd* operation, one based on a Cartesian representation of extended points called *Extended_cartesian<NT>* where *NT* is a field type, and finally *Filtered_extended_homogeneous<RT>* (an optimized version of the first). The following example uses the filtered homogeneous kernel to construct the intersection of two halfspaces.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Filtered_extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_2.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Filtered_extended_homogeneous<RT> Extended_kernel;
typedef CGAL::Nef_polyhedron_2<Extended_kernel> Nef_polyhedron;
typedef Nef_polyhedron::Line  Line;

int main()
{
  Nef_polyhedron N1(Line(1,0,0));
  Nef_polyhedron N2(Line(0,1,0), Nef_polyhedron::EXCLUDED);
  Nef_polyhedron N3 = N1 * N2; // line (*)
  return 0;
}
```

File: `examples/Nef_2/nef_2_intersection.cpp`

After line (*) *N3* is the intersection of *N1* and *N2*. The member types of *Nef_polyhedron_2< Extended_homogeneous<NT> >* map to corresponding types of the standard CGAL geometry kernel (type equality in pseudo-code notation):

```
CGAL::Nef_polyhedron_2< CGAL::Extended_cartesian<FT> >::Point
  == CGAL::Cartesian<FT>::Point_2

CGAL::Nef_polyhedron_2< CGAL::Extended_homogeneous<RT> >::Point
   == CGAL::Homogeneous<RT>::Point_2

CGAL::Nef_polyhedron_2< CGAL::Filtered_extended_homogeneous<RT> >::Point
   == CGAL::Homogeneous<RT>::Point_2
```

The same holds for the types *Line* and *Direction* in the local scope of *Nef_polyhedron_2<...>*.

Class

CGAL::Topological_explorer

Definition

An instance D of the data type *Topological_explorer* is a decorator for interfacing the topological structure of a plane map P (read-only).

A plane map P consists of a triple (V,E,F) of vertices, edges, and faces. We collectively call them objects. An edge e is a pair of vertices *(v,w)* with incidence operations v = *source(e)*, w = *target(e)*. The list of all edges with source v is called the adjacency list *A(v)*.

Edges are paired into twins. For each edge e = *(v,w)* there's an edge *twin(e)* = *(w,v)* and *twin(twin(e))* == e[1].

An edge e = *(v,w)* knows two adjacent edges *en* = *next(e)* and *ep* = *previous(e)* where *source(en)* = w, *previous(en)* = e and *target(ep)* = v and *next(ep)* = e. By this symmetric *previous-next* relationship all edges are partitioned into face cycles. Two edges e and e' are in the same face cycle if $e = next^*(e')$. All edges e in the same face cycle have the same incident face $f = face(e)$. The cyclic order on the adjacency list of a vertex v = *source(e)* is given by *cyclic_adj_succ(e)* = *twin(previous(e))* and *cyclic_adj_pred(e)* = *next(twin(e))*.

A vertex v is embedded via coordinates *point(v)*. By the embedding of its source and target an edge corresponds to a segment. P has the property that the embedding is always *order-preserving*. This means a ray fixed in *point(v)* of a vertex v and swept around counterclockwise meets the embeddings of *target(e)* ($e \in A(v)$) in the cyclic order defined by the list order of A.

The embedded face cycles partition the plane into maximal connected subsets of points. Each such set corresponds to a face. A face is bounded by its incident face cycles. For all the edges in the non-trivial face cycles it holds that the face is left of the edges. There can also be trivial face cycles in form of isolated vertices in the interior of a face. Each such vertex v knows its surrounding face f = *face(v)*.

Plane maps are attributed, for each object $u \in V \cup E \cup F$ we attribute an information *mark(u)* of type *Mark*. *Mark* fits the concepts assignable, default-constructible, and equal-comparable.

Types

Topological_explorer:: Plane_map	The underlying plane map type
Topological_explorer:: Point	The point type of vertices.
Topological_explorer:: Mark	All objects (vertices, edges, faces) are attributed by a *Mark* object.
Topological_explorer:: Size_type	The size type.

Local types are handles, iterators and circulators of the following kind: *Vertex_const_handle*, *Vertex_const_iterator*, *Halfedge_const_handle*, *Halfedge_const_iterator*, *Face_const_handle*, *Face_const_iterator*. Additionally the following circulators are defined.

Topological_explorer:: Halfedge_around_vertex_const_circulator

circulating the outgoing halfedges in $A(v)$.

[1]The existence of the edge pairs makes P a bidirected graph, the *twin* links make P a map.

Topological_explorer:: Halfedge_around_face_const_circulator

circulating the halfedges in the face cycle of a face f.

Topological_explorer:: Hole_const_iterator iterating all holes of a face f. The type is convertible to *Halfedge_const_handle*.

Topological_explorer:: Isolated_vertex_const_iterator

iterating all isolated vertices of a face f. The type generalizes *Vertex_const_handle*.

Operations

Vertex_const_handle *D.source(Halfedge_const_handle e)*

returns the source of e.

Vertex_const_handle *D.target(Halfedge_const_handle e)*

returns the target of e.

Halfedge_const_handle *D.twin(Halfedge_const_handle e)*

returns the twin of e.

bool *D.is_isolated(Vertex_const_handle v)*

returns *true* iff $A(v) = \emptyset$.

Halfedge_const_handle *D.first_out_edge(Vertex_const_handle v)*

returns one halfedge with source v. It's the starting point for the circular iteration over the halfedges with source v.
Precondition: *!is_isolated(v)*.

Halfedge_const_handle *D.last_out_edge(Vertex_const_handle v)*

returns the halfedge with source v that is the last in the circular iteration before encountering *first_out_edge(v)* again.
Precondition: *!is_isolated(v)*.

Halfedge_const_handle *D.cyclic_adj_succ(Halfedge_const_handle e)*

returns the edge after e in the cyclic ordered adjacency list of *source(e)*.

Halfedge_const_handle	*D.cyclic_adj_pred(Halfedge_const_handle e)*	
		returns the edge before *e* in the cyclic ordered adjacency list of *source(e)*.
Halfedge_const_handle	*D.next(Halfedge_const_handle e)*	
		returns the next edge in the face cycle containing *e*.
Halfedge_const_handle	*D.previous(Halfedge_const_handle e)*	
		returns the previous edge in the face cycle containing *e*.
Face_const_handle	*D.face(Halfedge_const_handle e)*	
		returns the face incident to *e*.
Face_const_handle	*D.face(Vertex_const_handle v)*	
		returns the face incident to *v*. *Precondition*: *is_isolated(v)*.
Halfedge_const_handle	*D.halfedge(Face_const_handle f)*	
		returns a halfedge in the bounding face cycle of *f* (*Halfedge_const_handle()* if there is no bounding face cycle).

Iteration

Vertex_const_iterator	*D.vertices_begin()*	iterator over vertices of the map.
Vertex_const_iterator	*D.vertices_end()*	past-the-end iterator for vertices.
Halfedge_const_iterator	*D.halfedges_begin()*	iterator over halfedges of the map.
Halfedge_const_iterator	*D.halfedges_end()*	past-the-end iterator for halfedges.
Face_const_iterator	*D.faces_begin()*	iterator over faces of the map.
Face_const_iterator	*D.faces_end()*	past-the-end iterator for faces

Halfedge_around_vertex_const_circulator

D.out_edges(Vertex_const_handle v)

returns a circulator for the cyclic adjacency list of v.

Halfedge_around_face_const_circulator

D.face_cycle(Face_const_handle f)

returns a circulator for the outer face cycle of f.

Hole_const_iterator *D.holes_begin(Face_const_handle f)*

returns an iterator for all holes in the interior of f. A *Hole_iterator* can be assigned to a *Halfedge_around_face_const_circulator*.

Hole_const_iterator *D.holes_end(Face_const_handle f)*

returns the past-the-end iterator of f.

Isolated_vertex_const_iterator

D.isolated_vertices_begin(Face_const_handle f)

returns an iterator for all isolated vertices in the interior of f.

Isolated_vertex_const_iterator

D.isolated_vertices_end(Face_const_handle f)

returns the past the end iterator of f.

Associated Information

The type *Mark* is the general attribute of an object.

Point *D.point(Vertex_const_handle v)*

returns the embedding of v.

Mark *D.mark(Vertex_const_handle v)*

returns the mark of v.

Mark *D.mark(Halfedge_const_handle e)*

returns the mark of e.

Mark *D.mark(Face_const_handle f)*

returns the mark of f.

Statistics and Integrity

Size_type *D.number_of_vertices()* returns the number of vertices.

Size_type *D.number_of_halfedges()* returns the number of halfedges.

Size_type *D.number_of_edges()* returns the number of halfedge pairs.

Size_type *D.number_of_faces()* returns the number of faces.

Size_type *D.number_of_face_cycles()* returns the number of face cycles.

Size_type *D.number_of_connected_components()*

calculates the number of connected components of P.

void *D.print_statistics(std::ostream& os = std::cout)*

print the statistics of P: the number of vertices, edges, and faces.

void *D.check_integrity_and_topological_planarity(bool faces=true)*

checks the link structure and the genus of P.

Class

CGAL::Explorer

Definition

An instance E of the data type *Explorer* is a decorator to explore the structure of the plane map underlying the Nef polyhedron. It inherits all topological adjacency exploration operations from *Topological_explorer*. *Explorer* additionally allows one to explore the geometric embedding.

The position of each vertex is given by a so-called extended point, which is either a standard affine point or the tip of a ray touching an infinimaximal square frame centered at the origin. A vertex v is called a *standard* vertex if its embedding is a *standard* point and *non-standard* if its embedding is a *non-standard* point. By the straightline embedding of their source and target vertices, edges correspond to either affine segments, rays or lines or are part of the bounding frame.

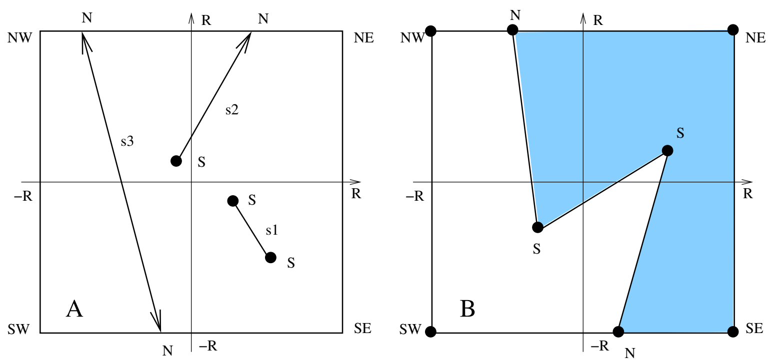

Figure 20.2: Extended geometry: standard vertices are marked by S, non-standard vertices are marked by N. **A**: The possible embeddings of edges: an affine segment s1, an affine ray s2, an affine line s3. **B**: A plane map embedded by extended geometry: note that the frame is arbitrarily large, the 6 vertices on the frame are at infinity, the two faces represent a geometrically unbounded area, however they are topologically closed by the frame edges. No standard point can be placed outside the frame.

Inherits From

Topological_explorer

Types

Explorer:: Point	the point type of finite vertices.
Explorer:: Ray	the ray type of vertices on the frame.

Iterators, handles, and circulators are inherited from *Topological_explorer*.

Creation

Explorer is copy constructable and assignable. An object can be obtained via the *Nef_polyhedron_2::explorer()* method of *Nef_polyhedron_2*.

Operations

bool *E.is_standard(Vertex_const_handle v)*

returns true iff *v*'s position is a standard point.

Point *E.point(Vertex_const_handle v)*

returns the standard point that is the embedding of *v*.
Precondition: *E.is_standard(v)*.

Ray *E.ray(Vertex_const_handle v)*

returns the ray defining the non-standard point on the frame.
Precondition: *!E.is_standard(v)*.

bool *E.is_frame_edge(Halfedge_const_handle e)*

returns true iff *e* is part of the infinimaximal frame.

ExtendedKernelTraits_2

Concept

Definition

ExtendedKernelTraits_2 is a kernel concept providing extended geometry[2]. Let K be an instance of the data type *ExtendedKernelTraits_2*. The central notion of extended geometry are extended points. An extended point represents either a standard affine point of the Cartesian plane or a non-standard point representing the equivalence class of rays where two rays are equivalent if one is contained in the other.

Let R be an infinimaximal number[3], F be the square box with corners $NW(-R,R)$, $NE(R,R)$, $SE(R,-R)$, and $SW(-R,-R)$. Let p be a non-standard point and let r be a ray defining it. If the frame F contains the source point of r then let $p(R)$ be the intersection of r with the frame F, if F does not contain the source of r then $p(R)$ is undefined. For a standard point let $p(R)$ be equal to p if p is contained in the frame F and let $p(R)$ be undefined otherwise. Clearly, for any standard or non-standard point p, $p(R)$ is defined for any sufficiently large R. Let f be any function on standard points, say with k arguments. We call f *extensible* if for any k points $p_1, \ldots, p_k$ the function value $f(p_1(R), \ldots, p_k(R))$ is constant for all sufficiently large R. We define this value as $f(p_1, \ldots, p_k)$. Predicates like lexicographic order of points, orientation, and incircle tests are extensible.

An extended segment is defined by two extended points such that it is either an affine segment, an affine ray, an affine line, or a segment that is part of the square box. Extended directions extend the affine notion of direction to extended objects.

This extended geometry concept serves two purposes. It offers functionality for changing between standard affine and extended geometry. At the same time it provides extensible geometric primitives on the extended geometric objects.

Types

Affine kernel types

ExtendedKernelTraits_2:: Standard_kernel	the standard affine kernel.
ExtendedKernelTraits_2:: Standard_RT	the standard ring type.
ExtendedKernelTraits_2:: Standard_point_2	standard points.
ExtendedKernelTraits_2:: Standard_segment_2	standard segments.
ExtendedKernelTraits_2:: Standard_line_2	standard oriented lines.
ExtendedKernelTraits_2:: Standard_direction_2	standard directions.
ExtendedKernelTraits_2:: Standard_ray_2	standard rays.

[2] It is called extended geometry for simplicity, though it is not a real geometry in the classical sense.
[3] A finite but very large number.

ExtendedKernelTraits_2:: Standard_aff_transformation_2

standard affine transformations.

Extended kernel types

ExtendedKernelTraits_2:: RT — the ring type of our extended kernel.

ExtendedKernelTraits_2:: Point_2 — extended points.

ExtendedKernelTraits_2:: Segment_2 — extended segments.

ExtendedKernelTraits_2:: Direction_2 — extended directions.

*enum Point_type { SWCORNER,
LEFTFRAME,
NWCORNER,
BOTTOMFRAME,
STANDARD,
TOPFRAME,
SECORNER,
RIGHTFRAME,
NECORNER}*

a type descriptor for extended points.

Operations

Interfacing the affine kernel types

Point_2 *K.construct_point(Standard_point_2 p)*

creates an extended point and initializes it to the standard point *p*.

Point_2 *K.construct_point(Standard_line_2 l)*

creates an extended point and initializes it to the equivalence class of all the rays underlying the oriented line *l*.

Point_2 *K.construct_point(Standard_point_2 p1, Standard_point_2 p2)*

creates an extended point and initializes it to the equivalence class of all the rays underlying the oriented line *l(p1,p2)*.

Point_2	*K.construct_point(Standard_point_2 p, Standard_direction_2 d)*	
		creates an extended point and initializes it to the equivalence class of all the rays underlying the ray starting in *p* in direction *d*.
Point_2	*K.construct_opposite_point(Standard_line_2 l)*	
		creates an extended point and initializes it to the equivalence class of all the rays underlying the oriented line opposite to *l*.
Point_type	*K.type(Point_2 p)*	determines the type of *p* and returns it.
bool	*K.is_standard(Point_2 p)*	
		returns *true* iff *p* is a standard point.
Standard_point_2	*K.standard_point(Point_2 p)*	
		returns the standard point represented by *p*. *Precondition*: *K.is_standard(p)*.
Standard_line_2	*K.standard_line(Point_2 p)*	
		returns the oriented line representing the bundle of rays defining *p*. *Precondition*: *!K.is_standard(p)*.
Standard_ray_2	*K.standard_ray(Point_2 p)*	
		a ray defining *p*. *Precondition*: *!K.is_standard(p)*.
Point_2	*K.NE()*	returns the point on the northeast frame corner.
Point_2	*K.SE()*	returns the point on the southeast frame corner.
Point_2	*K.NW()*	returns the point on the northwest frame corner.
Point_2	*K.SW()*	returns the point on the southwest frame corner.

Geometric kernel calls

Point_2	*K.source(Segment_2 s)*	
		returns the source point of *s*.

Point_2 *K.target(Segment_2 s)*

returns the target point of *s*.

Segment_2 *K.construct_segment(Point_2 p, Point_2 q)*

constructs a segment *pq*.

int *K.orientation(Segment_2 s, Point_2 p)*

returns the orientation of *p* with respect to the line through *s*.

int *K.orientation(Point_2 p1, Point_2 p2, Point_2 p3)*

returns the orientation of *p3* with respect to the line through *p1p2*.

bool *K.left_turn(Point_2 p1, Point_2 p2, Point_2 p3)*

return true iff the *p3* is left of the line through *p1p2*.

bool *K.is_degenerate(Segment_2 s)*

return true iff *s* is degenerate.

int *K.compare_xy(Point_2 p1, Point_2 p2)*

returns the lexicographic order of *p1* and *p2*.

int *K.compare_x(Point_2 p1, Point_2 p2)*

returns the order on the *x*-coordinates of *p1* and *p2*.

int *K.compare_y(Point_2 p1, Point_2 p2)*

returns the order on the *y*-coordinates of *p1* and *p2*.

Point_2 *K.intersection(Segment_2 s1, Segment_2 s2)*

returns the point of intersection of the lines supported by *s1* and *s2*.
Precondition: the intersection point exists.

Direction_2	*K.construct_direction(Point_2 p1, Point_2 p2)*	
		returns the direction of the vector *p2 - p1*.
bool	*K.strictly_ordered_ccw(Direction_2 d1, Direction_2 d2, Direction_2 d3)*	
		returns *true* iff *d2* is in the interior of the counterclockwise angular sector between *d1* and *d3*.
bool	*K.strictly_ordered_along_line(Point_2 p1, Point_2 p2, Point_2 p3)*	
		returns *true* iff *p2* is in the relative interior of the segment *p1p3*.
bool	*K.contains(Segment_2 s, Point_2 p)*	
		returns true iff *s* contains *p*.
bool	*K.first_pair_closer_than_second(Point_2 p1, Point_2 p2, Point_2 p3, Point_2 p4)*	
		returns true iff $\|p1-p2\| < \|p3-p4\|$.
*const char**	*K.output_identifier()*	returns a unique identifier for kernel object Input/Output. Usually this should be the name of the model.

Has Models

Class

CGAL::Extended_cartesian<FT>

Definition

The class *Extended_cartesian<FT>* serves as a traits class for the class *CGAL::Nef_polyhedron_2<T>*. It uses a polynomial component representation based on a field number type *FT*.

#include <CGAL/Extended_cartesian.h>

Is Model for the Concepts

ExtendedKernelTraits_2 . . . . page 1585

Creation

Extended_cartesian<FT> traits;	default constructor.

Requirements

To make a field number type *FT_model* work with this class, you must provide a traits class for this number type: *CGAL::Number_type_traits<FT_model>* (See the support library manual.)

Operations

Fits all operation requirements of the concept.

See Also

CGAL::Extended_homogeneous<RT> . . . . page 1591

CGAL::Extended_homogeneous<RT>

Class

Definition

The class *Extended_homogeneous<RT>* serves as a traits class for the class *CGAL::Nef_polyhedron_2<T>*. It uses a polynomial component representation based on a Euclidean ring number type *RT*.

#include <CGAL/Extended_homogeneous.h>

Is Model for the Concepts

ExtendedKernelTraits_2 . . . . page 1585

Creation

Extended_homogeneous<RT> traits;	default constructor.

Requirements

To make an Euclidean ring number type *RT_model* work with this class the number type must support a gcd computation in namespace *CGAL::NTS*. CGAL provides a function template for this, which will be used by default when your number type is not one of the built-in number types, one of the number types distrubuted with CGAL or one of the LEDA number types.

Operations

Fits all operation requirements of the concept.

Chapter 21

2D Boolean Operations on Nef Polygons Embedded on the Sphere

Peter Hachenberger and Lutz Kettner

Contents

21.1 Introduction

Nef polyhedra are defined as a subset of the d-dimensional space obtained by a finite number of set complement and set intersection operations on halfspaces.

Due to the fact that all other binary set operations like union, difference and symmetric difference can be reduced to intersection and complement calculations, Nef polyhedra are also closed under those operations. Also, Nef polyhedra are closed under topological unary set operations. Given a Nef polyhedron one can determine its interior, its boundary, and its closure.

Additionally, a d-dimensional Nef polyhedron has the property, that its boundary is a (d-1)-dimensional Nef polyhedron. This property can be used as a way to represent 3-dimensional Nef polyhedra by means of planar Nef polyhedra. This is done by intersecting the neighborhood of a vertex in a 3D Nef polyhedron with an ε-sphere. The result is a planar Nef polyhedron embedded on the sphere.

The intersection of a halfspace going through the center of the ε-sphere, with the ε-sphere, results in a halfsphere which is bounded by a great circle. A binary operation of two halfspheres cuts the great circles into great arcs.

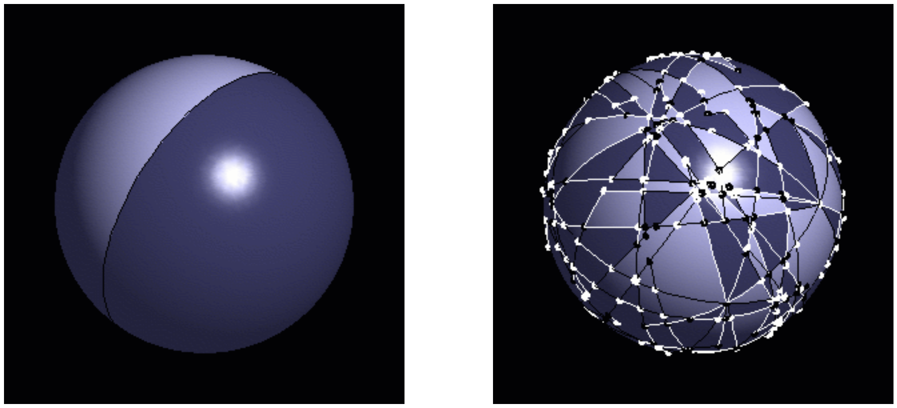

Figure 21.1: Two spherical Nef polyhedra. A closed halfspace on the left and a complex polyhedron on the right. The different colors indicate selected and unselected regions, lines and points.

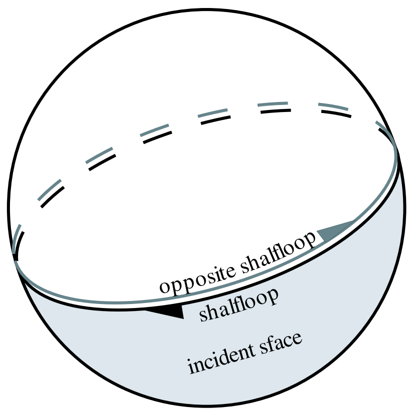

The incidence structure of planar Nef polyhedra can be reused. The items are denoted as $svertex$, $shalfedge$ and $sface$, analogous to their counterparts in *Nef_polyhedron_S2*. Additionally, there is the *shalfloop* reprsenting the great circles. The incidences are illustrated in the figure above.

21.2 Restricted Spherical Geometry

We introduce geometric objects that are part of the spherical surface S_2 and operations on them. We define types *Sphere_point*, *Sphere_circle*, *Sphere_segment*, and *Sphere_direction*. *Sphere_point*s are points on S_2, *Sphere_circle*s are oriented great circles of S_2, *Sphere_segment*s are oriented parts of *Sphere_circles* bounded by a pair of *Sphere_point*s, and *Sphere_direction*s are directions that are part of great circles. (a direction is usually defined to be a vector without length, that floats around in its underlying space and can be used to specify a movement at any point of the underlying space; in our case we use directions only at points that are part of the great circle that underlies also the direction.)

Note that we have to consider special geometric properties of the objects. For example two points that are part of a great circle define two *Sphere_segment*s, and two arbitrary *Sphere_segment*s can intersect in two points.

If we restrict our geometric objects to a so-called perfect hemisphere of S_2[1] then the restricted objects behave like in classical geometry, e.g., two points define exactly one segment, two segments intersect in at most one

[1] A perfect hemisphere of S_2 is an open half-sphere plus an open half-circle in the boundary of the open half-sphere plus one endpoint of the half-circle.

interior point (non-degenerately), or three non-cocircular sphere points can be qualified as being positively or negatively oriented.

21.3 Example Programs

21.3.1 First Example

In this first example *Nef_polyhedron_S2* is parametrized with a CGAL Kernel as traits class. The types comprising the spherical geometry can be retrieved from the type *Nef_polyhedron_S2<Traits>* as is done in the example with the type *Sphere_circle*. Then three Nef polyhedra are created: $N1$ is a halfsphere including the boundary, $N2$ is another halfsphere without the boundary, and $N3$ is the intersection of $N1$ and $N2$.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_S2.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Homogeneous<RT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Sphere_circle Sphere_circle;

int main()
{
  Nef_polyhedron N1(Sphere_circle(1,0,0));
  Nef_polyhedron N2(Sphere_circle(0,1,0), Nef_polyhedron::EXCLUDED);
  Nef_polyhedron N3 = N1 * N2;
  return 0;
}
```

File: examples/Nef_S2/nef_s2_simple.cpp

21.3.2 Construction and Combinations

Th example shows the different types of constructors: $N1$ is the complete sphere, $N2$ is a halfsphere which includes the boundary, $N3$ is created with the copy constructor, $N4$ is created as an arrangement of a set of *Sphere_segments*, and $N5$ is created as the empty set.

The example also shows the use of unary set operations, binary operations, and binary predicates: $N3$ is defined as the complement of $N2$, $N1$ is compared with the union of $N2$ and $N3$, $N5$ is united with $N2$ and then intersected with $N4$. At last, it is tested if $N5$ is a subset of $N2$ and if $N5$ is not equal to $N4$.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_S2.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Homogeneous<RT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Sphere_point Sphere_point;
```

```
typedef Nef_polyhedron::Sphere_segment Sphere_segment;
typedef Nef_polyhedron::Sphere_circle Sphere_circle;

int main() {

  Nef_polyhedron N1(Nef_polyhedron::COMPLETE);

  Sphere_circle c(1,1,1); // c : x + y + z = 0
  Nef_polyhedron N2(c, Nef_polyhedron::INCLUDED);
  Nef_polyhedron N3(N2.complement());
  CGAL_assertion(N1 == N2.join(N3));

  Sphere_point   p1(1,0,0), p2(0,1,0), p3(0,0,1);
  Sphere_segment s1(p1,p2), s2(p2,p3), s3(p3,p1);
  Sphere_segment triangle[3] = { s1, s2, s3 };
  Nef_polyhedron N4(triangle, triangle+3);
  Nef_polyhedron N5;
  N5 += N2;
  N5 = N5.intersection(N4);
  CGAL_assertion(N5 <= N2 && N5 != N4);

  return 0;
}
```

File: examples/Nef_S2/nef_s2_construction.cpp

21.3.3 Exploration

By recursively composing binary and unary operations one can end with a very complex rectilinear structure. *Nef_polyhedron_S2* allows read-only exploration of the structure.

In the following example, a random *Nef_polyhedron_S2 S* created from *n* halfspheres is explored. Each sface is composed of one outer sface cycles and an arbitrary number of inner sfaces cycles. The outer cycle is either an shalfloop or a cycle of shalfedges. An inner cycles additionally can be an isolated vertex. The example shows how to get the entry item *it* to all sface cycles of an sface *sf* and how to find out what type of item it is.

The macro *CGAL_forall_sface_cycles_of* is equivalent to a for-loop on the range *[sf->sface_cycles_begin(), sf->sface_cycles_end())*. An *SFace_cycle_const_iterator* either represents a *SVertex_const_handle*, a *SHalfede_const_handle* or a *SHalfloop_const_handle*. In order to find out which handle type is represented, the functions *is_svertex()*, *is_shafledge()* and *is_shalfloop()* are provided. Afterwards the iterator can be casted to the proper handle type.

```
#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>

21.3.4 Point Location

Using the *locate* function, it is possible to retrive an item at a certain location on the sphere. In the following example, the item at location *Sphere_point(1,0,0)* in a random *Nef_polyhedron_S2* is retrieved. *locate* returns an instance of type *Object_handle*, which is a container for any handle type. Here, it either a *SVertex_const_handle*, a *SHalfedge_const_handle*, a *SHafloop_const_handle* or a *SFace_const_handle*. The function *CGAL::assign* performs the cast operation and returns a boolean which indicates whether the cast was successful or not.

```
#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Nef_polyhedron_S2.h>
```

```
#include <CGAL/Nef_S2/create_random_Nef_S2.h>

typedef CGAL::Gmpq FT;
typedef CGAL::Cartesian<FT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron_S2;
typedef Nef_polyhedron_S2::SVertex_const_handle SVertex_const_handle;
typedef Nef_polyhedron_S2::SHalfedge_const_handle SHalfedge_const_handle;
typedef Nef_polyhedron_S2::SHalfloop_const_handle SHalfloop_const_handle;
typedef Nef_polyhedron_S2::SFace_const_handle SFace_const_handle;
typedef Nef_polyhedron_S2::Object_handle Object_handle;
typedef Nef_polyhedron_S2::Sphere_point Sphere_point;

int main() {

  Nef_polyhedron_S2 S;
  CGAL::create_random_Nef_S2(S,5);

  SVertex_const_handle sv;
  SHalfedge_const_handle se;
  SHalfloop_const_handle sl;
  SFace_const_handle sf;
  Object_handle o = S.locate(Sphere_point(1,0,0));
  if(CGAL::assign(sv,o))
    std::cout << "Locating svertex" << std::endl;
  else if(CGAL::assign(se,o))
    std::cout << "Locating shalfedge" << std::endl;
  else if(CGAL::assign(sl,o))
    std::cout << "Locating shalfloop" << std::endl;
  else if(CGAL::assign(sf,o))
    std::cout << "Locating sface" << std::endl;
  else {
    std::cout << "something wrong" << std::endl;
    return 1;
  }
  return 0;
}
```

21.3.5 Visualization

Nef_polyhedron_S2 provides an interface for OpenGL visualization via a Qt widget. The usage is shown in the following example:

```
#include <CGAL/basic.h>

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_S2.h>
#include <CGAL/Nef_S2/create_random_Nef_S2.h>
#include <CGAL/IO/Qt_widget_Nef_S2.h>
```

```
#include <qapplication.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Homogeneous<RT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron_S2;

int main(int argc, char* argv[]) {

  Nef_polyhedron_S2 S;
  create_random_Nef_S2(S,5);

  QApplication a(argc, argv);
  CGAL::Qt_widget_Nef_S2<Nef_polyhedron_S2>* w =
    new CGAL::Qt_widget_Nef_S2<Nef_polyhedron_S2>(S);
  a.setMainWidget(w);
  w->show();
  return a.exec();
}
```

2D Boolean Operations on Nef Polygons Embedded on the Sphere Reference Manual

Peter Hachenberger, Lutz Kettner, and Michael Seel

Nef polyhedra are defined as a subset of the d-dimensional space obtained by a finite number of set complement and set intersection operations on halfspaces.

Due to the fact that all other binary set operations like union, difference and symmetric difference can be reduced to intersection and complement calculations, Nef polyhedra are also closed under those operations. Also, Nef polyhedra are closed under topological unary set operations. Given a Nef polyhedron one can determine its interior, its boundary, and its closure.

Additionally, a d-dimensional Nef polyhedron has the property, that its boundary is a (d-1)-dimensional Nef polyhedron. This property can be used as a way to represent 3-dimensional Nef polyhedra by means of planar Nef polyhedra. This is done by intersecting the neighborhood of a vertex in a 3D Nef polyhedron with an ε-sphere. The result is a planar Nef polyhedron embedded on the sphere.

The intersection of a halfspace going through the center of the ε-sphere, with the ε-sphere, results in a halfsphere which is bounded by a great circle. A binary operation of two halfspheres cuts the great circles into great arcs.

The incidence structure of planar Nef polyhedra can be reused. The items are denoted as $svertex$, $shalfedge$ and $sface$, analogous to their counterparts in *Nef_polyhedron_2*. Additionally, there is the *shalfloop* representing the great circles.

21.5 Alphabetical List of Reference Pages

CGAL::Nef_polyhedron_S2<Traits>

Class

Definition

An instance of data type *Nef_polyhedron_S2<Traits>* is a subset of the sphere S_2 that is the result of forming complements and intersections starting from a finite set H of halfspaces bounded by a plane containing the origin. Halfspaces correspond to hemispheres of S_2 and are therefore modeled by oriented great circles of type *Sphere_circle*. *Nef_polyhedron_S2* is closed under all binary set operations *intersection*, *union*, *difference*, *complement* and under the topological operations *boundary*, *closure*, and *interior*.

#include <CGAL/Nef_polyhedron_S2.h>

Parameters

template < class Nef_polyhedronTraits_S2,
class Nef_polyhedronItems_S2 = CGAL::SM_items,
class Nef_polyhedronMarks = bool
class Nef_polyhedron_S2;

The first parameter requires one of the following exact kernels: *Homogeneous*, *Simple_homogeneous* parametrized with *Gmpz*, *leda_integer* or any other number type modeling $\mathbb{Z}$, or *Cartesian*, *Simple_cartesian* parametrized with *Gmpq*, *leda_rational*,*Quotient<Gmpz>* or any other number type modeling $\mathbb{Q}$.

The second parameter and the third parameter are for future considerations. Neither *Nef_polyhedronItems_S2* nor *Nef_polyhedronMarks* is specifed, yet. Do not use other than the default types for these two template parameters.

Types

Nef_polyhedron_S2<Traits>:: Sphere_point	points in the sphere surface.
Nef_polyhedron_S2<Traits>:: Sphere_segment	segments in the sphere surface.
Nef_polyhedron_S2<Traits>:: Sphere_circle	oriented great circles modeling spatial half-spaces.
Nef_polyhedron_S2<Traits>:: SVertex_const_handle	non-mutable handle to svertex.
Nef_polyhedron_S2<Traits>:: SHalfedge_const_handle	non-mutable handle to shalfedge.
Nef_polyhedron_S2<Traits>:: SHalfloop_const_handle	non-mutable handle to shalfloop.
Nef_polyhedron_S2<Traits>:: SFace_const_handle	non-mutable handle to sface.
Nef_polyhedron_S2<Traits>:: SVertex_const_iterator	non-mutable iterator over all svertices.
Nef_polyhedron_S2<Traits>:: SHalfedge_const_iterator	non-mutable iterator over all shalfedges.
Nef_polyhedron_S2<Traits>:: SHalfloop_const_iterator	non-mutable iterator over all shalfloops.
Nef_polyhedron_S2<Traits>:: SFace_const_iterator	non-mutable iterator over all sfaces.

Nef_polyhedron_S2<Traits>:: SHalfedge_around_svertex_const_circulator

circulating the adjacency list of an svertex v.

Nef_polyhedron_S2<Traits>:: SHalfedge_around_sface_const_circulator

circulating the sface cycle of an sface f.

Nef_polyhedron_S2<Traits>:: SFace_cycle_const_iterator — iterating all sface cycles of an sface f. The iterator has method *bool is_svertex()*, *bool is_shalfedge()*, *bool is_shalfloop()*, and can be converted to the corresponding handles *SVertex_const_handle*, *SHalfedge_const_handle*, or *SHalfloop_const_handle*.

Nef_polyhedron_S2<Traits>:: Mark — attributes of objects (vertices, edges, faces).

Nef_polyhedron_S2<Traits>:: size_type — size type

enum Boundary { *EXCLUDED, INCLUDED*}; — construction selection.

enum Content { *EMPTY, COMPLETE*}; — construction selection.

Creation

Nef_polyhedron_S2<Traits> N(Content sphere = EMPTY);

creates an instance *N* of type *Nef_polyhedron_S2<K>* and initializes it to the empty set if *sphere* == *EMPTY* and to the whole sphere if *sphere* == *COMPLETE*.

Nef_polyhedron_S2<Traits> N(Sphere_circle c, Boundary circle = INCLUDED);

creates a Nef polyhedron *N* containing the half-sphere left of *c* including *c* if *circle==INCLUDED*, excluding *c* if *circle==EXCLUDED*.

template <class Forward_iterator>
Nef_polyhedron_S2<Traits> N(Forward_iterator first, Forward_iterator beyond, Boundary b = INCLUDED)

creates a Nef polyhedron *N* from the set of sphere segments in the iterator range *[first,beyond)*. If the set of sphere segments is a simple polygon that separates the sphere surface into two regions, then the polygonal region that is left of the segment **first* is selected. The polygonal region includes its boundary if *b = INCLUDED* and excludes the boundary otherwise. *Forward_iterator* has to be an iterator with value type *Sphere_segment*.

Operations

void *N.clear(Content plane = EMPTY)*

makes *N* the empty set if *plane* == *EMPTY* and the full plane if *plane* == *COMPLETE*.

bool *N.is_empty()* returns true if *N* is empty, false otherwise.

bool *N.is_sphere()* returns true if *N* is the whole sphere, false otherwise.

Constructive Operations

Nef_polyhedron_S2<K> *N.complement()* returns the complement of *N* in the plane.

Nef_polyhedron_S2<K> *N.interior()* returns the interior of *N*.

Nef_polyhedron_S2<K> *N.closure()* returns the closure of *N*.

Nef_polyhedron_S2<K> *N.boundary()* returns the boundary of *N*.

Nef_polyhedron_S2<K> *N.regularization()* returns the regularized polyhedron (closure of interior).

Nef_polyhedron_S2<K> *N.intersection(Nef_polyhedron_S2<K> N1)*

returns $N \cap N1$.

Nef_polyhedron_S2<K> *N.join(Nef_polyhedron_S2<K> N1)*

returns $N \cup N1$.

Nef_polyhedron_S2<K> *N.difference(Nef_polyhedron_S2<K> N1)*

returns $N - N1$.

Nef_polyhedron_S2<K> *N.symmetric_difference(Nef_polyhedron_S2<K> N1)*

returns the symmectric difference *N - T* $\cup$ *T - N*.

Additionally there are operators **,+,-, ^,!* which implement the binary operations *intersection*, *union*, *difference*, *symmetric difference*, and the unary operation *complement* respectively. There are also the corresponding modification operations **=,+=,-=,^=*.

There are also comparison operations like *<,<=,>,>=,==,!=* which implement the relations subset, subset or equal, superset, superset or equal, equality, inequality, respectively.

Statistics and Integrity

Size_type	*N.number_of_svertices()*	returns the number of svertices.
Size_type	*N.number_of_shalfedges()*	returns the number of shalfedges.
Size_type	*N.number_of_sedges()*	returns the number of sedges.
Size_type	*N.number_of_shalfloops()*	returns the number of shalfloops.
Size_type	*N.number_of_sloops()*	returns the number of sloops.

Size_type	*N.number_of_sfaces()*	returns the number of sfaces.
Size_type	*N.number_of_sface_cycles()*	returns the number of sface cycles.
Size_type	*N.number_of_connected_components()*	calculates the number of connected components of P.
void	*N.print_statistics(std::ostream& os = std::cout)*	print the statistics of P: the number of vertices, edges, and faces.
void	*N.check_integrity_and_topological_planarity(bool faces=true)*	checks the link structure and the genus of P.

Exploration - Point location - Ray shooting

As Nef polyhedra are the result of forming complements and intersections starting from a set H of half-spaces that are defined by oriented lines in the plane, they can be represented by an attributed plane map $M = (V, E, F)$. For topological queries within M the following types and operations allow exploration access to this structure.

Types

Nef_polyhedron_S2<Traits>:: Object_handle

a generic handle to an object of the underlying plane map. The kind of object *(vertex, halfedge, face)* can be determined and the object can be assigned to a corresponding handle by the three functions:
bool assign(Vertex_const_handle& h, Object_handle)
bool assign(Halfedge_const_handle& h, Object_handle)
bool assign(Face_const_handle& h, Object_handle)
where each function returns *true* iff the assignment to h was done.

Operations

bool *N.contains(Object_handle h)*

returns true iff the object h is contained in the set represented by N.

bool *N.contained_in_boundary(Object_handle h)*

returns true iff the object h is contained in the 1-skeleton of N.

Object_handle *N.locate(Sphere_point p)*

returns a generic handle h to an object (face, halfedge, vertex) of the underlying plane map that contains the point p in its relative interior. The point p is contained in the set represented by N if *N.contains(h)* is true. The location mode flag m allows one to choose between different point location strategies.

Object_handle *N.ray_shoot(Sphere_point p, Sphere_direction d)*

returns a handle h with *N.contains(h)* that can be converted to a *Vertex_/Halfedge_/Face_const_handle* as described above. The object returned is intersected by the ray starting in p with direction d and has minimal distance to p. The operation returns an empty *Object_handle* if the ray shoot along d does not hit any object h of N with *N.contains(h)*.

Object_handle *N.ray_shoot_to_boundary(Sphere_point p, Sphere_direction d)*

returns a handle h that can be converted to a *Vertex_/Halfedge_const_handle* as described above. The object returned is part of the 1-skeleton of N, intersected by the ray starting in p with direction d and has minimal distance to p. The operation returns an empty *Object_handle* if the ray shoot along d does not hit any 1-skeleton object h of N. The location mode flag m allows one to choose between different point location strategies.

Iteration

bool *N.has_shalfloop() const*

returns true iff there is a shalfloop.

SHalfloop_const_handle *N.shalfloop() const* returns access to the sloop.

The list of all objects can be accessed via iterator ranges. For comfortable iteration we also provide iterations macros. The iterator range access operations are of the following kind:
SVertex_iterator svertices_begin()/svertices_end()
SHalfedge_iterator shalfedges_begin()/shalfedges_end()
SHalfloop_iterator shalfloops_begin()/shalfloops_end()
SFace_iterator sfaces_begin()/sfaces_end()

The macros are then *CGAL_forall_svertices(v,M)*, *CGAL_forall_shalfedges(e,M)*, *CGAL_forall_sfaces(f,M)*, *CGAL_forall_sface_cycles_of(fc,F)* where M is a sphere map and F is a sface.

Input and Output

A Nef polyhedron N can be visualized in an open GL window. The output operator is defined in the file *CGAL/IO/Nef_polyhedron_2_Window_stream.h*.

Implementation

Nef polyhedra are implemented on top of a halfedge data structure and use linear space in the number of vertices, edges and facets. Operations like *empty* take constant time. The operations *clear*, *complement*, *interior*, *closure*, *boundary*, *regularization*, input and output take linear time. All binary set operations and comparison operations take time $O(n \log n)$ where n is the size of the output plus the size of the input.

The point location and ray shooting operations are implemented in the naive way. The operations run in linear query time without any preprocessing.

Class

CGAL::Nef_polyhedron_S2<Traits>::Sphere_point

Definition

An object p of type *Sphere_point<R>* is a point on the surface of a unit sphere. Such points correspond to the nontrivial directions in space and similarly to the equivalence classes of all nontrivial vectors under normalization.

Types

Sphere_point:: RT	ring number type.

Creation

Sphere_point p;	creates some sphere point.
Sphere_point p(RT x, RT y, RT z);	creates a sphere point corresponding to the point of intersection of the ray starting at the origin in direction (x,y,z) and the surface of S_2.

Operations

Access to the coordinates is provided by the following operations. Note that the vector (x,y,z) is not normalized.

RT	*p.x()*	the x-coordinate.
RT	*p.y()*	the y-coordinate.
RT	*p.z()*	the z-coordinate.
bool	$p == q$	Equality.
bool	$p\ != q$	Inequality.
Sphere_point	*p.antipode()*	returns the antipode of p.

CGAL::Nef_polyhedron_S2<Traits>::Sphere_segment

Class

Definition

An object s of type *Sphere_segment* is a segment in the surface of a unit sphere that is part of a great circle trough the origin. Sphere segments are represented by two sphere points p and q plus an oriented plane h that contains p and q. The plane determines the sphere segment as follows. Let c be the circle in the intersection of h and S_2. Then s is that part of c that is swept, when we rotate p into q in counterclockwise rotation around the normal vector of h as seen from the positive halfspace.

Creation

Sphere_segment s; — creates some sphere segment.

Sphere_segment s(Sphere_point p1, Sphere_point p2, bool shorter_arc=true);

creates a spherical segment spanning the shorter arc from *p1* to *p2* if *shorter_arc* == *true*. Otherwise the longer arc is created.
Precondition: *p1 != p2* and *p1 != p2.opposite()*.

Sphere_segment s(Sphere_point p1, Sphere_point p2, Sphere_circle c);

creates a spherical segment spanning the arc from *p1* to *p2* as part of the oriented circle *c* (*p1 == p2* or *p1 == p2.opposite()* are possible.)
Precondition: *p1* and *p2* are contained in *c*.

Sphere_segment s(Sphere_circle c1, Sphere_circle c2);

creates the spherical segment as part of *c1* that is part of the halfsphere left of the oriented circle *c2*.
Precondition: *c1 != c2* as unoriented circles.

Operations

Sphere_point	*s.source()*	the source point of *s*.
Sphere_point	*s.target()*	the target point of *s*.
Sphere_circle	*s.sphere_circle()*	the great circle supporting *s*.
Sphere_segment	*s.opposite()*	returns the sperical segment oriented from *target()* to *source()* with the same point set as *s*.
Sphere_segment	*s.complement()*	returns the sperical segment oriented from *target()* to *source()* with the point set completing *s* to a full circle.

bool	*s.is_short()*	a segment is short iff it is shorter than a half-circle.
bool	*s.is_long()*	a segment is long iff it is longer than a half-circle.
bool	*s.is_degenerate()*	return true iff *s* is degenerate, i.e. source and target are the same.
bool	*s.is_halfcircle()*	return true iff *s* is a perfect half-circle, i.e. *source().antipode* == *target()*.
bool	*s.has_on(Sphere_point p)*	
		return true iff *s* contains *p*.
bool	*s.has_in_relative_interior(Sphere_point p)*	
		return true iff *s* contains *p* in its relative interior.

CGAL::Nef_polyhedron_S2<Traits>::Sphere_circle

Class

Definition

An object c of type *Sphere_circle* is an oriented great circle on the surface of a unit sphere. Such circles correspond to the intersection of an oriented plane (that contains the origin) and the surface of S_2. The orientation of the great circle is that of a counterclockwise walk along the circle as seen from the positive halfspace of the oriented plane.

Types

Sphere_circle:: RT — ring type.

Sphere_circle:: Plane_3 — plane a *Sphere_circle* lies in.

Creation

Sphere_circle c; — creates some great circle.

Sphere_circle c(Sphere_point p, Sphere_point q);

If p and q are opposite of each other, then we create the unique great circle on S_2 which contains p and q. This circle is oriented such that a walk along c meets p just before the shorter segment between p and q. If p and q are opposite of each other then we create any great circle that contains p and q.

Sphere_circle c(Plane_3 h); — creates the circle corresponding to the plane h.
Precondition: h contains the origin.

Sphere_circle c(RT x, RT y, RT z); — creates the circle orthogonal to the vector (x,y,z).

Sphere_circle c(Sphere_circle c, Sphere_point p);

creates a great circle orthogonal to c that contains p.
Precondition: p is not part of c.

Operations

Sphere_circle	*c.opposite()*	Returns a sphere circle in the oppostie direction of c.
bool	*c.has_on(Sphere_point p)*	returns true iff c contains p.
Plane_3	*c.plane()*	returns the plane supporting c.
Sphere_point	*c.orthogonal_pole()*	returns the point that is the pole of the hemisphere left of c.

Global functions

bool *equal_as_sets(const c1, const c2)*

returns true iff *c1* and *c2* are equal as unoriented circles.

CGAL::Nef_polyhedron_S2<Traits>::SVertex

Class

Definition

Figure 21.2 illustrates the incidence of a svertex on a sphere map.

The member function *out_sedge* returns the first outgoing shalfedge, and *incident_sface* returns the incident sface.

#include <CGAL/Nef_polyhedron_S2.h>

Types

The following types are the same as in *Nef_polyhedron_S2<Traits>*.

SVertex:: Mark	type of mark.
SVertex:: Sphere_point	sphere point type stored in SVertex.
SVertex:: SVertex_const_handle	const handle to SVertex.
SVertex:: SHalfedge_const_handle	const handle to SHalfedge.
SVertex:: SFace_const_handle	const handle to SFace.

Creation

There is no need for a user to create a *SVertex* explicitly. The class *Nef_polyhedron_S2<Traits>* manages the needed svertices internally.

Operations

Mark	*e.mark() const*	the mark of *e* .
Sphere_point	*e.point() const*	the sphere point of *e* .
bool	*e.is_isolated() const*	returns —true— if *e* has no adjacent sedges.
SVertex_const_handle	*e.twin() const*	the twin of *e* .
SHalfedge_const_handle	*e.out_sedge() const*	the first out sedge of *e* .
SFace_const_handle	*e.incident_sface() const*	the incident sface of *e* .

CGAL::Nef_polyhedron_S2<Traits>::SHalfedge

Definition

A shalfedge is a great arc on a sphere map. The figure below depicts the relationship between a shalfedge and its incident shalfedges, svertices, and sfaces on a sphere map. A shalfedge is an oriented sedge between two svertices. It is always paired with a shalfedge pointing in the opposite direction. The *twin()* member function returns this shalfedge of opposite orientation.

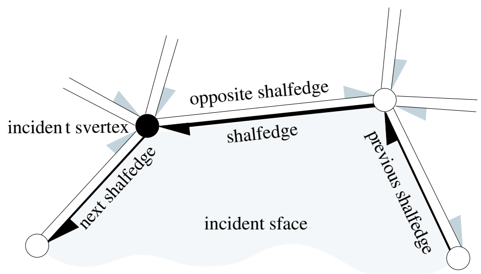

Figure 21.2: Incidences of an SHalfedge

The *snext()* member function points to the successor shalfedge around this sface while the *sprev()* member function points to the preceding shalfedge. An successive assignments of the form *se = se->snext()* cycles counterclockwise around the sface (or hole).

Similarly, the successive assignments of the form *se = se->snext()->twin()* cycle clockwise around the svertex and traverse all halfedges incident to this svertex. The assignment *se = se->cyclic_adj_succ()* can be used as a shortcut.

A const circulator is provided for each of the two circular orders. The circulators are bidirectional and assignable to *SHalfedge_const_handle*.

#include <CGAL/Nef_polyhedron_S2.h>

Types

The following types are the same as in *Nef_polyhedron_S2<Traits>*.

SHalfedge:: Mark	type of mark.
SHalfedge:: Sphere_circle	sphere circle type stored in SHalfedge.
SHalfedge:: SVertex_const_handle	const handle to SVertex.
SHalfedge:: SHalfedge_const_handle	const handle to SHalfedge.
SHalfedge:: SFace_const_handle	const handle to SFace.

Creation

There is no need for a user to create a *SHalfedge* explicitly. The class *Nef_polyhedron_S2<Traits>* manages the needed shalfedges internally.

Operations

Mark	*se.mark() const*	the mark of *se* .
Sphere_circle	*se.circle() const*	the sphere circle of *se* .
SHalfedge_const_handle	*se.twin() const*	the twin of *se* .
SVertex_const_handle	*se.source() const*	the source svertex of *se* .
SVertex_const_handle	*se.target() const*	equals *twin()->source()*.
SHalfedge_const_handle	*se.sprev() const*	the SHalfedge previous to *se* in a sface cycle.
SHalfedge_const_handle	*se.snext() const*	the next SHalfedge of *se* in a sface cycle.
SHalfedge_const_handle	*se.cyclic_adj_pred() const*	the edge before *se* in the cyclic ordered adjacency list of source().
SHalfedge_const_handle	*se.cyclic_adj_succ() const*	the edge after *se* in the cyclic ordered adjacency list of source().
SFace_const_handle	*se.incident_sface() const*	the incident sface of *se* .
bool	*se.in_outer_sface_cycle() const*	determines whether *se* is in an outer sface cycle.
bool	*se.in_inner_sface_cycle() const*	determines whether *se* is in an inner sface cycle.

CGAL::Nef_polyhedron_S2<Traits>::SHalfloop

Definition

A sloop is a great circle on a sphere. A shalfloop is an oriented sloop. It is always paired with a shalfloop whose supporting *Sphere_circle* is pointing in the opposite direction. The *twin()* member function returns this shalfloop of opposite orientation. Each *Nef_polyhedron_S2* can only have one sloop (resp. two shalfloops).

The figure below depicts the relationship between a shalfloop and sfaces on a sphere map.

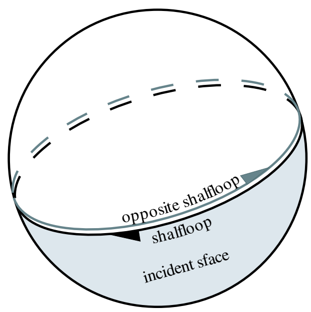

Figure 21.3: Incidences of an SHalfloop

#include <CGAL/Nef_polyhedron_S2.h>

Types

The following types are the same as in *Nef_polyhedron_S2<Traits>*.

SHalfloop:: Mark	type of mark.
SHalfloop:: Sphere_circle	sphere circle type stored in SHalfloop.
SHalfloop:: SHalfloop_const_handle	const handle to SHalfloop.
SHalfloop:: SFace_const_handle	const handle to SFace.

Creation

There is no need for a user to create a *SHalfloop* explicitly. The class *Nef_polyhedron_S2<Traits>* manages the needed shalfloops internally.

Operations

Mark	*se.mark() const*	the mark of *se* .
Sphere_circle	*se.circle() const*	the sphere circle of *se* .

SHalfloop_const_handle	*se.twin() const*	the twin of *se* .
SFace_const_handle	*se.incident_sface() const*	the incident sface of *se* .

CGAL::Nef_polyhedron_S2<Traits>::SFace

Definition

Figures 21.2 and 21.3 illustrate the incidences of an sface. An sface is described by its boundaries. An entry item to each boundary cycle can be accessed using the iterator range (*sface_cycles_begin()*/*sface_cycles_end()*). Additionally, *Nef_polyhedron_S2* provides the macro *CGAL_forall_sface_cylces_of*. The iterators are of type *SFace_cycle_const_iterator* and represent either a shalfedge, a shalfloop, or a svertex.

#include <CGAL/Nef_polyhedron_S2.h>

Types

The following types are the same as in *Nef_polyhedron_S2<Traits>*.

SFace:: Mark	type of mark.
SFace:: Object_list	list of Object handles.
SFace:: Vertex_const_handle	const handle to Vertex.
SFace:: Volume_const_handle	const handle to Volume.
SFace:: SFace_const_handle	const handle to SFace.
SFace:: SFace_cycle_const_iterator	const iterator over the entries to all sface cycles of a sface.

Creation

There is no need for a user to create a *SFace* explicitly. The class *Nef_polyhedron_S2<Traits>* manages the needed sfaces internally.

Operations

Mark	*sf.mark() const*	the mark of *sf*.
SFace_cycle_const_iterator	*sf.sface_cycle_begin() const*	iterator over the entries to all sface cycles of *sf*.
SFace_cycle_const_iterator	*sf.sface_cycle_end() const*	past-the-end iterator.

See Also

CGAL::Nef_polyhedron_S2<Traits> . . . . page 1603
CGAL::Nef_polyhedron_S2<Traits>::SVertex . . . . page 1613

Class

CGAL::Nef_polyhedron_S2<Traits>::SFace_cycle_iterator

Definition

The type *SFace_cycle_iterator* iterates over a list of *Object_handles*. Each item of that list can either be assigned to *SVertex_handle*, *SHalfedge_handle* or *SHalfloop_handle*. To find out which of these assignment works out, the member functions *is_svertex()*, *is_shalfedge()* and *is_shalfloop()* are provided.

#include <CGAL/Nef_polyhedron_S2.h>

Types

SFace_cycle_iterator:: SVertex_handle	const handle to SVertex.
SFace_cycle_iterator:: SHalfedge_handle	const handle to SHalfedge.
SFace_cycle_iterator:: SHalfloop_handle	const handle to SHalfloop.

Creation

SFace_cycle_iterator sfc;	default constructor.

Operations

bool	*sfc.is_svertex() const*	returns true if *sfc* represents a *SVertex_handle*.
bool	*sfc.is_shalfedge() const*	returns true if *sfc* represents a *SHalfedge_handle*.
bool	*sfc.is_shalfloop() const*	returns true if *sfc* represents a *SHalfloop_handle*.
SVertex_handle	*SVertex_handle(sfc)*	casts *sfc* to *SVertex_handle*.
SHalfedge_handle	*SHalfedge_handle(sfc)*	casts *sfc* to *SHalfedge_handle*.
SHalfloop_handle	*SHalfloop_handle(sfc)*	casts *sfc* to *SHalfloop_handle*.

CGAL::Qt_widget_Nef_S2<Nef_polyhedron_S2>

Definition

The class *Qt_widget_Nef_S2* uses the OpenGL interface of Qt in order to display a *Nef_polyhedron_S2*. Its purpose is to provide an easy to use viewer for *Nef_polyhedron_S2*. There are no means provided to enhance the functionality of the viewer.

In addition to the functions inherited from the Qt class *QGLWidget*, *Qt_widget_Nef_S2* only has a single public constructor. For the usage of *Qt_widget_Nef_S2* see the example below.

#include <CGAL/IO/Qt_widget_Nef_S2.h>

Parameters

The template parameter expects an instantiation of *Nef_polyhedron_S2<Traits>*.

Creation

Qt_widget_Nef_S2<Nef_polyhedron_S2> W(Nef_polyhedron_S2 N);

Creates a widget *W* for displaying the *Nef_polyhedron_S2* N.

Example

This example creates some random *Sphere_segments* and distributes them on two *Nef_polyhedron_2*. The two Nef polyhedra are combined by a symmetric diffrence and the result is displayed in a Qt widget.

```
#include <CGAL/basic.h>

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_S2.h>
#include <CGAL/Nef_S2/create_random_Nef_S2.h>
#include <CGAL/IO/Qt_widget_Nef_S2.h>
#include <qapplication.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Homogeneous<RT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron_S2;

int main(int argc, char* argv[]) {
```

```
  Nef_polyhedron_S2 S;
  create_random_Nef_S2(S,5);

  QApplication a(argc, argv);
  CGAL::Qt_widget_Nef_S2<Nef_polyhedron_S2>* w =
    new CGAL::Qt_widget_Nef_S2<Nef_polyhedron_S2>(S);
  a.setMainWidget(w);
  w->show();
  return a.exec();
}
```

Chapter 22

2D Polygon Partitioning

Susan Hert

Contents

22.1 Introduction

A *partition* of a polygon P is a set of polygons such that the interiors of the polygons do not intersect and the union of the polygons is equal to the interior of the original polygon P. This chapter describes functions for partitioning planar polygons into two types of subpolygons — y-monotone polygons and convex polygons. The partitions are produced without introducing new (Steiner) vertices.

All the partitioning functions present the same interface to the user. That is, the user provides a pair of input iterators, *first* and *beyond*, an output iterator *result*, and a traits class *traits*. The points in the range [*first*, *beyond*) are assumed to define a simple polygon whose vertices are in counterclockwise order. The computed partition polygons, whose vertices are also oriented counterclockwise, are written to the sequence starting at position *result* and the past-the-end iterator for the resulting sequence of polygons is returned. The traits classes for the functions specify the types of the input points and output polygons as well as a few other types and function objects that are required by the various algorithms.

22.2 Monotone Partitioning

A *y-monotone polygon* is a polygon whose vertices $v_1,\ldots,v_n$ can be divided into two chains $v_1,\ldots,v_k$ and $v_k,\ldots,v_n,v_1$, such that any horizontal line intersects either chain at most once. For producing a y-monotone partition of a given polygon, the sweep-line algorithm presented in [dBvKOS97] is implemented by the function *y_monotone_partition_2*. This algorithm runs in $O(n \log n)$ time and requires $O(n)$ space. This algorithm does not guarantee a bound on the number of polygons produced with respect to the optimal number.

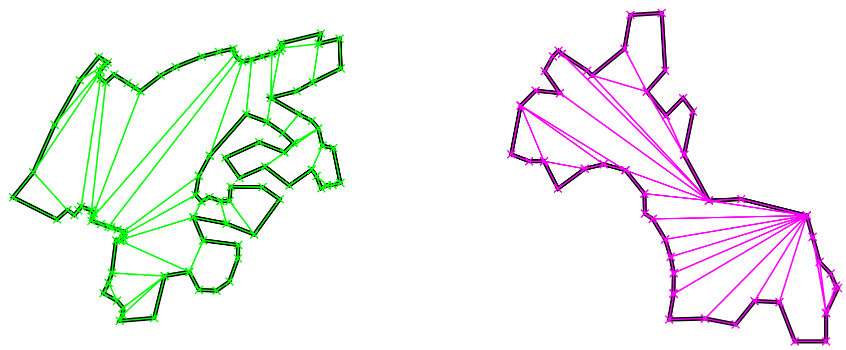

Figure 22.1: Examples of an optimal convex partition (left) and an approximately optimal convex partition (right).

For checking the validity of the partitions produced by *y_monotone_partition_2*, we provide a function *is_y_monotone_2*, which determines if a sequence of points in 2D defines a *y*-monotone polygon or not. For examples of the use of these functions, see the corresponding reference pages.

22.3 Convex Partitioning

Three functions are provided for producing convex partitions of polygons. One produces a partition that is optimal in the number of pieces. The other two functions produce approximately optimal convex partitions. Both these functions produce convex decompositions by first decomposing the polygon into simpler polygons; the first uses a triangulation and the second a monotone partition. These two functions both guarantee that they will produce no more than four times the optimal number of convex pieces but they differ in their runtime complexities. Though the triangulation-based approximation algorithm often results in fewer convex pieces, this is not always the case.

An optimal convex partition can be produced using the function *optimal_convex_partition_2*. This function provides an implementation of Greene's dynamic programming algorithm for optimal partitioning [Gre83]. This algorithm requires $O(n^4)$ time and $O(n^3)$ space in the worst case.

The function *approx_convex_partition_2* implements the simple approximation algorithm of Hertel and Mehlhorn [HM83] that produces a convex partitioning of a polygon from a triangulation by throwing out unnecessary triangulation edges. The triangulation used in this function is one produced by the 2-dimensional constrained triangulation package of CGAL. For a given triangulation, this convex partitioning algorithm requires $O(n)$ time and space to construct a decomposition into no more than four times the optimal number of convex pieces.

The sweep-line approximation algorithm of Greene [Gre83], which, given a monotone partition of a polygon, produces a convex partition in $O(n \log n)$ time and $O(n)$ space, is implemented by the function *greene_approx_convex_partition_2*. The function *y_monotone_partition_2* described in Section 22.2 is used to produce the monotone partition. This algorithm provides the same worst-case approximation guarantee as the algorithm of Hertel and Mehlhorn implemented with *approx_convex_partition_2* but can sometimes produce better results (*i.e.*, convex partitions with fewer pieces).

Examples of the uses of all of these functions are provided with the corresponding reference pages.

2D Polygon Partitioning Reference Manual

Susan Hert

A *partition* of a polygon is a set of polygons such that the interiors of the polygons do not intersect and the union of the polygons is equal to the interior of the original polygon. Functions are available for partitioning planar polygons into two types of subpolygons — y-monotone polygons and convex polygons.

The function that produces a y-monotone partitioning is based on the algorithm presented in [dBvKOS97] which requires $O(n \log n)$ time and $O(n)$ space for a polygon with n vertices and guarantees nothing about the number of polygons produced with respect to the optimal number. Three functions are provided for producing convex partitions. Two of these functions produce approximately optimal partitions and one results in an optimal partition, where "optimal" is defined in terms of the number of partition polygons. The two functions that implement approximation algorithms are guaranteed to produce no more than four times the optimal number of convex pieces. The optimal partitioning function provides an implementation of Greene's dynamic programming algorithm [Gre83], which requires $O(n^4)$ time and $O(n^3)$ space to produce a convex partitioning. One of the approximation algorithms is also due to Greene [Gre83] and requires $O(n \log n)$ time and $O(n)$ space to produce a convex partitioning given a y-monotone partitioning. The other approximation algorithm is a result of Hertel and Mehlhorn [HM83], which requires $O(n)$ time and space to produce a convex partitioning from a triangulation of a polygon. Each of the partitioning functions uses a traits class to supply the primitive types and predicates used by the algorithms.

Assertions

The assertion flags for this package use *PARTITION* in their names (*e.g.*, *CGAL_PARTITION_NO_POSTCONDITIONS*). The precondition checks for the planar polygon partitioning functions are: counterclockwise ordering of the input vertices and simplicity of the polygon these vertices represent. The postcondition checks are: simplicity, counterclockwise orientation, and convexity (or y-monotonicity) of the partition polygons and validity of the partition (*i.e.*, the partition polygons are nonoverlapping and the union of these polygons is the same as the original polygon) .

Function

CGAL::approx_convex_partition_2

Definition

Function that produces a set of convex polygons that represent a partitioning of a polygon defined on a sequence of points. The number of convex polygons produced is no more than four times the minimal number.

#include <CGAL/partition_2.h>

template <class InputIterator, class OutputIterator, class Traits>
OutputIterator approx_convex_partition_2(InputIterator first, InputIterator beyond, OutputIterator result, Traits traits = Default_traits)

computes a partition of the polygon defined by the points in the range [*first*, *beyond*) into convex polygons. The counterclockwise-oriented partition polygons are written to the sequence starting at position *result*. The past-the-end iterator for the resulting sequence of polygons is returned.
Precondition: The points in the range [*first*, *beyond*) define a simple counterclockwise-oriented polygon.

Requirements

1. *Traits* is a model of the concept *PartitionTraits_2* and, for the purposes of checking the postcondition that the partition produced is valid, it should also be a model of the concept *ConvexPartitionIsValidTraits_2*.
2. *OutputIterator::value_type* should be *Traits::Polygon_2*.
3. *InputIterator::value_type* should be *Traits::Point_2*, which should also be the type of the points stored in an object of type *Traits::Polygon_2*.
4. Points in the range $[first, beyond)$ must define a simple polygon whose vertices are oriented counterclockwise.

The default traits class *Default_traits* is *Partition_traits_2*, with the representation type determined by *InputIterator1::value_type*.

Implementation

This function implements the algorithm of Hertel and Mehlhorn [HM83] and is based on the class *CGAL::Constrained_triangulation_2*. Given a triangulation of the polygon, the function requires $O(n)$ time and space for a polygon with n vertices.

Example

The following program computes an approximately optimal convex partitioning of a polygon using the default traits class and stores the partition polygons in the list *partition_polys*.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Partition_traits_2.h>
#include <CGAL/partition_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_polygon_2.h>
#include <cassert>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Partition_traits_2<K>                         Traits;
typedef Traits::Point_2                                     Point_2;
typedef Traits::Polygon_2                                   Polygon_2;
typedef Polygon_2::Vertex_iterator
   Vertex_iterator;
typedef std::list<Polygon_2>                                Polygon_list;
typedef CGAL::Creator_uniform_2<int, Point_2>               Creator;
typedef CGAL::Random_points_in_square_2<Point_2, Creator>
   Point_generator;

void make_polygon(Polygon_2& polygon)
{
   polygon.push_back(Point_2(391, 374));
   polygon.push_back(Point_2(240, 431));
   polygon.push_back(Point_2(252, 340));
   polygon.push_back(Point_2(374, 320));
   polygon.push_back(Point_2(289, 214));
   polygon.push_back(Point_2(134, 390));
   polygon.push_back(Point_2( 68, 186));
   polygon.push_back(Point_2(154, 259));
   polygon.push_back(Point_2(161, 107));
   polygon.push_back(Point_2(435, 108));
   polygon.push_back(Point_2(208, 148));
   polygon.push_back(Point_2(295, 160));
   polygon.push_back(Point_2(421, 212));
   polygon.push_back(Point_2(441, 303));
}

int main()
{
   Polygon_2    polygon;
   Polygon_list partition_polys;
```

```
/*
   CGAL::random_polygon_2(50, std::back_inserter(polygon),
                          Point_generator(100));
*/
   make_polygon(polygon);
   CGAL::approx_convex_partition_2(polygon.vertices_begin(),
                                   polygon.vertices_end(),
                                   std::back_inserter(partition_polys));
   assert(CGAL::convex_partition_is_valid_2(polygon.vertices_begin(),
                                            polygon.vertices_end(),
                                            partition_polys.begin(),
                                            partition_polys.end()));
   return 0;
}
```

File: examples/Partition_2/approx_convex_partition_2.cpp

CGAL::convex_partition_is_valid_2

Definition

Function that determines if a given set of polygons represents a valid convex partitioning for a given sequence of points that represent a simple, counterclockwise-oriented polygon. A convex partition is valid if the polygons do not overlap, the union of the polygons is the same as the original polygon given by the sequence of points, and if each partition polygon is convex.

#include <CGAL/partition_is_valid_2.h>

template<class InputIterator, class ForwardIterator, class Traits>
bool convex_partition_is_valid_2(InputIterator point_first, InputIterator point_beyond, ForwardIterator poly_first, ForwardIterator poly_beyond, Traits traits = Default_traits)

determines if the polygons in the range [*poly_first*, *poly_beyond*) define a valid convex partition of the polygon defined by the points in the range [*point_first*, *point_beyond*). The function returns *true* iff the partition is valid and otherwise returns *false*.
Precondition: The points in the range [*point_first*, *point_beyond*) define a simple, counterclockwise-oriented polygon.

Requirements

1. *Traits* is a model of the concept *ConvexPartitionIsValidTraits_2*.
2. *InputIterator::value_type* should be *Traits::Point_2*, which should also be the type of the points stored in an object of type *Traits::Polygon_2*.
3. *ForwardIterator::value_type* should be *Traits::Polygon_2*.

The default traits class *Default_traits* is *Partition_traits_2*, with the representation type determined by *InputIterator::value_type*.

CGAL::optimal_convex_partition_2 . . . . page 1646
CGAL::partition_is_valid_2 . . . . page 1651
CGAL::is_convex_2

Implementation

This function calls *partition_is_valid_2* using the function object *Is_convex_2* to determine the convexity of each partition polygon. Thus the time required by this function is $O(n \log n + e \log e)$ where n is the total number of vertices in the partition polygons and e the total number of edges.

Example

See the example presented with the function *approx_convex_partition_2* for an illustration of the use of this function.

ConvexPartitionIsValidTraits_2

Concept

Definition

Requirements of a traits class used by *convex_partition_is_valid_2* for testing the validity of a convex partition of a polygon.

Types

All types required by the concept *PartitionIsValidTraits_2* are required except the function object type *Is_valid*. The following type is required instead:

ConvexPartitionIsValidTraits_2:: Is_convex_2 — Model of the concept *PolygonIsValid* that tests if a sequence of points is convex or not.

Creation

Only a copy constructor is required.

ConvexPartitionIsValidTraits_2 traits(& tr);

Operations

The following function that creates an instance of the above predicate object type must exist instead of the function *is_valid_object* required by *PartitionIsValidTraits_2*.

Is_convex_2 *traits.is_convex_2_object(t)*

CGAL::greene_approx_convex_partition_2

Definition

Function that produces a set of convex polygons that represent a partitioning of a polygon defined on a sequence of points. The number of convex polygons produced is no more than four times the minimal number.

#include <CGAL/partition_2.h>

template <class InputIterator, class OutputIterator, class Traits>
OutputIterator greene_approx_convex_partition_2(InputIterator first, InputIterator beyond, OutputIterator result, Traits traits = Default_traits)

computes a partition of the polygon defined by the points in the range [*first*, *beyond*) into convex polygons. The counterclockwise-oriented partition polygons are written to the sequence starting at position *result*. The past-the-end iterator for the resulting sequence of polygons is returned.
Precondition: The points in the range [*first*, *beyond*) define a simple, counterclockwise-oriented polygon.

Requirements

1. *Traits* is a model of the concepts *PartitionTraits_2* and *YMonotonePartitionTraits_2*. For the purpose of checking the validity of the y-monotone partition produced as a preprocessing step for the convex partitioning, it must also be a model of *YMonotonePartitionIsValidTraits_2*. For the purpose of checking the postcondition that the convex partition is valid, *Traits* must also be a model of *ConvexPartitionIsValidTraits_2*.
2. *OutputIterator::value_type* is equivalent to *Traits::Polygon_2*.
3. *InputIterator::value_type* is equivalent to *Traits::Point_2*, which should also be equivalent to the type of the points stored in an object of type *Traits::Polygon_2*.

The default traits class *Default_traits* is *Partition_traits_2*, with the representation type determined by *InputIterator::value_type*.

CGAL::partition_is_valid_2 . . . . page 1651
CGAL::y_monotone_partition_2 . . . . page 1662

Implementation

This function implements the approximation algorithm of Greene [Gre83] and requires $O(n \log n)$ time and $O(n)$ space to produce a convex partitioning given a y-monotone partitioning of a polygon with n vertices. The function *y_monotone_partition_2* is used to produce the monotone partition.

Example

The following program computes an approximately optimal convex partitioning of a polygon using the default traits class and stores the partition polygons in the list *partition_polys*.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Partition_traits_2.h>
#include <CGAL/partition_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_polygon_2.h>
#include <cassert>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Partition_traits_2<K>                         Traits;
typedef Traits::Point_2                                     Point_2;
typedef Traits::Polygon_2                                   Polygon_2;
typedef Polygon_2::Vertex_iterator
   Vertex_iterator;
typedef std::list<Polygon_2>                                Polygon_list;
typedef CGAL::Creator_uniform_2<int, Point_2>               Creator;
typedef CGAL::Random_points_in_square_2< Point_2, Creator >
   Point_generator;

void make_polygon(Polygon_2& polygon)
{
   polygon.push_back(Point_2(391, 374));
   polygon.push_back(Point_2(240, 431));
   polygon.push_back(Point_2(252, 340));
   polygon.push_back(Point_2(374, 320));
   polygon.push_back(Point_2(289, 214));
   polygon.push_back(Point_2(134, 390));
   polygon.push_back(Point_2( 68, 186));
   polygon.push_back(Point_2(154, 259));
   polygon.push_back(Point_2(161, 107));
   polygon.push_back(Point_2(435, 108));
   polygon.push_back(Point_2(208, 148));
   polygon.push_back(Point_2(295, 160));
   polygon.push_back(Point_2(421, 212));
   polygon.push_back(Point_2(441, 303));
}

CGAL::is_y_monotone_2

Function

Definition

Function for testing the y-monotonicity of a sequence of points.

#include <CGAL/is_y_monotone_2.h>

template<class InputIterator, class Traits>
bool *is_y_monotone_2(InputIterator first, InputIterator beyond, Traits traits)*

Determines if the sequence of points in the range [*first*, *beyond*) define a y-monotone polygon or not. If so, the function returns *true*, otherwise it returns *false*.

Requirements

1. *Traits* is a model of the concept *IsYMonotoneTraits_2*.
2. *InputIterator::value_type* should be *Traits::Point_2*.

The default traits class *Default_traits* is the kernel in which the type *InputIterator::value_type* is defined.

See Also

CGAL::Is_y_monotone_2<Traits> . . . . page 1645
CGAL::y_monotone_partition_2 . . . . page 1662
CGAL::y_monotone_partition_is_valid_2 . . . . page 1665

Implementation

This function requires $O(n)$ time for a polygon with n vertices.

Example

The following program computes a y-monotone partitioning of a polygon using the default traits class and stores the partition polygons in the list *partition_polys*. It then asserts that each of the partition polygons is, in fact, a y-monotone polygon and that the partition is valid. (Note that the assertions are superfluous unless the postcondition checking done by *y_monotone_partition_2* has been turned off during compilation.)

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Partition_traits_2.h>
#include <CGAL/partition_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_polygon_2.h>
#include <cassert>
#include <list>
```

```
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Partition_traits_2<K>                         Traits;
typedef Traits::Point_2                                     Point_2;
typedef Traits::Polygon_2                                   Polygon_2;
typedef std::list<Polygon_2>                                Polygon_list;
typedef CGAL::Creator_uniform_2<int, Point_2>               Creator;
typedef CGAL::Random_points_in_square_2<Point_2, Creator>
   Point_generator;

void make_polygon(Polygon_2& polygon)
{
   polygon.push_back(Point_2(391, 374));
   polygon.push_back(Point_2(240, 431));
   polygon.push_back(Point_2(252, 340));
   polygon.push_back(Point_2(374, 320));
   polygon.push_back(Point_2(289, 214));
   polygon.push_back(Point_2(134, 390));
   polygon.push_back(Point_2( 68, 186));
   polygon.push_back(Point_2(154, 259));
   polygon.push_back(Point_2(161, 107));
   polygon.push_back(Point_2(435, 108));
   polygon.push_back(Point_2(208, 148));
   polygon.push_back(Point_2(295, 160));
   polygon.push_back(Point_2(421, 212));
   polygon.push_back(Point_2(441, 303));
}

int main( )
{
   Polygon_2    polygon;
   Polygon_list partition_polys;

/*
   CGAL::random_polygon_2(50, std::back_inserter(polygon),
                          Point_generator(100));
*/
   make_polygon(polygon);
   CGAL::y_monotone_partition_2(polygon.vertices_begin(),
                                polygon.vertices_end(),
                                std::back_inserter(partition_polys));

   std::list<Polygon_2>::const_iterator   poly_it;
   for (poly_it = partition_polys.begin(); poly_it !=
   partition_polys.end();
        poly_it++)
   {
      assert(CGAL::is_y_monotone_2((*poly_it).vertices_begin(),
                                   (*poly_it).vertices_end()));
   }

   assert(CGAL::partition_is_valid_2(polygon.vertices_begin(),
```

```
                                                    polygon.vertices_end(),
                                                    partition_polys.begin(),
                                                    partition_polys.end()));
   return 0;
}
```

Concept

IsYMonotoneTraits_2

Definition

Requirements of a traits class to be used with the function *is_y_monotone_2* that tests whether a sequence of 2D points defines a y-monotone polygon or not.

Types

The following two types are required:

IsYMonotoneTraits_2:: Point_2	The point type of the polygon vertices.
IsYMonotoneTraits_2:: Less_yx_2	Predicate object type that compares *Point_2*s lexicographically. Must provide *bool operator()(Point_2 p, Point_2 q)* where *true* is returned iff $p <_{xy} q$. We have $p <_{xy} q$, iff $p_x < q_x$ or $p_x = q_x$ and $p_y < q_y$, where p_x and p_y denote x and y coordinate of point p resp.

Creation

Only a copy constructor is required.

IsYMonotoneTraits_2 traits(& tr);

Operations

The following function that creates an instance of the above predicate object type must exist:

Less_yx_2	*traits.less_yx_2_object()*

Implementation

This test requires $O(n)$ time for a polygon with n vertices.

Function

CGAL::optimal_convex_partition_2

Function that produces a set of convex polygons that represent a partitioning of a polygon defined on a sequence of points. The number of convex polygons produced is minimal.

#include <CGAL/partition_2.h>

template <class InputIterator, class OutputIterator, class Traits>
OutputIterator optimal_convex_partition_2(InputIterator first, InputIterator beyond, OutputIterator result, Traits traits = Default_traits)

computes a partition of the polygon defined by the points in the range [*first*, *beyond*) into convex polygons. The counterclockwise-oriented partition polygons are written to the sequence starting at position *result*. The past-the-end iterator for the resulting sequence of polygons is returned.
Precondition: The points in the range [*first*, *beyond*) define a simple, counterclockwise-oriented polygon.

Requirements

1. *Traits* is a model of the concept *OptimalConvexPartitionTraits_2*. For the purposes of checking the postcondition that the partition is valid, *Traits* should also be a model of *ConvexPartitionIsValidTraits_2*.

2. *OutputIterator::value_type* should be *Traits::Polygon_2*.

3. *InputIterator::value_type* should be *Traits::Point_2*, which should also be the type of the points stored in an object of type *Traits::Polygon_2*.

The default traits class *Default_traits* is *Partition_traits_2*, with the representation type determined by *InputIterator::value_type*.

CGAL::partition_is_valid_2 . . . . page 1651
CGAL::Partition_is_valid_traits_2<Traits, PolygonIsValid> . . . . page 1657

Implementation

This function implements the dynamic programming algorithm of Greene [Gre83], which requires $O(n^4)$ time and $O(n^3)$ space to produce a partitioning of a polygon with n vertices.

Example

The following program computes an optimal convex partitioning of a polygon using the default traits class and stores the partition polygons in the list *partition_polys*. It then asserts that the partition produced is valid. The traits class used for testing the validity is derived from the traits class used to produce the partition with the function object class *CGAL::Is_convex_2* used to define the required *Is_valid* type. (Note that this assertion is superfluous unless the postcondition checking for *optimal_convex_partition_2* has been turned off.)

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Partition_traits_2.h>
#include <CGAL/Partition_is_valid_traits_2.h>

OptimalConvexPartitionTraits_2

Concept

Definition

Requirements of a traits class to be used with the function *optimal_convex_partition_2* that computes an optimal convex partition of a polygon.

Refines

PartitionTraits_2 . . . . page 1655

Types

In addition to the types listed with the concept *PartitionTraits_2*, the following types are required:

OptimalConvexPartitionTraits_2:: Segment_2 A segment type

OptimalConvexPartitionTraits_2:: Ray_2 A ray type

OptimalConvexPartitionTraits_2:: Object_2 A general object type that can be either a point or a segment

OptimalConvexPartitionTraits_2:: Construct_segment_2

Function object type that provides *Segment_2 operator()(Point_2 p, Point_2 q)*, which constructs and returns the segment defined by the points p and q.

OptimalConvexPartitionTraits_2:: Construct_ray_2

Function object type that provides *Ray_2 operator()(Point_2 p, Point_2 q)*, which constructs and returns the ray from point p through point q.

OptimalConvexPartitionTraits_2:: Collinear_are_ordered_along_line_2

Predicate object type that determines orderings of *Point_2*s on a line. Must provide *bool operator()(Point_2 p, Point_2 q, Point_2 r)* that returns *true*, iff q lies between p and r and p, q, and r satisfy the precondition that they are collinear.

OptimalConvexPartitionTraits_2:: Are_strictly_ordered_along_line_2

Predicate object type that determines orderings of *Point_2*s. Must provide *bool operator()(Point_2 p, Point_2 q, Point_2 r)* that returns *true*, iff the three points are collinear and q lies strictly between p and r. Note that *false* should be returned if $q{=}{=}p$ or $q{=}{=}r$.

OptimalConvexPartitionTraits_2:: Intersect_2	Function object type that provides *Object_2 operator()(Segment_2 s1, Segment_2 s2)* that returns the intersection of two segments (which may be either a segment or a point).
OptimalConvexPartitionTraits_2:: Assign_2	Function object type that provides *bool operator()(Segment_2 s1, Object_2 o)* that returns *true* if *o* is a segment and assigns the value of *o* to *s1*; returns *false* otherwise.

Creation

Only a copy constructor is required.

OptimalConvexPartitionTraits_2 traits(& tr);

Operations

In addition to the functions required by *PartitionTraits_2*, the following functions that create instances of the above function object types must exist:

Collinear_are_ordered_along_line_2	*traits.collinear_are_ordered_along_line_2_object() const*
Construct_segment_2	*traits.construct_segment_2_object() const*
Construct_ray_2	*traits.construct_ray_2_object() const*
Are_strictly_ordered_along_line_2	*traits.are_strictly_ordered_along_line_2_object() const*

Has Models

CGAL::partition_is_valid_2

Definition

Function that determines if a given set of polygons represents a valid partition for a given sequence of points that define a simple, counterclockwise-oriented polygon. A valid partition is one in which the polygons are nonoverlapping and the union of the polygons is the same as the original polygon.

#include <CGAL/partition_is_valid_2.h>

```
template<class InputIterator, class ForwardIterator, class Traits>
bool    partition_is_valid_2( InputIterator point_first,
                              InputIterator point_beyond,
                              ForwardIterator poly_first,
                              ForwardIterator poly_beyond,
                              Traits traits = Default_traits)
```

returns *true* iff the polygons in the range [*poly_first*, *poly_beyond*) define a valid partition of the polygon defined by the points in the range [*point_first*, *point_beyond*) and *false* otherwise. Each polygon must also satisfy the property tested by *Traits::Is_valid()*.
Precondition: Points in the range [*point_first*, *point_beyond*) define a simple, counterclockwise-oriented polygon.

Requirements

1. *Traits* is a model of the concept *PartitionIsValidTraits_2* and the concept defining the requirements for the validity test implemented by *Traits::Is_valid()*.
2. *InputIterator::value_type* should be *Traits::Point_2*, which should also be the type of the points stored in an object of type *Traits::Polygon_2*.
3. *ForwardIterator::value_type* should be *Traits::Polygon_2*.

The default traits class *Default_traits* is *Partition_traits_2*, with the representation type determined by *InputIterator::value_type*.

CGAL::y_monotone_partition_2 . . . . . . page 1662
CGAL::is_convex_2

Implementation

This function requires $O(n \log n + e \log e + \Sigma_{i=1}^{p} m_i)$ where n is the total number of vertices of the p partition polygons, e is the total number of edges of the partition polygons and m_i is the time required by *Traits::Is_valid()* to test if partition polygon p_i is valid.

Example

See the example presented with the function *optimal_convex_partition_2* for an illustration of the use of this function.

advanced

PartitionIsValidTraits_2

Definition

Requirements of a traits class that is used by *partition_is_valid_2*, *convex_partition_is_valid_2*, and *y_monotone_partition_is_valid_2* for testing if a given set of polygons are nonoverlapping and if their union is a polygon that is the same as a polygon represented by a given sequence of points. Note that the traits class for *partition_is_valid_2* may have to satisfy additional requirements if each partition polygon is to be tested for having a particular property; see, for example, the descriptions of the function *is_convex_2* and the concept *YMonotonePartitionTraits_2* for the additional requirements for testing for convexity and y-monotonicity, respectively.

Types

PartitionIsValidTraits_2:: Point_2 — The point type on which the partitioning algorithm operates.

PartitionIsValidTraits_2:: Polygon_2 — The polygon type created by the partitioning function. This type should provide a nested type *Vertex_const_iterator* that is the type of the non-mutable iterator over the polygon vertices.

PartitionIsValidTraits_2:: Is_valid — A model of the concept *PolygonIsValid*

PartitionIsValidTraits_2:: Less_xy_2 — Predicate object type that compares *Point_2*s lexicographically. Must provide *bool operator()(Point_2 p, Point_2 q)* where *true* is returned iff $p <_{xy} q$. We have $p <_{xy} q$, iff $p_x < q_x$ or $p_x = q_x$ and $p_y < q_y$, where p_x and p_y denote the x and y coordinates of point p, respectively.

PartitionIsValidTraits_2:: Left_turn_2 — Predicate object type that provides *bool operator()(Point_2 p,Point_2 q,Point_2 r)*, which returns *true* iff r lies to the left of the oriented line through p and q.

PartitionIsValidTraits_2:: Orientation_2 — Predicate object type that provides *CGAL::Orientation operator()(Point_2 p, Point_2 q, Point_2 r)* that returns *CGAL::LEFT_TURN*, if r lies to the left of the oriented line l defined by p and q, returns *CGAL::RIGHT_TURN* if r lies to the right of l, and returns *CGAL::COLLINEAR* if r lies on l.

Creation

Only a copy constructor is required.

PartitionIsValidTraits_2 traits(& tr);

Operations

The following functions that create instances of the above predicate object types must exist.

Orientation_2	*traits.is_valid_object()*
Less_xy_2	*traits.less_xy_2_object()*
Left_turn_2	*traits.left_turn_2_object()*
Orientation_2	*traits.orientation_2_object()*

PartitionTraits_2

Definition

The polygon partitioning functions are each parameterized by a traits class that defines the primitives used in the algorithms. Many requirements are common to all traits classes. The concept PartitionTraits_2 defines this common set of requirements.

Types

PartitionTraits_2:: Point_2	The point type on which the partitioning algorithm operates.
PartitionTraits_2:: Polygon_2	The polygon type to be created by the partitioning algorithm. For testing the validity postcondition of the partition, this type should provide a nested type *Vertex_const_iterator* that is the type of the iterator over the polygon vertices and member functions *Vertex_const_iterator vertices_begin()* and *Vertex_const_iterator vertices_end()*.
PartitionTraits_2:: Less_xy_2	Predicate object type that compares *Point_2*s lexicographically. Must provide *bool operator()(Point_2 p, Point_2 q)* where *true* is returned iff $p <_{xy} q$. We have $p <_{xy} q$, iff $p_x < q_x$ or $p_x = q_x$ and $p_y < q_y$, where p_x and p_y denote the x and y coordinates of point p, respectively.
PartitionTraits_2:: Less_yx_2	Same as *Less_xy_2* with the roles of x and y interchanged.
PartitionTraits_2:: Left_turn_2	Predicate object type that provides *bool operator()(Point_2 p,Point_2 q,Point_2 r)*, which returns *true* iff r lies to the left of the oriented line through p and q.
PartitionTraits_2:: Orientation_2	Predicate object type that provides *CGAL::Orientation operator()(Point_2 p, Point_2 q, Point_2 r)* that returns *CGAL::LEFT_TURN*, if r lies to the left of the oriented line l defined by p and q, returns *CGAL::RIGHT_TURN* if r lies to the right of l, and returns *CGAL::COLLINEAR* if r lies on l.
PartitionTraits_2:: Compare_y_2	Predicate object type that provides *CGAL::Comparision_result operator()(Point_2 p, Point_2 q)* to compare the y values of two points. The operator must return *CGAL::SMALLER* if $p_y < q_y$, *CGAL::LARGER* if $p_y > q_y$ and *CGAL::EQUAL* if $p_y = q_y$.
PartitionTraits_2:: Compare_x_2	The same as *Compare_y_2*, except that x coordinates are compared instead of y.

Creation

A copy constructor and default constructor are required.

PartitionTraits_2 traits;

PartitionTraits_2 traits(& tr);

Operations

The following functions that create instances of the above predicate object types must exist.

Less_yx_2	*traits.less_yx_2_object()*
Less_xy_2	*traits.less_xy_2_object()*
Left_turn_2	*traits.left_turn_2_object()*
Orientation_2	*traits.orientation_2_object()*
Compare_y_2	*traits.compare_y_2_object()*
Compare_x_2	*traits.compare_x_2_object()*

CGAL::Partition_is_valid_traits_2<Traits, PolygonIsValid>

Class

Definition

Class that derives a traits class for *partition_is_valid_2* from a given traits class by defining the validity testing function object in terms of a supplied template parameter.

#include <CGAL/Partition_is_valid_traits_2.h>

Inherits From

Traits

Is Model for the Concepts

PartitionIsValidTraits_2

Types

typedef PolygonIsValid	*Is_valid;*
typedef Traits::Point_2	*Point_2;*
typedef Traits::Polygon_2	*Polygon_2;*
typedef Traits::Less_xy_2	*Less_xy_2;*
typedef Traits::Left_turn_2	*Left_turn_2;*
typedef Traits::Orientation_2	*Orientation_2;*

Operations

The constructors and member functions for creating instances of the above types are inherited from *Traits*. In addition, the following member function is defined:

Is_valid *traits.is_valid_object(Traits traits) const*

function returning an instance of *Is_valid*

PolygonIsValid

Functor
Concept

Definition

Function object that determines if a sequence of points represents a valid partition polygon or not, where “valid” can assume any of several meanings (*e.g.*, convex or *y*-monotone).

Creation

PolygonIsValid f(Traits t);

Traits is a model of the concept required by the function that checks for validity of the polygon.

Operations

template<class InputIterator>
bool f(InputIterator first, InputIterator beyond)

returns *true* iff the points of type *Traits::Point_2* in the range [*first*,*beyond*) define a valid polygon.

Has Models

Function

CGAL::y_monotone_partition_2

Definition

Function that produces a set of y-monotone polygons that represent a partitioning of a polygon defined on a sequence of points.

#include <CGAL/partition_2.h>

template <class InputIterator, class OutputIterator, class Traits>
OutputIterator y_monotone_partition_2(InputIterator first, InputIterator beyond, OutputIterator result, Traits traits = Default_traits)

computes a partition of the polygon defined by the points in the range [*first*, *beyond*) into y-monotone polygons. The counterclockwise-oriented partition polygons are written to the sequence starting at position *result*. The past-the-end iterator for the resulting sequence of polygons is returned.
Precondition: The points in the range [*first*, *beyond*) define a simple, counterclockwise-oriented polygon.

Requirements

1. *Traits* is a model of the concept *YMonotonePartitionTraits_2* and, for the purposes of checking the postcondition that the partition is valid, it should also be a model of *YMonotonePartitionIsValidTraits_2*.
2. *OutputIterator::value_type* should be *Traits::Polygon_2*.
3. *InputIterator::value_type* should be *Traits::Point_2*, which should also be the type of the points stored in an object of type *Traits::Polygon_2*.

The default traits class *Default_traits* is *Partition_traits_2*, with the representation type determined by *InputIterator::value_type*.

CGAL::partition_is_valid_2 . . . . . page 1651
CGAL::y_monotone_partition_is_valid_2 . . . . . page 1665

Implementation

This function implements the algorithm presented by de Berg *et al.* [dBvKOS97] which requires $O(n \log n)$ time and $O(n)$ space for a polygon with n vertices.

Example

The following program computes a y-monotone partitioning of a polygon using the default traits class and stores the partition polygons in the list *partition_polys*. It then asserts that each partition polygon produced is, in fact, y-monotone and that the partition is valid. (Note that these assertions are superfluous unless the postcondition checking for *y_monotone_partition_2* has been turned off.)

CGAL::y_monotone_partition_is_valid_2

Function

Definition

Function that determines if a given set of polygons represents a valid y-monotone partitioning for a given sequence of points that define a simple, counterclockwise-oriented polygon. A valid partition is one in which the polygons are nonoverlapping and the union of the polygons is the same as the original polygon and each polygon is y-monotone

#include <CGAL/partition_is_valid_2.h>

```
template<class InputIterator, class ForwardIterator, class Traits>
bool    y_monotone_partition_is_valid_2( InputIterator point_first,
                                         InputIterator point_beyond,
                                         ForwardIterator poly_first,
                                         ForwardIterator poly_beyond,
                                         Traits traits = Default_traits)
```

determines if the polygons in the range [*poly_first*, *poly_beyond*) define a valid y-monotone partition of the polygon represented by the points in the range [*point_first*, *point_beyond*). The function returns *true* iff the partition is valid and otherwise returns false.
Precondition: Points in the range [*point_first*, *point_beyond*) define a simple, counterclockwise-oriented polygon.

Requirements

1. *Traits* is a model of the concept *YMonotonePartitionIsValidTraits_2*.
2. *InputIterator::value_type* should be *Traits::Point_2*, which should also be the type of the points stored in an object of type *Traits::Polygon_2*.
3. *ForwardIterator::value_type* should be *Traits::Polygon_2*.

The default traits class *Default_traits* is *Partition_traits_2*, with the representation type determined by *InputIterator::value_type*.

See Also

CGAL::y_monotone_partition_2 . . . . . page 1662
CGAL::is_y_monotone_2 . . . . . page 1639
CGAL::partition_is_valid_2 . . . . . page 1651
CGAL::Partition_is_valid_traits_2<Traits, PolygonIsValid> . . . . . page 1657

Implementation

This function uses the function *partition_is_valid_2* together with the function object *Is_y_monotone_2* to determine if each polygon is y-monotone or not. Thus the time required is $O(n \log n + e \log e)$ where n is the total number of vertices of the partition polygons and e is the total number of edges.

Example

See the example presented with the function *y_monotone_partition_2* for an illustration of the use of this function.

advanced

YMonotonePartitionIsValidTraits_2

Concept

Definition

Requirements of a traits class that is used by *y_monotone_partition_is_valid_2* for testing the validity of a *y*-monotone partition of a polygon.

Types

All types required by the concept *PartitionIsValidTraits_2* are required except the function object type *Is_valid*. The following type is required instead:

YMonotonePartitionIsValidTraits_2:: Is_y_monotone_2

Model of the concept *PolygonIsValid* that tests if a sequence of points is *y*-monotone or not.

Creation

Only a copy constructor is required.

YMonotonePartitionIsValidTraits_2 traits(& tr);

Operations

The following function that creates an instance of the above predicate object type must exist instead of the function *is_valid_object* required by *PartitionIsValidTraits_2*.

Is_y_monotone_2   *traits.is_y_monotone_2_object(t)*

Concept

YMonotonePartitionTraits_2

Definition

Requirements of a traits class to be used with the function *y_monotone_partition_2*.

Refines

PartitionTraits_2 . . . . page 1655

Types

In addition to the types defined for the concept *PartitionTraits_2*, the following types are also required:

YMonotonePartitionTraits_2:: Line_2

YMonotonePartitionTraits_2:: Compare_x_at_y_2

Predicate object type that provides *CGAL::Comparision_result operator()(Point_2 p, Line_2 h)* to compare the x coordinate of p and the horizontal projection of p on h.

YMonotonePartitionTraits_2:: Construct_line_2

Function object type that provides *Line_2 operator()(Point_2 p, Point_2 q)*, which constructs and returns the line defined by the points p and q.

YMonotonePartitionTraits_2:: Is_horizontal_2 Function object type that provides *bool operator()(Line_2 l)*, which returns *true* iff the line l is horizontal.

Creation

A copy constructor and default constructor are required.

YMonotonePartitionTraits_2 traits;

YMonotonePartitionTraits_2 traits(YMonotonePartitionTraits tr);

Operations

In addition to the functions required for the concept *PartitionTraits_2*, the following functions that create instances of the above function object types must exist.

Construct_line_2 *traits.construct_line_2_object()*

Compare_x_at_y_2 *traits.compare_x_at_y_2_object()*

Is_horizontal_2 *traits.is_horizontal_2_object()*

Chapter 23

2D Straight Skeleton and Polygon Offsetting

Fernando Cacciola

Contents

23.1 Definitions

23.1.1 2D Contour

A *2D contour* is a closed sequence (a cycle) of 3 or more *connected 2D oriented straight line segments* called *contour edges*. The endpoints of the contour edges are called *vertices*. Each contour edge shares its endpoints with at least two other contour edges.

If the edges intersect only at the vertices and at most are coincident along a line but do not *cross* one another, the contour is classified as *simple*.
A contour is topologically equivalent to a *disk* and if it is simple, is said to be a *Jordan Curve*.
Contours partition the plane in two open regions: one bounded and one unbounded. If the bounded region of a contour is only one *singly-connected set*, the contour is said to be *strictly-simple*.
The *Orientation* of a contour is given by the order of the vertices around the region they bound. It can be *CLOCKWISE* (CCW) or *COUNTERCLOCKWISE* (CW).
The *bounded side* of a contour edge is the side facing the bounded region of the contour. If the contour is oriented CCW, the bounded side of an edge is its left side.

A contour with a null edge (a segment of length zero given by two consecutive coincident vertices), or with edges not connected to the bounded region (an antenna: 2 consecutive edges going forth and back along the same line), is said to be *degenerate* (collinear edges are *not* considered a degeneracy).

23.1.2 2D Polygon with Holes

A *2D polygon* is a contour.
A *2D polygon with holes* is a contour, called the *outer contour*, having zero or more contours, called *inner contours*, or *holes*, in its bounded region. The intersection of the bounded region of the outer contour and the unbounded regions of each inner contour is the *interior* of the polygon with holes. The orientation of the holes must be opposite to the orientation of the outer contour and there cannot be any intersection among any contour. A hole cannot be in the bounded region of any other hole.
A polygon with holes is strictly-simple if its interior is a singly-connected set.
The orientation of a polygon with holes is the orientation of its outer contour. The bounded side of *any* edge, whether of the outer contour or a hole, is the *same* for all edges. That is, if the outer contour is oriented CCW and the holes CW, both contour and hole edges face the polygon interior to their left.

Throughout the rest of this chapter the term *polygon* will be used as a shortcut for *polygon with holes*.

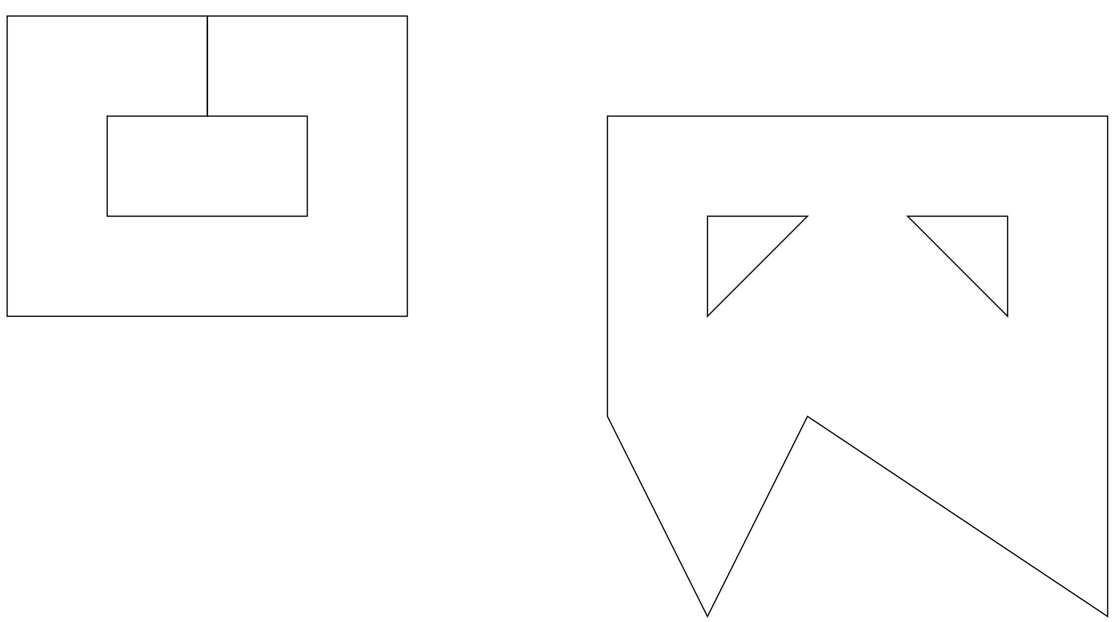

Figure 23.1: Examples of strictly simple polygons: One with no holes and two edges coincident (left) and one with 2 holes (right).

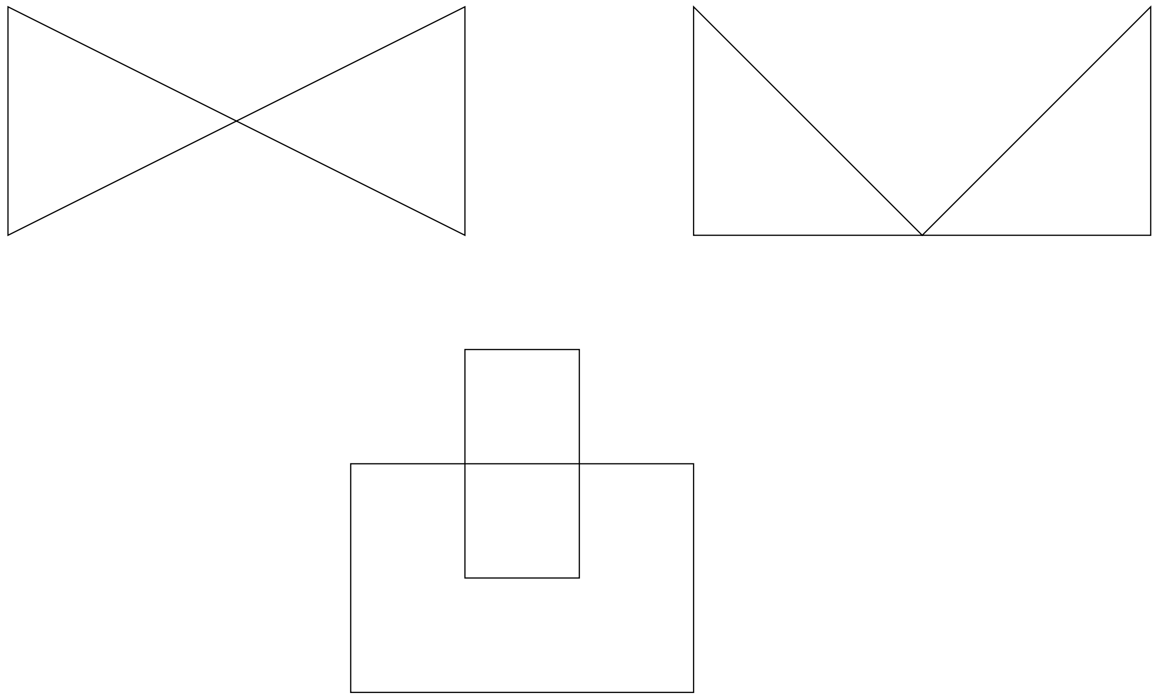

Figure 23.2: Examples of non-simple polygons: One folding into itself, that is, non-planar (left), one with a vertex touching an edge (right), and one with a hole crossing into the outside (bottom)

23.1.3 Inward Offset of a Non-degenerate Strictly-Simple Polygon with Holes

For any 2D non-degenerate strictly-simple polygon with holes called the *source*, there can exist a *set* of 0, 1 or more *inward offset polygons with holes*, or just offset polygons for short, at some euclidean distance $t > 0$ (each being strictly simple and non-degenerate). Any contour edge of such offset polygon, called an *offset edge* corresponds to *some* contour edge of the source polygon, called its *source edge*. An offset edge is parallel to its source edge and has the same orientation. The Euclidean distance between the *lines* supporting an offset edge and its source edge is exactly t.

An offset edge is always located to the bounded side of its source edge (which is an oriented straight line segment).

An offset polygon can have less, equal or more sides as its source polygon.

If the source polygon has no holes, no offset polygon has holes. If the source polygon has holes, any of the offset polygons can have holes itself, but it might as well have no holes at all (if the distance is sufficiently large).

Each offset polygon has the same orientation as the source polygon.

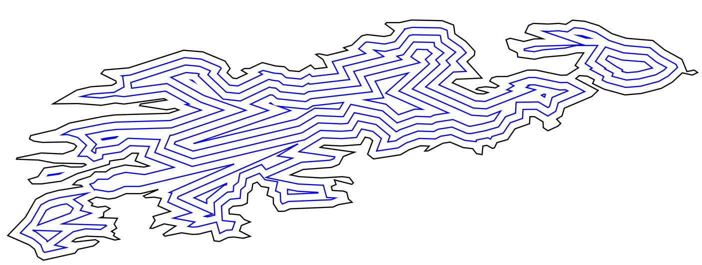

Figure 23.3: Offset contours of a sample polygon

23.1.4 Straight Skeleton of a 2D Non-degenerate Strictly-Simple Polygon with Holes

The *2D straight skeleton* of a non-degenerate strictly-simple polygon with holes [AAAG95] is a special partitioning of the polygon interior into *straight skeleton regions* corresponding to the monotone areas traced by a continuous *inward offsetting* of the contour edges. Each region corresponds to exactly 1 contour edge.
These regions are bounded by angular bisectors of the supporting lines of the contour edges and each such region is itself a non-convex non-degenerate strictly-simple polygon.

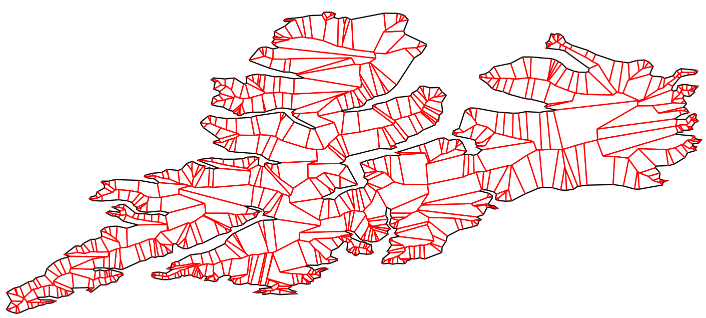

Figure 23.4: Straight skeleton of a complex shaggy contour

Angular Bisecting Lines and Offset Bisectors

Given two points and a line passing through them, the perpendicular line passing through the midpoint is the bisecting line (or bisector) of those points.

Two non-parallel lines, intersecting at a point, are bisected by two other lines passing through that intersection point.

Two parallel lines are bisected by another parallel line placed halfway in between.

Given just one line, any perpendicular line can be considered the bisecting line (any bisector of any two points along the single line).

The bisecting lines of two edges are the lines bisecting the supporting lines of the edges (if the edges are parallel or collinear, there is just one bisecting line).

The halfplane to the bounded side of the line supporting a contour edge is called the *offset zone* of the contour edge.

Given any number of contour edges (not necessarily consecutive), the intersection of their offset zones is called their *combined offset zone*.

Any two contour edges define an *offset bisector*, as follows: If the edges are non-parallel, their bisecting lines can be decomposed as 4 rays originating at the intersection of the supporting lines. Only one of these rays is contained in the combined offset zone of the edges (which one depends on the possible combinations of orientations). This ray is the offset bisector of the non-parallel contour edges.

If the edges are parallel (but not collinear) and have opposite orientation, the entire and unique bisecting line is their offset bisector. If the edges are parallel but have the same orientation, there is no offset bisector between them.

If the edges are collinear and have the same orientation, their offset bisector is given by a perpendicular ray to the left of the edges which originates at the midpoint of the combined complement of the edges. (The *complement*

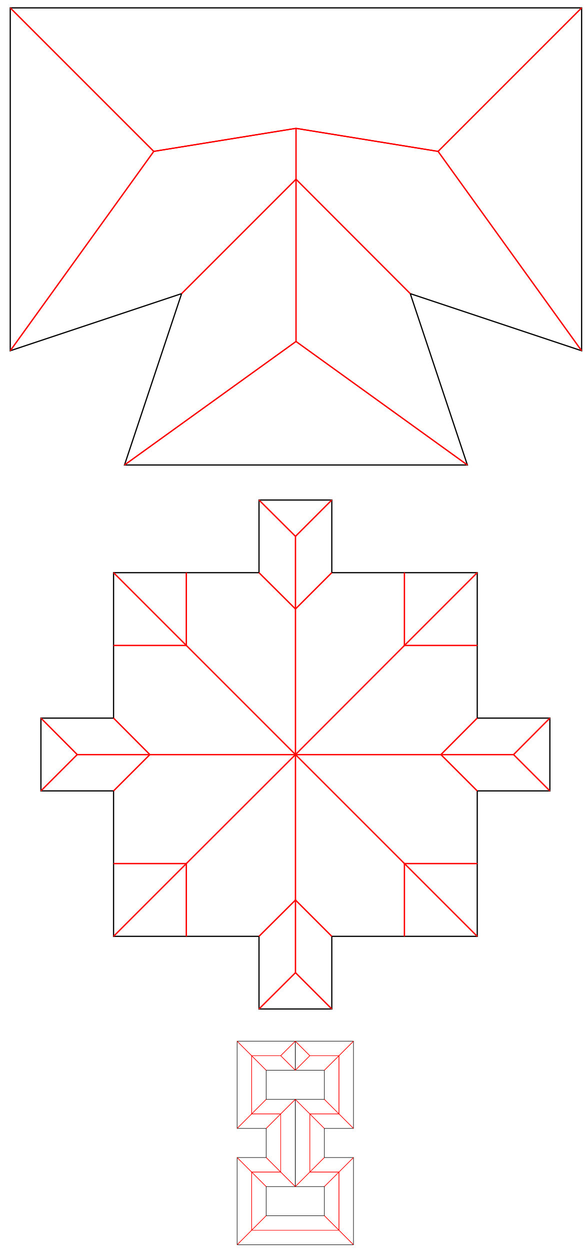

Figure 23.5: Other examples: A vertex-event (left), the case of several collinear edges (middle), and the case of a validly simple polygon with tangent edges (right).

of an edge/segment are the two rays along its supporting line which are not the segment and the *combined complement* of N collinear segments is the intersection of the complements of each segment). If the edges are collinear but have opposite orientation, there is no offset bisector between them.

Faces, Edges and Vertices

Each region of the partitioning defined by a straight skeleton is called a *face*. Each face is bounded by straight line segments, called *edges*. Exactly one edge per face is a *contour edge* (corresponds to a side of the polygon) and the rest of the edges, located in the interior of the polygon, are called *skeleton edges*, or *bisectors*.

The bisectors of the straight skeleton are segments of the offset bisectors as defined previously. Since an offset bisector is a ray of a bisecting line of 2 contour edges, each skeleton edge (or bisector) is uniquely given by two contour edges. These edges are called the *defining contour edges* of the bisector.

The intersection of the edges are called *vertices*. Although in a simple polygon, only 2 edges intersect at a vertex, in a straight skeleton, 3 or more edges intersect a any given vertex. That is, vertices in a straight skeleton have degree $>= 3$.

A *contour vertex* is a vertex for which 2 of its incident edges are contour edges.

A *skeleton vertex* is a vertex who's incident edges are all skeleton edges.

A *contour bisector* is a bisector who's defining contour edges are consecutive. Such a bisector is incident upon 1 contour vertex and 1 skeleton vertex and touches the input polygon at exactly 1 endpoint.

An *inner bisector* is a bisector who's defining contour edges are not consecutive. Such a bisector is incident upon 2 skeleton vertices and is strictly contained in the interior of the polygon.

23.2 Representation

This CGAL package represents a straight skeleton as a specialized *Halfedge Data Structure* (HDS) whose vertices embeds 2D Points (see the *StraightSkeleton_2* concept in the reference manual for details).

Its halfedges, by considering the source and target points, implicitly embeds 2D oriented straight line segments (each halfedge per see does not embed a segment explicitly).

A face of the straight skeleton is represented as a face in the HDS. Both contour and skeleton edges are represented by pairs of opposite HDS halfedges, and both contour and skeleton vertices are represented by HDS vertices.

In a HDS, a border halfedge is a halfedge which is incident upon an unbounded face. In the case of the straight skeleton HDS, such border halfedges are oriented such that their left side faces outwards the polygon. Therefore, the opposite halfedge of any border halfedge is oriented such that its left side faces inward the polygon.

This CGAL package requires the input polygon (with holes) to be non-degenerate, strictly-simple, and oriented counter-clockwise.

The skeleton halfedges are oriented such that their *left* side faces inward the region they bound. That is, the vertices (both contour and skeleton) of a face are circulated in counter-clockwise order. There is one and only one contour halfedge incident upon any face.

The contours of the input polygon are traced by the border halfedges of the HDS (those facing outward), but in the opposite direction. That is, the vertices of the contours can only by traced from the straight skeleton data structure by circulating the border halfedges, and the resulting vertex sequence will be reversed w.r.t the input vertex sequence.

A skeleton edge, according to the definition given in the previous section, is defined by 2 contour edges. In the representation, each one of the opposite halfedges that represent a skeleton edge is associated with one of the opposite halfedges that correspond to one of its defining contour edges. Thus, the 2 opposite halfedges of a skeleton edge link the edge to its 2 defining contour edges.

Starting from any border contour halfedge, circulating the structure walks through border counter halfedges and traces the vertices of the polygon's contours (in opposite order).

Starting from any non-border but contour halfedge, circulating the structure walks counter-clockwise around the face corresponding to that contour halfedge. The vertices around a face always describe a non-convex non-degenerate strictly-simple polygon.

A vertex is the intersection of contour and/or skeleton edges. Since a skeleton edge is defined by 2 contour edges, any vertex is itself defined by a unique set of contour edges. These are called the *defining contour edges* of the vertex.

A vertex is identified by it's set of defining contour edges. Two vertices are distinct if they have differing sets of defining contour edges. Note that vertices can be distinct even if they are geometrically embedded at the same point.

The *degree* of a vertex is the number of halfedges around the vertex incident upon (pointing to) the vertex. As with any halfedge data structure, there is one outgoing halfedge for each incoming (incident) halfedge around a vertex. The degree of the vertex counts only incoming (incident) halfedges.

In a straight skeleton, the degree of a vertex is not only the number of incident halfedges around the vertex but also the number of defining contour halfedges. The vertex itself is the point where all the defining contour edges simultaneously collide.

Contour vertices have exactly two defining contour halfedges, which are the contour edges incident upon the vertex; and 3 incident halfedges. One and only one of the incident halfedges is a skeleton halfedge. The degree of a contour vertex is exactly 3.

Skeleton vertices have at least 3 defining contour halfedges and 3 incident skeleton halfedges. If more than 3 edges collide simultaneously at the same point and time (like in any regular polygon with more than 3 sides), the corresponding skeleton vertex will have more than 3 defining contour halfedges and incident skeleton halfedges. That is, the degree of a skeleton vertex is $>= 3$ (the algorithm initially produces nodes of degree 3 but in the end all coincident nodes are merged to form higher degree nodes). All halfedges incident upon a skeleton vertex are skeleton halfedges.

The defining contour halfedges and incident halfedges around a vertex can be traced using the circulators provided by the vertex class. The degree of a vertex is not cached and cannot be directly obtained from the vertex, but you can calculate this number by manually counting the number of incident halfedges around the vertex.

Each vertex stores a 2D point and a *time*, which is the euclidean distance from the vertex's point to the *lines* supporting each of the defining contour edges of the vertex (the distance is the same to each line). Unless the polygon is convex, this distance is not equidistant to the edges, as in the case of a Medial Axis, therefore, the time of a skeleton vertex does not correspond to the distance from the polygon to the vertex (so it cannot be used to obtain the deep of a region in a shape, for instance).
If the polygon *is* convex, the straight skeleton is exactly equivalent to the polygon's Voronoi diagram and each vertex time is the equidistance to the defining edges.
Contour vertices have time zero.

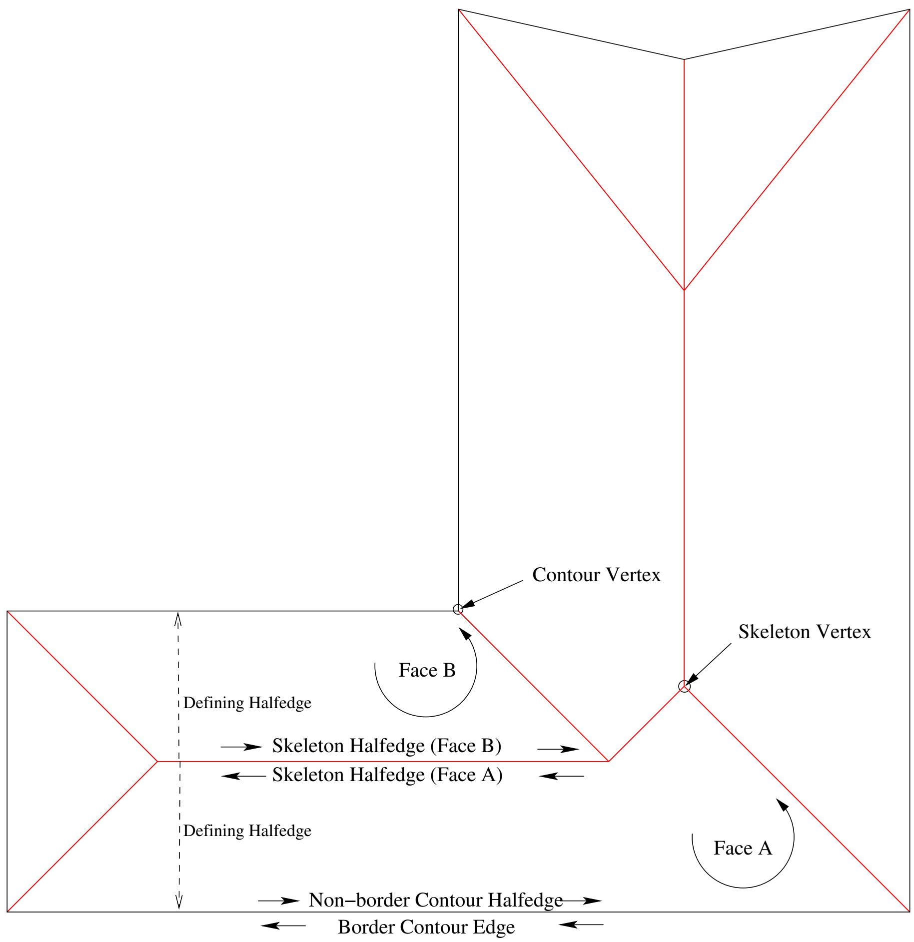

Figure 23.6: Straight Skeleton Data Structure

23.3 API

23.3.1 Create a Straight Skeleton

The straight skeleton data structure is defined by the *StraightSkeleton_2* concept and modeled in the *Straight_skeleton_2<Traits,Items,Alloc>* class.

The simplest way to construct a straight skeleton is via the free functions *create_interior_straight_skeleton_2* and *create_exterior_straight_skeleton_2*, as shown in the following example:

```
#include<boost/shared_ptr.hpp>

#include<CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include<CGAL/Polygon_2.h>
#include<CGAL/create_straight_skeleton_2.h>

#include "print.h"

typedef CGAL::Exact_predicates_inexact_constructions_kernel K ;

typedef K::Point_2                    Point ;
typedef CGAL::Polygon_2<K>            Polygon_2 ;
typedef CGAL::Straight_skeleton_2<K> Ss ;

typedef boost::shared_ptr<Ss> SsPtr ;

int main()
{
  Polygon_2 poly ;

  poly.push_back( Point(-1,-1) ) ;
  poly.push_back( Point(0,-12) ) ;
  poly.push_back( Point(1,-1) ) ;
  poly.push_back( Point(12,0) ) ;
  poly.push_back( Point(1,1) ) ;
  poly.push_back( Point(0,12) ) ;
  poly.push_back( Point(-1,1) ) ;
  poly.push_back( Point(-12,0) ) ;

  // You can pass the polygon via an iterator pair
  SsPtr iss =
   CGAL::create_interior_straight_skeleton_2(poly.vertices_begin(),
   poly.vertices_end());

  // Or you can pass the polygon directly, as below.

  // To create an exterior straight skeleton you need to specify a
   maximum offset.
  double lMaxOffset = 5 ;
  SsPtr oss = CGAL::create_exterior_straight_skeleton_2(lMaxOffset,
   poly);

  print_straight_skeleton(*iss);
  print_straight_skeleton(*oss);
```

```
  return 0;
}
```

File: examples/Straight_skeleton_2/Create_straight_skeleton_2.cpp

The input to these functions is the polygon, which can be given as an iterator pair or directly as a *Polygon_2* object. In the case of the exterior skeleton, a maximum offset must be specified as well (see the ref manual for details on this max offset parameter).

23.3.2 Create a Straight Skeleton from a Polygon With Holes

If *Polygon_with_holes_2* is used, you can pass an instance of it directly to the function creating the interior skeleton, as shown below. Notice that a different header must be included in this case.

```
#include<boost/shared_ptr.hpp>

#include<CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include<CGAL/Polygon_with_holes_2.h>
#include<CGAL/create_straight_skeleton_from_polygon_with_holes_2.h>

#include "print.h"

typedef CGAL::Exact_predicates_inexact_constructions_kernel K ;

typedef K::Point_2                    Point ;
typedef CGAL::Polygon_2<K>            Polygon_2 ;
typedef CGAL::Polygon_with_holes_2<K> Polygon_with_holes ;
typedef CGAL::Straight_skeleton_2<K>  Ss ;

typedef boost::shared_ptr<Ss> SsPtr ;

int main()
{
  Polygon_2 outer ;

  outer.push_back( Point(-1,-1) ) ;
  outer.push_back( Point(0,-12) ) ;
  outer.push_back( Point(1,-1) ) ;
  outer.push_back( Point(12,0) ) ;
  outer.push_back( Point(1,1) ) ;
  outer.push_back( Point(0,12) ) ;
  outer.push_back( Point(-1,1) ) ;
  outer.push_back( Point(-12,0) ) ;

  Polygon_2 hole ;

  hole.push_back( Point(-1,0) ) ;
  hole.push_back( Point(0,1 ) ) ;
  hole.push_back( Point(1,0 ) ) ;
```

```
  hole.push_back( Point(0,-1) ) ;

  Polygon_with_holes poly( outer ) ;

  poly.add_hole( hole ) ;

  SsPtr iss = CGAL::create_interior_straight_skeleton_2(poly);

  print_straight_skeleton(*iss);

  return 0;
}
```

File: examples/Straight_skeleton_2/Create_straight_skeleton_from_polygon_with_holes_2.cpp

23.3.3 Create Offset Polygons from a Straight Skeleton

If you already have a straight skeleton instance, the simpler way to generate offset polygons is to call *create_offset_polygons_2* as shown in the next example, passing the desired offset and the straight skeleton. You can reuse the same skeleton to generate offsets at a different distance, which is recommended because producing the straight skeleton is much slower then generating offset polygons.

```
#include<vector>

#include<boost/shared_ptr.hpp>

#include<CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include<CGAL/Polygon_2.h>
#include<CGAL/create_offset_polygons_2.h>

#include "print.h"

typedef CGAL::Exact_predicates_inexact_constructions_kernel K ;

typedef K::Point_2                   Point ;
typedef CGAL::Polygon_2<K>           Polygon_2 ;
typedef CGAL::Straight_skeleton_2<K> Ss ;

typedef boost::shared_ptr<Polygon_2> PolygonPtr ;
typedef boost::shared_ptr<Ss> SsPtr ;

typedef std::vector<PolygonPtr> PolygonPtrVector ;

int main()
{
  Polygon_2 poly ;

  poly.push_back( Point(-1,-1) ) ;
  poly.push_back( Point(0,-12) ) ;
  poly.push_back( Point(1,-1) ) ;
  poly.push_back( Point(12,0) ) ;
  poly.push_back( Point(1,1) ) ;
```

```
  poly.push_back( Point(0,12) ) ;
  poly.push_back( Point(-1,1) ) ;
  poly.push_back( Point(-12,0) ) ;

  SsPtr ss = CGAL::create_interior_straight_skeleton_2(poly);

  double lOffset = 1 ;

  PolygonPtrVector offset_polygons =
   CGAL::create_offset_polygons_2<Polygon_2>(lOffset,*ss);

  print_polygons(offset_polygons);

  return 0;
}
```

File: examples/Straight_skeleton_2/Create_offset_polygons_2.cpp

23.3.4 Create Offset Polygons from a Polygon (With or Without Holes)

If you need offset polygons at just one single distance, you can hide away the construction of the straight skeleton by calling directly the functions *create_interior_skeleton_and_offset_polygons_2* and *create_exterior_skeleton_and_offset_polygons_2* as shown in the following examples:

```
#include<vector>

#include<boost/shared_ptr.hpp>

#include<CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include<CGAL/Polygon_2.h>
#include<CGAL/create_offset_polygons_2.h>

#include "print.h"

typedef CGAL::Exact_predicates_inexact_constructions_kernel K ;

typedef K::FT                        FT ;
typedef K::Point_2                   Point ;
typedef CGAL::Polygon_2<K>           Polygon_2 ;
typedef CGAL::Straight_skeleton_2<K> Ss ;

typedef boost::shared_ptr<Polygon_2> PolygonPtr ;
typedef boost::shared_ptr<Ss> SsPtr ;

typedef std::vector<PolygonPtr> PolygonPtrVector ;

int main()
{
  Polygon_2 poly ;

  poly.push_back( Point(-1,-1) ) ;
```

```
  poly.push_back( Point(0,-12) ) ;
  poly.push_back( Point(1,-1) ) ;
  poly.push_back( Point(12,0) ) ;
  poly.push_back( Point(1,1) ) ;
  poly.push_back( Point(0,12) ) ;
  poly.push_back( Point(-1,1) ) ;
  poly.push_back( Point(-12,0) ) ;

  FT lOffset = 1 ;

  PolygonPtrVector inner_offset_polygons =
   CGAL::create_interior_skeleton_and_offset_polygons_2(lOffset,poly);
  PolygonPtrVector outer_offset_polygons =
   CGAL::create_exterior_skeleton_and_offset_polygons_2(lOffset,poly);

  print_polygons(inner_offset_polygons);
  print_polygons(outer_offset_polygons);

  return 0;
}
```

File: examples/Straight_skeleton_2/Create_skeleton_and_offset_polygons_2.cpp

... and using a *Polygon_with_holes_2* directly when available:

```
#include<vector>
#include<iterator>
#include<iostream>
#include<iomanip>
#include<string>

#include<boost/shared_ptr.hpp>

#include<CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include<CGAL/Polygon_with_holes_2.h>
#include<CGAL/create_offset_polygons_from_polygon_with_holes_2.h>

#include "print.h"

typedef CGAL::Exact_predicates_inexact_constructions_kernel K ;

typedef K::Point_2                    Point ;
typedef CGAL::Polygon_2<K>            Polygon_2 ;
typedef CGAL::Polygon_with_holes_2<K> Polygon_with_holes ;
typedef CGAL::Straight_skeleton_2<K>  Ss ;

typedef boost::shared_ptr<Polygon_2> PolygonPtr ;
typedef boost::shared_ptr<Ss> SsPtr ;

typedef std::vector<PolygonPtr> PolygonPtrVector ;

int main()
```

```
{
  Polygon_2 outer ;

  outer.push_back( Point(-1,-1) ) ;
  outer.push_back( Point(0,-12) ) ;
  outer.push_back( Point(1,-1) ) ;
  outer.push_back( Point(12,0) ) ;
  outer.push_back( Point(1,1) ) ;
  outer.push_back( Point(0,12) ) ;
  outer.push_back( Point(-1,1) ) ;
  outer.push_back( Point(-12,0) ) ;

  Polygon_2 hole ;

  hole.push_back( Point(-1,0) ) ;
  hole.push_back( Point(0,1 ) ) ;
  hole.push_back( Point(1,0 ) ) ;
  hole.push_back( Point(0,-1) ) ;

  Polygon_with_holes poly( outer ) ;

  poly.add_hole( hole ) ;

  double lOffset = 0.2 ;

  PolygonPtrVector offset_polygons =
   CGAL::create_interior_skeleton_and_offset_polygons_2(lOffset,poly);

  print_polygons(offset_polygons);

  return 0;
}
```

File: examples/Straight_skeleton_2/Create_saop_from_polygon_with_holes_2.cpp

If the input polygon has holes, there can be holes in the offset polygons. However, the polygons generated by all the offsetting functions shown before do not have any parent-hole relationship computed; that is, they just instances of *Polygon_2* instead of *Polygon_with_holes_2*. If *Polygon_with_holes_2* are available and you need the offsetting to produce them, you can call the function *arrange_offset_polygons_2* passing the result of any of the offsetting functions described so far. That function arranges the offset polygons detecting and distributing holes within parents. As a shortcut, you can use the function *create_interior_skeleton_and_offset_polygon_with_holes_2* as shown below:

```
#include<vector>

#include<boost/shared_ptr.hpp>

#include<CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include<CGAL/Polygon_with_holes_2.h>
#include<CGAL/create_offset_polygons_from_polygon_with_holes_2.h>

#include "print.h"
```

```
typedef CGAL::Exact_predicates_inexact_constructions_kernel K ;

typedef K::Point_2                    Point ;
typedef CGAL::Polygon_2<K>            Polygon_2 ;
typedef CGAL::Polygon_with_holes_2<K> PolygonWithHoles ;
typedef CGAL::Straight_skeleton_2<K>  Ss ;

typedef boost::shared_ptr<PolygonWithHoles> PolygonWithHolesPtr ;

typedef std::vector<PolygonWithHolesPtr> PolygonWithHolesPtrVector;

int main()
{
  Polygon_2 outer ;

  outer.push_back( Point( 0.0, 0.0) ) ;
  outer.push_back( Point(10.0, 0.0) ) ;
  outer.push_back( Point(10.0, 4.5) ) ;
  outer.push_back( Point(12.0, 4.5) ) ;
  outer.push_back( Point(12.0, 2.0) ) ;
  outer.push_back( Point(16.0, 2.0) ) ;
  outer.push_back( Point(16.0, 8.0) ) ;
  outer.push_back( Point(12.0, 8.0) ) ;
  outer.push_back( Point(12.0, 5.5) ) ;
  outer.push_back( Point(10.0, 5.5) ) ;
  outer.push_back( Point(10.0,10.0) ) ;
  outer.push_back( Point( 0.0,10.0) ) ;

  Polygon_2 hole ;

  hole.push_back( Point(3.0,3.0) ) ;
  hole.push_back( Point(3.0,7.0) ) ;
  hole.push_back( Point(7.0,7.0) ) ;
  hole.push_back( Point(7.0,3.0) ) ;

  PolygonWithHoles poly( outer ) ;

  poly.add_hole( hole ) ;

  double lOffset = 1 ;

  PolygonWithHolesPtrVector offset_poly_with_holes =
   CGAL::create_interior_skeleton_and_offset_polygons_with_holes_2(lOffset,poly);

  print_polygons_with_holes(offset_poly_with_holes);

  return 0;
}
```

File: examples/Straight_skeleton_2/Create_skeleton_and_offset_polygons_with_holes_2.cpp

advanced

Consider an input polygon with parallel edges separated a distance $2*t$. If you produce an offset polygon at distance t, these parallel edges will just collapse each other and vanish from the result, keeping the output as a *simple polygon*, just like the input. However, if you request an offset polygon at a distance $t-epsilon$, the result will still be a simple polygon but with edges that are so close to each other that will almost intersect. If a kernel with exact constructions is used, the offsetting algorithm can guarantee that the output contains only simple polygons. However, if inexact constructions are used the roundoff in the coordinates of the output points will cause parallel edges that *almost* collapse-but not so-to become really collinear or even cross each other.

Thus, it is neccessary to use a kernel with exact constructions if offset polygons must be simple, yet computing a straight skeleton using that kernel is very slow, much more than computing the offset polygons. To help with this, it is possible to construct the straight skeleton using the recommended kernel *Exact_predicates_inexact_constructions_kernel*, then convert the skeleton to a different kernel via the function *convert_straight_skeleton_2* and input the converted skeleton to the offsetting functions.

All the offsetting functions that take polygons as input (and create the straight skeleton under the hood) apply that optimization automatically: that is, the output polygons are defined over the same kernel of the input polygons, whatever that is, yet the straight skeleton is constructed with the faster recommended kernel and converted if necessary.

Notice how some of the examples above use *Exact_predicates_exact_constructions_kernel*. In all cases, the straight skeleton is constructed using *Exact_predicates_inexact_constructions_kernel*.

advanced

23.3.5 Low level API

All the high level functions described above are just wrappers around the low level API described here. This low level API is richer and provides options and configurations not covered by any of those functions.

The straight skeleton construction algorithm is encapsulated in the class *Straight_skeleton_builder_2*<*Gt,Ss,Visitor*> which is parameterized on a geometric traits (class *Straight_skeleton_builder_traits*<*Kernel*>) and the Straight Skeleton class (Ss).

The offset contours construction algorithm is encapsulated in the class *Polygon_offset_builder_2*<*Ss,Gt,Container*> which is parameterized on the Straight Skeleton class (Ss), a geometric traits (class *Polygon_offset_builder_traits*<*Kernel*>) and a container type where the resulting offset polygons are generated.

To construct the straight skeleton of a polygon with holes the user must:

(1) Instantiate the straight skeleton builder.

(2) Enter one contour at a time, starting from the outer contour, via the method *enter_contour*. The input polygon with holes must be non-degenerate, strictly-simple and counter-clockwise oriented (see the definitions at the beginning of this chapter). Collinear edges are allowed. The insertion order of each hole is unimportant but the outer contour must be entered first.

(3) Call *construct_skeleton* once *all* the contours have been entered. You cannot enter another contour once the skeleton has been constructed.

To construct a set of inward offset contours the user must:

(1) Construct the straight skeleton of the source polygon with holes.

(2) Instantiate the polygon offset builder passing in the straight skeleton as a parameter.

(3) Call *construct_offset_contours* passing the desired offset distance and an output iterator that can store a *boost::shared_ptr* of *Container* instances into a resulting sequence (typically, a back insertion iterator)

Each element in the resulting sequence is an *offset contour*, given by a *boost::shared_ptr* holding a dynamically allocated instance of the Container type. Such a container can be any model of the *VertexContainer_2* concept, for example, a *CGAL::Polygon_2*, or just a *std::vector* of 2D points.

The resulting sequence of offset contours can contain both outer and inner contours. Each offset hole (inner offset contour) would logically belong in the interior of some of the outer offset contours. However, this algorithm returns a sequence of contours in arbitrary order and there is no indication whatsoever of the parental relationship between inner and outer contours.

On the other hand, each outer contour is counter-clockwise oriented while each hole is clockwise-oriented. And since offset contours do form simple polygons with holes, it is guaranteed that no hole will be inside another hole, no outer contour will be inside any other contour, and each hole will be inside exactly 1 outer contour.

Parental relationships are *not* automatically reconstructed by this algorithm because this relation is not directly given by the input polygon with holes and must be done as a post processing step. The function *arrange_offset_polygons_2* can be used to do that efficiently.

A user can reconstruct the parental relationships as a post processing operation by testing each inner contour (which is identified by being clockwise) against each outer contour (identified as being counter-clockwise) for insideness.

This algorithm requires exact predicates but not exact constructions Therefore, the *Exact_predicates_inexact_constructions_kernel* should be used.

```

    Polygon_2::area() is signed.
        if ( lArea > lLargestArea )
        {
          f = i ;
          lLargestArea = lArea ;
        }
      }

      // Remove the offset contour that corresponds to the frame.
      offset_contours.erase(f);

      print_polygons(offset_contours);
    }
  }

  return 0;
}
```

File: examples/Straight_skeleton_2/Low_level_API.cpp

23.3.6 Exterior Skeletons and Exterior Offset contours

This CGAL package can only construct the straight skeleton and offset contours in the *interior* of a polygon with holes. However, constructing exterior skeletons and exterior offsets is possible:

Say you have some polygon made of 1 outer contour C0 and 1 hole C1, and you need to obtain some exterior offset contours.
The interior region of a polygon with holes is connected while the exterior region is not: there is an unbounded region outside the outer contour, and one bounded region inside each hole. To construct an offset contour you need to construct an straight skeleton. Thus, to construct exterior offset contours for a polygon with holes, you need to construct, *separately*, the exterior skeleton of the outer contour and the interior skeleton of each hole.
Constructing the interior skeleton of a hole is directly supported by this CGAL package; you just need to input the hole's vertices in reversed order as if it were an outer contour.
Constructing the exterior skeleton of the outer contour is possible by means of the following trick: place the contour as a hole of a big rectangle (call it *frame*). If the frame is sufficiently separated from the contour, the resulting skeleton will be practically equivalent to a *real* exterior skeleton.
To construct exterior offset contours in the inside of each hole you just use the skeleton constructed in the interior, and, if required, revert the orientation of each resulting offset contour.
Constructing exterior offset contours in the outside of the outer contour is just a little bit more involved: Since the contour is placed as a hole of a frame, you will always obtain 2 offset contours for any given distance; one is the offseted frame and the other is the offseted contour. Thus, from the resulting offset contour sequence, you always need to discard the offsetted frame, easily identified as the offset contour with the largest area.
It is necessary to place the frame sufficiently away from the contour. If it is not, it could occur that the outward offset contour collides and merges with the inward offset frame, resulting in 1 instead of 2 offset contours.
However, the proper separation between the contour and the frame is not directly given by the offset distance at which you want the offset contour. That distance must be at least the desired offset plus the largest euclidean distance between an offset vertex and its original.
This CGAL packages provides a helper function to compute the required separation: *compute_outer_frame_margin*

If you use this function to place the outer frame you are guaranteed to obtain an offset contour corresponding exclusively to the frame, which you can always identify as the one with the largest area and which you can simple remove from the result (to keep just the relevant outer contours).

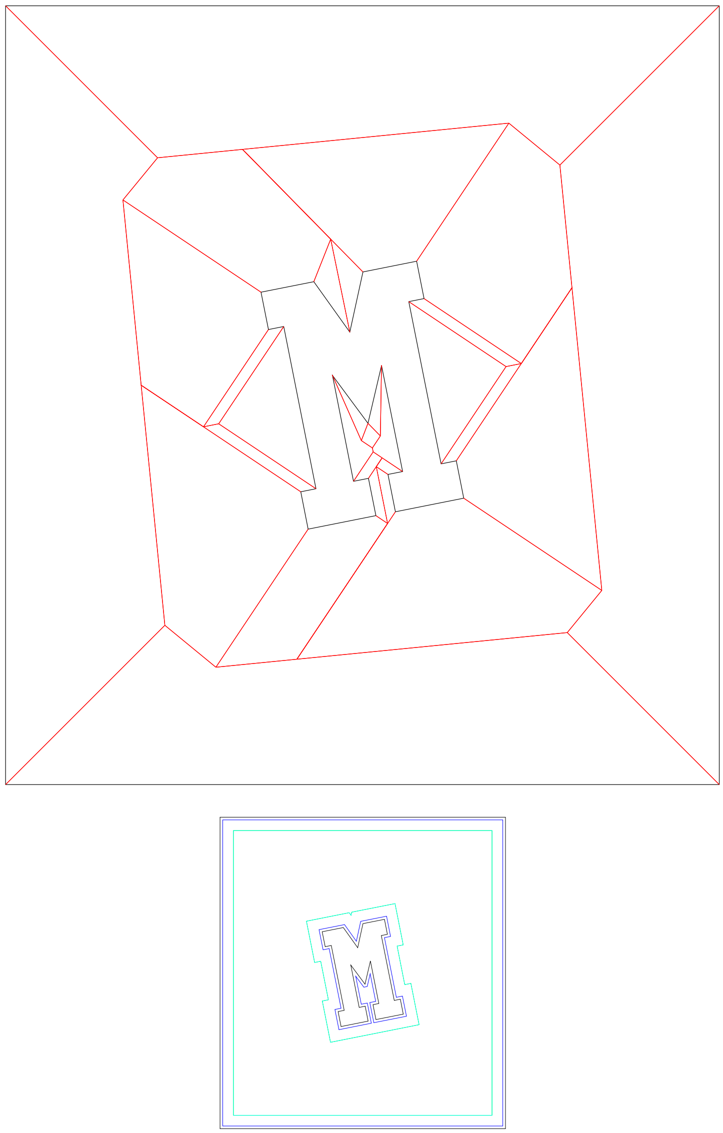

Figure 23.7: Exterior skeleton obtained using a frame (left) and 2 sample exterior offset contours (right)

23.4 Straight Skeletons, Medial Axis and Voronoi Diagrams

The straight skeleton of a polygon is similar to the medial axis and the Voronoi diagram of a polygon in the way it partitions it; however, unlike the medial axis and Voronoi diagram, the bisectors are not equidistant to its defining edges but to the supporting lines of such edges. As a result, Straight Skeleton bisectors might not be located in the center of the polygon and so cannot be regarded as a proper Medial Axis in its geometrical meaning.

On the other hand, only reflex vertices (whose internal angle $> pi$) are the source of deviations of the bisectors from its center location. Therefore, for convex polygons, the straight skeleton, the medial axis and the Voronoi diagram are exactly equivalent, and, if a non-convex polygon contains only vertices of low reflexivity, the straight skeleton bisectors will be placed nearly equidistant to their defining edges, producing a straight skeleton pretty much alike a proper medial axis.

23.5 Usages of the Straight Skeletons

The most natural usage of straight skeletons is offsetting: growing and shrinking polygons (provided by this CGAL package).

Another usage, perhaps its very first, is roof design: The straight skeleton of a polygonal roof directly gives the layout of each tent. If each skeleton edge is lifted from the plane a height equal to its offset distance, the resulting roof is "correct" in that water will always fall down to the contour edges (roof border) regardless of were in the roof it falls. [LD03] gives an algorithm for roof design based on the straight skeleton.

Just like medial axes, 2D straight skeletons can also be used for 2D shape description and matching. Essentially, all the applications of image-based skeletonization (for which there is a vast literature) are also direct applications of the straight skeleton, specially since skeleton edges are simply straight line segments.

Consider the subgraph formed only by *inner bisectors* (that is, only the skeleton halfedges which are not incident upon a contour vertex). Call this subgraph a *skeleton axis*. Each node in the skeleton axis whose degree is $>= 3$ roots more than one skeleton tree. Each skeleton tree roughly corresponds to a region in the input topologically equivalent to a rectangle; that is, without branches. For example, a simple letter "H" would contain 2 higher degree nodes separating the skeleton axis in 5 trees; while the letter "@" would contain just 1 higher degree node separating the skeleton axis in 2 curly trees.

Since a skeleton edge is a 2D straight line, each branch in a skeleton tree is a polyline. Thus, the path-length of the tree can be directly computed. Furthermore, the polyline for a particular tree can be interpolated to obtain curve-related information.

Pruning each skeleton tree cutting off branches whose length is below some threshold; or smoothing a given branch, can be used to reconstruct the polygon without undesired details, or fit into a particular canonical shape.

Each skeleton edge in a skeleton branch is associated with 2 contour edges which are facing each other. If the polygon has a bottleneck (it almost touches itself), a search in the skeleton graph measuring the distance between each pair of contour edges will reveal the location of the bottleneck, allowing you to cut the shape in two. Likewise, if two shapes are too close to each other along some part of their boundaries (a near contact zone), a similar search in an exterior skeleton of the two shapes at once would reveal the parts of near contact, allowing you to stitch the shapes. These *cut and stitch* operations can be directly executed in the straight skeleton itself instead of the input polygon (because the straight skeleton contains a graph of the connected contour edges).

23.6 Straight Skeleton of a General Figure in the Plane

A straight skeleton can also be defined for a general multiply-connected planar directed straight-line graph [AA95] by considering all the edges as embedded in an unbounded region. The only difference is that in this case some faces will be only partially bounded.

The current version of this CGAL package can only construct the straight skeleton in the interior of a simple polygon with holes, that is it doesn't handle general polygonal figures in the plane.

2D Straight Skeleton and Polygon Offsetting Reference Manual

This chapter introduces the concepts and classes that correspond to the CGAL *2D Straight Skeleton* package. The packages provides an algorithm for the construction of the straight skeleton in the interior of a simple polygon with holes and an algorithm for the construction of inward offset contours based on the straight skeleton.

StraightSkeleton_2

Concept

Definition

The concept StraightSkeleton_2 describes the requirements for the data structure used to represent a straight skeleton. It refines the concept *HalfedgeDS* and adds additional requirements on the nested types *Vertex*, *Halfedge*, and *Face* of the halfedge data structure.

Refines

HalfedgeDS

Types

StraightSkeleton_2:: Vertex	A model of the *StraightSkeletonVertex_2* concept used to represent the vertices of the straight skeleton
StraightSkeleton_2:: Halfedge	A model of the *StraightSkeletonHalfedge_2* concept used to represent the halfedges of the straight skeleton
StraightSkeleton_2:: Face	Any model of the *StraightSkeletonFace_2* concept used to represent the faces of the straight skeleton

Has Models

CGAL::Straight_skeleton_2<Traits,Items,Alloc>.

This concept explicitly protects all the modifying operations of the base *HalfedgeDS* concept. Only the algorithm classes, or clients explicitly bypassing the protection mechanism, can modify a straight skeleton.

Concept

StraightSkeletonVertex_2

Definition

The concept StraightSkeletonVertex_2 describes the requirements for the vertex type of the *StraightSkeleton_2* concept. It is a refinement of the *HalfedgeDSVertex* concept with support for storage of the incident halfedge. The StraightSkeletonVertex_2 concept requires the geometric embedding to be a 2D point.

Refines

HalfedgeDSVertex

Types

StraightSkeletonVertex_2:: Point_2 — The type of the 2D point being the geometric embedding of the vertex

StraightSkeletonVertex_2:: FT — A model of the *SqrtFieldNumberType* concept representing the time of a vertex (an Euclidean distance)

StraightSkeletonVertex_2:: Halfedge_around_vertex_const_circulator
StraightSkeletonVertex_2:: Halfedge_around_vertex_circulator

The circulator type used to visit all the incident halfedges around a vertex

StraightSkeletonVertex_2:: Defining_contour_halfedge_const_circulator
StraightSkeletonVertex_2:: Defining_contour_halfedge_circulator

The circulator type used to visit all the defining contour halfedges of a vertex

Creation

StraightSkeletonVertex_2 v; — Default constructor

StraightSkeletonVertex_2 v(int id, Point_2 p); — Constructs a contour vertex with ID number *id*, at the point *p*

StraightSkeletonVertex_2 v(int id, Point_2 p, FT time);

Constructs a skeleton vertex with ID number *id*, at point *p* and time *time*.

Access Functions

int	*v.id() const*	The ID of the vertex.
Point_2	*v.point() const*	The vertex point.
FT	*v.time() const*	The time of the vertex: the distance from the vertex point to the lines supporting the defining contour edges
Halfedge_handle	*v.primary_bisector()*	

Halfedge_const_handle

v.primary_bisector() const

Returns the skeleton halfedge incident upon the vertex (called the *primary* bisector).

Halfedge_around_vertex_circulator

v.halfedge_around_vertex_begin()

Halfedge_around_vertex_const_circulator

v.halfedge_around_vertex_begin() const

Returns a bi-directional circulator pointing to one of the incident halfedges (which one is unspecified).
There will always be as many incident halfedges as the degree of the vertex.
If this is a *contour* vertex, its degree is exactly 3, and from the halfedges pointed to by the circulator, 2 are contour and 1 is a bisector.
If this is an *skeleton* vertex, its degree is at least 3 and all of the halfedges pointed to by the circulator are bisectors.
Each halfedge pointed to by this circulator is the one which is oriented towards the vertex (according to the geometric embedding).

Defining_contour_halfedge_circulator

v.defining_contour_halfedges_begin()

Defining_contour_halfedge_const_circulator

v.defining_contour_halfedges_begin() const

Returns a bi-directional circulator pointing to one of the defining contour halfedges of the vertex (which one is unspecified).
There will always be as many incident defining contour halfedges as the degree of the vertex.
Each halfedge pointed to by this circulator is the one having its left side facing inwards (which happens to be the contour halfedge for which *is_border()* is *false*).

Queries

bool	*v.is_contour() const*	Returns *true* iff this is a contour vertex.
bool	*v.is_skeleton() const*	Returns *true* iff this is a skeleton vertex.

Has Models

CGAL::Straight_skeleton_vertex_base_2<Refs,Point,FT>.

StraightSkeletonHalfedge_2

Concept

Definition

The concept StraightSkeletonHalfedge_2 describes the requirements for the halfedge type of the *StraightSkeleton_2* concept. It is a refinement of the *HalfedgeDSHalfedge* concept. The StraightSkeletonHalfedge_2 concept requires no geometric embedding at all. The only geometric embedding used by the Straight Skeleton Data Structure are the 2D points in the contour and skeleton vertices. However, for any halfedge, there is a 2D segment implicitly given by its *source* and *target* vertices.

Refines

HalfedgeDSHalfedge

Creation

StraightSkeletonHalfedge_2 h;	Default Constructor.
StraightSkeletonHalfedge_2 h(int id);	Constructs a halfedge with ID *id*. It is the links to other halfedges what determines if this is a contour edge, a contour-skeleton edge or an inner-skeleton edge.

Access Functions

Halfedge_handle	*h.defining_contour_edge()*	
Halfedge_const_handle	*h.defining_contour_edge() const*	If this is a bisector halfedge, returns a handle to the inward-facing (non-border) contour halfedge corresponding to the defining contour edge which is to its left; if this is a contour halfedge, returns a handle to itself if *is_border()* is *false*, or to its opposite if it is *true*.

Queries

bool	*h.is_bisector() const*	Returns *true* iff this is a bisector (or skeleton) halfedge (i.e. is not a contour halfedge).
bool	*h.is_inner_bisector() const*	Returns *true* iff this is a bisector and is inner (i.e. is not incident upon a contour vertex).

Has Models

StraightSkeletonFace_2

Definition

The concept StraightSkeletonFace_2 describes the requirements for the face type of the *StraightSkeleton_2* concept. It is a refinement of the *HalfedgeDSFace* concept with support for storage of the incident halfedge.

Refines

HalfedgeDSFace

Creation

StraightSkeletonFace_2 f;	Default constructor
StraightSkeletonFace_2 f(int id);	Constructs a face with ID number *id*

Access Functions

int	*f.id() const*	The ID of the face.

Has Models

CGAL::Straight_skeleton_face_base_2<Refs>.

Concept

Concept

StraightSkeletonItemsConverter_2

Definition

The concept StraightSkeletonItemsConverter_2 describes the requirements for items converter passed as the third template argument to the class *Straight_skeleton_converter_2<SrcSs,TgtSs,ItemsConverter>*. It converts the *HDS* items from one type of straight skeleton to another

Types

StraightSkeletonItemsConverter_2:: Source_vertex_const_handle

A constant handle to a model of the *StraightSkeletonVertex_2* concept used to represent the vertices of the straight skeleton of the source type.

StraightSkeletonItemsConverter_2:: Source_halfedge_const_handle

A constant handle to model of the *StraightSkeletonHalfedge_2* concept used to represent the halfedges of the straight skeleton of the source type.

StraightSkeletonItemsConverter_2:: Source_face_const_handle

A constant handle to model of the *StraightSkeletonFace_2* concept used to represent the faces of the straight skeleton of the source type.

StraightSkeletonItemsConverter_2:: Tarvet_vertex

A model of the *StraightSkeletonVertex_2* concept used to represent the vertices of the straight skeleton of the target type.

StraightSkeletonItemsConverter_2:: Target_halfedge

A model of the *StraightSkeletonHalfedge_2* concept used to represent the halfedges of the straight skeleton of the target type.

StraightSkeletonItemsConverter_2:: Target_face

Any model of the *StraightSkeletonFace_2* concept used to represent the faces of the straight skeleton of the target type.

Operations

Target_vertex *conv.operator()(Source_vertex_const_handle v) const*

returns a new vertex with the same data as *v* converted to the corresponding target types.

Target_halfedge	*conv.operator()(Source_halfedge_const_handle h) const*	
		returns a new halfedge with the same data as h converted to the corresponding target types.
Target_face	*conv.operator()(Source_face_const_handle f) const*	
		returns a new face with the same data as f converted to the corresponding target types.

Has Models

StraightSkeletonBuilder_2_Visitor

Definition

The concept StraightSkeletonBuilder_2_Visitor describes the requirements of the visitor class required by the algorithm class *Straight_skeleton_builder_2<Gt,Ss,Visitor>* in its third template parameter.

Types

StraightSkeletonBuilder_2_Visitor:: Halfedge_const_handle

A constant handle to a straight skeleton halfedge.

StraightSkeletonBuilder_2_Visitor:: Vertex_const_handle

A constant handle to a straight skeleton vertex.

Creation

Operations

void *v.on_contour_edge_entered(Halfedge_const_handle const&) const*

Called for each contour halfedge added to the skeleton).

void *v.on_initialization_started(std::size_t number_of_vertices) const*

Called before the initialization stage (when initial events are discovered) is started.

void *v.on_contour_vertex_processed(Vertex_const_handle const& v, bool is_reflex, bool is_degenerate) const*

Called after the events for contour vertex v have been discovered. *is_reflex* is true if this vertex has an internal angle $> PI$, or *is_degenerate* is true if the internal angle is $= PI$.

void *v.on_edge_event_created(Vertex_const_handle const& node0, Vertex_const_handle const& node1) const*

Called after an edge event for nodes $node0$ and $node1$ has been discovered and put on the queue for later processing.

void *v.on_split_event_created(Vertex_const_handle const& node) const*

Called after a slipt event for node *node* has been discovered and put on the queue for later processing.

void *v.on_pseudo_split_event_created(Vertex_const_handle const& node0, Vertex_const_handle const& node1) const*

Called after a pseudo slipt event for nodes $node0$ and $node1$ has been discovered and put on the queue for later processing.

void *v.on_initialization_finished() const*

Called after all initial events have been discovered.

void *v.on_propagation_started() const*

Called before the propagation stage (when events are poped off the queue and processed) is started.

void *v.on_anihiliation_event_processed(Vertex_const_handle const& node0, Vertex_const_handle const& node1) const*

Called after an anhiliation event for nodes *node*0 and *node*1 has been processed. A new skeleton edge between these nodes has been added.

void *v.on_edge_event_processed(Vertex_const_handle const& seed0, Vertex_const_handle const& seed1, Vertex_const_handle const& newnode) const*

Called after an edge for nodes *seed*0 and *seed*1 has been processed. Skeleton vertex *newnode* and edges from *node*0 to *newnode* and *node*1 to *newnode* has been added.

void *v.on_split_event_processed(Vertex_const_handle const& seed, Vertex_const_handle const& newnode0, Vertex_const_handle const& newnode1) const*

Called after a split event for node *seed* has been processed. Skeleton vertices *newnode*0 and *newnode*1 have been added. An skeleton edge from *seed* to *newnode*0 has been added. In the final skeleton, *newnode*1 is removed and only *newnode*0 remains.

void *v.on_pseudo_split_event_processed(Vertex_const_handle const& seed0, Vertex_const_handle const& seed1, Vertex_const_handle const& newnode0, Vertex_const_handle const& newnode1) const*

Called after a pseudo split event for nodes *seed*0 and *seed*1 has been processed. Skeleton vertices *newnode*0 and *newnode*1 have been added. Skeleton edges from *seed*0 to *newnode*0 and *seed*1 to *newnode*1 has been added.

void *v.on_vertex_processed(Vertex_const_handle const& v) const*

Called after vertex *v* has been marked as already processed.

void *v.on_propagation_finished() const*

Called after all events have been processed.

void *v.on_cleanup_started() const*

Called when the skeleton clean up (when multiple nodes are merged) is started.

void *v.on_cleanup_finished() const*

Called when clean up finished.

void *v.on_algorithm_finished(bool finished_ok) const*

Called when the algorithm terminated. *finished_ok* is false if it terminated before completion or the resulting skeleton was found to be invalid.

void *v.on_error(char const* msg) const*

Called whenever an error was detected. *msg* is whatever error message accompanies the error. This pointer can be *null*.

StraightSkeletonBuilderTraits_2

Definition

The concept StraightSkeletonBuilderTraits_2 describes the requirements for the geometric traits class required by the algorithm class *Straight_skeleton_builder_2<Gt,Ss>*.

Types

StraightSkeletonBuilderTraits_2:: Kernel	A model of the *Kernel* concept.
StraightSkeletonBuilderTraits_2:: FT	A *SqrtFieldNumberType* provided by the kernel. This type is used to represent the coordinates of the input points, of the skeleton nodes and as the event time stored in the skeleton nodes.
boost::tuple<FT,FT> Vertex;	A pair of (x,y) coordinates representing a 2D Cartesian point.
boost::tuple<Vertex,Vertex> Edge;	A pair of vertices representing an edge
boost::tuple<Edge,Edge,Edge> EdgeTriple;	A triple of edges representing an event

StraightSkeletonBuilderTraits_2:: Equal_2

A predicate object type being a model of the *Kernel::Equal_2* function object concept.

StraightSkeletonBuilderTraits_2:: Left_turn_2

A predicate object type being a model of the *Kernel::LeftTurn_2* function object concept.

StraightSkeletonBuilderTraits_2:: Collinear_2

A predicate object type being a model of the *Kernel::Collinear_2* function object concept.

StraightSkeletonBuilderTraits_2:: Do_ss_event_exist_2

A predicate object type.
Must provide *bool operator()(EdgeTriple const& et) const*, which determines if, given the 3 *oriented* lines defined by the 3 input edges (3 pair of points), there exist an Euclidean distance $t \geq 0$ for which the corresponding 3 *offset lines at t* (parallel lines at an Euclidean distance of t) intersect in a single point.

Precondition: each edge in the triple must properly define an oriented line, that is, such points cannot be coincident.

StraightSkeletonBuilderTraits_2:: Compare_ss_event_times_2

A predicate object type.
Must provide *Comparison_result operator()(EdgeTriple const& x, EdgeTriple const& y) const*, which compares the *times* for the events determined by the edge-triples *x* and *y*.
The time of an event given by an edge triple (which defines 3 oriented lines) is the Euclidean distance *t* at which the corresponding offset lines at *t* intersect in a single point.

Precondition: *x* and *y* must be edge-triples corresponding to events that actually exist (as determined by the predicate *Exist_sls_event_2*).

StraightSkeletonBuilderTraits_2:: Compare_ss_event_distance_to_seed_2

A predicate object type.
Must provide *Comparison_result operator()(Point_2 const& p, EdgeTriple const& x, EdgeTriple const& y)*, which compares the Euclidean distance of the points of event for *x* and *y* to the point *p*.
The point of an event given by an edge triple (which defines 3 oriented lines) is the intersection point of the 3 corresponding offset lines at the time *t* of the event.
It must also provide *Comparison_result operator(EdgeTriple const& seed, EdgeTriple const& x, EdgeTriple const& y)()* which makes the same comparison as the first overload but where the seed point is given implicitly as the point of event for *seed*.

Precondition: *seed*, *x* and *y* must be edge-triples corresponding to events that actually exist (as determined by the predicate *Exist_sls_event_2*).

StraightSkeletonBuilderTraits_2:: Is_ss_event_inside_offset_zone_2

A predicate object type.
Must provide *bool operator()(EdgeTriple const& e, EdgeTriple const& zone)*, which determines if the point of event for *e* is inside the *offset zone* defined by the 3 *oriented* lines given by *zone*.
An offset zone given by 3 *oriented* lines is the intersection of the halfplanes to the left of each oriented line.

Precondition: *e* must be an edge-triple corresponding to an event that actually exist (as determined by the predicate *Exist_sls_event_2*), and the 3 oriented lines given by *zone* must be well defined (no point-pair can have coincident points).

StraightSkeletonBuilderTraits_2:: Are_ss_events_simultaneous_2

A predicate object type.
Must provide *bool operator()(EdgeTriple const& x, EdgeTriple const& y)*, which determines if the events given by *x* and *y* are coincident in time and space; that is, both triples of offset lines intersect at the same point and at the same Euclidean distance from their sources.

Precondition: *x* and *y* must be edge-triples corresponding to events that actually exist (as determined by the predicate *Exist_sls_event_2*).

StraightSkeletonBuilderTraits_2:: Construct_ss_event_time_and_point_2

A construction object type.
Must provide *boost::tuple< boost::optional<FT>, boost::optional<Point_2> > operator()(EdgeTriple const& e)*, which given the 3 *oriented* lines defined by the 3 input edges (3 pair of points), returns the Euclidean distance $t \geq 0$ and intersection point at which the corresponding 3 *offset lines at t* intersect.
If the values cannot be computed, not even approximately (because of overflow for instance), an empty optional must be returned.

Precondition: *e* must be an edge-triple corresponding to an event that actually exist (as determined by the predicate *Exist_sls_event_2*).

StraightSkeletonBuilderTraits_2:: Construct_ss_vertex_2

A construction object type.
Must provide *Vertex operator()(Point_2 const& p)*, which given a *Point_2 p* returns a Vertex encapsulating the corresponding (x,y) pair of *Cartesian* coordinates.

StraightSkeletonBuilderTraits_2:: Construct_ss_edge_2

A construction object type.
Must provide *Edge operator()(Point_2 const& s, Point_2 const& t)*, which given source and target points *s* and *t* returns an Edge encapsulating the corresponding input segment (in *Cartesian* coordinates.)

StraightSkeletonBuilderTraits_2:: Construct_ss_triedge_2

A construction object type.
Must provide *Triedge operator()(Edge const& e0, Edge const& e1, Edge const& e2)*, which given the 3 edges that define an event, *e0*, *e1* and *e2*, returns a Triedge encapsulating them.

Concept

PolygonOffsetBuilderTraits_2

Definition

The concept PolygonOffsetBuilderTraits_2 describes the requirements for the geometric traits class required by the algorithm class *Polygon_offset_builder_2<Ss,Gt,Polygon_2>*.

Types

PolygonOffsetBuilderTraits_2:: Kernel	A model of the *Kernel* concept.
PolygonOffsetBuilderTraits_2:: FT	A *SqrtFieldNumberType* provided by the kernel. This type is used to represent the coordinates of the input points and to specify the desired offset distance.
PolygonOffsetBuilderTraits_2:: Point_2	A 2D point type
boost::tuple<FT,FT> Vertex;	A pair of (x,y) coordinates representing a 2D Cartesian point.
boost::tuple<Vertex,Vertex> Edge;	A pair of vertices representing an edge
boost::tuple<Edge,Edge,Edge> EdgeTriple;	A triple of edges representing an event

PolygonOffsetBuilderTraits_2:: Compare_offset_against_event_time_2

A predicate object type.
Must provide *Comparison_result operator()(FT d, EdgeTriple const& et) const*, which compares the Euclidean distance d with the event time for *et*. Such event time is the Euclidean distance at which the *offset lines* intersect in a single point. The source of such offset lines is given by the 3 *oriented* lines defined by the edge-triple *et*
Precondition: *et* must be an edge-triple corresponding to an event that actually exist (that is, there must exist an offset distance $t > 0$ at which the offset lines do intersect at a single point.

PolygonOffsetBuilderTraits_2:: Construct_offset_point_2

A construction object type.
Must provide *boost::optional<Point_2> operator()(FT t, Edge const& x, Edge const& y) const*, which constructs the point of intersection of the lines obtained by offsetting the oriented lines given by x and y an Euclidean distance t. If the point cannot be computed, not even approximately (because of overflow for instance), an empty optional must be returned.

Precondition: x and y must intersect in a single point

PolygonOffsetBuilderTraits_2:: Construct_ss_vertex_2

A construction object type.
Must provide *Vertex operator()(Point_2 const& p)*, which given a *Point_2 p* returns a Vertex encapsulating the corresponding (x,y) pair of Cartesian coordinates.

PolygonOffsetBuilderTraits_2:: Construct_ss_edge_2

A construction object type.
Must provide *Edge operator()(Point_2 const& s, Point_2 const& t)*, which given source and target points *s* and *t* returns an Edge encapsulating the corresponding input segment (in Cartesian coordinates.)

PolygonOffsetBuilderTraits_2:: Construct_ss_triedge_2

A construction object type.
Must provide *Triedge operator()(Edge const& e0, Edge const& e1, Edge const& e2)*, which given the 3 edges that define an event, *e0*, *e1* and *e2*, returns a Triedge encapsulating them.

Has Models

CGAL::Polygon_offset_builder_traits_2<K>.

Concept

VertexContainer_2

Introduction

A model for the VertexContainer_2 concept defines the requirements for a resizable container of 2D points. It is used to output the offset polygons generated by the *Polygon_offset_builder_2<Ssds,Gt,Container>* class.

Types

VertexContainer_2:: Point_2	A 2D point type used to represent a vertex. Must be a model of the *Kernel::Point_2* concept
VertexContainer_2:: size_type	A unsigned integral type that can represent the number of vertices in the container.

Creation

VertexContainer_2 c;		Default constructor
size_type	*c.size() const*	Returns the number of vertices in the container.
void	*c.push_back(Point_2 v) const*	Adds the vertex v to the container, resizing its capacity if required.

Has Models

CGAL::Polygon_2

Any *standard BackInsertionSequence*, such as *vector*, *list* or *deque*, with a *value_type* being a model of the *Kernel::Point_2* concept.

CGAL::create_interior_straight_skeleton_2

Function

Definition

The function *create_interior_straight_skeleton_2* creates a straight skeleton in the interior of a 2D polygon with holes.

#include <CGAL/create_straight_skeleton_2.h>

```
template<class PointIterator, class HoleIterator, class K>
boost::shared_ptr< Straight_skeleton_2<K> >
        create_interior_straight_skeleton_2( PointIterator outer_contour_vertices_begin,
                                             PointIterator outer_contour_vertices_end,
                                             HoleIterator holes_begin,
                                             HoleIterator holes_end,
                                             K k = Exact_predicates_inexact_constructions_kernel)
```

returns a new *Straight_skeleton_2<K>* in the interior of the 2D polygon with holes whose outer boundary is given by the point sequence *[outer_contour_vertices_begin,outer_contour_vertices_end]* and its holes given by *[holes_begin,holes_end]*.

```
template<class PointIterator, class K>
boost::shared_ptr< Straight_skeleton_2<K> >
        create_interior_straight_skeleton_2( PointIterator outer_contour_vertices_begin,
                                             PointIterator outer_contour_vertices_end,
                                             K k = Exact_predicates_inexact_constructions_kernel)
```

returns a new *Straight_skeleton_2<K>* in the interior of the 2D polygon whose outer boundary is given by the point sequence *[outer_contour_vertices_begin,outer_contour_vertices_end]*.

```
template<class Polygon, class K>
boost::shared_ptr< Straight_skeleton_2<K> >
        create_interior_straight_skeleton_2( Polygon outer_contour,
                                             K k = Exact_predicates_inexact_constructions_kernel)
```

returns a new *Straight_skeleton_2<K>* in the interior of the 2D polygon *outer_contour*.

1. *K* is any CGAL kernel.

2. *PointIterator::value_type* is equivalent to *K2::Point_2*. A cartesian converter is used to convert from *K2::Point_2* to *K::Point_2*

3. *HoleIterator::value_type* and *Polygon* are *Polygon_2<K>* or a standard container of *K2::Point_2* elements

CGAL::create_exterior_straight_skeleton_2

Function

Definition

The function *create_exterior_straight_skeleton_2* creates a straight skeleton in the exterior of a 2D polygon with holes.

#include <CGAL/create_straight_skeleton_2.h>

template<class FT, class PointIterator, class K>
boost::shared_ptr< Straight_skeleton_2<K> >

create_exterior_straight_skeleton_2(FT max_offset,
PointIterator vertices_begin,
PointIterator vertices_end,
K k = Exact_predicates_inexact_constructions_kernel)

returns a new *Straight_skeleton_2<K>* in the *limited exterior* of the 2D polygon P given by the point sequence *[vertices_begin,vertices_end]*. The skeleton in the *limited exterior* of P is the skeleton in the interior of a polygon Q with P as its hole and a rectangular frame F as outer boundary. The outer boundary F is constructed by enlarging the bounding box of P a distance d. d is a margin sufficiently large to allow an outer offset at dinstance *max_offset* to be obtained from this exterior skeleton, as computed by the function *compute_outer_frame_margin*

template<class FT, class Polygon, class K>
boost::shared_ptr< Straight_skeleton_2<K> >

create_exterior_straight_skeleton_2(FT max_offset,
Polygon P,
K k = Exact_predicates_inexact_constructions_kernel)

returns a new *Straight_skeleton_2<K>* in the *limited exterior* of the 2D polygon P . The skeleton in the *limited exterior* of P is the skeleton in the interior of a polygon Q with P as its hole and a rectangular frame F as outer boundary. The outer boundary F is constructed by enlarging the bounding box of P a distance d. d is a margin sufficiently large to allow an outer offset at dinstance *max_offset* to be obtained from this exterior skeleton, as computed by the function *compute_outer_frame_margin*

Requirements

1. *K* is any CGAL kernel.
2. *PointIterator::value_type* is equivalent to *K2::Point_2*. A cartesian converter is used to convert from *K2::Point_2* to *K::Point_2*
3. *Polygon* is *Polygon_2<K>* or a standard container of *K2::Point_2* elements

CGAL::Straight_skeleton_2<Traits,Items,Alloc>

Definition

The class *Straight_skeleton_2<Traits,Items,Alloc>* provides a model for the *StraightSkeleton_2* concept which is the class type used to represent a straight skeleton.
It inherits from *HalfedgeDS_vector<Traits,Items,Alloc>*

#include <CGAL/Straight_skeleton_2.h>

Is Model for the Concepts

StraightSkeleton_2
DefaultConstructible
CopyConstructible
Assignable

See Also

StraightSkeletonVertex_2
StraightSkeletonHalfedge_2
StraightSkeleton_2

The only purpose of this class is to protect all the modifying operations in a *HalfedgeDS*. Normal users should not modify a straight skeleton. If an advanced user needs to get access to the modifying operations, it must call the required methods through the *::Base* class.

Class

CGAL::Straight_skeleton_vertex_base_2<Refs,Point,FT>

Definition

The class *Straight_skeleton_vertex_base_2<Refs,Point,FT>* provides a model for the *StraightSkeletonVertex_2* concept which is the vertex type required by the *StraightSkeleton_2* concept. The class *Straight_skeleton_vertex_base_2<Refs,Point,FT>* has three template arguments: the first is the model of the *StraightSkeleton_2* concept (the vertex container), the second is a Point type, and the third is a model of the *SqrtFieldNumberType*, which is the numeric type used to represent the time of a vertex (a Euclidean distance).

This class can be used as a base class allowing users of the straight skeleton data structure to decorate a vertex with additional data. The concrete vertex class must be given in the *HalfedgeDSItems* template parameter of the instantiation of the *HalfedgeDS_default* class used as the model for the *Straight_skeleton_2* concept.

CGAL::Straight_skeleton_items_converter_2<SrcSs, TgtSs, NTConverter>

Class

Definition

*Straight_skeleton_items_converter_2<SrcSs, TgtSs, NTConverter>*is a model of the *StraightSkeletonItemsConverter_2* concept

The first and second template parameters are the target and source straight skeleton types, resp.

The third template parameter *NTConverter* is a function object that must provide *TgtSs:Traits::FT operator()(SrcSs::Traits::FT n)* that converts *n* to an *TgtSs::Traits::FT* which has the same value. The default value of this parameter is *CGAL::NT_converter<SrcSs::Traits::FT, TgtSs::Traits::FT>*.

Is Model for the Concepts

StraightSkeletonItemsConverter_2

CGAL::Straight_skeleton_builder_2<Gt,Ss,Visitor> . . . . page 1726

Class

CGAL::Straight_skeleton_converter_2<SrcSs,TgtSs,ItemsCvt>

Definition

The class *Straight_skeleton_converter_2<SrcSs,TgtSs,ItemsCvt>* converts a straight skeleton instantiated using certain traits into another straight skeleton instantiated using a different traits.

The first and second template parameters are the source and target straight skeleton types, resp.

The third template parameter *ItemsConverter* is a function object that must model the concept *StraightSkeletonItemsConverter_2*. The default value of this parameter is *CGAL::Straight_skeleton_items_converter_2<SrcSs,TgtSs>*.

This conversion can be used to produce a straight skeleton with the fast *Exact_predicates_inexact_constructions_kernel* but then input that skeleton into *Polygon_offset_builder<Ss,Gt,Container>* instantiated with the slower *Exact_predicates_exact_constructions_kernel* obtaining only simple offset polygons without paying the runtime overhead of exact constructions for the straight skeleton itself.

Types

SrcSs	*Source_skeleton;*	The *SrcSs* template parameter corresponding to the source straight skeleton.
TgtSs	*Target_skeleton;*	The *TgtSs* template parameter corresponding to the target straight skeleton.
ItemsCvt	*Items_converter;*	The *ItemsCvt* template parameter corresponding to the items converter.

#include <CGAL/Straight_skeleton_converter_2.h>

Creation

Straight_skeleton_converter_2<SrcSs,TgtSs,ItemsCvt> c(Items_converter c);

Default constructor

Operations

boost::shared_ptr<Target_skeleton>

c.operator()(Source_skeleton const& s) const

returns a new straight skeleton data structure with the same combinatorial and geometric data as *s* using the items converter to convert the geometric embeeding to the types of the target traits.

convert_straight_skeleton_2<SrcSs,TgtSs,NTConverter>

Function

CGAL::convert_straight_skeleton_2<TgtSs,SrcSs,ItemsCvt>

Definition

The function *convert_straight_skeleton_2<TgtSs,SrcSs,ItemsCvt>* converts a straight skeleton instantiated using certain traits into another straight skeleton instantiated using a different traits.

#include <CGAL/Straight_skeleton_converter_2.h>

boost::shared_ptr<Target_skeleton, Source_skeleton, Items_converter>

convert_straight_skeleton_2(Source_skeleton s,
Items_converted ic = Items_converter())

returns a new straight skeleton data structure with the same combinatorial and geometric data as *s* using the items converter *ic* to convert the geometric embedding to the types of the target skeleton.
The first template parameter is the type of the target straight skeleton. This template parameter is not bound to a function argument so it must be explicitly specified.

CGAL::Straight_skeleton_builder_traits_2<Kernel>

Class

Definition

The class *Straight_skeleton_builder_traits_2<Kernel>* provides a model for the *StraightSkeletonBuilderTraits_2* concept which is the traits class required by the *Straight_skeleton_builder_2* algorithm class. The class *Straight_skeleton_builder_traits_2<Kernel>* has one template argument: a 2D CGAL Kernel. This parameter must be a model for the *Kernel* concept, such as the *Exact_predicates_inexact_constructions_kernel*, which is the recommended one.
It is unspecified which subset of the kernel is used into the output sequence and the returned iterator will be equal to *out*.

For any given input polygon, it in this traits class (and by extension in the builder class). This is to avoid restricting the choices in the implementation.

CGAL::Straight_skeleton_builder_2<Gt,Ssds>

Class

CGAL::Straight_skeleton_builder_2<Gt,Ss,Visitor>

Definition

The class *Straight_skeleton_builder_2<Gt,Ss,Visitor>* encapsulates the construction of the 2D straight skeleton in the interior of a polygon with holes. Its first template parameter, *Gt*, must be a model of the *StraightSkeletonBuilderTraits_2* concept, its second template parameter, *Ss*, must be a model of the *StraightSkeleton_2* concept, and its third template paramter, *Visitor*, must be a model of the *StraightSkeletonBuilder_2_Visitor* concept. If this last parameter is ommitted, the class *CGAL::Dummy_straight_skeleton_builder_2_visitor<Skel>* is used.

#include <CGAL/Straight_skeleton_builder_2.h>

Types

Straight_skeleton_builder_2<Gt,Ss,Visitor>:: Gt

The geometric traits (first template parameter)

Straight_skeleton_builder_2<Gt,Ss,Visitor>:: Ss

The straight skeleton (second template parameter)

Straight_skeleton_builder_2<Gt,Ss,Visitor>:: Point_2

The 2D point type as defined by the geometric traits

Creation

Straight_skeleton_builder_2<Gt,Ss,Visitor> b; Default constructs the builder class.

Methods

template<class InputPointIterator>

Straight_skeleton_builder_2&

b.enter_contour(InputPointIterator aBegin, InputPointIterator aEnd)

Defines the *contours* that form the *non-degenerate strictly-simple polygon with holes* whose *straight skeleton* is to be built.
Each contour must be input in turn starting with the *outer contour* and following with the holes (if any). The order of the holes is unimportant but the outer contour must be entered first. The outer contour must be oriented counter-clockwise while holes must be oriented clockwise.
It is an error to enter more than one outer contour or to enter a hole which is not inside the outer contour or inside another hole. It is also an error to enter a contour which crosses or touches any one another. It is possible however to enter a contour that touches itself in such a way that its interior region is still well defined and singly-connected (see the User Manual for examples).
The sequence [aBegin,aEnd) must iterate over each 2D point that corresponds to a vertex of the contour being entered. Vertices cannot be coincident (except consecutively since the method simply skip consecutive coincident vertices). Consecutive collinear edges are allowed.
InputPointIterator must be an *InputIterator* whose *value_type* is *Point_2*.

boost::shared_ptr<Ss>

b.construct_skeleton()

Constructs and returns the 2D straight skeleton in the interior of the polygon with holes as defined by the contours entered first by calling *enter_contour*. All the contours of the polygon with holes must be entered before calling *construct_skeleton*.
After *construct_skeleton* completes, you cannot enter more contours and/or call *construct_skeleton()* again. If you need another straight skeleton for another polygon you must instantiate and use another builder.
The result is a dynamically allocated instance of the *Ss* class, wrapped in a *boost::shared_ptr*.
If the construction process fails for whatever reason (such as a nearly-degenerate vertex whose internal or external angle is almost zero), the return value will be *null*, represented by a default constructed *shared_ptr*.
The algorithm automatically checks the consistency of the result, thus, if it is not *null*, it is guaranteed to be valid.

Algorithm

The implemented algorithm is closely based on [FO98] with the addition of *vertex events* as described in [EE98].

It simulates a grassfire propagation of moving polygon edges as they move inward at constant and equal speed. That is, the continuous inward offsetting of the polygon.

Since edges move at equal speed their movement can be characterized in a simpler setup as the movement of vertices. Vertices move along the angular bisector of adjacent edges.
The trace of a moving vertex is described by the algorithm as a *bisector*. Every position along a bisector corresponds to the vertex between two offset (moved) edges. Since edges move at constant speed, every position along a bisector also corresponds to the distance those two edges moved so far.
From the perspective of a dynamic system of moving edges, such a distance can be regarded as an *instant* (in time). Therefore, every distinct position along a bisector corresponds to a distinct instant in the offsetting process.
As they move inward, edges can expand or contract w.r.t to the endpoints sharing a vertex. If a vertex has an internal angle $< pi$, its incident edges will contract but if its internal angle $> pi$, they will expand. The movement of the edges, along with their extent change, result in collisions between non-adjacent edges. These collisions are called *events*, and they occur when the colliding edges have moved a certain distance, that is, at certain *instants*.
If non-consecutive edges *E(j),E(k)* move while edge *E(i)* contracts, they can collide at the point when *E(i)* shrinks to nothing (that is, the three edges might meet at a certain offset). This introduces a *topological change* in the polygon: Edges *E(j),E(k)* are now adjacent, edge *E(i)* disappears, and a new vertex appears. This topological change is called an *edge event*.
Similarly, consecutive expanding edges *E(i),E(i+1)* sharing a reflex vertex (internal angle $>= pi$) might collide with any edge *E(j)* on the rest of the same connected component of the polygon boundary (even far away from the initial edge's position). This also introduces a topological change: *E(j)* gets split in two edges and the connected component having *E(i),E(i+1) and E(j)* is split in two unconnected parts: one having *E(i)* and the corresponding subsegment of *E(j)* and the other with *E(i+1)* and the rest of *E(j)*. This is called a *split event*.
If a reflex vertex hits not an edge *E(j)* but another reflex vertex *E(j),E(j+1)*, and vice-versa (the reflex vertex V(j) hits V(i)), there is no actual split and the two unconnected parts have *E(i),E(j)* and *E(i+1),E(j+1)* (or *E(i),E(j+1)* and *E(i+1),E(j)*). This topological change is called a *vertex event*. Although similar to a split event in the sense that two new unconnected contours emerge introducing two new contour vertices, in the case of a vertex event one of the new contour vertices might be reflex; that is, a vertex event *may* result in one of the offset polygons having a *reflex* contour vertex which was not in the original polygon.

Edges movement is described by vertices movement, and these by bisectors. Therefore, the collision between edges *E(j),E(i),E(k)* (all in the same connected component) occurs when the moving vertices *E(j)->E(i)* and *E(i)->E(k)* meet ; that is, when the two bisectors describing the moving vertices *intersect* (Note: as the edges move inward and events occur, a vertex between edges A and B might exist even if A and B are not consecutive; that is, j and k are not necessarily i-1 and i+1 respectively, although initially they are).
Similarly, the collision between *E(i),E(i+1)* with *E(j)* (all in the same connected component) occurs when the bisector corresponding to the moving vertex *E(i)->E(i+1)* hits the moving edge *E(j)*.
Since each event changes the topology of the moving polygon, it is not possible or practical to foresee all events at once. Rather, the algorithm starts by estimating an initial set of potential events and from there it computes one next event at a time based on the previous one. The chaining of events is governed by their relative instants: events that occur first are processed first.
An initial set of *potential* split events is first computed independently (the computation of a potential split event is based solely on a reflex vertex and all other edges in the same connected component); and an initial set of *potential* edge events between initially consecutive bisectors is first computed independently (based solely on each bisector pair under consideration).
Events occur at certain instants and the algorithm must be able to order them accordingly. The correctness of the algorithm is uniquely and directly governed by the correct computation and ordering of the events. Any potential event might no longer be applicable after the topological change introduced by a prior event.
A grassfire propagation picks the next unprocessed event (starting from the first) and if it is still applicable processes it. Processing an event involves connecting edges, adding a new skeleton vertex (which corresponds the a contour vertex of the offset polygon) and calculating one new potential future event (which can be either an edge event or a split event -because of a prior vertex event-), based on the topological change just introduced. The propagation finishes when there are no new future events.

CGAL::Straight_skeleton_builder_2<Gt,Ss,Visitor>

CGAL::create_offset_polygons_2

Function

Definition

The function *create_offset_polygons_2* creates a straight skeleton in the interior of a 2D polygon with holes.

#include <CGAL/create_straight_skeleton_2.h>

template<class Polygon, class FT, class Straight_skeleton, class K>
std::vector< boost::shared_ptr<Polygon> >

create_offset_polygons_2(FT offset,
Straight_skeleton s,
,
K k = Exact_predicates_inexact_constructions_kernel)

returns a container with all the offset polygons at distance $offset$ obtained from the straight skeleton s.

1. K is any CGAL kernel.
2. FT is any number type implicitly convertible to $K::FT$.
3. *Straight_skeleton* is *Straight_skeleton_2<K2>*. If $K! = K2$ the straight skeleton is converted to *Straight_skeleton_2<K>*.
4. *Polygon* is a model of *VertexContainer_2*. If this first template parameter is omitted, *Polygon_2* is used.

Function

CGAL::arrange_offset_polygons_2

Definition

The function *arrange_offset_polygons_2* arranges the sequence of *Polygon_2* objects obtained by *create_offset_polygons_2* into *Polygon_with_holes_2* objects by determining geometric parent-hole relationships using a simple algorithm based on the particular characteristics of offset polygons. This function should not be used to arrange arbitrary polygons into polygons with holes unless they meet the requirements specified below.

#include <CGAL/arrange_offset_polygons_2.h>

```
template<class K, class InputPolygonPtrIterator, class OutputPolygonWithHolesPtrIterator>
void arrange_offset_polygons_2( InputPolygonPtrIterator begin,
                                InputPolygonPtrIterator end,
                                OutputPolygonWithHolesPtrIterator out,
                                K k)
```

determines parent-hole relationships among the polygons given by *[begin,end]* creating *boost::shared_ptr< Polygon_with_holes_2<K> >* objects added to the output sequence given *out*. A *CLOCKWISE* oriented polygon *H* is a hole of a *COUNTERCLOCKWISE* polygon *P*, iff at least one vertex of *H* is *ON_BOUNDED_SIDE* of *P*.

Requirements

1. *K* is any CGAL kernel.
2. *InputPolygonPtrIterator* is an input iterator whose *value_type* is a *smart ptr* (such as *boost::shared_ptr*) whose *element_type* is *Polygon_2<K>*.
3. *InputPolygonPtrIterator* is an output iterator whose *value_type* is a *smart ptr* (such as *boost::shared_ptr*) whose *element_type* is *Polygon_with_holes_2<K>*.
4. The input polygons must be simple.
5. The set of input polygons are unique and interior disjoint. That is, given distinct polygons *P* and *Q*, there are vertices of *P* which are not on the boundary of *Q* and are all on the bounded or unbounded side of *Q* (but not both).

CGAL::create_interior_skeleton_and_offset_polygons_2

Definition

The function *create_interior_skeleton_and_offset_polygons_2* creates inner offset polygons directly from an input polygon via a temporarily created straight skeleton.

#include <CGAL/create_offset_polygons_2.h>

```
template<class FT, class Polygon, class HoleIterator, class OffsettingK, class SkeletonK>
std::vector< boost::shared_ptr<Polygon> >
        create_interior_skeleton_and_offset_polygons_2( FT offset,
                                                        Polygon outer_boundary,
                                                        HoleIterator holes_begin,
                                                        HoleIterator holes_end,
                                                        OffsettingK ofk = CGAL::Exact_predicates_inexact_constructions_kernel,
                                                        SkeletonK ssk = CGAL::Exact_predicates_inexact_constructions_kernel)
```

returns a container with all the inner offset polygons at distance $offset$ of the 2D polygon with holes whose outer boundary is *outer_boundary* and its holes are given by *[holes_begin,holes_end]*. A temporary straight skeleton is constructed in the interior of the input polygon to obtain the offsets. The construction of this skeleton is the most expensive operation, therefore, to construct offsets at more than one single distance, use the separate functions *create_interior_straight_skeleton_2* and *create_offset_polygons_2* instead.

```
template<class FT, class Polygon, class OffsettingK, class SkeletonK>
std::vector< boost::shared_ptr<Polygon> >
        create_interior_skeleton_and_offset_polygons_2( FT offset,
                                                        Polygon poly,
                                                        OffsettingK ofk = CGAL::Exact_predicates_inexact_constructions_kernel,
                                                        SkeletonK ssk = CGAL::Exact_predicates_inexact_constructions_kernel)
```

returns a container with all the inner offset polygons at distance $offset$ of the 2D polygon *poly*. A temporary straight skeleton is constructed in the interior of the input polygon to obtain the offsets. The construction of this skeleton is the most expensive operation, therefore, to construct offsets at more than one single distance, use the separate functions *create_interior_straight_skeleton_2* and *create_offset_polygons_2* instead.

#include <CGAL/create_offset_polygons_from_polygon_with_holes_2.h>

template<class FT, class OffsettingK, class SkeletonK>
std::vector< boost::shared_ptr< Polygon_2<OffsettingK> > >

create_interior_skeleton_and_offset_polygons_2(FT offset, CGAL::Polygon_with_holes< OffsettingK> poly_with_holes, OffsettingK ofk = CGAL::Exact_predicates_inexact_constructions_kernel, SkeletonK ssk = CGAL::Exact_predicates_inexact_constructions_kernel)

returns a container with all the inner offset polygons at distance $offset$ of the 2D polygon with holes $poly_with_holes$. A temporary straight skeleton is constructed in the interior of the input polygon to obtain the offsets. The construction of this skeleton is the most expensive operation, therefore, to construct offsets at more than one single distance, use the separate functions *create_interior_straight_skeleton_2* and *create_offset_polygons_2* instead.

CGAL::create_exterior_skeleton_and_offset_polygons_2

Definition

The function *create_exterior_skeleton_and_offset_polygons_2* creates outer offset polygons directly from an input polygon via a temporarily created straight skeleton.

#include <CGAL/create_offset_polygons_2.h>

```
template<class FT, class Polygon, class OffsettingK, class SkeletonK>
std::vector< boost::shared_ptr<Polygon> >

        create_exterior_skeleton_and_offset_polygons_2( FT offset,
                                                        Polygon poly,
                                                        OffsettingK ofk = Exact_predicates_inexact_constructions_kernel,
                                                        SkeletonK ssk = Exact_predicates_inexact_constructions_kernel)
```

returns a container with all the outer offset polygons at distance $offset$ of the 2D polygon *poly*. A temporary straight skeleton is constructed in the *limited exterior* of the input polygon to obtain the offsets. The construction of this skeleton is the most expensive operation, therefore, to construct offsets at more than one single distance, use the separate functions *create_exterior_straight_skeleton_2* and *create_offset_polygons_2* instead. The exterior skeleton is limited by an outer rectangular frame placed at a margin sufficiently large to allow the offset polygons to be constructed.

#include <CGAL/create_offset_polygons_from_polygon_with_holes_2.h>

```
template<class FT, class OffsettingK, class SkeletonK>
std::vector< boost::shared_ptr< Polygon_with_holes_2<OffsettingK> > >

        create_exterior_skeleton_and_offset_polygons_with_holes_2( FT offset,
                                                                   CGAL::Polygon_2< OffsettingK> poly_with_holes,
                                                                   OffsettingK ofk = Exact_predicates_inexact_constructions_kernel,
                                                                   SkeletonK ssk = Exact_predicates_inexact_constructions_kernel)
```

returns a container with all the outer offset polygons *with holes* at distance $offset$ of the 2D polygon *poly*. This is equivalent to *arrange_offset_polygons_2(create_exterior_skeleton_and_offset_polygons_2(offset,poly,okk,ssk))*.

Requirements

1. *OffsettingK* is the CGAL kernel used to instantiate *Polygon_offset_builder_traits_2<K>* for constructing the offset polygons.

2. *SkeletonK* is the CGAL kernel used to instantiate *Straight_skeleton_builder_traits_2<K>* for constructing the straight skeleton. If *SkeletonK != OffsettingK* the constructed straight skeleton is converted to *Straight_skeleton_2<OffsettingK>*.

3. *FT* is any number type implicitly convertible to *OffsettingK::FT*.

4. *Straight_skeleton* is *Straight_skeleton_2<K2>*. If $K! = K2$ the straight skeleton is converted to *Straight_skeleton_2<K>*.

Class

CGAL::Polygon_offset_builder_traits_2<Kernel>

Definition

The class *Polygon_offset_builder_traits_2<Kernel>* provides a model for the *PolygonOffsetBuilderTraits_2* concept which is the traits class required by the *Polygon_offset_builder_2* algorithm class. The class *Polygon_offset_builder_traits_2<Kernel>* has one template argument: a 2D CGAL Kernel. This parameter must be a model for the *Kernel* concept, such as the *Exact_predicates_inexact_constructions_kernel*, which is the recommended one. It is unspecified which subset of the kernel is used in this traits class (and by extension in the builder class). This is to avoid restricting the choices in the implementation.

#include <CGAL/Polygon_offset_builder_traits_2.h>

CGAL::Polygon_offset_builder_2<Ss,Gt,Container>

Class

Definition

The class *Polygon_offset_builder_2<Ss,Gt,Container>* encapsulates the construction of inward offset contours of a 2D simple polygon with holes. The construction is based on the straight skeleton of the interior of the polygon. Its first template parameter, *Ss*, must be a model of the *StraightSkeleton_2* concept, its second template parameter, *Gt*, must be a model of the *StraightSkeletonBuilderTraits_2* concept, and its third template parameter must be a model of the *VertexContainer_2* concept.

#include <CGAL/Polygon_offset_builder_2.h>

Types

Polygon_offset_builder_2<Ss,Gt,Container>:: Ss

The straight skeleton (first template parameter)

Polygon_offset_builder_2<Ss,Gt,Container>:: Gt

The geometric traits (second template parameter)

Polygon_offset_builder_2<Ss,Gt,Container>:: Container

The container of 2D vertices that represents each offset contour generated by the algorithm (third template parameter)

Polygon_offset_builder_2<Ss,Gt,Container>:: FT

The *SqrtFieldNumberType* used to specify the desired offset distance, provided by the geometric traits *Gt*.

Creation

Polygon_offset_builder_2<Ss,Gt,Container> b(Ss ss);

Constructs the builder class using the given Straight Skeleton instance.

Methods

template<class OutputIterator>

OutputIterator *b.construct_offset_contours(FT t, OutputIterator out)*

Given the straight skeleton passed in the constructor which corresponds to the interior of a non-degenerate strictly-simple polygon with holes P, returns *all* the offset contours of P at the Euclidean distance t.

Such offset contours are polygons in the interior of P. Provided exact constructions are used, these polygons are simple.

For any offset distance t there are 0, 1 or more offset contours.

For each resulting offset contour, a default constructed instance of *Container* type (which must be a model of the *VertexContainer_2* concept), is dynamically allocated and each offset vertex is added to it.

A *boost::shared_ptr* holding onto the dynamically allocated container is inserted into the output sequence via the OutputIterator *out*.

OutputIterator must be a model of the *OutputIterator* category whose *value_type* is a *boost::shared_ptr* holding the dynamically allocated instances of type Container.

The method returns an OutputIterator past-the-end of the resulting sequence, which contains each offset contour generated.

You can call *construct_offset_contours* with different offset distances (there is no need to construct the builder again). If you call it with an offset distance so large that there are no offset contours at that distance, no contour is inserted into the output sequence and the returned iterator will be equal to *out*.

For any given input polygon, its offset polygons at a certain distance are composed of several contours. This method returns all such contours in an unspecified order and with no parental relationship between them (that is why it is called *construct_offset_contours* and not *construct_offset_polygons*).

Those offset contours in the resulting sequence which are oriented counter-clockwise are outer contours and those oriented clockwise are holes. It is up to the user to match each hole to its parent in order to reconstruct the parent-hole relationship of the conceptual output. It is sufficient to test each hole against each parent as there won't be a hole inside a hole, a parent inside any other contour, or a hole inside more than one parent. The recommended insideness test is to perform a regularized Boolean set operation. *do_intersect* from the *Boolean Set Operations* package will work fine in our case since it is guaranteed that no hole would cross halfway outside any parent (in the presence of such cases, subtracting the parent from the hole works better as it correctly rejects halfway holes).

If there are degenerate, or nearly degenerate vertices; that is, vertices whose internal or external angle approaches *0*, numerical overflow may prevent some of the polygon contours to be constructed. If that happens, the failed contour just won't be added into the resulting sequence.

Function

CGAL::compute_outer_frame_margin

Definition

The function *compute_outer_frame_margin* computes the separation required between a polygon and the outer frame used to obtain an exterior skeleton suitable for the computation of outer offset polygons at a given distance.

#include <CGAL/compute_outer_frame_margin.h>

template <class InputIterator, class Traits>
boost::optional< typename Traits::FT >

compute_outer_frame_margin(InputIterator first,
InputIterator beyond,
typename Traits::FT offset,
Traits traits = Default_traits)

Given a non-degenerate strictly-simple 2D polygon whose vertices are passed in the range [*first*,*beyond*), calculates the largest euclidean distance *d* between each input vertex and its corresponding offset vertex at a distance *offset*.
If such a distance can be approximately computed, returns an *optional<FT>* with the value *d + (offset * 1.05)*. If the distance cannot be computed, not even approximately, due to overflow for instance, returns an empty *optional<FT>* (an *absent result*).
This result is the required separation between the input polygon and the rectangular frame used to construct an exterior offset contour at distance *offset* (which is done by placing the polygon as a hole of that frame).
Such a separation must be computed in this way because if the frame is too close to the polygon, the inward offset contour from the frame could collide with the outward offset contour of the polygon, resulting in a merged contour offset instead of two contour offsets, one of them corresponding to the frame.
Simply using *2*offset* as the separation is incorrect since *offset* is the distance between an offset line and its original, not between an offset vertex and its original. The later, which is calculated by this function and needed to place the frame sufficiently away from the polygon, can be thousands of times larger than *offset*.
If the result is *absent*, any attempt to construct an exterior offset polygon at distance *offset* will fail. This will occur whenever the polygon has a vertex with an internal angle approaching *0* (because the offset vertex of a vertex whose internal angle equals 0 is at *infinity*).

Precondition: offset > 0.
Precondition: The range [*first*,*beyond*) contains the vertices of a non-degenerate strictly-simple 2D polygon.

The default traits class *Default_traits* is an instance of the class *Polygon_offset_builder_traits_2<Kernel>* parameterized on the kernel in which the type *InputIterator::value_type* is defined.

Requirements

1. *InputIterator::value_type* is equivalent to *Traits::Point_2*.
2. *Traits* must be a model for *PolygonOffsetBuilderTraits_2*

Chapter 24

2D Minkowski Sums

Ron Wein

Contents

24.1 Introduction

Given two sets $A, B \in \mathbb{R}^d$, their *Minkowski sum*, denoted by $A \oplus B$, is the set $\{a + b \mid a \in A, b \in B\}$. Minkowski sums are used in many applications, such as motion planning and computer-aided design and manufacturing. This package contains functions for computing planar Minkowski sums of two polygons (namely A and B are two closed polygons in $\mathbb{R}^2$), and for a polygon and a disc (an operation also known as *offsetting* or *dilating* a polygon).

24.2 Computing the Minkowski Sum of Two Polygons

Computing the Minkowski sum of two convex polygons P and Q with m and n vertices respectively is very easy, as $P \oplus Q$ is a convex polygon bounded by copies of the $m + n$ edges, and these edges are sorted by the angle they form with the x-axis. As the two input polygons are convex, their edges are already sorted by the angle they form with the x-axis. The Minkowski sum can therefore be computed in $O(m + n)$ time, by starting from two bottommost vertices in P and in Q and performing "merge sort" on the edges.

If the polygons are not convex, it is possible to use one of the following approaches:

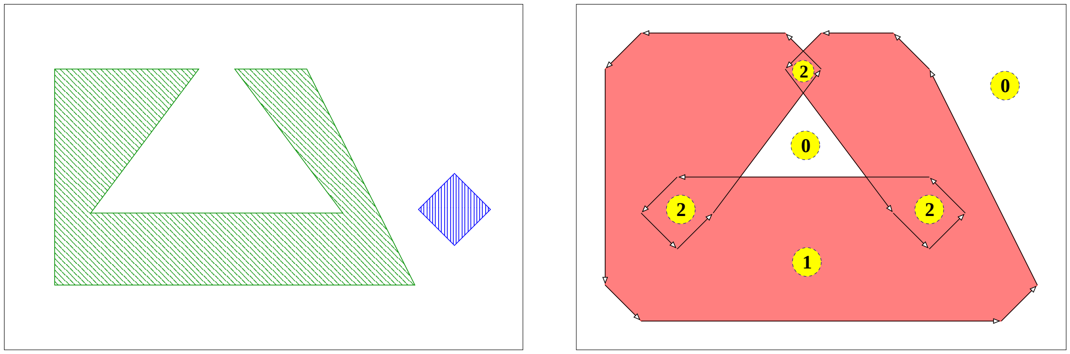

Figure 24.1: Computing the convolution of a convex polygon and a non-convex polygon (left). The convolution consists of a single self-intersecting cycle, drawn as a sequence of arrows (right). The winding number associated with each face of the arrangement induced by the segments forming the cycle appears in dashed circles. The Minkowski sum of the two polygons is shaded.

Decomposition: We decompose P and Q into convex sub-polygons, namely we obtain two sets of convex polygons $P_1, \ldots, P_k$ and $Q_1, \ldots, Q_\ell$ such that $\bigcup_{i=1}^{k} P_i = P$ and $\bigcup_{i=j}^{\ell} Q_j = Q$. We then calculate the pairwise sums $S_{ij} = P_i \oplus Q_j$ using the simple procedure described above, and compute the union $P \oplus Q = \bigcup_{ij} S_{ij}$.

This approach relies on a decomposition strategy that computes the convex decomposition of the input polygons and its performance depends on the quality of the decomposition.

Convolution: Let us denote the vertices of the input polygons by $P = (p_0, \ldots, p_{m-1})$ and $Q = (q_0, \ldots, q_{n-1})$. We assume that both P and Q have positive orientations (i.e. their boundaries wind in a counterclockwise order around their interiors) and compute the convolution of the two polygon boundaries. The *convolution* of these two polygons [GRS83], denoted $P * Q$, is a collection of line segments of the form $[p_i + q_j, p_{i+1} + q_j]$,[1] where the vector $\mathbf{p_i p_{i+1}}$ lies between $\mathbf{q_{j-1} q_j}$ and $\mathbf{q_j q_{j+1}}$,[2] and — symmetrically — of segments of the form $[p_i + q_j, p_i + q_{j+1}]$, where the vector $\mathbf{q_j q_{j+1}}$ lies between $\mathbf{p_{i-1} p_i}$ and $\mathbf{p_i p_{i+1}}$.

The segments of the convolution form a number of closed (not necessarily simple) polygonal curves called *convolution cycles*. The Minkowski sum $P \oplus Q$ is the set of points having a non-zero winding number with respect to the cycles of $P * Q$.[3] See Figure 24.1 for an illustration.

The number of segments in the convolution of two polygons is usually smaller than the number of segments that constitute the boundaries of the sub-sums S_{ij} when using the decomposition approach. As both approaches construct the arrangement of these segments and extract the sum from this arrangement, computing Minkowski sum using the convolution approach usually generates a smaller intermediate arrangement, hence it is faster and consumes less space.

24.2.1 Computing Minkowski Sum using Convolutions

The function *minkowski_sum_2 (P, Q)* accepts two simple polygons P and Q, represented using the *Polygon_2<Kernel,Container>* class-template and uses the convolution method in order to compute and return their Minkowski sum $S = P \oplus Q$.

As the input polygons may not be convex, their Minkowski sum may not be simply connected and contain polygonal holes; see for example Figure 24.1. S is therefore an instance of the *Polygon_with_holes_2< Kernel,Container>* class-template, defined in the Boolean Set-Operations package: The outer boundary of S

[1] Throughout this chapter, we increment or decrement an index of a vertex modulo the size of the polygon.

[2] We say that a vector $\mathbf{v}$ lies between two vectors $\mathbf{u}$ and $\mathbf{w}$ if we reach $\mathbf{v}$ strictly before reaching $\mathbf{w}$ if we move all three vectors to the origin and rotate $\mathbf{u}$ counterclockwise. Note that this also covers the case where $\mathbf{u}$ has the same direction as $\mathbf{v}$.

[3] Informally speaking, the winding number of a point $p \in \mathbb{R}^2$ with respect to some planar curve γ is an integer number counting how many times does γ wind in a counterclockwise direction around p.

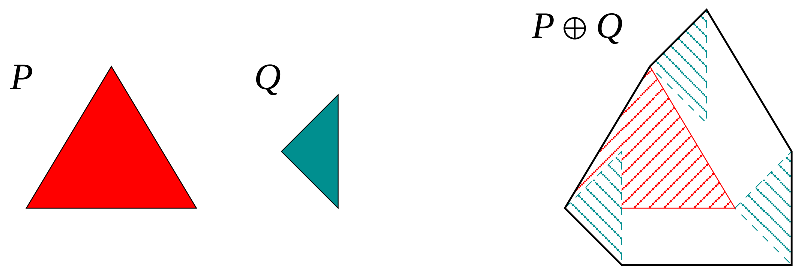

Figure 24.2: Computing the Minkowski sum of two triangles, as done in the example program *Minkowski_sum_2/sum_triangles.cpp*.

is a polygon that can be accessed using *S.outer_boundary()*, and its polygonal holes are given by the range *[S.holes_begin(), S.holes_end())* (where *S* contains *S.number_of_holes()* holes in its interior).

The following example program constructs the Minkowski sum of two triangles, as depicted in Figure 24.2. The result in this case is a convex hexagon. This program, as other example programs in this chapter, includes the auxiliary header file *ms_rational_nt.h* which defines *Number_type* as either *Gmpq* or *Quotient<MP_Float>*, depending on whether the GMP library is installed or not. The file *print_util.h* includes auxiliary functions for printing polygons.

```
#include "ms_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/minkowski_sum_2.h>
#include <iostream>

#include "print_utils.h"

typedef CGAL::Cartesian<Number_type>                Kernel;
typedef Kernel::Point_2                             Point_2;
typedef CGAL::Polygon_2<Kernel>                     Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel>          Polygon_with_holes_2;

int main ()
{
  // Construct the first polygon (a triangle).
  Polygon_2   P;

  P.push_back (Point_2 (0, 0));
  P.push_back (Point_2 (6, 0));
  P.push_back (Point_2 (3, 5));

  // Construct the second polygon (a triangle).
  Polygon_2   Q;

  Q.push_back (Point_2 (0, 0));
  Q.push_back (Point_2 (2, -2));
  Q.push_back (Point_2 (2, 2));

  // Compute the Minkowski sum.
  Polygon_with_holes_2  sum = minkowski_sum_2 (P, Q);
```

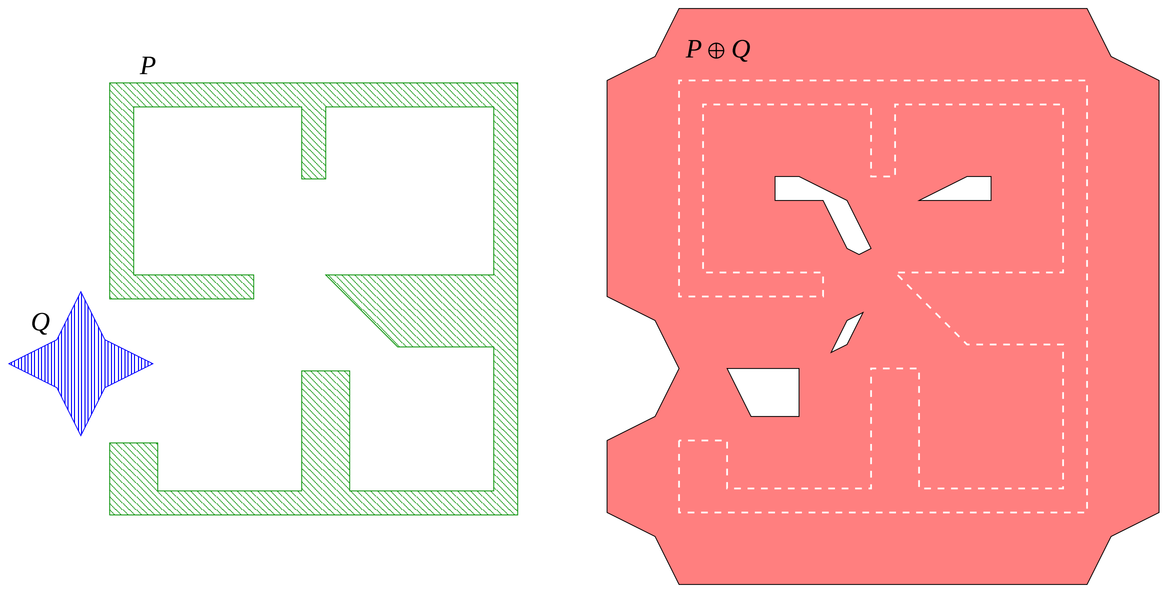

Figure 24.3: Computing the Minkowski sum of two non-convex polygons P and Q, as done in the example programs *Minkowski_sum_2/sum_with_holes.cpp* and *Minkowski_sum_2/sum_by_decomposition.cpp*.

```
  CGAL_assertion (sum.number_of_holes() == 0);

  std::cout << "P = "; print_polygon (P);
  std::cout << "Q = "; print_polygon (Q);
  std::cout << "P (+) Q = "; print_polygon (sum.outer_boundary());

  return (0);
}
```

File: examples/Minkowski_sum_2/sum_triangles.cpp

In the following program we compute the Minkowski sum of two polygons that are read from an input file. In this case, the sum is not simple and contains four holes, as illustrated in Figure 24.3. Note that this example uses the predefined CGAL kernel with exact constructions. In general, instantiating polygons with this kernel yields the fastest running times for Minkowski-sum computations.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/minkowski_sum_2.h>
#include <iostream>
#include <fstream>

#include "print_utils.h"

struct Kernel : public CGAL::Exact_predicates_exact_constructions_kernel
   {};

typedef Kernel::Point_2                                    Point_2;
typedef CGAL::Polygon_2<Kernel>                            Polygon_2;
```

```
typedef CGAL::Polygon_with_holes_2<Kernel>
    Polygon_with_holes_2;

int main ()
{
  // Open the input file.
  std::ifstream    in_file ("rooms_star.dat");

  if (! in_file.is_open())
  {
    std::cerr << "Failed to open the input file." << std::endl;
    return (1);
  }

  // Read the two polygons from the file and compute their Minkowski sum.
  Polygon_2    P, Q;

  in_file >> P >> Q;
  in_file.close();

  // Compute and print the Minkowski sum.
  Polygon_with_holes_2  sum = minkowski_sum_2 (P, Q);

  std::cout << "P (+) Q = "; print_polygon_with_holes (sum);

  return (0);
}
```

File: examples/Minkowski_sum_2/sum_with_holes.cpp

24.2.2 Decomposition Strategies

In order to compute Minkowski sums using the decomposition method, it is possible to call the function *minkowski_sum_2 (P, Q, decomp)*, where *decomp* is an instance of a class that models the concept *PolygonConvexDecomposition_2*, namely it should provide a method named *decompose()* that receives a planar polygon and returns a range of convex polygons that represents its convex decomposition.

The Minkowski-sum package includes four models of the concept *PolygonConvexDecomposition_2*. The first three are classes that wrap the decomposition functions included in the Planar Polygon Partitioning package, while the fourth is an implementation of a decomposition algorithm introduced in [AFH02]. The convex decompositions that it creates usually yield efficient running times for Minkowski sum computations:

- The class *Optimal_convex_decomposition<Kernel>* uses the dynamic-programming algorithm of Greene [Gre83] for computing an optimal decomposition of a polygon into a minimal number of convex sub-polygons. The main drawback of this strategy is that it runs in $O(n^4)$ time and $O(n^3)$ in the worst case,where n is the number of vertices in the input polygon.
- The class *Hertel_Mehlhorn_convex_decomposition<Kernel>* implements the approximation algorithm suggested by Hertel and Mehlhorn [HM83], which triangulates the input polygon and proceeds by throwing away unnecessary triangulation edges. This algorithm requires $O(n)$ time and space and guarantees that the number of sub-polygons it generates is not more than four times the optimum.

- The class *Greene_convex_decomposition<Kernel>* is an implementation of Greene's approximation algorithm [Gre83], which computes a convex decomposition of the polygon based on its partitioning into y-monotone polygons. This algorithm runs in $O(n \log n)$ time and $O(n)$ space, and has the same approximation guarantee as Hertel and Mehlhorn's algorithm.

- The class *Small_side_angle_bisector_convex_decomposition<Kernel>* uses a heuristic improvement to the angle-bisector decomposition method suggested by Chazelle and Dobkin [CD85], which runs in $O(n^2)$ time. It starts by examining each pair of reflex vertices in the input polygon such that the entire interior of the diagonal connecting these vertices is contained in the polygon. Out of all available pairs, the vertices p_i and p_j are selected such that the number of reflex vertices from p_i to p_j (or from p_j to p_i) is minimal. The polygon is split by the diagonal $p_i p_j$ and we continue recursively on both resulting sub-polygons. In case it is not possible to eliminate two reflex vertices at once any more, each reflex vertex is eliminated by a diagonal that is closest to the angle bisector emanating from this vertex.

The following example demonstrates the computation of the Minkowski sum of the same input polygons as used in *Minkowski_sum_2/sum_with_holes.cpp* (as depicted in Figure 24.3), using the small-side angle-bisector decomposition strategy:

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/minkowski_sum_2.h>
#include <CGAL/Small_side_angle_bisector_decomposition_2.h>
#include <iostream>
#include <fstream>

#include "print_utils.h"

struct Kernel : public CGAL::Exact_predicates_exact_constructions_kernel
   {};

typedef Kernel::Point_2                                  Point_2;
typedef CGAL::Polygon_2<Kernel>                          Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel>
   Polygon_with_holes_2;

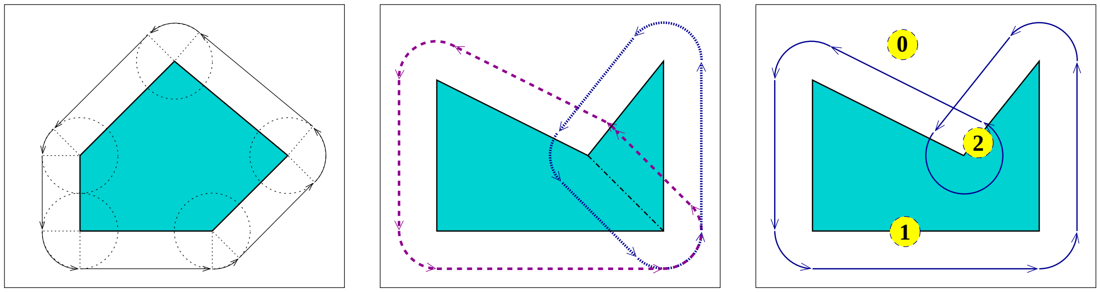
int main ()
{
  // Open the input file.
  std::ifstream    in_file ("rooms_star.dat");

  if (! in_file.is_open())
  {
    std::cerr << "Failed to open the input file." << std::endl;
    return (1);
  }

  // Read the two polygons from the file and compute their Minkowski sum.
  Polygon_2   P, Q;

  in_file >> P >> Q;
  in_file.close();

  // Compute the Minkowski sum using the decomposition approach.
  CGAL::Small_side_angle_bisector_decomposition_2<Kernel>  ssab_decomp;
```



(a) (b) (c)

Figure 24.4: (a) Offsetting a convex polygon. (b) Computing the offset of a non-convex polygon by decomposing it to convex sub-polygons. (c) Offsetting a non-convex polygon by computing its convolution with a disc. The convolution cycle induces an arrangement with three faces, whose winding numbers are shown enclosed in dashed circles.

```
  Polygon_with_holes_2  sum = minkowski_sum_2 (P, Q, ssab_decomp);

  std::cout << "P (+) Q = "; print_polygon_with_holes (sum);

  return (0);
}
```

File: `examples/Minkowski_sum_2/sum_by_decomposition.cpp`

24.3 Offsetting a Polygon

The operation of computing the Minkowski sum $P \oplus B_r$ of a polygon P with b_r, a disc of radius r centered at the origin, is widely known as *offsetting* the polygon P by a radius r.

Let $P = (p_0, \ldots, p_{n-1})$ be the polygon vertices, ordered in a counterclockwise orientation around its interior. If P is a convex polygon the offset is easily computed by shifting each polygon edge by r away from the polygon, namely to the right side of the edge. As a result we obtain a collection of n disconnected *offset edges*. Each pair of adjacent offset edges, induced by $p_{i-1}p_i$ and p_ip_{i+1}, are connected by a circular arc of radius r, whose supporting circle is centered at p_i. The angle that defines such a circular arc equals $180^\circ - \angle(p_{i-1}, p_i, p_{i+1})$; see Figure 24.4(a) for an illustration. The running time of this simple process is of course linear with respect to the size of the polygon.

If P is not convex, its offset can be obtained by decomposing it to convex sub-polygons $P_1, \ldots P_m$ such that $\bigcup_{i=1}^{m} P_i = P$, computing the offset of each sub-polygon and finally calculating the union of these sub-offsets (see Figure 24.4(b)). However, as was the case with the Minkowski sum of a pair of polygons, here it is also more efficient to compute the *convolution cycle* of the polygon with the disc B_r,[4] which can be constructed by applying the process described in the previous paragraph. The only difference is that a circular arc induced by a reflex vertex p_i is defined by an angle $540^\circ - \angle(p_{i-1}, p_i, p_{i+1})$; see Figure 24.4(c) for an illustration. We finally compute the winding numbers of the faces of the arrangement induced by the convolution cycle to obtain the offset polygon.

[4]As the disc is convex, it is guaranteed that the convolution curve is comprised of a single cycle.

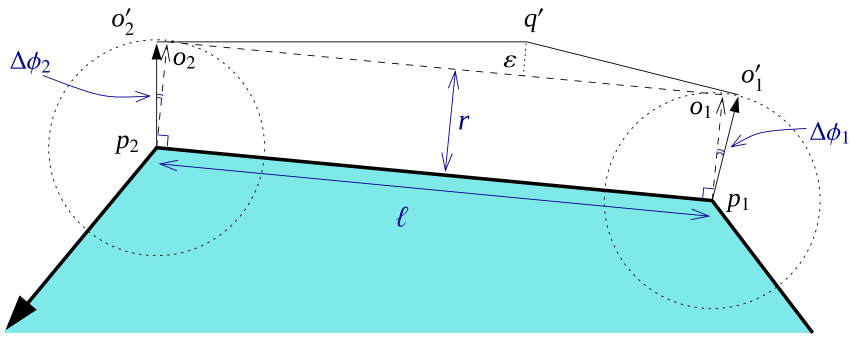


Figure 24.5: Approximating the offset edge $o_1 o_2$ induced by the polygon edge $p_1 p_2$ by two line segments $o'_1 q'$ and $q' o'_2$.

24.3.1 Approximating the Offset with a Guaranteed Error-Bound

Let us assume that we are given a counterclockwise-oriented polygon $P = (p_0, \ldots, p_{n-1})$, whose vertices all have rational coordinates (i.e., for each vertex $p_i = (x_i, y_i)$ we have $x_i, y_i \in \mathbb{Q}$, and we wish to compute its Minkowski sum with a disc of radius r, where r is also a rational number. The boundary of this sum is comprised of line segments and circular arcs, where:

- Each circular arc is supported by a circle of radius r centered at one of the polygon vertices. The equation of this circle is $(x - x_i)^2 + (y - y_i)^2 = r^2$, and has only rational coefficients.
- Each line segment is supported by a line parallel to one of the polygon edges $p_i p_{i+1}$, which lies at distance r from this edge. If we denote the supporting line of $p_i p_{i+1}$ by $ax + by + c = 0$, where $a, b, c \in \mathbb{Q}$, then the offset edge is supported by the line $ax + by + (c + \ell \cdot r) = 0$, where ℓ is the length of the edge $p_i p_{i+1}$ and is in general *not* a rational number. The line segments that comprise the offset boundaries therefore cannot be represented as segments of lines with rational coefficients. We mention that the locus of all points that lie at distance r from the line $ax + by + c = 0$ is given by:

  $$\frac{(ax + by + c)^2}{a^2 + b^2} = r^2 \, .$$

  Thus, the linear offset edges are segments of curves of an algebraic curve of degree 2 (a conic curve) with rational coefficients. This curve is actually a pair of the parallel lines $ax + by + (c \pm \ell \cdot r) = 0$. In Section 24.3.2 we use this representation to construct the offset polygon in an exact manner using the traits class for conic arcs.

The class-template *Gps_circle_segment_traits_2<Kernel>*, included in the Boolean Set-Operations package is used for representing general polygons whose edges are circular arcs or line segments, and for applying set operations (e.g. intersection, union, etc.) on such general polygon. It should be instantiated with a geometric kernel that employs exact rational arithmetic, such that the curves that comprise the polygon edges should be arcs of circles with rational coefficients or segments of lines with rational coefficients. As in our case the line segments do not satisfy this requirement, we apply a simple approximation scheme, such that each irrational line segment is approximated by two rational segments:

1. Consider the example depicted in Figure 24.5, where the exact offset edge $o_1 o_2$ is obtained by shifting the polygon edge $p_1 p_2$ by a vector whose length is r that form an angle ϕ with the x-axis. We select two points o'_1 and o'_2 with rational coordinates on the two circles centered at p_1 and p_2, respectively. These points are selected such that if we denote the angle that the vector $\mathbf{p_j o_j}$ forms with the x-axis by ϕ'_j (for $j = 1, 2$), we have $\phi'_1 < \phi < \phi'_2$.

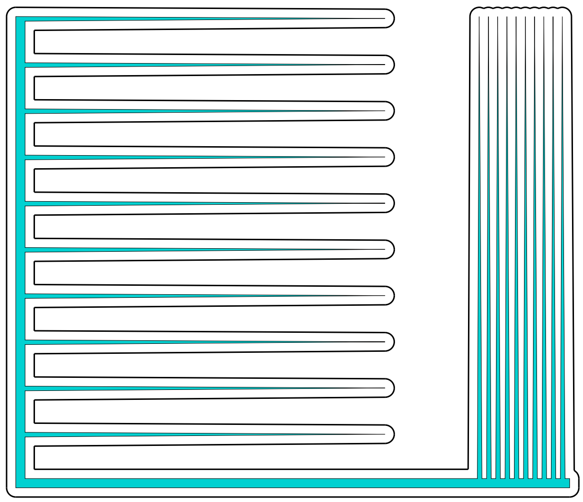

Figure 24.6: The offset computation performed by the example programs *Minkowski_sum_2/approx_offset.cpp* and *Minkowski_sum_2/exact_offset.cpp*. The input polygon is shaded and the boundary of its offset is drawn in a thick black line.

2. We construct two tangents to the two circles at o'_1 and o'_2, respectively. The tangent lines have rational coefficients.

3. We compute the intersection point of the two tangents, denoted q'. The two line segments $o'_1 q'$ and $q' o'_2$ approximate the original offset edge $o_1 o_2$.

The function *approximated_offset_2 (P, r, eps)* accepts a polygon P, an offset radius r and $\varepsilon > 0$. It constructs an approximation for the offset of P by the radius r using the procedure explained above. Furthermore, it is guaranteed that the approximation error, namely the distance of the point q' from $o_1 o_2$ is bounded by ε. Using this function, we are capable of working with the *Gps_circle_segment_traits_2<Kernel>* class, which considerably speeds up the (approximate) construction of the offset polygon and the application of set operations on such polygons. The function returns an object of the nested type *Gps_circle_segment_traits_2<Kernel> ::Polygon_with_holes_2* representing the approximated offset polygon (recall that if P is not convex, its offset may not be simple and may contain holes, whose boundary is also comprised of line segments and circular arcs).

The following example demonstrates the construction of an approximated offset of a non-convex polygon, as depicted in Figure 24.6. Note that we use a geometric kernel parameterized with a filtered rational number-type. Using filtering considerably speeds up the construction of the offset.

```
#include "ms_rational_nt.h"
#include <CGAL/Lazy_exact_nt.h>
#include <CGAL/Cartesian.h>
#include <CGAL/approximated_offset_2.h>
#include <CGAL/offset_polygon_2.h>
#include <CGAL/Timer.h>
#include <iostream>

typedef CGAL::Lazy_exact_nt<Number_type>           Lazy_exact_nt;

struct Kernel : public CGAL::Cartesian<Lazy_exact_nt> {};
```

```
typedef CGAL::Polygon_2<Kernel>                          Polygon_2;

typedef CGAL::Gps_circle_segment_traits_2<Kernel>  Gps_traits_2;
typedef Gps_traits_2::Polygon_2                          Offset_polygon_2;
typedef Gps_traits_2::Polygon_with_holes_2
    Offset_polygon_with_holes_2;

int main ()
{
  // Open the input file.
  std::ifstream    in_file ("spiked.dat");

  if (! in_file.is_open())
  {
    std::cerr << "Failed to open the input file." << std::endl;
    return (1);
  }

  // Read the input polygon.
  Polygon_2        P;

  in_file >> P;
  in_file.close();

  std::cout << "Read an input polygon with "
            << P.size() << " vertices." << std::endl;

  // Approximate the offset polygon.
  const Number_type             radius = 5;
  const double                  err_bound = 0.00001;
  Offset_polygon_with_holes_2  offset;
  CGAL::Timer                   timer;

  timer.start();
  offset = approximated_offset_2 (P, radius, err_bound);
  timer.stop();

  std::cout << "The offset polygon has "
            << offset.outer_boundary().size() << " vertices, "
            << offset.number_of_holes() << " holes." << std::endl;
  std::cout << "Offset computation took "
            << timer.time() << " seconds." << std::endl;
  return (0);
}
```

File: examples/Minkowski_sum_2/approx_offset.cpp

24.3.2 Computing the Exact Offset

As we previously mentioned, it is possible to represent offset polygons in an exact manner, if we treat their edges as arcs of conic curves with rational coefficients. The function *offset_polygon_2 (P, r, traits)* computes the offset of the polygon P by a rational radius r in an exact manner. The *traits* parameter should be an instance of an arrangement-traits class that is capable of handling conic arcs in an exact manner; using the *Arr_conic_traits_2* class with the number types provided by the CORE library is the preferred option. The function returns an object of the nested type *Gps_traits_2<ArrConicTraits>::Polygons_with_holes_2* (see the documentation of the Boolean Set-Operations package for more details on the traits-class adapter *Gps_traits_2*), which represented the exact offset polygon.

The following example demonstrates the construction of the offset of the same polygon that serves as an input for the example program *Minkowski_sum_2/approx_offset.cpp*, presented in the previous subsection (see also Figure 24.6). Note that the resulting polygon is smaller than the one generated by the approximated-offset function (recall that each irrational line segment in this case is approximated by two rational line segments), but the offset computation is considerably slower:

```
#include <CGAL/basic.h>

#ifndef CGAL_USE_CORE
#include <iostream>
int main ()
{
  std::cout << "Sorry, this example needs CORE ..." << std::endl;
  return (0);
}
#else

#include <CGAL/Cartesian.h>
#include <CGAL/CORE_algebraic_number_traits.h>
#include <CGAL/Arr_conic_traits_2.h>
#include <CGAL/offset_polygon_2.h>
#include <CGAL/Timer.h>
#include <iostream>

typedef CGAL::CORE_algebraic_number_traits     Nt_traits;
typedef Nt_traits::Rational                    Rational;
typedef Nt_traits::Algebraic                   Algebraic;

struct Rat_kernel : public CGAL::Cartesian<Rational> {};
struct Alg_kernel : public CGAL::Cartesian<Algebraic> {};
struct Conic_traits_2 : public CGAL::Arr_conic_traits_2<Rat_kernel,
                                                        Alg_kernel,
                                                        Nt_traits> {};

typedef CGAL::Polygon_2<Rat_kernel>            Polygon_2;

typedef CGAL::Gps_traits_2<Conic_traits_2>     Gps_traits_2;
typedef Gps_traits_2::Polygon_2                Offset_polygon_2;
typedef Gps_traits_2::Polygon_with_holes_2
   Offset_polygon_with_holes_2;

int main ()
{
  // Open the input file.
  std::ifstream    in_file ("spiked.dat");

  if (! in_file.is_open())
  {
```

```
    std::cerr << "Failed to open the input file." << std::endl;
    return (1);
  }

  // Read the input polygon.
  Polygon_2        P;

  in_file >> P;
  in_file.close();

  std::cout << "Read an input polygon with "
            << P.size() << " vertices." << std::endl;

  // Compute the offset polygon.
  Conic_traits_2                traits;
  const Rational                radius = 5;
  Offset_polygon_with_holes_2   offset;
  CGAL::Timer                   timer;

  timer.start();
  offset = offset_polygon_2 (P, radius, traits);
  timer.stop();

  std::cout << "The offset polygon has "
            << offset.outer_boundary().size() << " vertices, "
            << offset.number_of_holes() << " holes." << std::endl;
  std::cout << "Offset computation took "
            << timer.time() << " seconds." << std::endl;
  return (0);
}

#endif
```

advanced

Both functions *approximated_offset_2()* and *offset_polygon_2()* also have overloaded versions that accept a decomposition strategy and use the polygon-decomposition approach to compute (or approximate) the offset. These functions are less efficient than their counterparts that employ the convolution approach, and are only included in the package for the sake of completeness.

advanced

24.3.3 Computing Inner Offsets

An operation closely related to the offset computation, is obtaining the *inner offset* of a polygon, or *insetting* it by a given radius. The inset of a polygon P with radius r is the set of points iside P whose distance from the polygon boundary, denoted ∂P, is at least r — namely: $\{p \in P \mid \mathrm{dist}(p, \partial P) \geq r\}$. Note that the resulting set may not be connected in case P is a non-convex polygon that has some narrow components, and thus is characterized by a (possibly empty) set of polygons whose edges are line segments and circular arcs of radius r.

The offset can be computed using the convolution method if we traverse the polygon in a *clockwise* orientation (and not in *counterclockwise* orientation, as done in case of ofsetting a polygon). As in case of the offset functions, the Minkowski-sum package contains two functions for insetting a simple polygon:

The function *approximated_inset_2 (P, r, eps, oi)* accepts a polygon P, an inset radius r and $\varepsilon > 0$. It constructs an approximation for the inset of P by the radius r, with the approximation error bounded by ε. The function returns its output via the output iterator *oi*, whose value-type must be *Gps_circle_segment_traits_2<Kernel> ::Polygon_2* representing the polygons that approximates the inset polygon.

```
#include "ms_rational_nt.h"
#include <CGAL/Lazy_exact_nt.h>
#include <CGAL/Cartesian.h>
#include <CGAL/approximated_offset_2.h>
#include <CGAL/offset_polygon_2.h>
#include <CGAL/Timer.h>
#include <iostream>

typedef CGAL::Lazy_exact_nt<Number_type>           Lazy_exact_nt;

struct Kernel : public CGAL::Cartesian<Lazy_exact_nt> {};
typedef CGAL::Polygon_2<Kernel>                    Polygon_2;

typedef CGAL::Gps_circle_segment_traits_2<Kernel>  Gps_traits_2;
typedef Gps_traits_2::Polygon_2                    Offset_polygon_2;
typedef Gps_traits_2::Polygon_with_holes_2
   Offset_polygon_with_holes_2;

int main ()
{
  // Open the input file.
  std::ifstream    in_file ("tight.dat");

  if (! in_file.is_open())
  {
    std::cerr << "Failed to open the input file." << std::endl;
    return (1);
  }

  // Read the input polygon.
  Polygon_2        P;

  in_file >> P;
  in_file.close();

  std::cout << "Read an input polygon with "
            << P.size() << " vertices." << std::endl;

  // Approximate the offset polygon.
  const Number_type                       radius = 1;
  const double                            err_bound = 0.00001;
  std::list<Offset_polygon_2>             inset_polygons;
  std::list<Offset_polygon_2>::iterator   iit;
  CGAL::Timer                             timer;
```

```
  timer.start();
  approximated_inset_2 (P, radius, err_bound,
                        std::back_inserter (inset_polygons));
  timer.stop();

  std::cout << "The inset comprises "
            << inset_polygons.size() << " polygon(s)." << std::endl;
  for (iit = inset_polygons.begin(); iit != inset_polygons.end(); ++iit)
  {
      std::cout << "    Polygon with "
                << iit->size() << " vertices." << std::endl;
  }
  std::cout << "Inset computation took "
            << timer.time() << " seconds." << std::endl;
  return (0);
}
```

File: examples/Minkowski_sum_2/approx_inset.cpp

Similarly, the function *inset_polygon_2 (P, r, traits, oi)* computes the exact inset of *P* with radius *r*, and returns its output via the given output iterator *oi*. The *traits* parameter should be an instance of an arrangement-traits class that is capable of handling conic arcs in an exact manner, whereas *oi*'s value-type must be *Gps_traits_2< ArrConicTraits>::Polygons_2*.

```
#include <CGAL/basic.h>

                   std::back_inserter (inset_polygons));
  timer.stop();

  std::cout << "The inset comprises "
            << inset_polygons.size() << " polygon(s)." << std::endl;
  for (iit = inset_polygons.begin(); iit != inset_polygons.end(); ++iit)
  {
      std::cout << "    Polygon with "
                << iit->size() << " vertices." << std::endl;
  }
  std::cout << "Inset computation took "
            << timer.time() << " seconds." << std::endl;
  return (0);
}

#endif
```

File: examples/Minkowski_sum_2/exact_inset.cpp

advanced

Unlike the offset functions, there are no overloaded versions of the inset functions that use convex polygon decomposition to compute insets, as this method cannot be easily generalized for inset computations.

advanced

In this context let us mention that there exist overloaded versions of the functions *approximated_offset_2 (P, r, eps)* and *offset_polygon_2 (P, r, traits)* that accept a *polygon with holes P* and computed its offset. This ofset is obtain by taking the outer offset of P's outer boundary, and computing the inner offsets of P's holes. The former polygon defines the output boundary of $P \oplus B_r$, and the latter define the holes within the result.

Acknowledgements

Andreas Fabri and Laurent Rineau helped tracing and solving several bugs in the approximated offset function. They have also suggested a few algorithmic improvements that made their way into version 3.4, yielding a faster approximation scheme.

Planar Minkowski Sums
Reference Manual

Ron Wein

Introduction

This package consist of functions for computing the Minkowksi sum of two polygons in the plane. Namely, given two polygons $P, Q \in \mathbb{R}^2$ it computes $P \oplus Q = \{p + q \mid p \in P, q \in Q\}$.

In addition, the package also includes functions for offsetting a polygon, namely computing its Minkowski sum with a disc of a given radius, and for insetting a polygon (namely computing its inner offset). It is possible to compute the exact representation of the offset (or the inset), or to approximate it with guaranteed error bounds, in order to speed up the computation time.

CGAL::minkowski_sum_2

Function

#include <CGAL/minkowski_sum_2.h>

template<class Kernel, class Container>
Polygon_with_holes_2<Kernel,Container>

minkowski_sum_2(Polygon_2<Kernel,Container> P,
Polygon_2<Kernel,Container> Q)

Computes the Minkowski sum $P \oplus Q$ of the two given polygons. The function computes the convolution cycles of the two polygons and extract the regions having positive winding number with respect to these cycles. This method work very efficiently, regardless of whether P and Q are convex or non-convex. Note that as the input polygons may not be convex, their Minkowski sum may not be a simple polygon. The result is therefore represented as a polygon with holes.
Precondition: Both P and Q are simple polygons.

template<class Kernel, class Container, class DecompositionStrategy>
Polygon_with_holes_2<Kernel,Container>

minkowski_sum_2(Polygon_2<Kernel,Container> P,
Polygon_2<Kernel,Container> Q,
DecompositionStrategy decomp)

Computes the Minkowski sum $P \oplus Q$ of the two given polygons. If the input polygons P and Q are not convex, the function decomposes them into convex sub-polygons $P_1, \ldots, P_k$ and $Q_1, \ldots, Q_\ell$ and computes the union of pairwise sub-sums (namely $\bigcup_{i,j} (P_i \oplus Q_j)$). The decomposition is performed using the given decomposition strategy *decomp*, which must be an instance of a class that models the concept *PolygonConvexDecomposition*. Note that as the input polygons may not be convex, their Minkowski sum may not be a simple polygon. The result is therefore represented as a polygon with holes.
Precondition: Both P and Q are simple polygons.

Function

CGAL::approximated_offset_2

#include <CGAL/approximated_offset_2.h>

template<class Kernel, class Container>
typename Gps_circle_segment_traits_2<Kernel>::Polygon_with_holes_2

approximated_offset_2(Polygon_2<Kernel, Container> P,
typename Kernel::FT r,
double eps)

Provides a guaranteed approximation of the offset of the given polygon P by a given radius r — namely, the function computes the Minkowski sum $P \oplus B_r$, where B_r is a disc of radius r centered at the origin. The function actually outputs a set S that contains the Minkowski sum, such that the approximation error is bounded by *eps*. Note that as the input polygon may not be convex, its offset may not be a simple polygon. The result is therefore represented as a polygon with holes, whose edges are either line segments or circular arcs.
Precondition: P is a simple polygon.

template<class Kernel, class Container>
typename Gps_circle_segment_traits_2<Kernel>::Polygon_with_holes_2

approximated_offset_2(Polygon_with_holes_2<Kernel, Container> wh,
typename Kernel::FT r,
double eps)

Provides a guaranteed approximation of offset the given polygon with holes *pwh* by a given radius r, such that the approximation error is bounded by *eps*. It does so by offsetting outer boundary of *pwh* and insetting its holes. The result is represented as a generalized polygon with holes, such that the edges of the polygon correspond to line segment and circular arcs.
Precondition: *pwh* is *not* unbounded (it has a valid outer boundary).

template<class Kernel, class Container, class DecompositionStrategy>
typename Gps_circle_segment_traits_2<Kernel>::Polygon_with_holes_2

approximated_offset_2(Polygon_2<Kernel, Container> P,
typename Kernel::FT r,
double eps,

DecompositionStrategy decomp)

Provides a guaranteed approximation of the offset of the given polygon P by a radius r, as described above. If the input polygon P is not convex, the function decomposes it into convex sub-polygons $P_1, \ldots, P_k$ and computes the union of the sub-offsets (namely $\bigcup_i (P_i \oplus B_r)$). The decomposition is performed using the given decomposition strategy *decomp*, which must be an instance of a class that models the concept *PolygonConvexDecomposition*.
Precondition: P is a simple polygon.

CGAL::approximated_inset_2

#include <CGAL/approximated_offset_2.h>

template<class Kernel, class Container, class OutputIterator>
OutputIterator approximated_inset_2(Polygon_2<Kernel, Container> pgn, typename Kernel::FT r, double eps, OutputIterator oi)

Provides a guaranteed approximation of the inset, or inner offset, of the given polygon P by a given radius r. Namely, the function computes the set of points inside the polygon whose distance from P's boundary is at least r: $\{p \in P \mid \mathrm{dist}(p, \partial P) \geq r\}$, with the approximation error bounded by *eps*. Note that as the input polygon may not be convex, its inset may comprise several disconnected components. The result is therefore represented as a sequence of generalized polygons, whose edges are either line segments or circular arcs. The output sequence is returned via the output iterator *oi*, whose value-type must be *Gps_circle_segment_traits_2< Kernel>::Polygon_2*.
Precondition: P is a simple polygon.

CGAL::offset_polygon_2

#include <CGAL/offset_polygon_2.h>

template<class ConicTraits, class Container>
typename Gps_traits_2<ConicTraits>::Polygon_with_holes_2

offset_polygon_2(Polygon_2<typename ConicTraits::Rat_kernel, Container> P,
typename ConicTraits::Rat_kernel::FT r,
ConicTraits traits)

Computes the offset of the given polygon P by a given radius r — namely, the function computes the Minkowski sum $P \oplus B_r$, where B_r is a disc of radius r centered at the origin. Note that as the input polygon may not be convex, its offset may not be a simple polygon. The result is therefore represented as a generalized polygon with holes, such that the edges of the polygon correspond to line segments and circular arcs, both are special types of conic arcs, as represented by the *traits* class.
Precondition: P is a simple polygon.

template<class ConicTraits, class Container>
typename Gps_traits_2<ConicTraits>::Polygon_with_holes_2

offset_polygon_2(Polygon_with_holes_2<typename ConicTraits::Rat_kernel, Container> pwh,
typename ConicTraits::Rat_kernel::FT r,
ConicTraits traits)

Computes the offset of the given polygon with holes *pwh* by a given radius r. It does so by offsetting outer boundary of *pwh* and insetting its holes. The result is represented as a generalized polygon with holes, such that the edges of the polygon correspond to line segments and circular arcs, both are special types of conic arcs, as represented by the *traits* class.
Precondition: *pwh* is *not* unbounded (it has a valid outer boundary).

template<class ConicTraits, class Container, class DecompositionStrategy>
typename Gps_traits_2<ConicTraits>::Polygon_with_holes_2

offset_polygon_2(Polygon_2<typename ConicTraits::Rat_kernel, Container> P,
typename ConicTraits::Rat_kernel::FT r,
DecompositionStrategy decomp,

Function

ConicTraits traits)

Computes the exact representation of the offset of the given polygon P by a radius r, as described above. If P is not convex, the function decomposes it into convex sub-polygons $P_1, \ldots, P_k$ and computes the union of sub-offsets (namely $\bigcup_i (P_i \oplus B_r)$). The decomposition is performed using the given decomposition strategy *decomp*, which must be an instance of a class that models the concept *PolygonConvexDecomposition*.
Precondition: P is a simple polygon.

CGAL::inset_polygon_2

#include <CGAL/offset_polygon_2.h>

```
template<class ConicTraits, class Container, class OutputIterator>
OutputIterator    inset_polygon_2( Polygon_2<typename ConicTraits::Rat_kernel, Container> P,
                                   typename ConicTraits::Rat_kernel::FT r,
                                   ConicTraits traits,
                                   OutputIterator oi)
```

Computes the inset, or inner offset, of the given polygon P by a given radius r — namely, the function computes the set of points inside the polygon whose distance from P's boundary is at least r: $\{p \in P \mid \mathrm{dist}(p, \partial P) \geq r\}$. Note that as the input polygon may not be convex, its inset may comprise several disconnected components. The result is therefore represented as a sequence of generalized polygons, such that the edges of each polygon correspond to line segments and circular arcs, both are special types of conic arcs, as represented by the *traits* class. The output sequence is returned via the output iterator *oi*, whose value-type must be *Gps_traits_2< ConicTraits>::Polygon_2*.
Precondition: P is a simple polygon.

Function

PolygonConvexDecomposition_2

A model of the PolygonConvexDecomposition_2 concept is capable of decomposing an input polygon P into a set of convex sub-polygons $P_1, \ldots, P_k$, such that $\cup_{i=1}^{k} P_k = P$.

Types

PolygonConvexDecomposition_2:: Kernel	the geometric kernel type.
PolygonConvexDecomposition_2:: Point_2	the point type, used to represent polygon vertices.
PolygonConvexDecomposition_2:: Polygon_2	the polygon type.

Creation

PolygonConvexDecomposition_2 decomp;	default constructor.

Operations

template <class OutputIterator>
OutputIterator *decomp(Polygon_2 P, OutputIterator oi)*

decomposes the input polygon P into convex sub-polygons, and writes them to the output iterator *oi*. The value-type of the output iterator must be *Polygon_2*. The function returns a past-the-end iterator for the convex sub-polygons.

CGAL::Small_side_angle_bisector_decomposition_2<Kernel,Container>

Class

Definition

The *Small_side_angle_bisector_decomposition_2<Kernel,Container>* class implements a simple yet efficient heuristic for decomposing an input polygon into convex sub-polygons. It is based on the algorithm suggested by Flato and Halperin [FH00], but without introducing Steiner points. The algorithm operates in two major steps. In the first step, it tries to subdivide the polygon by connect two reflex vertices with an edge. When this is not possible any more, it eliminates the reflex vertices one by one by connecting them to other convex vertices, such that the new edge best approximates the angle bisector of the reflex vertex. The algorithm operates in $O(n^2)$ time an takes $O(n)$ space at the worst case, where n is the size of the input polygon.

The *Polygon_2* type defined by the class is simply *Polygon_2<Kernel,Container>*. The *Container* parameter is by default *std::vector<typename Kernel::Point_2>*.

#include <CGAL/Small_side_angle_bisector_decomposition_2.h>

CGAL::Hertel_Mehlhorn_convex_decomposition_2<Kernel,Container>

Class

Definition

The *Hertel_Mehlhorn_convex_decomposition_2<Kernel,Container>* class implements the approximation algorithm of Hertel and Mehlhorn for decomposing a polygon into convex sub-polygons [HM83]. This algorithm constructs a triangulation of the input polygon and proceeds by removing unnecessary triangulation edges. Given the triangulation, the algorithm requires $O(n)$ time and space to construct a convex decomposition (where n is the size of the input polygon), whose size is guaranteed to be no more than four times the size of the optimal decomposition.

The *Polygon_2* type defined by the class is simply *Polygon_2<Kernel,Container>*. The *Container* parameter is by default *std::vector<typename Kernel::Point_2>*.

Chapter 25

3D Polyhedral Surfaces

Lutz Kettner

Contents

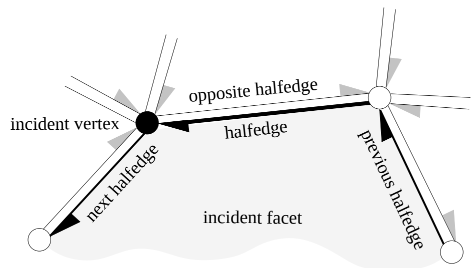
25.1 Introduction

Polyhedral surfaces in three dimensions are composed of vertices, edges, facets and an incidence relationship on them. The organization beneath is a halfedge data structure, which restricts the class of representable surfaces to orientable 2-manifolds – with and without boundary. If the surface is closed we call it a *polyhedron*, for example, see the above model of a hammerhead:

The polyhedral surface is realized as a container class that manages vertices, halfedges, facets with their incidences, and that maintains the combinatorial integrity of them. It is based on the highly flexible design of the halfedge data structure, see the introduction in Chapter 26 and [Ket99]. However, the polyhedral surface can be used and understood without knowing the underlying design. Some of the examples in this chapter introduce also gradually into first applications of this flexibility.

25.2 Definition

A polyhedral surface *CGAL::Polyhedron_3<PolyhedronTraits_3>* in three dimensions consists of vertices V, edges E, facets F and an incidence relation on them. Each edge is represented by two halfedges with opposite orientations. The incidences stored with a halfedge are illustrated in the following figure:



Vertices represent points in space. Edges are straight line segments between two endpoints. Facets are planar polygons without holes. Facets are defined by the circular sequence of halfedges along their boundary. The polyhedral surface itself can have holes (with at least two facets surrounding it since a single facet cannot have a hole). The halfedges along the boundary of a hole are called *border halfedges* and have no incident facet. An edge is a *border edge* if one of its halfedges is a border halfedge. A surface is *closed* if it contains no border halfedges. A closed surface is a boundary representation for polyhedra in three dimensions. The convention is that the halfedges are oriented counterclockwise around facets as seen from the outside of the polyhedron. An implication is that the halfedges are oriented clockwise around the vertices. The notion of the solid side of a facet as defined by the halfedge orientation extends to polyhedral surfaces with border edges although they do not define a closed object. If normal vectors are considered for the facets, normals point outwards (following the right-hand rule).

The strict definition can be found in [Ket99]. One implication of this definition is that the polyhedral surface is always an orientable and oriented 2-manifold with border edges, i.e., the neighborhood of each point on the polyhedral surface is either homeomorphic to a disc or to a half disc, except for vertices where many holes and surfaces with boundary can join. Another implication is that the smallest representable surface avoiding self intersections is a triangle (for polyhedral surfaces with border edges) or a tetrahedron (for polyhedra). Boundary representations of orientable 2-manifolds are closed under Euler operations. They are extended with operations that create or close holes in the surface.

Other intersections besides the incidence relation are not allowed. However, this is not automatically verified in the operations, since self intersections are not easy to check efficiently. *CGAL::Polyhedron_3< PolyhedronTraits_3>* does only maintain the combinatorial integrity of the polyhedral surface (using Euler operations) and does not consider the coordinates of the points or any other geometric information.

CGAL::Polyhedron_3<PolyhedronTraits_3> can represent polyhedral surfaces as well as polyhedra. The interface is designed in such a way that it is easy to ignore border edges and work only with polyhedra.

25.3 Example Programs

The polyhedral surface is based on the highly flexible design of the halfedge data structure. Examples for this flexibility can be found in Section 25.5 and in Section 26.3. This design is not a prerequisite to understand the following examples. See also the Section 25.6 below for some advanced examples.

25.3.1 First Example Using Defaults

The first example instantiates a polyhedron using a kernel as traits class. It creates a tetrahedron and stores the reference to one of its halfedges in a *Halfedge_handle*. Handles, also know as *trivial iterators*, are used to keep references to halfedges, vertices, or facets for future use. There is also a *Halfedge_iterator* type for enumerating halfedges. Such an iterator type can be used wherever a handle is required. Respective *Halfedge_const_handle* and *Halfedge_const_iterator* for a constant polyhedron and similar handles and iterators with *Vertex_* and *Facet_* prefix are provided too.

The example continues with a test if the halfedge actually refers to a tetrahedron. This test checks the connected component referred to by the halfedge *h* and not the polyhedral surface as a whole. This examples works only on the combinatorial level of a polyhedral surface. The next example adds the geometry.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>

typedef CGAL::Simple_cartesian<double>     Kernel;
typedef CGAL::Polyhedron_3<Kernel>         Polyhedron;
typedef Polyhedron::Halfedge_handle        Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    if ( P.is_tetrahedron(h))
        return 0;
    return 1;
}
```

File: `examples/Polyhedron/polyhedron_prog_simple.cpp`

25.3.2 Example with Geometry in Vertices

We add geometry to the our construction of a tetrahedron. Four points are passed as arguments to the construction. This example demonstrates in addition the use of the vertex iterator and the access to the point in the vertices. Note the natural access notation *v->point()*. Similarly, all information stored in a vertex, halfedge, and facet can be accessed with a member function given a handle or iterator. For example, given a halfedge handle *h* we can write *h->next()* to get a halfedge handle to the next halfedge, *h->opposite()* for the opposite halfedge, *h->vertex()* for the incident vertex at the tip of *h*, and so on. The output of the program will be "`1 0 0\n0 1 0\n0 0 1\n0 0 0\n`".

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>

typedef CGAL::Simple_cartesian<double>     Kernel;
typedef Kernel::Point_3                    Point_3;
typedef CGAL::Polyhedron_3<Kernel>         Polyhedron;
typedef Polyhedron::Vertex_iterator        Vertex_iterator;

int main() {
    Point_3 p( 1.0, 0.0, 0.0);
    Point_3 q( 0.0, 1.0, 0.0);
```

```
    Point_3 r( 0.0, 0.0, 1.0);
    Point_3 s( 0.0, 0.0, 0.0);

    Polyhedron P;
    P.make_tetrahedron( p, q, r, s);
    CGAL::set_ascii_mode( std::cout);
    for ( Vertex_iterator v = P.vertices_begin(); v != P.vertices_end();
   ++v)
        std::cout << v->point() << std::endl;
    return 0;
}
```

File: examples/Polyhedron/polyhedron_prog_tetra.cpp

The polyhedron offers a point iterator for convenience. The above `for` loop simplifies to a single statement by using *std::copy* and the ostream iterator adaptor.

```
std::copy( P.points_begin(), P.points_end(),
           std::ostream_iterator<Point_3>(std::cout,"\n"));
```

25.3.3 Example for Affine Transformation

An affine transformation *A* can act as a functor transforming points and a point iterator is conveniently defined for polyhedral surfaces. So, assuming we want only the point coordinates of a polyhedron *P* transformed, *std::transform* does the job in a single line.

```
std::transform( P.points_begin(), P.points_end(), P.points_begin(), A);
```

25.3.4 Example Computing Plane Equations

The polyhedral surface has already provisions to store a plane equation for each facet. However, it does not provide a function to compute plane equations.

This example computes the plane equations of a polyhedral surface. The actual computation is implemented in the `compute_plane_equations` function. Depending on the arithmetic (exact/inexact) and the shape of the facets (convex/non-convex) different methods are useful. We assume here strictly convex facets and exact arithmetic. In our example a homogeneous representation with `int` coordinates is sufficient. The four plane equations of the tetrahedron are the output of the program.

```
#include <CGAL/Homogeneous.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>
#include <algorithm>

struct Plane_equation {
    template <class Facet>
    typename Facet::Plane_3 operator()( Facet& f) {
        typename Facet::Halfedge_handle h = f.halfedge();
```

```
        typedef typename Facet::Plane_3  Plane;
        return Plane( h->vertex()->point(),
                      h->next()->vertex()->point(),
                      h->next()->next()->vertex()->point());
    }
};

typedef CGAL::Homogeneous<int>      Kernel;
typedef Kernel::Point_3             Point_3;
typedef Kernel::Plane_3             Plane_3;
typedef CGAL::Polyhedron_3<Kernel>  Polyhedron;

int main() {
    Point_3 p( 1, 0, 0);
    Point_3 q( 0, 1, 0);
    Point_3 r( 0, 0, 1);
    Point_3 s( 0, 0, 0);
    Polyhedron P;
    P.make_tetrahedron( p, q, r, s);
    std::transform( P.facets_begin(), P.facets_end(), P.planes_begin(),
                    Plane_equation());
    CGAL::set_pretty_mode( std::cout);
    std::copy( P.planes_begin(), P.planes_end(),
               std::ostream_iterator<Plane_3>( std::cout, "\n"));
    return 0;
}
```

File: examples/Polyhedron/polyhedron_prog_planes.cpp

25.3.5 Example with a Vector Instead of a List Representation

The polyhedron class template has actually four parameters, where three of them have default values. Using the default values explicitly in our examples above for three parameter—ignoring the fourth parameter, which would be a standard allocator for container class— the definition of a polyhedron looks like:

```
typedef CGAL::Polyhedron_3< Traits,
                            CGAL::Polyhedron_items_3,
                            CGAL::HalfedgeDS_default>      Polyhedron;
```

The *CGAL::Polyhedron_items_3* class contains the types used for vertices, edges, and facets. The *CGAL::HalfedgeDS_default* class defines the halfedge data structure used, which is a list-based representation in this case. An alternative is a vector-based representation. Using a vector provides random access for the elements in the polyhedral surface and is more space efficient, but elements cannot be deleted arbitrarily. Using a list allows arbitrary deletions, but provides only bidirectional iterators and is less space efficient. The following example creates again a tetrahedron with given points, but in a vector-based representation.

The vector-based representation resizes automatically if the reserved capacity is not sufficient for the new items created. Upon resizing all handles, iterators, and circulators become invalid. Their correct update in the halfedge data structure is costly, thus it is advisable to reserve enough space in advance as indicated with the alternative constructor in the comment.

advanced

Note that the polyhedron and not the underlying halfedge data structure triggers the resize operation, since the resize operation requires some preconditions, such as valid incidences, to be fulfilled that only the polyhedron can guarantee.

advanced

```
#include <CGAL/Cartesian.h>
#include <CGAL/HalfedgeDS_vector.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>

typedef CGAL::Cartesian<double>                              Kernel;
typedef Kernel::Point_3                                      Point_3;
typedef CGAL::Polyhedron_3< Kernel,
                            CGAL::Polyhedron_items_3,
                            CGAL::HalfedgeDS_vector>   Polyhedron;

int main() {
    Point_3 p( 1.0, 0.0, 0.0);
    Point_3 q( 0.0, 1.0, 0.0);
    Point_3 r( 0.0, 0.0, 1.0);
    Point_3 s( 0.0, 0.0, 0.0);

    Polyhedron P;    // alternative constructor: Polyhedron P(4,12,4);
    P.make_tetrahedron( p, q, r, s);
    CGAL::set_ascii_mode( std::cout);
    std::copy( P.points_begin(), P.points_end(),
               std::ostream_iterator<Point_3>( std::cout, "\n"));
    return 0;
}
```

File: examples/Polyhedron/polyhedron_prog_vector.cpp

25.3.6 Example with Circulator Writing Object File Format (OFF)

We create a tetrahedron and write it to *std::cout* using the Object File Format (OFF) [Phi96]. This example makes use of STL algorithms (*std::copy*, *std::distance*), STL *std::ostream_iterator*, and CGAL circulators. The polyhedral surface provides convenient circulators for the counterclockwise circular sequence of halfedges around a facet and the clockwise circular sequence of halfedges around a vertex.

However, the computation of the vertex index in the inner loop of the facet output is not advisable with the *std::distance* function, since it takes linear time for non random-access iterators, which leads to quadratic runtime. For better runtime the vertex index needs to be stored separately and computed once before writing the facets. It can be stored, for example, in the vertex itself or in a hash-structure. See also the following Section 25.4 for file I/O.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>

typedef CGAL::Simple_cartesian<double>                     Kernel;
```

```
typedef Kernel::Point_3                                Point_3;
typedef CGAL::Polyhedron_3<Kernel>                     Polyhedron;
typedef Polyhedron::Facet_iterator                     Facet_iterator;
typedef Polyhedron::Halfedge_around_facet_circulator
   Halfedge_facet_circulator;

int main() {
    Point_3 p( 0.0, 0.0, 0.0);
    Point_3 q( 1.0, 0.0, 0.0);
    Point_3 r( 0.0, 1.0, 0.0);
    Point_3 s( 0.0, 0.0, 1.0);

    Polyhedron P;
    P.make_tetrahedron( p, q, r, s);

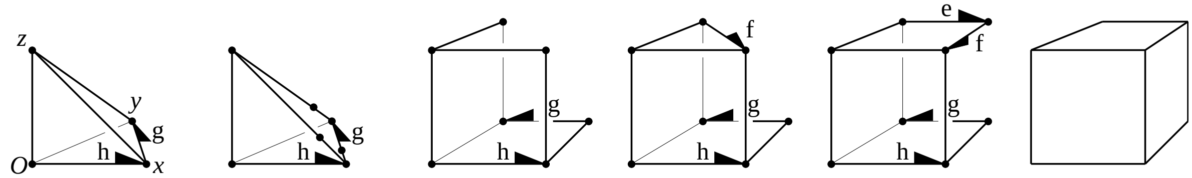
    // Write polyhedron in Object File Format (OFF).
    CGAL::set_ascii_mode( std::cout);
    std::cout << "OFF" << std::endl << P.size_of_vertices() << ' '
              << P.size_of_facets() << " 0" << std::endl;
    std::copy( P.points_begin(), P.points_end(),
               std::ostream_iterator<Point_3>( std::cout, "\n"));
    for (  Facet_iterator i = P.facets_begin(); i != P.facets_end();
   ++i) {
        Halfedge_facet_circulator j = i->facet_begin();
        // Facets in polyhedral surfaces are at least triangles.
        CGAL_assertion( CGAL::circulator_size(j) >= 3);
        std::cout << CGAL::circulator_size(j) << ' ';
        do {
            std::cout << ' ' << std::distance(P.vertices_begin(),
   j->vertex());
        } while ( ++j != i->facet_begin());
        std::cout << std::endl;
    }
    return 0;
}
```

File: examples/Polyhedron/polyhedron_prog_off.cpp

25.3.7 Example Using Euler Operators to Build a Cube

Euler operators are the natural way of modifying polyhedral surfaces. We provide a set of operations for polyhedra: *split_facet()*, *join_facet()*, *split_vertex()*, *join_vertex()*, *split_loop()*, and *join_loop()*. We add further convenient operators, such as *split_edge()*. However, they could be implemented using the six operators above. Furthermore, we provide more operators to work with polyhedral surfaces with border edges, for example, creating and deleting holes. We refer to the references manual for the definition and illustrative figures of the Euler operators.

The following example implements a function that appends a unit cube to a polyhedral surface. To keep track of the different steps during the creation of the cube a sequence of sketches might help with labels for the different handles that occur in the program code. The following Figure shows six selected steps from the creation sequence. These steps are also marked in the program code.



(a) **(b)** **(c)** **(d)** **(e)** **(f)**

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>

template <class Poly>
typename Poly::Halfedge_handle make_cube_3( Poly& P) {
    // appends a cube of size [0,1]^3 to the polyhedron P.
    CGAL_precondition( P.is_valid());
    typedef typename Poly::Point_3         Point;
    typedef typename Poly::Halfedge_handle Halfedge_handle;
    Halfedge_handle h = P.make_tetrahedron( Point( 1, 0, 0),
                                            Point( 0, 0, 1),
                                            Point( 0, 0, 0),
                                            Point( 0, 1, 0));
    Halfedge_handle g = h->next()->opposite()->next();             //
   Fig. (a)
    P.split_edge( h->next());
    P.split_edge( g->next());
    P.split_edge( g);                                               //
   Fig. (b)
    h->next()->vertex()->point()     = Point( 1, 0, 1);
    g->next()->vertex()->point()     = Point( 0, 1, 1);
    g->opposite()->vertex()->point() = Point( 1, 1, 0);             //
   Fig. (c)
    Halfedge_handle f = P.split_facet( g->next(),
                                       g->next()->next()->next()); //
   Fig. (d)
    Halfedge_handle e = P.split_edge( f);
    e->vertex()->point() = Point( 1, 1, 1);                         //
   Fig. (e)
    P.split_facet( e, f->next()->next());                           //
   Fig. (f)
    CGAL_postcondition( P.is_valid());
    return h;
}

typedef CGAL::Simple_cartesian<double>     Kernel;
typedef CGAL::Polyhedron_3<Kernel>         Polyhedron;
typedef Polyhedron::Halfedge_handle        Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = make_cube_3( P);
    return (P.is_tetrahedron(h) ? 1 : 0);
}
```

File: `examples/Polyhedron/polyhedron_prog_cube.cpp`

25.4 File I/O

Simple file I/O for polyhedral surfaces is already provided in the library. The file I/O considers so far only the topology of the surface and its point coordinates. It ignores a possible plane equation or any user-added attributes, such as color.

The default file format supported in CGAL for output as well as for input is the Object File Format, OFF, with file extension `.off`, which is also understood by Geomview [Phi96]. For OFF an ASCII and a binary format exist. The format can be selected with the CGAL modifiers for streams, *set_ascii_mode* and *set_binary_mode* respectively. The modifier *set_pretty_mode* can be used to allow for (a few) structuring comments in the output. Otherwise, the output would be free of comments. The default for writing is ASCII without comments. Both, ASCII and binary format, can be read independent of the stream setting. Since this file format is the default format, iostream operators are provided for it.

#include <CGAL/IO/Polyhedron_iostream.h>

template <class PolyhedronTraits_3>
ostream& *ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P*

template <class PolyhedronTraits_3>
istream& *istream& in >> CGAL::Polyhedron_3<PolyhedronTraits_3>& P*

Additional formats supported for writing are OpenInventor (`.iv`) [Wer94], VRML 1.0 and 2.0 (`.wrl`) [BPP95, VRM96, HW96], and Wavefront Advanced Visualizer object format (`.obj`). Another convenient output function writes a polyhedral surface to a Geomview process spawned from the CGAL program. These output functions are provided as stream operators, now acting on the stream type of the respective format.

#include <CGAL/IO/Polyhedron_inventor_ostream.h>
#include <CGAL/IO/Polyhedron_VRML_1_ostream.h>
#include <CGAL/IO/Polyhedron_VRML_2_ostream.h>
#include <CGAL/IO/Polyhedron_geomview_ostream.h>

template <class PolyhedronTraits_3>
Inventor_ostream& *Inventor_ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P*

template <class PolyhedronTraits_3>
VRML_1_ostream& *VRML_1_ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P*

template <class PolyhedronTraits_3>
VRML_2_ostream& *VRML_2_ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P*

template <class PolyhedronTraits_3>
Geomview_stream& *Geomview_stream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P*

All these file formats have in common that they represent a surface as a set of facets. Each facet is a list of indices pointing into a set of vertices. Vertices are represented as coordinate triples. The file I/O for polyhedral surfaces *CGAL::Polyhedron_3* imposes certain restrictions on these formats. They must represent a permissible polyhedral surface, e.g., a 2-manifold and no isolated vertices, see Section 25.1.

Some example programs around the different file formats are provided in the distribution under examples/Polyhedron_IO/ and demo/Polyhedron_IO/. We show an example converting OFF input into VRML 1.0 output.

```
// examples/Polyhedron_IO/polyhedron2vrml.cpp
// ----------------------------------------

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/IO/Polyhedron_VRML_1_ostream.h>
#include <iostream>

typedef CGAL::Simple_cartesian<double> Kernel;
typedef CGAL::Polyhedron_3<Kernel>     Polyhedron;

int main() {
    Polyhedron P;
    std::cin >> P;
    CGAL::VRML_1_ostream out( std::cout);
    out << P;
    return ( std::cin && std::cout) ? 0 : 1;
}
```

25.5 Extending Vertices, Halfedges, and Facets

In Section 25.3.5 we have seen how to change the default list representation

```
typedef CGAL::Polyhedron_3< Traits,
                            CGAL::Polyhedron_items_3,
                            CGAL::HalfedgeDS_default>      Polyhedron;
```

to a vector based representation of the underlying halfedge data structure. Now we want to look a bit closer at the second template argument, Polyhedron_items_3, that specifies what kind of vertex, halfedge, and facet is used. The implementation of Polyhedron_items_3 looks a bit involved with nested wrapper class templates. But ignoring this technicality, what remains are three local typedefs that define the Vertex, the Halfedge, and the Face for the polyhedral surface. Note that we use here Face instead of facet. Face is the term used for the halfedge data structure. Only the top layer of the polyhedral surface gives alias names renaming face to facet.

```
class Polyhedron_items_3 {
public:
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef typename Traits::Point_3 Point;
        typedef CGAL::HalfedgeDS_vertex_base<Refs, CGAL::Tag_true, Point>
     Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef CGAL::HalfedgeDS_halfedge_base<Refs>
     Halfedge;
    };
```

```
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef typename Traits::Plane_3 Plane;
        typedef CGAL::HalfedgeDS_face_base<Refs, CGAL::Tag_true, Plane>
    Face;
    };
};
```

If we look up in the reference manual the definitions of the three classes used in the typedefs, we will see the confirmation that the default polyhedron uses all supported incidences, a point in the vertex class, and a plane equation in the face class. Note how the wrapper class provides two template parameters, `Refs`, which we discuss a bit later, and `Traits`, which is the geometric traits class used by the polyhedral surface and which provides us here with the types for the point and the plane equation.

Using this example code we can write our own items class. Instead, we illustrate an easier way if we only want to exchange one class. We use a simpler face without the plane equation but with a color attribute added. To simplify the creation of a vertex, halfedge, or face class, it is always recommended to derive from one of the given base classes. Even if the base class would contain no data it would provide convenient type definitions. So, we derive from the base class, repeat the mandatory constructors if necessary—which is not the case for faces but would be for vertices—and add the color attribute.

```
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
};
```

The new items class is derived from the old items class and the wrapper containing the face typedef gets overridden. Note that the name of the wrapper and its template parameters are fixed. They cannot be changed even if, as in this example, a template parameter is not used.

```
struct My_items : public CGAL::Polyhedron_items_3 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};
```

When we use our new items class with the polyhedral surface, our new face class is used in the halfedge data structure and the color attribute is available in the type `Polyhedron::Facet`. However, `Polyhedron::Facet` is not the same type as our local face typedef for `My_face`, but it is derived therefrom. Thus, everything that we put in the local face type except constructors is then available in the `Polyhedron::Facet` type. For more details, see the Chapter 26 on the halfedge data structure design.

Pulling all pieces together, the full example program illustrates how easy the color attribute can be accessed once it is defined.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/IO/Color.h>
#include <CGAL/Polyhedron_3.h>

// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
```

```
};

// An items type using my face.
struct My_items : public CGAL::Polyhedron_items_3 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};

typedef CGAL::Simple_cartesian<double>        Kernel;
typedef CGAL::Polyhedron_3<Kernel, My_items>  Polyhedron;
typedef Polyhedron::Halfedge_handle           Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    h->facet()->color = CGAL::RED;
    return 0;
}
```

File: examples/Polyhedron/polyhedron_prog_color.cpp

We come back to the first template parameter, Refs, of the wrapper classes. This parameter provides us with local types that allow us to make further references between vertices, halfedges, and facets, which have not already been prepared for in the current design. These local types are Vertex_handle, Halfedge_handle, Face_handle, and there respective ..._const_handle. We add now a new vertex reference to a face class as follows. Encapsulation and access functions could be added for a more thorough design, but we omit that here for the sake of brevity. The integration of the face class with the items class works as illustrated above.

```
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    typedef typename Refs::Vertex_handle Vertex_handle;
    Vertex_handle vertex_ref;
};
```

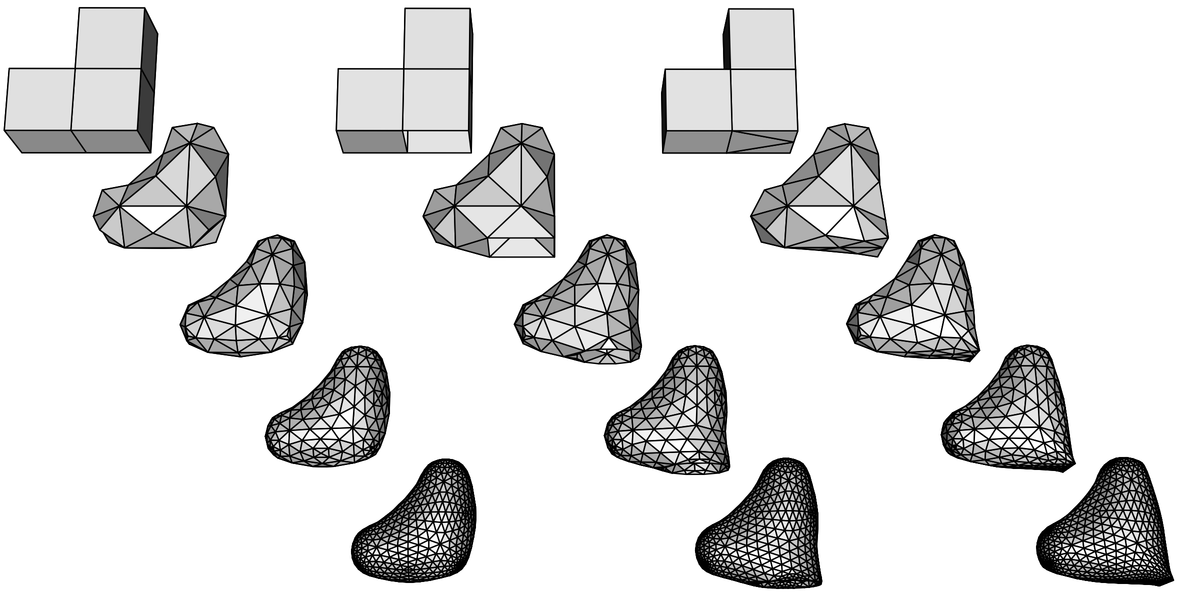
More advanced examples can be found in the Section 26.3 illustrating further the design of the halfedge data structure.

25.6 Advanced Example Programs

25.6.1 Example Creating a Subdivision Surface

This program reads a polyhedral surface from the standard input and writes a refined polyhedral surface to the standard output. Input and output are in the Object File Format, OFF, with the common file extension .off, which is also understood by Geomview [Phi96].

The refinement is a single step of the $\sqrt{3}$-scheme for creating a subdivision surface [Kob00]. Each step subdivides a facet into triangles around a new center vertex, smoothes the position of the old vertices, and flips the old edges. The program is organized along this outline. In each of these parts, the program efficiently uses the knowledge that the newly created vertices, edges, and facets have been added to the end of the sequences. The program needs additional processing memory only for the smoothing step of the old vertices.



The above figure shows three example objects, each subdivided four times. The initial object for the left sequence is the closed surface of three unit cubes glued together to a corner. The example program shown here can handle only closed surfaces, but the extended example `examples/Polyhedron/polyhedron_prog_subdiv_with_boundary.cpp` handles surfaces with boundary. So, the middle sequence starts with the same surface where one of the facets has been removed. The boundary subdivides to a nice circle. The third sequence creates a sharp edge using a trick in the object presentation. The sharp edge is actually a hole whose vertex coordinates pinch the hole shut to form an edge. The example directory `examples/Polyhedron/` contains the OFF files used here.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <iostream>
#include <algorithm>
#include <vector>
#include <cmath>

typedef CGAL::Cartesian<double>                                Kernel;
typedef Kernel::Vector_3                                       Vector;
typedef Kernel::Point_3                                        Point;
typedef CGAL::Polyhedron_3<Kernel>                             Polyhedron;

typedef Polyhedron::Vertex                                     Vertex;
typedef Polyhedron::Vertex_iterator
   Vertex_iterator;
typedef Polyhedron::Halfedge_handle
   Halfedge_handle;
typedef Polyhedron::Edge_iterator
   Edge_iterator;
typedef Polyhedron::Facet_iterator
   Facet_iterator;
```

```
typedef Polyhedron::Halfedge_around_vertex_const_circulator
    HV_circulator;
typedef Polyhedron::Halfedge_around_facet_circulator
    HF_circulator;

void create_center_vertex( Polyhedron& P, Facet_iterator f) {
    Vector vec( 0.0, 0.0, 0.0);
    std::size_t order = 0;
    HF_circulator h = f->facet_begin();
    do {
        vec = vec + ( h->vertex()->point() - CGAL::ORIGIN);
        ++ order;
    } while ( ++h != f->facet_begin());
    CGAL_assertion( order >= 3); // guaranteed by definition of
    polyhedron
    Point center =  CGAL::ORIGIN + (vec / static_cast<double>(order));
    Halfedge_handle new_center = P.create_center_vertex( f->halfedge());
    new_center->vertex()->point() = center;
}

struct Smooth_old_vertex {
    Point operator()( const Vertex& v) const {
        CGAL_precondition((CGAL::circulator_size( v.vertex_begin()) & 1)
    == 0);
        std::size_t degree = CGAL::circulator_size( v.vertex_begin()) /
    2;
        double alpha = ( 4.0 - 2.0 * std::cos( 2.0 * CGAL_PI / degree)) /
     9.0;
        Vector vec = (v.point() - CGAL::ORIGIN) * ( 1.0 - alpha);
        HV_circulator h = v.vertex_begin();
        do {
            vec = vec + ( h->opposite()->vertex()->point() -
    CGAL::ORIGIN)
              * alpha / static_cast<double>(degree);
            ++ h;
            CGAL_assertion( h != v.vertex_begin()); // even degree
    guaranteed
            ++ h;
        } while ( h != v.vertex_begin());
        return (CGAL::ORIGIN + vec);
    }
};

void flip_edge( Polyhedron& P, Halfedge_handle e) {
    Halfedge_handle h = e->next();
    P.join_facet( e);
    P.split_facet( h, h->next()->next());
}

void subdiv( Polyhedron& P) {
    if ( P.size_of_facets() == 0)
        return;
    // We use that new vertices/halfedges/facets are appended at the end.
    std::size_t nv = P.size_of_vertices();
```

```
    Vertex_iterator last_v = P.vertices_end();
    -- last_v;  // the last of the old vertices
    Edge_iterator last_e = P.edges_end();
    -- last_e;  // the last of the old edges
    Facet_iterator last_f = P.facets_end();
    -- last_f;  // the last of the old facets

    Facet_iterator f = P.facets_begin();    // create new center vertices
    do {
        create_center_vertex( P, f);
    } while ( f++ != last_f);

    std::vector<Point> pts;                       // smooth the old vertices
    pts.reserve( nv);  // get intermediate space for the new points
    ++ last_v; // make it the past-the-end position again
    std::transform( P.vertices_begin(), last_v, std::back_inserter( pts),
                    Smooth_old_vertex());
    std::copy( pts.begin(), pts.end(), P.points_begin());

    Edge_iterator e = P.edges_begin();              // flip the old edges
    ++ last_e; // make it the past-the-end position again
    while ( e != last_e) {
        Halfedge_handle h = e;
        ++e; // careful, incr. before flip since flip destroys current
   edge
        flip_edge( P, h);
    };
    CGAL_postcondition( P.is_valid());
}

int main() {
    Polyhedron P;
    std::cin >> P;
    P.normalize_border();
    if ( P.size_of_border_edges() != 0) {
        std::cerr << "The input object has border edges. Cannot
   subdivide."
                  << std::endl;
        std::exit(1);
    }
    subdiv( P);
    std::cout << P;
    return 0;
}
```

25.6.2 Example Using the Incremental Builder and Modifier Mechanism

A utility class *CGAL::Polyhedron_incremental_builder_3* helps in creating polyhedral surfaces from a list of points followed by a list of facets that are represented as indices into the point list. This is particularly useful for implementing file reader for common file formats. It is used here to create a triangle.

A modifier mechanism allows to access the internal representation of the polyhedral surface, i.e., the halfedge data structure, in a controlled manner. A modifier is basically a callback mechanism using a function object. When called, the function object receives the internal halfedge data structure as a parameter and can modify it. On return, the polyhedron can check the halfedge data structure for validity. Such a modifier object must always return with a halfedge data structure that is a valid polyhedral surface. The validity check is implemented as an expensive postcondition at the end of the *delegate()* member function, i.e., it is not called by default, only when expensive checks are activated.

In this example, *Build_triangle* is such a function object derived from *CGAL::Modifier_base<HalfedgeDS>*. The *delegate()* member function of the polyhedron accepts this function object and calls its *operator()* with a reference to its internally used halfedge data structure. Thus, this member function in *Build_triangle* can create the triangle in the halfedge data structure.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_incremental_builder_3.h>
#include <CGAL/Polyhedron_3.h>

// A modifier creating a triangle with the incremental builder.
template <class HDS>
class Build_triangle : public CGAL::Modifier_base<HDS> {
public:
    Build_triangle() {}
    void operator()( HDS& hds) {
        // Postcondition: 'hds' is a valid polyhedral surface.
        CGAL::Polyhedron_incremental_builder_3<HDS> B( hds, true);
        B.begin_surface( 3, 1, 6);
        typedef typename HDS::Vertex   Vertex;
        typedef typename Vertex::Point Point;
        B.add_vertex( Point( 0, 0, 0));
        B.add_vertex( Point( 1, 0, 0));
        B.add_vertex( Point( 0, 1, 0));
        B.begin_facet();
        B.add_vertex_to_facet( 0);
        B.add_vertex_to_facet( 1);
        B.add_vertex_to_facet( 2);
        B.end_facet();
        B.end_surface();
    }
};

typedef CGAL::Simple_cartesian<double>     Kernel;
typedef CGAL::Polyhedron_3<Kernel>         Polyhedron;
typedef Polyhedron::HalfedgeDS             HalfedgeDS;

int main() {
    Polyhedron P;
    Build_triangle<HalfedgeDS> triangle;
    P.delegate( triangle);
    CGAL_assertion( P.is_triangle( P.halfedges_begin()));
    return 0;
}
```

File: examples/Polyhedron/polyhedron_prog_incr_builder.cpp

3D Polyhedral Surfaces Reference Manual

Lutz Kettner

Polyhedral surfaces in three dimensions are composed of vertices, edges, facets and an incidence relationship on them. The organization beneath is a halfedge data structure, which restricts the class of representable surfaces to orientable 2-manifolds – with and without boundary. If the surface is closed we call it a *polyhedron*.

The polyhedral surface is realized as a container class managing vertices, halfedges, facets with their incidences, and maintaining the combinatorial integrity of them. Its local types for the vertices, halfedges and facets are documented separately. A default traits class, a default items class and an incremental builder conclude the references. The polyhedral surface is based on the highly flexible design of the halfedge data structure, see the reference for *HalfedgeDS* in Chapter 26.3.7 or [Ket99], but the default instantiation of the polyhedral surface can be used without knowing the halfedge data structure.

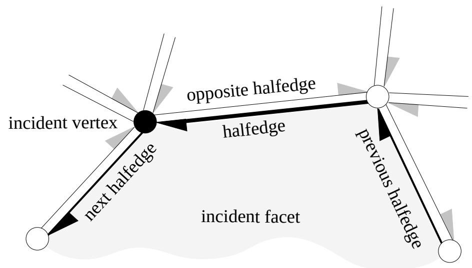
CGAL::Polyhedron_3<Traits>

Definition

A polyhedral surface *Polyhedron_3<Traits>* consists of vertices V, edges E, facets F and an incidence relation on them. Each edge is represented by two halfedges with opposite orientations.



Vertices represent points in 3d-space. Edges are straight line segments between two endpoints. Facets are planar polygons without holes defined by the circular sequence of halfedges along their boundary. The polyhedral surface itself can have holes. The halfedges along the boundary of a hole are called *border halfedges* and have no incident facet. An edge is a *border edge* if one of its halfedges is a border halfedge. A surface is *closed* if it contains no border halfedges. A closed surface is a boundary representation for polyhedra in three dimensions. The convention is that the halfedges are oriented counterclockwise around facets as seen from the outside of the polyhedron. An implication is that the halfedges are oriented clockwise around the vertices. The notion of the solid side of a facet as defined by the halfedge orientation extends to polyhedral surfaces with border edges although they do not define a closed object. If normal vectors are considered for the facets, normals point outwards (following the right hand rule).

The strict definition can be found in [Ket99]. One implication of this definition is that the polyhedral surface is always an orientable and oriented 2-manifold with border edges, i.e., the neighborhood of each point on the polyhedral surface is either homeomorphic to a disc or to a half disc, except for vertices where many holes and surfaces with boundary can join. Another implication is that the smallest representable surface is a triangle (for polyhedral surfaces with border edges) or a tetrahedron (for polyhedra). Boundary representations of orientable 2-manifolds are closed under Euler operations. They are extended with operations that create or close holes in the surface.

Other intersections besides the incidence relation are not allowed, although they are not automatically handled, since self intersections are not easy to check efficiently. *Polyhedron_3<Traits>* does only maintain the combinatorial integrity of the polyhedral surface (using Euler operations) and does not consider the coordinates of the points or any geometric information.

The class *Polyhedron_3<Traits>* can represent polyhedral surfaces as well as polyhedra. The interface is designed in such a way that it is easy to ignore border edges and work only with polyhedra.

The sequence of edges can be ordered in the data structure on request such that the sequence starts with the non-border edges and ends with the border edges. Border edges are then itself ordered such that the halfedge which is incident to the facet comes first and the halfedge incident to the hole comes thereafter. This normalization step counts simultaneously the number of border edges. This number is zero if and only if the surface is a closed polyhedron. Note that this class does not maintain this counter nor the halfedge order during further modifications. There is no automatic caching done for auxiliary information.

#include <CGAL/Polyhedron_3.h>

Parameters

The full template declaration of *Polyhedron_3<Traits>* states four template parameters:

template < class PolyhedronTraits_3,
class PolyhedronItems_3 = CGAL::Polyhedron_items_3,
template < class T, class I> class HalfedgeDS = CGAL::HalfedgeDS_default,
class Alloc = CGAL_ALLOCATOR(int)>
class Polyhedron_3;

The first parameter requires a model of the *PolyhedronTraits_3* concept as argument, for example *CGAL::Polyhedron_traits_3*. The second parameter expects a model of the *PolyhedronItems_3* concept. By default, the class *CGAL::Polyhedron_items_3* is preselected. The third parameter is a class template. A model of the *HalfedgeDS* concept is expected. By default, the class *CGAL::HalfedgeDS_default* is preselected, which is a list based implementation of the halfedge data structure. The fourth parameter *Alloc* requires a standard allocator for STL container classes. The *rebind* mechanism from *Alloc* will be used to create appropriate allocators internally. A default is provided with the macro *CGAL_ALLOCATOR(int)* from the *<CGAL/memory.h>* header file.

Types

Polyhedron_3<Traits>:: Traits	traits class selected for *PolyhedronTraits_3*.
Polyhedron_3<Traits>:: Items	items class selected for *PolyhedronItems_3*.
Polyhedron_3<Traits>:: HalfedgeDS	instantiated halfedge data structure.
Polyhedron_3<Traits>:: size_type	size type of *HalfedgeDS*.
Polyhedron_3<Traits>:: difference_type	difference type of *HalfedgeDS*.
Polyhedron_3<Traits>:: iterator_category	iterator category of *HalfedgeDS* for all iterators.
Polyhedron_3<Traits>:: circulator_category	circulator category of all circulators; bidirectional category if the *Items::Halfedge* provides a *prev()* member function, otherwise forward category.
Polyhedron_3<Traits>:: allocator_type	allocator type *Alloc*.
Polyhedron_3<Traits>:: Vertex	vertex type.
Polyhedron_3<Traits>:: Halfedge	halfedge type.
Polyhedron_3<Traits>:: Facet	facet type.
Polyhedron_3<Traits>:: Point_3	point stored in vertices.
Polyhedron_3<Traits>:: Plane_3	plane equation stored in facets (if supported).

The following handles, iterators, and circulators have appropriate non-mutable counterparts, i.e., *const_handle*, *const_iterator*, and *const_circulator*. The mutable types are assignable to their non-mutable counterparts. Both circulators are assignable to the *Halfedge_iterator*. The iterators are assignable to the respective handle types. Wherever the handles appear in function parameter lists, the corresponding iterators can be used as well. For convenience, the *Edge_iterator* enumerates every other halfedge. It is based on the *CGAL::N_step_adaptor* class. For convenience, the *Point_iterator* enumerates all points in the polyhedral surface in the same order as the *Vertex_iterator*, but with the value type *Point*. It is based on the *CGAL::Iterator_project* adaptor. Similarly, a *Plane_iterator* is provided.

Polyhedron_3<Traits>:: Vertex_handle	handle to vertex.

Polyhedron_3<Traits>:: Halfedge_handle	handle to halfedge.
Polyhedron_3<Traits>:: Facet_handle	handle to facet.

Polyhedron_3<Traits>:: Vertex_iterator	iterator over all vertices.
Polyhedron_3<Traits>:: Halfedge_iterator	iterator over all halfedges.
Polyhedron_3<Traits>:: Facet_iterator	iterator over all facets.

Polyhedron_3<Traits>:: Halfedge_around_vertex_circulator

circulator of halfedges around a vertex (cw).

Polyhedron_3<Traits>:: Halfedge_around_facet_circulator

circulator of halfedges around a facet (ccw).

Polyhedron_3<Traits>:: Edge_iterator	iterator over all edges (every other halfedge).
Polyhedron_3<Traits>:: Point_iterator	iterator over all points.
Polyhedron_3<Traits>:: Plane_iterator	iterator over all plane equations.

advanced

Types for Tagging Optional Features

The following types are equal to either *CGAL::Tag_true* or *CGAL::Tag_false*, depending on whether the named feature is supported or not.

Polyhedron_3<Traits>:: Supports_vertex_halfedge	*Vertex::halfedge().*
Polyhedron_3<Traits>:: Supports_vertex_point	*Vertex::point().*
Polyhedron_3<Traits>:: Supports_halfedge_prev	*Halfedge::prev().*
Polyhedron_3<Traits>:: Supports_halfedge_vertex	*Halfedge::vertex().*
Polyhedron_3<Traits>:: Supports_halfedge_facet	*Halfedge::facet().*
Polyhedron_3<Traits>:: Supports_facet_halfedge	*Facet::halfedge().*
Polyhedron_3<Traits>:: Supports_facet_plane	*Facet::plane().*
Polyhedron_3<Traits>:: Supports_removal	supports removal of individual elements.

Polyhedron_3<Traits> P(Traits traits = Traits());

Polyhedron_3<Traits> P(size_type v, size_type h, size_type f, Traits traits = Traits());

a polyhedron *P* with storage reserved for *v* vertices, *h* halfedges, and *f* facets. The reservation sizes are a hint for optimizing storage allocation.

void *P.reserve(size_type v, size_type h, size_type f)*

reserve storage for *v* vertices, *h* halfedges, and *f* facets. The reservation sizes are a hint for optimizing storage allocation. If the *capacity* is already greater than the requested size nothing happens. If the *capacity* changes all iterators and circulators might invalidate.

Halfedge_handle	*P.make_tetrahedron()*	

a tetrahedron is added to the polyhedral surface. Returns a halfedge of the tetrahedron.

Halfedge_handle	*P.make_tetrahedron(Point p1, Point p2, Point p3, Point p4)*	

a tetrahedron is added to the polyhedral surface with its vertices initialized to p_1, p_2, p_3, and p_4. Returns that halfedge of the tetrahedron which incident vertex is initialized to p_1. The incident vertex of the next halfedge is p_2, and the vertex thereafter is p_3. The remaining fourth vertex is initialized to p_4.

Halfedge_handle	*P.make_triangle()*	

a triangle with border edges is added to the polyhedral surface. Returns a non-border halfedge of the triangle.

Halfedge_handle	*P.make_triangle(Point p1, Point p2, Point p3)*	

a triangle with border edges is added to the polyhedral surface with its vertices initialized to p_1, p_2, and p_3. Returns that non-border halfedge of the triangle which incident vertex is initialized to p_1. The incident vertex of the next halfedge is p_2, and the vertex thereafter is p_3.

Access Member Functions

bool	*P.empty() const*	returns true if *P* is empty.
size_type	*P.size_of_vertices() const*	number of vertices.
size_type	*P.size_of_halfedges() const*	number of halfedges (incl. border halfedges).
size_type	*P.size_of_facets() const*	number of facets.
size_type	*P.capacity_of_vertices() const*	space reserved for vertices.
size_type	*P.capacity_of_halfedges() const*	space reserved for halfedges.
size_type	*P.capacity_of_facets() const*	space reserved for facets.
size_t	*P.bytes() const*	bytes used for the polyhedron.
size_t	*P.bytes_reserved() const*	bytes reserved for the polyhedron.
allocator_type	*P.get_allocator() const*	allocator object.
Vertex_iterator	*P.vertices_begin()*	iterator over all vertices.
Vertex_iterator	*P.vertices_end()*	past-the-end iterator.
Halfedge_iterator	*P.halfedges_begin()*	iterator over all halfedges.
Halfedge_iterator	*P.halfedges_end()*	past-the-end iterator.
Facet_iterator	*P.facets_begin()*	iterator over all facets (excluding holes).

Facet_iterator	*P.facets_end()*	past-the-end iterator.
Edge_iterator	*P.edges_begin()*	iterator over all edges.
Edge_iterator	*P.edges_end()*	past-the-end iterator.
Point_iterator	*P.points_begin()*	iterator over all points.
Point_iterator	*P.points_end()*	past-the-end iterator.
Plane_iterator	*P.planes_begin()*	iterator over all plane equations.
Plane_iterator	*P.planes_end()*	past-the-end iterator.
Traits	*P.traits() const*	returns the traits class.

Combinatorial Predicates

bool *P.is_closed() const*

returns *true* if there are no border edges.

bool *P.is_pure_bivalent() const*

returns *true* if all vertices have exactly two incident edges.

bool *P.is_pure_trivalent() const*

returns *true* if all vertices have exactly three incident edges.

bool *P.is_pure_triangle() const*

returns *true* if all facets are triangles.

bool *P.is_pure_quad() const*

returns *true* if all facets are quadrilaterals.

bool *P.is_triangle(Halfedge_const_handle h) const*

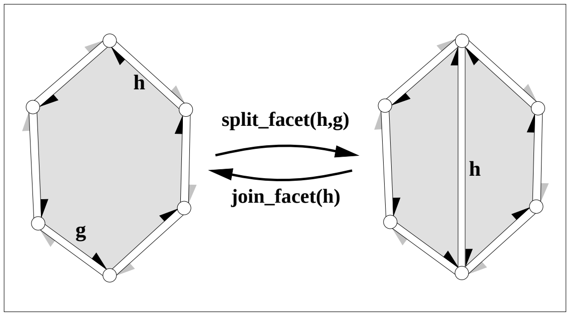
true iff the connected component denoted by *h* is a triangle.

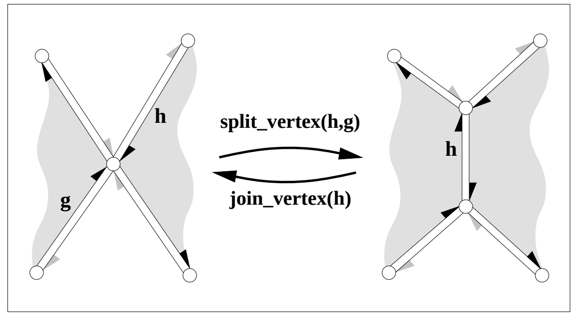
bool *P.is_tetrahedron(Halfedge_const_handle h) const*

true iff the connected component denoted by *h* is a tetrahedron.

Euler Operators (Combinatorial Modifications)

The following Euler operations modify consistently the combinatorial structure of the polyhedral surface. The geometry remains unchanged.





Halfedge_handle *P.split_facet(Halfedge_handle h, Halfedge_handle g)*

splits the facet incident to *h* and *g* into two facets with a new diagonal between the two vertices denoted by *h* and *g* respectively. The second (new) facet is a copy of the first facet. Returns *h->next()* after the operation, i.e., the new diagonal. The new face is to the right of the new diagonal, the old face is to the left. The time is proportional to the distance from *h* to *g* around the facet.
Precondition: *h* and *g* are incident to the same facet. *h != g* (no loops). *h->next() != g* and *g->next() != h* (no multi-edges).

Halfedge_handle *P.join_facet(Halfedge_handle h)*

joins the two facets incident to *h*. The facet incident to *h->opposite()* gets removed. Both facets might be holes. Returns the predecessor of *h* around the facet. The invariant *join_facet(split_facet(h, g))* returns *h* and keeps the polyhedron unchanged. The time is proportional to the size of the facet removed and the time to compute *h->prev()*.
Precondition: The degree of both vertices incident to *h* is at least three (no antennas).
Requirement: *Supports_removal* $\equiv$ *CGAL::Tag_true*.

Halfedge_handle *P.split_vertex(Halfedge_handle h, Halfedge_handle g)*

splits the vertex incident to *h* and *g* into two vertices, the old vertex remains and a new copy is created, and connects them with a new edge. Let *hnew* be *h->next()->opposite()* after the split, i.e., a halfedge of the new edge. The split regroups the halfedges around the two vertices. The halfedge sequence *hnew*, *g->next()->opposite()*, ..., *h* remains around the old vertex, while the halfedge sequence *hnew->opposite()*, *h->next()->opposite()* (before the split), ..., *g* is regrouped around the new vertex. The split returns *hnew*, i.e., the new halfedge incident to the old vertex. The time is proportional to the distance from *h* to *g* around the vertex.
Precondition: *h* and *g* are incident to the same vertex. *h != g* (antennas are not allowed).
Note: A special application of the split is *split_vertex(h,h->next()->opposite())* which is equivalent to an edge split of the halfedge *h->next()* that creates a new vertex on the halfedge *h->next()*. See also *split_edge(h)* below.

Halfedge_handle *P.join_vertex(Halfedge_handle h)*

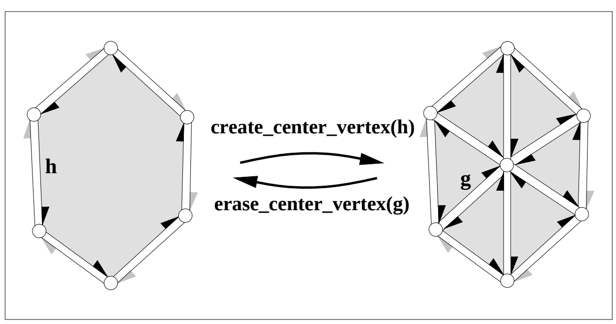
joins the two vertices incident to *h*. The vertex denoted by *h->opposite()* gets removed. Returns the predecessor of *h* around the vertex, i.e., *h->opposite()->prev()*. The invariant *join_vertex(split_vertex(h, g))* returns *h* and keeps the polyhedron unchanged. The time is proportional to the degree of the vertex removed and the time to compute *h->prev()* and *h->opposite()->prev()*.
Precondition: The size of both facets incident to *h* is at least four (no multi-edges).
Requirement: *Supports_removal* ≡ *CGAL::Tag_true*.

Halfedge_handle *P.split_edge(Halfedge_handle h)*

splits the halfedge *h* into two halfedges inserting a new vertex that is a copy of *h->opposite()->vertex()*. Is equivalent to *split_vertex(h->prev(), h->opposite())*. The call of *prev()* can make this method slower than a direct call of *split_vertex()* if the previous halfedge is already known and computing it would be costly when the halfedge data structure does not support the *prev()* member function. Returns the new halfedge *hnew* pointing to the inserted vertex. The new halfedge is followed by the old halfedge, i.e., *hnew->next() == h*.

Halfedge_handle *P.flip_edge(Halfedge_handle h)*

performs an edge flip. It returns *h* after rotating the edge *h* one vertex in the direction of the face orientation.
Precondition: *h != Halfedge_handle()* and both facets incident to *h* are triangles.



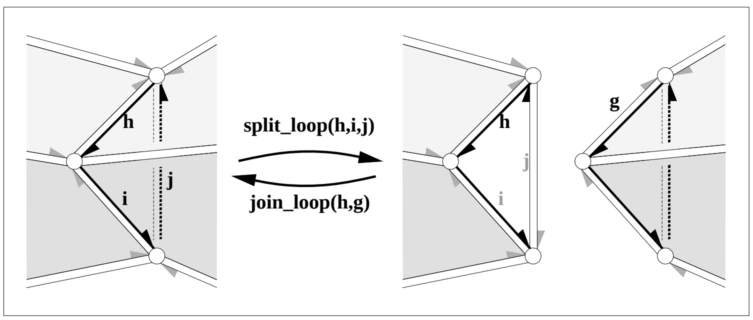
Halfedge_handle *P.create_center_vertex(Halfedge_handle h)*

barycentric triangulation of *h->facet()*. Creates a new vertex, a copy of *h->vertex()*, and connects it to each vertex incident to *h->facet()* splitting *h->facet()* into triangles. *h* remains incident to the original facet, all other triangles are copies of this facet. Returns the halfedge *h->next()* after the operation, i.e., a halfedge pointing to the new vertex. The time is proportional to the size of the facet.
Precondition: *h* is not a border halfedge.

Halfedge_handle *P.erase_center_vertex(Halfedge_handle g)*

reverses *create_center_vertex*. Erases the vertex pointed to by g and all incident halfedges thereby merging all incident facets. Only *g->facet()* remains. The neighborhood of *g->vertex()* may not be triangulated, it can have larger facets. Returns the halfedge *g->prev()*. Thus, the invariant h == *erase_center_vertex(create_center_vertex(h))* holds if h is not a border halfedge. The time is proportional to the sum of the size of all incident facets.
Precondition: None of the incident facets of *g->vertex()* is a hole. There are at least two distinct facets incident to the facets that are incident to *g->vertex()*. (This prevents the operation from collapsing a volume into two facets glued together with opposite orientations, such as would happen with any vertex of a tetrahedron.)
Requirement: *Supports_removal* $\equiv$ *CGAL::Tag_true*.

Euler Operators Modifying Genus



Halfedge_handle *P.split_loop(Halfedge_handle h, Halfedge_handle i, Halfedge_handle j)*

cuts the polyhedron into two parts along the cycle (h,i,j) (edge j runs on the backside of the three dimensional figure above). Three new vertices (one copy for each vertex in the cycle) and three new halfedges (one copy for each halfedge in the cycle), and two new triangles are created. h,i,j will be incident to the first new triangle. The return value will be the halfedge incident to the second new triangle which is the copy of *h-opposite()*.
Precondition: h,i,j denote distinct, consecutive vertices of the polyhedron and form a cycle: i.e., *h->vertex()* == *i->opposite()->vertex()*, ..., *j->vertex()* == *h->opposite()->vertex()*. The six facets incident to h,i,j are all distinct.

Halfedge_handle *P.join_loop(Halfedge_handle h, Halfedge_handle g)*

glues the boundary of the two facets denoted by h and g together and returns h. Both facets and the vertices along the facet denoted by g gets removed. Both facets may be holes. The invariant *join_loop(h, split_loop(h, i, j))* returns h and keeps the polyhedron unchanged.
Precondition: The facets denoted by h and g are different and have equal degree (i.e., number of edges).
Requirement: *Supports_removal* $\equiv$ *CGAL::Tag_true*.

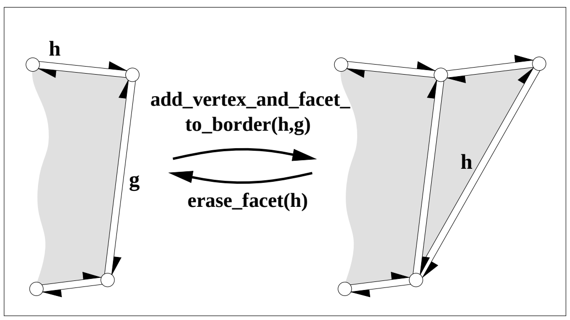
Modifying Facets and Holes

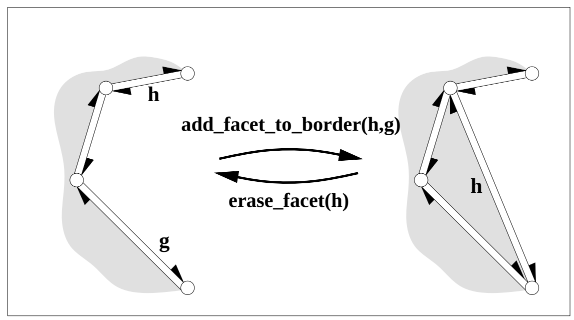
Halfedge_handle *P.make_hole(Halfedge_handle h)*

removes the incident facet of *h* and changes all halfedges incident to the facet into border edges. Returns *h*. See *erase_facet(h)* for a more generalized variant.
Precondition: None of the incident halfedges of the facet is a border edge.
Requirement: *Supports_removal* ≡ *CGAL::Tag_true*.

Halfedge_handle *P.fill_hole(Halfedge_handle h)*

fills a hole with a newly created facet. Makes all border halfedges of the hole denoted by *h* incident to the new facet. Returns *h*.
Precondition: *h.is_border()*.





Halfedge_handle *P.add_vertex_and_facet_to_border(Halfedge_handle h, Halfedge_handle g)*

creates a new facet within the hole incident to *h* and *g* by connecting the tip of *g* with the tip of *h* with two new halfedges and a new vertex and filling this separated part of the hole with a new facet, such that the new facet is incident to *g*. Returns the halfedge of the new edge that is incident to the new facet and the new vertex.
Precondition: *h->is_border()*, *g->is_border()*, *h != g*, and *g* can be reached along the same hole starting with *h*.

Halfedge_handle *P.add_facet_to_border(Halfedge_handle h, Halfedge_handle g)*

creates a new facet within the hole incident to *h* and *g* by connecting the vertex denoted by *g* with the vertex denoted by *h* with a new halfedge and filling this separated part of the hole with a new facet, such that the new facet is incident to *g*. Returns the halfedge of the new edge that is incident to the new facet.
Precondition: *h->is_border()*, *g->is_border()*, *h != g*, *h->next() != g*, and *g* can be reached along the same hole starting with *h*.

Erasing

void *P.erase_facet(Halfedge_handle h)*

removes the incident facet of *h* and changes all halfedges incident to the facet into border edges or removes them from the polyhedral surface if they were already border edges. If this creates isolated vertices they get removed as well. See *make_hole(h)* for a more specialized variant.
Precondition: *h->is_border() == false*.
Requirement: *Supports_removal* ≡ *CGAL::Tag_true*.

void *P.erase_connected_component(Halfedge_handle h)*

removes the vertices, halfedges, and facets that belong to the connected component of *h*.
Requirement: *Supports_removal* ≡ *CGAL::Tag_true*.

unsigned int *P.keep_largest_connected_components(unsigned int nb_components_to_keep)*

Erases the small connected components and the isolated vertices. Keep *nb_components_to_keep* largest connected components. Returns the number of connected components erased (ignoring isolated vertices).
Requirement: supports vertices, halfedges, and removal operation.

void *P.clear()*

removes all vertices, halfedges, and facets.

Operations with Border Halfedges

advanced

Halfedges incident to a hole are called *border halfedges*. An halfedge is a *border edge* if itself or its opposite halfedge are border halfedges. The only requirement to work with border halfedges is that the *Halfedge* class provides a member function *is_border()* returning a *bool*. Usually, the halfedge data structure supports facets and a *NULL* facet pointer will indicate a border halfedge, but this is not the only possibility. The *is_border()* predicate divides the edges into two classes, the border edges and the non-border edges. The following normalization reorganizes the sequential storage of the edges such that the non-border edges precede the border edges, and that for each border edge the latter one of the two halfedges is a border halfedge (the first one is a non-border halfedge in conformance with the polyhedral surface definition). The normalization stores the number of border halfedges and the halfedge iterator the border edges start at within the data structure. Halfedge insertion or removal and changing the border status of a halfedge invalidate these values. They are not automatically updated.

void *P.normalize_border()*

sorts halfedges such that the non-border edges precede the border edges. For each border edge the halfedge iterator will reference the halfedge incident to the facet right before the halfedge incident to the hole.

size_type *P.size_of_border_halfedges() const*

number of border halfedges.
Precondition: last *normalize_border()* call still valid, see above.

size_type *P.size_of_border_edges() const*

number of border edges. Since each border edge of a polyhedral surface has exactly one border halfedge, this number is equal to *size_of_border_halfedges()*.
Precondition: last *normalize_border()* call still valid, see above.

Halfedge_iterator *P.border_halfedges_begin()*

halfedge iterator starting with the border edges. The range [*halfedges_begin(), border_halfedges_begin()*) denotes all non-border halfedges. The range [*border_halfedges_begin(), halfedges_end()*) denotes all border edges.
Precondition: last *normalize_border()* call still valid, see above.

Edge_iterator *P.border_edges_begin()*

edge iterator starting with the border edges. The range [*edges_begin(), border_edges_begin()*) denotes all non-border edges. The range [*border_edges_begin(), edges_end()*) denotes all border edges.
Precondition: last *normalize_border()* call still valid, see above.

advanced

Miscellaneous

void *P.inside_out()*

reverses facet orientations (incl. plane equations if supported).

bool *P.is_valid(bool verbose = false, int level = 0) const*

returns *true* if the polyhedral surface is combinatorially consistent. If *verbose* is *true*, statistics are printed to *cerr*. For *level == 1* the normalization of the border edges is checked too. This method checks in particular level 3 of *CGAL::Halfedge_data_structure_decorator::is_valid* from page 26.4 and that each facet is at least a triangle and that the two incident facets of a non-border edge are distinct.

bool *P.normalized_border_is_valid(bool verbose = false) const*

returns *true* if the border halfedges are in normalized representation, which is when enumerating all halfedges with the iterator: The non-border edges precede the border edges and for border edges, the second halfedge is the border halfedge. The halfedge iterator *border_halfedges_begin()* denotes the first border edge. If *verbose* is *true*, statistics are printed to *cerr*.

advanced

void *P.delegate(CGAL::Modifier_base<HDS>& m)*

calls the *operator()* of the modifier *m*. See *CGAL::Modifier_base* for a description of modifier design and its usage.
Precondition: The polyhedral surface must be valid when the modifier returns from execution.

Example

This example program instantiates a polyhedron using the default traits class and creates a tetrahedron.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>

typedef CGAL::Simple_cartesian<double>     Kernel;
typedef CGAL::Polyhedron_3<Kernel>         Polyhedron;
typedef Polyhedron::Halfedge_handle        Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    if ( P.is_tetrahedron(h))
        return 0;
    return 1;
}
```

CGAL::Polyhedron_3<Traits>::Facet

Class

Definition

A facet optionally stores a plane equation, and a reference to an incident halfedge that points to the facet. Type tags indicate whether these member functions are supported. Figure 25.1 depicts the relationship between a halfedge and its incident halfedges, vertices, and facets. The circulator is assignable to the *Halfedge_handle*. The circulator is bidirectional if the halfedge provided to the polyhedron with the *Items* template argument provides a member function *prev()*, otherwise it is of the forward category.

#include <CGAL/Polyhedron_3.h>

Types

Facet:: Vertex	type of incident vertices.
Facet:: Halfedge	type of incident halfedges.
Facet:: Plane_3	plane equation type stored in facets.

Facet:: Vertex_handle	handle to vertex.
Facet:: Halfedge_handle	handle to halfedge.
Facet:: Facet_handle	handle to facet.
Facet:: Halfedge_around_facet_circulator	circulator of halfedges around a facet.

Facet:: Vertex_const_handle
Facet:: Halfedge_const_handle
Facet:: Facet_const_handle
Facet:: Halfedge_around_facet_const_circulator

Facet:: Supports_facet_halfedge	≡ *CGAL::Tag_true* or *CGAL::Tag_false*.
Facet:: Supports_facet_plane	≡ *CGAL::Tag_true* or *CGAL::Tag_false*.

Creation

Facet f;	default constructor.

Operations available if *Supports_facet_plane* ≡ *CGAL::Tag_true*

Plane_3&	*f.plane()*	
const Plane_3&	*f.plane() const*	plane equation.

Operations available if *Supports_facet_halfedge* ≡ *CGAL::Tag_true*

Halfedge_handle	*f.halfedge()*	
Halfedge_const_handle	*f.halfedge() const*	an incident halfedge that points to *f*.

Halfedge_around_facet_circulator		
	f.facet_begin()	
Halfedge_around_facet_const_circulator		
	f.facet_begin() const	
		circulator of halfedges around the facet (counterclockwise).
void	*f.set_halfedge(Halfedge_handle h)*	
		sets incident halfedge to h. *Precondition*: h is incident, i.e., *h->facet()* $==f$.
std::size_t	*f.facet_degree() const*	
		the degree of the facet, i.e., number of edges on the boundary of this facet.
bool	*f.is_triangle() const*	
		returns *true* if the facet is a triangle.
bool	*f.is_quad() const*	returns *true* if the facet is a quadrilateral.

CGAL::Polyhedron_3<Traits>::Halfedge

Definition

Figure 25.1 depicts the relationship between a halfedge and its incident halfedges, vertices, and facets. A halfedge is an oriented edge between two vertices. It is always paired with a halfedge pointing in the opposite direction. The *opposite()* member function returns this halfedge of opposite orientation. If a halfedge is incident to a facet the *next()* member function points to the successor halfedge around this facet. For border edges the *next()* member function points to the successor halfedge along the hole. For more than two border edges at a vertex, the next halfedge along a hole is not uniquely defined, but a consistent assignment of the next halfedge will be maintained in the data structure. An invariant is that successive assignments of the form *h = h->next()* cycle counterclockwise around the facet (or hole) and traverse all halfedges incident to this facet (or hole). A similar invariant is that successive assignments of the form *h = h->next()->opposite()* cycle clockwise around the vertex and traverse all halfedges incident to this vertex. Two circulators are provided for these circular orders.

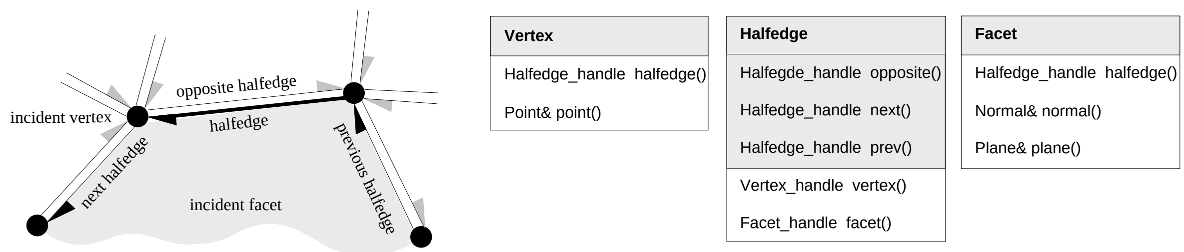

Figure 25.1: The three classes *Vertex*, *Halfedge*, and *Facet* of the polyhedral surface. Member functions with shaded background are mandatory. The others are optionally supported.

The incidences encoded in *opposite()* and *next()* are available for each instantiation of polyhedral surfaces. The other incidences are optionally available as indicated with type tags. The *prev()* member function points to the preceding halfedge around the same facet. It is always available, though it might perform a search around the facet using the *next()* member function to find the previous halfedge if the underlying halfedge data structure does not provide an efficient *prev()* member function for halfedges. Handles to the incident vertex and facet are optionally stored.

The circulators are assignable to the *Halfedge_handle*. The circulators are bidirectional if the halfedge provided to the polyhedron with the *Items* template argument provides a member function *prev()*, otherwise they are of the forward category.

#include <CGAL/Polyhedron_3.h>

Types

Halfedge:: Vertex	type of incident vertices.
Halfedge:: Facet	type of incident facets.
Halfedge:: Vertex_handle	handle to vertex.
Halfedge:: Halfedge_handle	handle to halfedge.
Halfedge:: Facet_handle	handle to facet.
Halfedge:: Halfedge_around_vertex_circulator	circulator of halfedges around a vertex.
Halfedge:: Halfedge_around_facet_circulator	circulator of halfedges around a facet.

Halfedge:: Vertex_const_handle
Halfedge:: Halfedge_const_handle
Halfedge:: Facet_const_handle
Halfedge:: Halfedge_around_vertex_const_circulator
Halfedge:: Halfedge_around_facet_const_circulator

Halfedge:: Supports_halfedge_prev	≡ *CGAL::Tag_true* or *CGAL::Tag_false*.
Halfedge:: Supports_halfedge_vertex	≡ *CGAL::Tag_true* or *CGAL::Tag_false*.
Halfedge:: Supports_halfedge_face	≡ *CGAL::Tag_true* or *CGAL::Tag_false*.

Creation

Halfedge h;	default constructor.

Operations

Halfedge_handle	*h.opposite()*	
Halfedge_const_handle	*h.opposite() const*	the opposite halfedge.
Halfedge_handle	*h.next()*	
Halfedge_const_handle	*h.next() const*	the next halfedge around the facet.
Halfedge_handle	*h.prev()*	
Halfedge_const_handle	*h.prev() const*	the previous halfedge around the facet.
Halfedge_handle	*h.next_on_vertex()*	
Halfedge_const_handle	*h.next_on_vertex() const*	the next halfedge around the vertex (clockwise). Is equal to *h.next()->opposite()*.
Halfedge_handle	*h.prev_on_vertex()*	
Halfedge_const_handle	*h.prev_on_vertex() const*	the previous halfedge around the vertex (counterclockwise). Is equal to *h.opposite()->prev()*.
bool	*h.is_border() const*	is true if *h* is a border halfedge.
bool	*h.is_border_edge() const*	is true if *h* or *h.opposite()* is a border halfedge.

Halfedge_around_vertex_circulator

h.vertex_begin()

Halfedge_around_vertex_const_circulator

h.vertex_begin() const — circulator of halfedges around the vertex (clockwise).

Halfedge_around_facet_circulator

h.facet_begin()

Halfedge_around_facet_const_circulator		
	h.facet_begin() const	circulator of halfedges around the facet (counterclockwise).
std::size_t	*h.vertex_degree() const*	the degree of the incident vertex, i.e., number of edges emanating from this vertex.
bool	*h.is_bivalent() const*	returns *true* if the incident vertex has exactly two incident edges.
bool	*h.is_trivalent() const*	returns *true* if the incident vertex has exactly three incident edges.
std::size_t	*h.facet_degree() const*	the degree of the incident facet, i.e., number of edges on the boundary of this facet.
bool	*h.is_triangle() const*	returns *true* if the incident facet is a triangle.
bool	*h.is_quad() const*	returns *true* if the incident facet is a quadrilateral.

Operations available if *Supports_halfedge_vertex* $\equiv$ *CGAL::Tag_true*

Vertex_handle	*h.vertex()*	
Vertex_const_handle	*h.vertex() const*	the incident vertex of *h*.

Operations available if *Supports_halfedge_facet* $\equiv$ *CGAL::Tag_true*

Facet_handle	*h.facet()*	
Facet_const_handle	*h.facet() const*	the incident facet of *h*. If *h* is a border halfedge the result is default construction of the handle.

Implementation

The member functions *prev()* and *prev_on_vertex()* work in constant time if *Supports_halfedge_prev* $\equiv$ *CGAL::Tag_true*. Otherwise both methods search for the previous halfedge around the incident facet.

Class

CGAL::Polyhedron_3<Traits>::Vertex

Definition

A vertex optionally stores a point and a reference to an incident halfedge that points to the vertex. Type tags indicate whether these member functions are supported. Figure 25.1 depicts the relationship between a halfedge and its incident halfedges, vertices, and facets. The circulator is assignable to the *Halfedge_handle*. The circulator is bidirectional if the halfedge provided to the polyhedron with the *Items* template argument provides a member function *prev()*, otherwise it is of the forward category.

#include <CGAL/Polyhedron_3.h>

Types

Vertex:: Halfedge	type of incident halfedges.
Vertex:: Facet	type of incident facets.
Vertex:: Point_3	point type stored in vertices.
Vertex:: Vertex_handle	handle to vertex.
Vertex:: Halfedge_handle	handle to halfedge.
Vertex:: Facet_handle	handle to facet.
Vertex:: Halfedge_around_vertex_circulator	circulator of halfedges around a vertex.
Vertex:: Vertex_const_handle	
Vertex:: Halfedge_const_handle	
Vertex:: Facet_const_handle	
Vertex:: Halfedge_around_vertex_const_circulator	
Vertex:: Supports_vertex_halfedge	≡ *CGAL::Tag_true* or *CGAL::Tag_false*.
Vertex:: Supports_vertex_point	≡ *CGAL::Tag_true* or *CGAL::Tag_false*.

Creation

Vertex v;	default constructor.
Vertex v(Point p);	vertex initialized with a point.

Operations available if *Supports_vertex_point* ≡ *CGAL::Tag_true*

Point_3&	*v.point()*	
const Point_3&	*v.point() const*	the point.

Operations available if *Supports_vertex_halfedge* ≡ *CGAL::Tag_true*

Halfedge_handle	*v.halfedge()*	
Halfedge_const_handle	*v.halfedge() const*	an incident halfedge that points to *v*.
Halfedge_around_vertex_circulator		
	v.vertex_begin()	
Halfedge_around_vertex_const_circulator		
	v.vertex_begin() const	
		circulator of halfedges around the vertex (clockwise).
void	*v.set_halfedge(Halfedge_handle h)*	
		sets incident halfedge to *h*. *Precondition*: *h* is incident, i.e., *h->vertex() == v*.
std::size_t	*v.vertex_degree() const*	
		the degree of the vertex, i.e., number of edges emanating from this vertex.
bool	*v.is_bivalent() const*	
		returns *true* if the vertex has exactly two incident edges.
bool	*v.is_trivalent() const*	
		returns *true* if the vertex has exactly three incident edges.

Class

CGAL::Polyhedron_incremental_builder_3<HDS>

Definition

The auxiliary class *Polyhedron_incremental_builder_3<HDS>* supports the incremental construction of polyhedral surfaces, which is for example convenient when constructing polyhedral surfaces from file formats, such as the Object File Format (OFF) [Phi96], OpenInventor [Wer94] or VRML [BPP95, VRM96]. *Polyhedron_incremental_builder_3<HDS>* needs access to the internal halfedge data structure of type *HDS* of the polyhedral surface. It is intended to be used within a modifier, see *CGAL::Modifier_base*.

The incremental builder might be of broader interest for other uses of the halfedge data structures, but it is specifically bound to the definition of polyhedral surfaces given here. During construction all conditions of polyhedral surfaces are checked and in case of violation an error status is set. A diagnostic message will be issued to *cerr* if the *verbose* flag has been set at construction time.

The incremental construction starts with a list of all point coordinates and concludes with a list of all facet polygons. Edges are not explicitly specified. They are derived from the vertex incidence information provided from the facet polygons. The polygons are given as a sequence of vertex indices. The halfedge data structure *HDS* must support vertices (i.e., *Supports_halfedge_vertex* $\equiv$ *CGAL::Tag_true*). Vertices and facets can be added in arbitrary order as long as a call to *add_vertex_to_facet()* refers only to a vertex index that is already known. Some methods return already handles to vertices, facets, and halfedges newly constructed. They can be used to initialize additional fields, however, the incidences in the halfedge-data structure are not stable and are not allowed to be changed.

The incremental builder can work in two modes: *RELATIVE_INDEXING* (the default), in which a polyhedral surface already contained in the halfedge data structure is ignored and all indices are relative to the newly added surface, or *ABSOLUTE_INDEXING*, in which all indices are absolute indices including an already existing polyhedral surface. The former mode allows to create easily independent connected components, while the latter mode allows to to continue the construction of an existing surface, the absolute indexing allows to address existing vertices when creating new facets.

#include <CGAL/Polyhedron_incremental_builder_3.h>

Types

Polyhedron_incremental_builder_3<HDS>:: HalfedgeDS	halfedge data structure *HDS*.
Polyhedron_incremental_builder_3<HDS>:: Point_3	point type of the vertex.
Polyhedron_incremental_builder_3<HDS>:: size_type	size type.

typedef typename HalfedgeDS::Vertex_handle	*Vertex_handle;*
typedef typename HalfedgeDS::Halfedge_handle	*Halfedge_handle;*
typedef typename HalfedgeDS::Face_handle	*Facet_handle;*

Constants

enum { *RELATIVE_INDEXING, ABSOLUTE_INDEXING*}*;*

two different indexing modes.

Creation

Polyhedron_incremental_builder_3<HDS> B(HDS& hds, bool verbose = false);

stores a reference to the halfedge data structure *hds* of a polyhedral surface in its internal state. An existing polyhedral surface in *hds* remains unchanged. The incremental builder appends the new polyhedral surface. If *verbose* is *true*, diagnostic messages will be printed to *cerr* in case of malformed input data.

Surface Creation

To build a polyhedral surface, the following regular expression gives the correct and allowed order and nesting of method calls from this section:

$$begin\_surface\ (add\_vertex \mid (begin\_facet\ add\_vertex\_to\_facet * end\_facet)) * end\_surface$$

void *B.begin_surface(size_type v, size_type f, size_type h = 0, int mode = RELATIVE_INDEXING)*

starts the construction. v is the number of new vertices to expect, f the number of new facets, and h the number of new halfedges. If h is unspecified (== *0*) it is estimated using Euler's equation (plus 5% for the so far unknown holes and genus of the object). These values are used to reserve space in the halfedge data structure *hds*. If the representation supports insertion these values do not restrict the class of constructible polyhedra. If the representation does not support insertion the object must fit into the reserved sizes.
If *mode* is set to *ABSOLUTE_INDEXING* the incremental builder uses absolute indexing and the vertices of the old polyhedral surface can be used in new facets (needs preprocessing time linear in the size of the old surface). Otherwise relative indexing is used starting with new indices for the new construction.

Vertex_handle *B.add_vertex(Point_3 p)*

adds a new vertex for p and returns its handle.

Facet_handle *B.begin_facet()* starts a new facet and returns its handle.

void *B.add_vertex_to_facet(size_type i)*

adds a vertex with index i to the current facet. The first point added with *add_vertex()* has the index 0 if *mode* was set to *RELATIVE_INDEXING*, otherwise the first vertex in the referenced *hds* has the index 0.

Halfedge_handle *B.end_facet()* ends a newly constructed facet. Returns the handle to the halfedge incident to the new facet that points to the vertex added first. The halfedge can be safely used to traverse the halfedge cycle around the new facet.

void *B.end_surface()* ends the construction.

Additional Operations

template <class InputIterator>
Halfedge_handle *B.add_facet(InputIterator first, InputIterator beyond)*

is a synonym for *begin_facet()*, a call to *add_vertex_to_facet()* for each value in the range *[first,beyond)*, and a call to *end_facet()*. Returns the return value of *end_facet()*.
Precondition: The value type of *InputIterator* is *std::size_t*. All indices must refer to vertices already added.

template <class InputIterator>
bool *B.test_facet(InputIterator first, InputIterator beyond)*

returns *true* if a facet described by the vertex indices in the range *[first,beyond)* can be successfully inserted, e.g., with *add_facet(first,beyond)*.
Precondition: The value type of *InputIterator* is *std::size_t*. All indices must refer to vertices already added.

Vertex_handle *B.vertex(std::size_t i)*

returns handle for the vertex of index *i*, or *Vertex_handle* if there is no *i*-th vertex.

bool *B.error() const* returns error status of the builder.

void *B.rollback()* undoes all changes made to the halfedge data structure since the last *begin_surface()* in relative indexing, and deletes the whole surface in absolute indexing. It needs a new call to *begin_surface()* to start inserting again.

bool *B.check_unconnected_vertices()*

returns *true* if unconnected vertices are detected. If *verbose* was set to *true* (see the constructor above) debug information about the unconnected vertices is printed.

bool *B.remove_unconnected_vertices()*

returns *true* if all unconnected vertices could be removed successfully. This happens either if no unconnected vertices had appeared or if the halfedge data structure supports the removal of individual elements.

Example

A modifier class creates a new triangle in the halfedge data structure using the incremental builder.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_incremental_builder_3.h>
#include <CGAL/Polyhedron_3.h>

// A modifier creating a triangle with the incremental builder.
template <class HDS>
class Build_triangle : public CGAL::Modifier_base<HDS> {
public:
    Build_triangle() {}
    void operator()( HDS& hds) {
        // Postcondition: 'hds' is a valid polyhedral surface.
        CGAL::Polyhedron_incremental_builder_3<HDS> B( hds, true);
        B.begin_surface( 3, 1, 6);
        typedef typename HDS::Vertex   Vertex;
        typedef typename Vertex::Point Point;
        B.add_vertex( Point( 0, 0, 0));
        B.add_vertex( Point( 1, 0, 0));
        B.add_vertex( Point( 0, 1, 0));
        B.begin_facet();
        B.add_vertex_to_facet( 0);
        B.add_vertex_to_facet( 1);
        B.add_vertex_to_facet( 2);
        B.end_facet();
        B.end_surface();
    }
};

typedef CGAL::Simple_cartesian<double>     Kernel;
typedef CGAL::Polyhedron_3<Kernel>         Polyhedron;
typedef Polyhedron::HalfedgeDS             HalfedgeDS;

int main() {
    Polyhedron P;
    Build_triangle<HalfedgeDS> triangle;
    P.delegate( triangle);
    CGAL_assertion( P.is_triangle( P.halfedges_begin()));
    return 0;
}
```

File: examples/Polyhedron/polyhedron_prog_incr_builder.cpp

Concept

PolyhedronItems_3

Definition

The PolyhedronItems_3 concept extends the *HalfedgeDSItems* concept on page 1873. In addition to the requirements stated there, a model for this concept must fulfill the following requirements for the local *PolyhedronItems_3::Vertex_wrapper<Refs,Traits>::Vertex* type and *PolyhedronItems_3::Face_wrapper< Refs,Traits>::Face* type in order to support the point for vertices and the optional plane equation for facets. Note that the items class uses face instead of facet. Only the polyhedral surface renames faces to facets.

Refines

HalfedgeDSItems . . . . page 1854

Types in *PolyhedronItems_3::Vertex_wrapper<Refs,Traits>::Vertex*

Vertex:: Point	point type stored in vertices. A *HalfedgeDS* has no dimension, so this type is named *Point* and not *Point_3*.
Vertex:: Supports_vertex_point	≡ *CGAL::Tag_true*. A point is always required.

Operations

Point&	*v.point()*	
const Point&	*v.point() const*	point.

Types in *PolyhedronItems_3::Face_wrapper<Refs,Traits>::Face*

Types for (optionally) associated geometry in faces. If it is not supported the respective type has to be defined, although it can be an arbitrary dummy type, such as *void** or *Tag_false*.

Face:: Plane	plane type stored in faces. A *HalfedgeDS* has no dimension, so this type is named *Plane* and not *Plane_3*.
Face:: Supports_face_plane	either *CGAL::Tag_true* or *CGAL::Tag_false*.

Operations required if *Supports_face_plane* ≡ *CGAL::Tag_true*

Plane&	*f.plane()*	
const Plane&	*f.plane() const*	plane equation.

Has Models

CGAL::HalfedgeDS_halfedge_base<Refs> . . . . page 1871
CGAL::HalfedgeDS_face_base<Refs> . . . . page 1868

Example

We define our own items class based on the available *CGAL::HalfedgeDS_face_base* base class for faces. We derive the the *Halfedge_wrapper* without further modifications from the *CGAL::HalfedgeDS_items_2*, replace the *Face_wrapper* definition with our new definition, and also replace the *Vertex_wrapper* with a definition that uses *Point_3* instead of *Point_2* as point type. The result is a model for the *PolyhedronItems_3* concept similar to the available *CGAL::Polyhedron_items_3* class. See also there for another illustrative example.

```
#include <CGAL/HalfedgeDS_bases.h>

struct My_items : public CGAL::HalfedgeDS_items_2 {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef typename Traits::Point_3 Point;
        typedef CGAL::HalfedgeDS_vertex_base< Refs, CGAL::Tag_true,
   Point> Vertex;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef typename Traits::Plane_3 Plane;
        typedef CGAL::HalfedgeDS_face_base< Refs, CGAL::Tag_true, Plane>
     Face;
    };
};
```

CGAL::Polyhedron_items_3

Definition

The class *Polyhedron_items_3* is a model of the *PolyhedronItems_3* concept. It provides definitions for vertices with points, halfedges, and faces with plane equations. The polyhedron traits class must provide the respective types for the point and the plane equation. Vertices and facets both contain a halfedge handle to an incident halfedge.

#include <CGAL/Polyhedron_items_3.h>

Is Model for the Concepts

PolyhedronItems_3 . . . . page 1818

Types in *Polyhedron_items_3::Vertex_wrapper<Refs,Traits>::Vertex*

typedef Traits::Point_3	*Point;*
typedef CGAL::Tag_true	*Supports_vertex_point;*

Types in *Polyhedron_items_3::Face_wrapper<Refs,Traits>::Face*

typedef Traits::Plane_3	*Plane;*
typedef CGAL::Tag_true	*Supports_face_plane;*

Creation

Polyhedron_items_3 items;	default constructor.

Operations

Supported as required by the *PolyhedronItems_3* concept.

CGAL::Polyhedron_3<Traits> . . . . page 1795
CGAL::Polyhedron_min_items_3 . . . . page 1822
CGAL::HalfedgeDS_min_items . . . . page 1879
CGAL::HalfedgeDS_items_2 . . . . page 1873

Example

The following example program defines a new face class based on the *CGAL::HalfedgeDS_face_base* and adds a new color member variable. The new face class is used to replace the face definition in the *CGAL::Polyhedron_items_3* class. The main function illustrates the access to the new member variable. See also the *PolyhedronItems_3* concept for another illustrative example.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/IO/Color.h>
#include <CGAL/Polyhedron_3.h>

// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
};

// An items type using my face.
struct My_items : public CGAL::Polyhedron_items_3 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};

typedef CGAL::Simple_cartesian<double>        Kernel;
typedef CGAL::Polyhedron_3<Kernel, My_items>  Polyhedron;
typedef Polyhedron::Halfedge_handle           Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    h->facet()->color = CGAL::RED;
    return 0;
}
```

File: examples/Polyhedron/polyhedron_prog_color.cpp

Class

CGAL::Polyhedron_min_items_3

Definition

The class *Polyhedron_min_items_3* is a minimal model of the *PolyhedronItems_3* concept. It provides definitions for vertices containing points, halfedges, and faces. The polyhedron traits class must provide the respective type for the point. Vertices and facets both do *not* contain a halfedge handle to an incident halfedge.

#include <CGAL/Polyhedron_min_items_3.h>

Is Model for the Concepts

PolyhedronItems_3 . . . . page 1818

Types in *Polyhedron_min_items_3::Vertex_wrapper<Refs,Traits>::Vertex*

typedef Traits::Point_3	*Point;*
typedef CGAL::Tag_true	*Supports_vertex_point;*

Types in *Polyhedron_min_items_3::Face_wrapper<Refs,Traits>::Face*

typedef CGAL::Tag_false	*Supports_face_plane;*

Creation

Polyhedron_min_items_3 items;	default constructor.

Operations

Supported as required by the *PolyhedronItems_3* concept.

See Also

CGAL::Polyhedron_3<Traits> . . . . page 1795

CGAL::HalfedgeDS_items_2 . . . . page 1873

PolyhedronTraits_3

Required types and member functions for the PolyhedronTraits_3 concept. This geometric traits concept is used in the polyhedral surface data structure *CGAL::Polyhedron_3<Traits>*. This concept is a subset of the 3d kernel traits and any CGAL kernel model can be used directly as template argument.

Refines

CopyConstructable, *Assignable*.

Types

PolyhedronTraits_3:: Point_3 — point type.

PolyhedronTraits_3:: Plane_3 — plane equation. Even if plane equations are not supported with a particular polyhedral surface this type has to be defined (some dummy type).

PolyhedronTraits_3:: Construct_opposite_plane_3

is an unary function object that reverses the plane orientation. Must provide *Plane_3 operator()(Plane_3 plane)* that returns the reversed plane. Required only if plane equations are supported and the *inside_out()* method is used to reverse the polyhedral surface orientation.

Creation

PolyhedronTraits_3 traits(traits2); — copy constructor.

PolyhedronTraits_3& *traits = traits2* — assignment.

Operations

Construct_opposite_plane_3 *traits.construct_opposite_plane_3_object()*

returns an instance of this function object.

Has Models

CGAL::Polyhedron_traits_3<Kernel> . . . . page 1824
CGAL::Polyhedron_traits_with_normals_3<Kernel> . . . . page 1826
All models of the *CGAL::Kernel* concept, e.g., *Simple_cartesian<FieldNumberType>*.

See Also

CGAL::Polyhedron_3<Traits> . . . . page 1795

Class

CGAL::Polyhedron_traits_3<Kernel>

Definition

The class *Polyhedron_traits_3<Kernel>* is a model of the *PolyhedronTraits_3* concept. It defines the geometric types and primitive operations used in the polyhedral surface data structure *CGAL::Polyhedron_3< PolyhedronTraits_3>* in terms of the CGAL *Kernel*. It keeps a local copy of the kernel which makes it suitable for kernels with local state.

#include <CGAL/Polyhedron_traits_3.h>

Is Model for the Concepts

PolyhedronTraits_3 . . . . page 1823

Types

Polyhedron_traits_3<Kernel>:: Kernel		the *Kernel* model.
typedef Kernel::Point_3	*Point_3;*	
typedef Kernel::Plane_3	*Plane_3;*	
typedef Kernel::Construct_opposite_plane_3	*Construct_opposite_plane_3;*	

Creation

Polyhedron_traits_3<Kernel> traits;	default constructor, uses *Kernel()* as local reference to the kernel.
Polyhedron_traits_3<Kernel> traits(Kernel kernel);	stores *kernel* as local reference.

Operations

Construct_opposite_plane_3	*traits.construct_opposite_plane_3_object()*	forwarded to *kernel*.

See Also

CGAL::Polyhedron_traits_with_normals_3<Kernel> . . . . .page 1826

Implementation

Since the *PolyhedronTraits_3* concept is a subset of the 3D kernel concept, this class just forwards the relevant types and access member functions from its template argument. However, it is useful for testing sufficiency of requirements.

Example

Instantiation of a polyhedral surface with the Cartesian kernel based on double coordinates.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>

typedef CGAL::Simple_cartesian<double>     Kernel;
typedef CGAL::Polyhedron_3<Kernel>         Polyhedron;
typedef Polyhedron::Halfedge_handle        Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    if ( P.is_tetrahedron(h))
        return 0;
    return 1;
}
```

File: examples/Polyhedron/polyhedron_prog_simple.cpp

CGAL::Polyhedron_traits_with_normals_3<Kernel>

Definition

The class *Polyhedron_traits_with_normals_3<Kernel>* is a model of the *PolyhedronTraits_3* concept. It defines the geometric types and primitive operations used in the polyhedral surface data structure *CGAL::Polyhedron_3<PolyhedronTraits_3>*. *Polyhedron_traits_with_normals_3<Kernel>* uses the normal vector from *Kernel* for the plane equation in facets. It keeps a local copy of the kernel which makes it suitable for kernels with local state.

#include <CGAL/Polyhedron_traits_with_normals_3.h>

Is Model for the Concepts

PolyhedronTraits_3 . . . . page 1823

Types

Polyhedron_traits_with_normals_3<Kernel>:: Kernel		the *Kernel* model.
typedef Kernel::Point_3	*Point_3;*	
typedef Kernel::Vector_3	*Plane_3;*	
typedef Kernel::Construct_opposite_vector_3	*Construct_opposite_plane_3;*	

Creation

Polyhedron_traits_with_normals_3<Kernel> traits;	default constructor, uses *Kernel()* as local reference to the kernel.
Polyhedron_traits_with_normals_3<Kernel> traits(Kernel kernel);	stores *kernel* as local reference.

Operations

Construct_opposite_plane_3 *traits.construct_opposite_plane_3_object()*

forwarded to *kernel*.

See Also

CGAL::Polyhedron_traits_3<Kernel> . . . . page 1824

Example

We use this traits class to instantiate a polyhedral surface with a normal vector and no plane equation for each facet. We compute the normal vector assuming exact arithmetic (integers in this example) and convex planar facets.

```
#include <CGAL/Homogeneous.h>
#include <CGAL/Polyhedron_traits_with_normals_3.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>
#include <algorithm>

struct Normal_vector {
    template <class Facet>
    typename Facet::Plane_3 operator()( Facet& f) {
        typename Facet::Halfedge_handle h = f.halfedge();
        // Facet::Plane_3 is the normal vector type. We assume the
        // CGAL Kernel here and use its global functions.
        return CGAL::cross_product(
          h->next()->vertex()->point() - h->vertex()->point(),
          h->next()->next()->vertex()->point() -
   h->next()->vertex()->point());
    }
};

typedef CGAL::Homogeneous<int>                                Kernel;
typedef Kernel::Point_3                                       Point_3;
typedef Kernel::Vector_3                                      Vector_3;
typedef CGAL::Polyhedron_traits_with_normals_3<Kernel> Traits;
typedef CGAL::Polyhedron_3<Traits>                            Polyhedron;

int main() {
    Point_3 p( 1, 0, 0);
    Point_3 q( 0, 1, 0);
    Point_3 r( 0, 0, 1);
    Point_3 s( 0, 0, 0);
    Polyhedron P;
    P.make_tetrahedron( p, q, r, s);
    std::transform( P.facets_begin(), P.facets_end(), P.planes_begin(),
                    Normal_vector());
    CGAL::set_pretty_mode( std::cout);
    std::copy( P.planes_begin(), P.planes_end(),
               std::ostream_iterator<Vector_3>( std::cout, "\n"));
    return 0;
}
```

File: examples/Polyhedron/polyhedron_prog_normals.cpp

Function

CGAL::operator<<

Definition

This operator writes the polyhedral surface *P* to the output stream *out* using the Object File Format, OFF, with file extension `.off`, which is also understood by GeomView [Phi96]. The output is in ASCII format. From the polyhedral surface, only the point coordinates and facets are written. Neither normal vectors nor color attributes are used.

For OFF an ASCII and a binary format exist. The format can be selected with the CGAL modifiers for streams, *set_ascii_mode* and *set_binary_mode* respectively. The modifier *set_pretty_mode* can be used to allow for (a few) structuring comments in the output. Otherwise, the output would be free of comments. The default for writing is ASCII without comments.

#include <CGAL/IO/Polyhedron_iostream.h>

template <class PolyhedronTraits_3>
ostream& *ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P*

See Also

CGAL::Polyhedron_3<Traits> . . . . page 1795
operator>> . . . . page 1829

CGAL::operator>>

Definition

This operator reads a polyhedral surface in Object File Format, OFF, with file extension `.off`, which is also understood by Geomview [Phi96], from the input stream *in* and appends it to the polyhedral surface *P*. Only the point coordinates and facets from the input stream are used to build the polyhedral surface. Neither normal vectors nor color attributes are evaluated. If the stream *in* does not contain a permissible polyhedral surface the *ios::badbit* of the input stream *in* is set and *P* remains unchanged.

For OFF an ASCII and a binary format exist. The stream detects the format automatically and can read both.

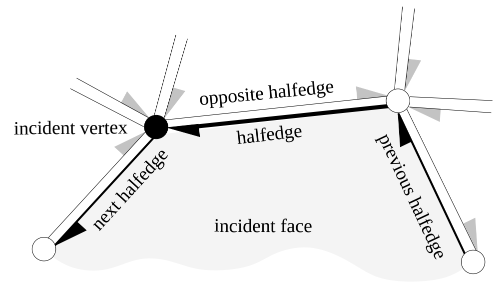
#include <CGAL/IO/Polyhedron_iostream.h>

template <class PolyhedronTraits_3>
istream& *istream& in >> CGAL::Polyhedron_3<PolyhedronTraits_3>& P*

See Also

Implementation

This operator is implemented using the modifier mechanism for polyhedral surfaces and the *CGAL::Polyhedron_incremental_builder_3* class, which allows the construction in a single, efficient scan pass of the input and handles also all the possible flexibility of the polyhedral surface.



Chapter 26

Halfedge Data Structures

Lutz Kettner

Contents

26.1 Introduction

A halfedge data structure (abbreviated as *HalfedgeDS*, or *HDS* for template parameters) is an edge-centered data structure capable of maintaining incidence information of vertices, edges and faces, for example for planar maps, polyhedra, or other orientable, two-dimensional surfaces embedded in arbitrary dimension. Each edge is decomposed into two halfedges with opposite orientations. One incident face and one incident vertex are stored in each halfedge. For each face and each vertex, one incident halfedge is stored. Reduced variants of the halfedge data structure can omit some of these information, for example the halfedge pointers in faces or the storage of faces at all.

The halfedge data structure is a combinatorial data structure, geometric interpretation is added by classes built on top of the halfedge data structure. These classes might be more convenient to use than the halfedge data structure directly, since the halfedge data structure is meant as an implementation layer. See for example the *CGAL::Polyhedron_3* class in Chapter 25.

The data structure provided here is also known as the FE-structure [Wei85], as halfedges [Män88, BFH95] or as the doubly connected edge list (DCEL) [dBvKOS97], although the original reference for the DCEL [MP78]

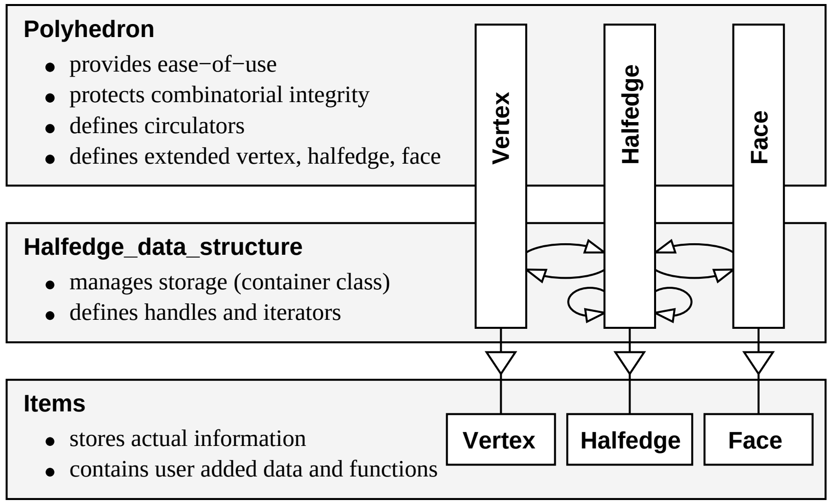


Figure 26.1: Responsibilities of the different layers in the halfedge data-structure design.

describes a different data structure. The halfedge data structure can also be seen as one of the variants of the quad-edge data structure [GS85]. In general, the quad-edge data can represent non-orientable 2-manifolds, but the variant here is restricted to orientable 2-manifolds only. An overview and comparison of these different data structures together with a thorough description of the design implemented here can be found in [Ket99].

The design presented here is a revised and incompatible version of the previous design [Ket98] as used in CGAL R2.2 and earlier releases. Files and identifier names are disjoint with the old design which allows for both versions to co-exists. However, classes using a halfedge data structure can only use one design. For example the polyhedral surface *Polyhedron_3* uses by default the new design. See Chapter 25 for how to still select the old implementation.

26.2 Software Design

Figure 26.1 illustrates the responsibilities of the three layers of the software design, with the *CGAL::Polyhedron_3* as an example for the top layer. The items provide the space for the information that is actually stored, i.e., with member variables and access member functions in *Vertex*, *Halfedge*, and *Face* respectively. Halfedges are required to provide a reference to the next halfedge and to the opposite halfedge. Optionally they may provide a reference to the previous halfedge, to the incident vertex, and to the incident face. Vertices and faces may be empty. Optionally they may provide a reference to the incident halfedge. The options mentioned are supported in the halfedge data structure and the polyhedron, for example, Euler operations update the optional references if they are present. Furthermore, the item classes can be extended with arbitrary attributes and member functions, which will be promoted by inheritance to the actual classes used for the polyhedron.

Vertices, halfedges, and faces are passed as local types of the *Items* class to the halfedge data structure and polyhedron. Implementations for vertices, halfedges and faces are provided that fulfill the mandatory part of the requirements. They can be used as base classes for extensions by the user. Richer implementations are also provided to serve as defaults; for polyhedra they provide all optional incidences, a three-dimensional point in the vertex type and a plane equation in the face type.

The *Halfedge_data_structure*, concept *HalfedgeDS*, is responsible for the storage organization of the items. Currently, implementations using internally a bidirectional list or a vector are provided. The *HalfedgeDS* defines the handles and iterators belonging to the items. These types are promoted to the declaration of the items themselves and are used there to provide the references to the incident items. This promotion of types is done with a template parameter *Refs* of the item types. The halfedge data structure provides member functions to insert and delete items, to traverse all items, and it gives access to the items.

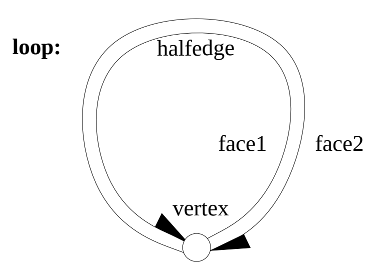
There are two different models for the *HalfedgeDS* concept available, *HalfedgeDS_list* and *HalfedgeDS_vector*, and more might come. Therefore we have kept their interface small and factored out common functionality into separate helper classes, *HalfedgeDS_decorator*, *HalfedgeDS_const_decorator*, and *HalfedgeDS_items_decorator*, which are not shown in Figure 26.1, but would be placed at the side of the *HalfedgeDS* since they broaden that interface but do not hide it. These helper classes contain operations that are useful to implement the operations in the next layer, for example, the polyhedron. They add, for example, the Euler operations and partial operations from which further Euler operations can be built, such as inserting an edge into the ring of edges at a vertex. Furthermore, the helper classes contain adaptive functionality. For example, if the *prev()* member function is not provided for halfedges, the *find_prev()* member function of a helper class searches in the positive direction along the face for the previous halfedge. But if the *prev()* member function is provided, the *find_prev()* member function simply calls it. This distinction is resolved at compile time with a technique called *compile-time tags*, similar to iterator tags in [SL95].

The *Polyhedron_3* as an example for the third layer adds the geometric interpretation, provides an easy-to-use interface of high-level functions, and unifies the access to the flexibility provided underneath. It renames face to facet, which is more common for three-dimensional surfaces. The interface is designed to protect the integrity of the internal representation, the handles stored in the items can no longer directly be written by the user. The polyhedron adds the convenient and efficient circulators, see *Circulator*, for accessing the circular sequence of edges around a vertex or around a facet. To achieve this, the *Polyhedron_3* derives new vertices, halfedges and facets from those provided in *Items*. These new items are those actually used in the *HalfedgeDS*, which gives us the coherent type structure in this design, especially if compared to our previous design.

26.3 Example Programs

26.3.1 The Default Halfedge Data Structure

The following example program uses the default halfedge data structure and the decorator class. The default halfedge data structure uses a list-based representation. All incidences of the items and a point type for vertices are defined. The trivial traits class provides the type used for the point. The program creates a loop, consisting of two halfedges, one vertex and two faces, and checks its validity.



```
#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>

struct Traits { typedef int Point_2; };
typedef CGAL::HalfedgeDS_default<Traits> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS> Decorator;
```

```
int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}
```

File: examples/HalfedgeDS/hds_prog_default.cpp

26.3.2 A Minimal Halfedge Data Structure

The following program defines a minimal halfedge data structure using the minimal items class *CGAL::HalfedgeDS_min_items* and a list-based halfedge data structure. The result is a data structure maintaining only halfedges with next and opposite pointers. No vertices or faces are stored. The data structure represents an *undirected graph*.

```
#include <CGAL/HalfedgeDS_min_items.h>
#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>

// no traits needed, argument can be arbitrary dummy.
typedef CGAL::HalfedgeDS_default<int, CGAL::HalfedgeDS_min_items> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS>  Decorator;

int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}
```

File: examples/HalfedgeDS/hds_prog_graph.cpp

26.3.3 The Default with a Vector Instead of a List

The default halfedge data structure uses a list internally and the maximal base classes. We change the list to a vector representation here. Again, a trivial traits class provides the type used for the point. Note that for the vector storage the size of the halfedge data structure should be reserved beforehand, either with the constructor as shown in the example or with the *reserve()* member function. One can later resize the data structure with further calls to the *reserve()* member function, but only if the data structure is in a consistent, i.e., *valid*, state.

```
#include <CGAL/HalfedgeDS_items_2.h>
#include <CGAL/HalfedgeDS_vector.h>
#include <CGAL/HalfedgeDS_decorator.h>

struct Traits { typedef int Point_2; };
typedef CGAL::HalfedgeDS_vector< Traits, CGAL::HalfedgeDS_items_2> HDS;
```

```
typedef CGAL::HalfedgeDS_decorator<HDS>  Decorator;

int main() {
    HDS hds(1,2,2);
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}
```

File: examples/HalfedgeDS/hds_prog_vector.cpp

26.3.4 Example Adding Color to Faces

This example re-uses the base class available for faces and adds a member variable *color*.

```
#include <CGAL/HalfedgeDS_items_2.h>
#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/IO/Color.h>

// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
    My_face() {}
    My_face( CGAL::Color c) : color(c) {}
};

// An items type using my face.
struct My_items : public CGAL::HalfedgeDS_items_2 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};

struct My_traits { // arbitrary point type, not used here.
    typedef int  Point_2;
};

typedef CGAL::HalfedgeDS_default<My_traits, My_items> HDS;
typedef HDS::Face                                     Face;
typedef HDS::Face_handle                              Face_handle;

int main() {
    HDS hds;
    Face_handle f = hds.faces_push_back( Face( CGAL::RED));
    f->color = CGAL::BLUE;
    CGAL_assertion( f->color == CGAL::BLUE);
    return 0;
}
```

File: examples/HalfedgeDS/hds_prog_color.cpp

26.3.5 Example Defining a More Compact Halfedge

advanced

The halfedge data structure as presented here is slightly less space efficient as, for example, the winged-edge data structure [Bau75], the DCEL [MP78] or variants of the quad-edge data structure [GS85]. On the other hand, it does not require any search operations during traversals. A comparison can be found in [Ket99].

The following example trades traversal time for a compact storage representation using traditional C techniques (i.e., type casting and the assumption that pointers, especially those from malloc or new, point to even addresses). The idea goes as follows: The halfedge data structure allocates halfedges pairwise. Concerning the vector-based data structure this implies that the absolute value of the difference between a halfedge and its opposite halfedge is always one with respect to C pointer arithmetic. We can replace the opposite pointer by a single bit encoding the sign of this difference. We will store this bit as the least significant bit in the next halfedge handle. Furthermore, we do not implement a pointer to the previous halfedge. What remains are three pointers per halfedge.

We use the static member function *halfedge_handle()* to convert from pointers to halfedge handles. The same solution can be applied to the list-based halfedge data structure *CGAL::HalfedgeDS_list*, see examples/HalfedgeDS/hds_prog_compact2.cpp. Here is the example for the vector-based data structure.

```
#include <CGAL/HalfedgeDS_items_2.h>
#include <CGAL/HalfedgeDS_vector.h>
#include <CGAL/HalfedgeDS_decorator.h>
#include <cstddef>

// Define a new halfedge class. We assume that the Halfedge_handle can
// be created from a pointer (e.g. the HalfedgeDS is based here on the
// In_place_list or a std::vector with such property) and that halfedges
// are allocated in pairs. We encode the opposite pointer in a single
   bit,
// which is stored in the lower bit of the next-pointer. We use the
// static member function HDS::halfedge_handle to translate pointer to
// handles.
template <class Refs>
class My_halfedge {
public:
    typedef Refs                                    HDS;
    typedef My_halfedge<Refs>                       Base_base;
    typedef My_halfedge<Refs>                       Base;
    typedef My_halfedge<Refs>                       Self;
    typedef CGAL::Tag_false                         Supports_halfedge_prev;
    typedef CGAL::Tag_true
   Supports_halfedge_vertex;
    typedef CGAL::Tag_true                          Supports_halfedge_face;
    typedef typename Refs::Vertex_handle            Vertex_handle;
    typedef typename Refs::Vertex_const_handle      Vertex_const_handle;
    typedef typename Refs::Halfedge                 Halfedge;
    typedef typename Refs::Halfedge_handle          Halfedge_handle;
    typedef typename Refs::Halfedge_const_handle Halfedge_const_handle;
    typedef typename Refs::Face_handle              Face_handle;
```

```
    typedef typename Refs::Face_const_handle     Face_const_handle;
private:
    std::ptrdiff_t  nxt;
public:
    My_halfedge() : nxt(0), f( Face_handle()) {}

    Halfedge_handle opposite() {
        // Halfedge could be different from My_halfedge (e.g. pointer for
        // linked list). Get proper handle from 'this' pointer first, do
        // pointer arithmetic, then convert pointer back to handle again.
        Halfedge_handle h = HDS::halfedge_handle(this); // proper handle
        if ( nxt & 1)
            return HDS::halfedge_handle( &* h + 1);
        return HDS::halfedge_handle( &* h - 1);
    }
    Halfedge_const_handle opposite() const { // same as above
        Halfedge_const_handle h = HDS::halfedge_handle(this); // proper
   handle
        if ( nxt & 1)
            return HDS::halfedge_handle( &* h + 1);
        return HDS::halfedge_handle( &* h - 1);
    }
    Halfedge_handle next() {
        return HDS::halfedge_handle((Halfedge*)(nxt & (~
   std::ptrdiff_t(1))));
    }
    Halfedge_const_handle next() const {
        return HDS::halfedge_handle((const Halfedge*)
                                    (nxt & (~ std::ptrdiff_t(1))));
    }
    void  set_opposite( Halfedge_handle h) {
        CGAL_precondition(( &* h - 1 == &* HDS::halfedge_handle(this)) ||
                          ( &* h + 1 == &* HDS::halfedge_handle(this)));
        if ( &* h - 1 == &* HDS::halfedge_handle(this))
            nxt |= 1;
        else
            nxt &= (~ std::ptrdiff_t(1));
    }
    void  set_next( Halfedge_handle h) {
        CGAL_precondition( ((std::ptrdiff_t)(&*h) & 1) == 0);
        nxt = ((std::ptrdiff_t)(&*h)) | (nxt & 1);
    }
private:    // Support for the Vertex_handle.
    Vertex_handle     v;
public:
    // the incident vertex.
    Vertex_handle          vertex()                      { return v; }
    Vertex_const_handle    vertex() const                { return v; }
    void                   set_vertex( Vertex_handle w) { v = w; }

private:
    Face_handle      f;
public:
    Face_handle            face()                        { return f; }
```

```
    Face_const_handle      face() const                 { return f; }
    void                   set_face( Face_handle g)     { f = g; }
    bool                   is_border() const { return f == Face_handle();
   }
};

// Replace halfedge in the default items type.
struct My_items : public CGAL::HalfedgeDS_items_2 {
    template <class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef My_halfedge<Refs> Halfedge;
    };
};

struct Traits { typedef int Point_2; };
typedef CGAL::HalfedgeDS_vector<Traits, My_items> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS>  Decorator;

int main() {
    HDS hds(1,2,2);
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}
```

26.3.6 Example Using the Halfedge Iterator

Two edges are created in the default halfedge data structure. The halfedge iterator is used to count the halfedges.

```
#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>

struct Traits { typedef int Point_2; };
typedef CGAL::HalfedgeDS_default<Traits> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS>  Decorator;
typedef HDS::Halfedge_iterator           Iterator;

int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    decorator.create_segment();
    CGAL_assertion( decorator.is_valid());
    int n = 0;
    for ( Iterator i = hds.halfedges_begin(); i != hds.halfedges_end();
   ++i )
        ++n;
```

```
    CGAL_assertion( n == 4);  // == 2 edges
    return 0;
}
```

File: examples/HalfedgeDS/hds_prog_halfedge_iterator.cpp

26.3.7 Example for an Adapter to Build an Edge Iterator

Three edges are created in the default halfedge data structure. The adapter *N_step_adaptor* is used to declare the edge iterator used in counting the edges.

```
#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>
#include <CGAL/N_step_adaptor.h>

struct Traits { typedef int Point_2; };
typedef CGAL::HalfedgeDS_default<Traits>            HDS;
typedef CGAL::HalfedgeDS_decorator<HDS>             Decorator;
typedef HDS::Halfedge_iterator                      Halfedge_iterator;
typedef CGAL::N_step_adaptor< Halfedge_iterator, 2> Iterator;

int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    decorator.create_segment();
    CGAL_assertion( decorator.is_valid());
    int n = 0;
    for ( Iterator e = hds.halfedges_begin(); e != hds.halfedges_end();
   ++e)
        ++n;
    CGAL_assertion( n == 2);  // == 2 edges
    return 0;
}
```

Halfedge Data Structure Reference Manual

Lutz Kettner

A halfedge data structure (abbreviated as *HalfedgeDS*, or *HDS* for template parameters) is an edge-centered data structure capable of maintaining incidence information of vertices, edges and faces, for example for planar maps or polyhedral surfaces. It is a combinatorial data structure, geometric interpretation is added by classes built on top of the halfedge data structure. These classes might be more convenient to use than the halfedge data structure directly, since the halfedge data structure is meant as an implementation layer. See for example the *CGAL::Polyhedron_3* class in Chapter 25.6.2.

The data structure provided here is known as the FE-structure [Wei85], as halfedges [Män88, BFH95] or as the doubly connected edge list (DCEL) [dBvKOS97], although the original reference for the DCEL [MP78] describes a related but different data structure. The halfedge data structure can also be seen as one of the variants of the quad-edge data structure [GS85]. In general, the quad-edge data can represent non-orientable 2-manifolds, but the variant here is restricted to orientable 2-manifolds only. An overview and comparison of these different data structures together with a thorough description of the design implemented here can be found in [Ket99].

HalfedgeDS<Traits,Items,Alloc>

Definition

The concept of a halfedge data structure (abbreviated as *HalfedgeDS*, or *HDS* for template parameters) defines an edge-centered data structure capable of maintaining incidence information of vertices, edges, and faces, for example for planar maps or polyhedral surfaces. It is a combinatorial data structure, geometric interpretation is added by classes built on top of the halfedge data structure.

The data structure defined here is known as the FE-structure [Wei85], as halfedges [Män88, BFH95] or as the doubly connected edge list (DCEL) [dBvKOS97], although the original reference for the DCEL [MP78] describes a different data structure. The halfedge data structure can also be seen as one of the variants of the quad-edge data structure [GS85]. In general, the quad-edge data can represent non-orientable 2-manifolds, but the variant here is restricted to orientable 2-manifolds only. An overview and comparison of these different data structures together with a thorough description of the design implemented here can be found in [Ket99].

Each edge is represented by two halfedges with opposite orientations. Each halfedge can store a reference to an incident face and an incident vertex. For each face and each vertex an incident halfedge is stored. Reduced variants of the halfedge data structure can omit some of these incidences, for example the reference to halfedges in vertices or the storage of vertices at all. See Figure 26.2 for the incidences, the mandatory and optional member functions possible for vertices, halfedges, and faces.

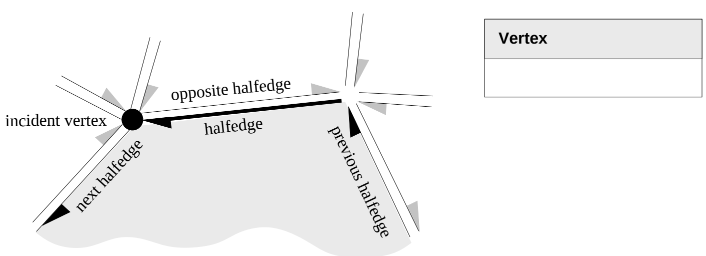

Figure 26.2: The three classes *Vertex*, *Halfedge*, and *Face* of the halfedge data structure. Member functions with shaded background are mandatory. The others are optionally supported.

A HalfedgeDS<Traits,Items,Alloc> organizes the internal storage of its items. Examples are a list-based or a vector-based storage. The HalfedgeDS<Traits,Items,Alloc> exhibits most of the characteristics of the container class used internally, for example the iterator category. A vector resizes automatically when a new item exceeds the reserved space. Since resizing is an expensive operation for a HalfedgeDS<Traits,Items,Alloc> in general and only possible in a well defined state of the data structure (no dangling handles), it must be called explicitly in advance for a HalfedgeDS<Traits,Items,Alloc> before inserting new items beyond the current capacity. Classes built on top of a HalfedgeDS<Traits,Items,Alloc> are advised to call the *reserve()* member function before creating new items.

Parameters

A HalfedgeDS<Traits,Items,Alloc> is a class template and will be used as argument for other class templates, for example *CGAL::Polyhedron_3*. The template parameters to instantiate the HalfedgeDS<Traits,Items,Alloc> will be provided by this other class template. Therefore, the three template parameters and their meaning are mandatory. We distinguish between the template HalfedgeDS<Traits,Items,Alloc> and an instantiation of it.

Traits is a traits class that will be passed to the item types in *Items*. It will not be used in HalfedgeDS< Traits,Items,Alloc> itself. *Items* is a model of the *HalfedgeDSItems* concept. *Alloc* is an allocator that fulfills all requirements of allocators for STL container classes. The *rebind* mechanism from *Alloc* will be used to create appropriate allocators internally. A default argument is mandatory for *Alloc*, for example, the macro *CGAL_ALLOCATOR(int)* from the <*CGAL/memory.h*> header file can be used as default allocator.

Types

HalfedgeDS<Traits,Items,Alloc>:: Traits	traits class.
HalfedgeDS<Traits,Items,Alloc>:: Items	model of *HalfedgeDSItems* concept.
HalfedgeDS<Traits,Items,Alloc>:: size_type	size type.
HalfedgeDS<Traits,Items,Alloc>:: difference_type	difference type.
HalfedgeDS<Traits,Items,Alloc>:: iterator_category	iterator category for all iterators.
HalfedgeDS<Traits,Items,Alloc>:: allocator_type	allocator type *Alloc*.
HalfedgeDS<Traits,Items,Alloc>:: Vertex	model of *HalfedgeDSVertex* concept.
HalfedgeDS<Traits,Items,Alloc>:: Halfedge	model of *HalfedgeDSHalfedge* concept.
HalfedgeDS<Traits,Items,Alloc>:: Face	model of *HalfedgeDSFace* concept.

The following handles and iterators have appropriate non-mutable counterparts, i.e., *const_handle* and *const_iterator*. The mutable types are assignable to their non-mutable counterparts. The iterators are assignable to the respective handle types. Wherever the handles appear in function parameter lists, the corresponding iterators can be used as well. **Note:** The handle types must have a default constructor that creates a unique and always the same handle value. It will be used in analogy to *NULL* for pointers.

HalfedgeDS<Traits,Items,Alloc>:: Vertex_handle	handle to vertex.
HalfedgeDS<Traits,Items,Alloc>:: Halfedge_handle	handle to halfedge.
HalfedgeDS<Traits,Items,Alloc>:: Face_handle	handle to face.
HalfedgeDS<Traits,Items,Alloc>:: Vertex_iterator	iterator over all vertices.
HalfedgeDS<Traits,Items,Alloc>:: Halfedge_iterator	iterator over all halfedges.
HalfedgeDS<Traits,Items,Alloc>:: Face_iterator	iterator over all faces.

advanced

Types for Tagging Optional Features

The following types are equal to either *CGAL::Tag_true* or *CGAL::Tag_false*, depending on whether the named feature is supported or not.

HalfedgeDS<Traits,Items,Alloc>:: Supports_vertex_halfedge	*Vertex::halfedge()*.
HalfedgeDS<Traits,Items,Alloc>:: Supports_halfedge_prev	*Halfedge::prev()*.
HalfedgeDS<Traits,Items,Alloc>:: Supports_halfedge_vertex	*Halfedge::vertex()*.
HalfedgeDS<Traits,Items,Alloc>:: Supports_halfedge_face	*Halfedge::face()*.
HalfedgeDS<Traits,Items,Alloc>:: Supports_face_halfedge	*Face::halfedge()*.
HalfedgeDS<Traits,Items,Alloc>:: Supports_removal	removal of individual elements.

The following dependencies among these options must be regarded:

Vertices are supported $\Longleftrightarrow$ *Supports_halfedge_vertex* $\equiv$ *CGAL::Tag_true*.
Faces are supported $\Longleftrightarrow$ *Supports_halfedge_face* $\equiv$ *CGAL::Tag_true*.
Supports_vertex_halfedge $\equiv$ *CGAL::Tag_true* $\Longrightarrow$ *Supports_halfedge_vertex* $\equiv$ *CGAL::Tag_true*.
Supports_vertex_point $\equiv$ *CGAL::Tag_true* $\Longrightarrow$ *Supports_halfedge_vertex* $\equiv$ *CGAL::Tag_true*.
Supports_face_halfedge $\equiv$ *CGAL::Tag_true* $\Longrightarrow$ *Supports_halfedge_face* $\equiv$ *CGAL::Tag_true*.

advanced

Static Member Functions

When writing an items type, such as a user defined vertex, certain functions need to create a handle but knowing only a pointer, for example, the *this*-pointer. The following static member functions of HalfedgeDS< Traits,Items,Alloc> create such a corresponding handle for an item type from a pointer. This conversion encapsulates possible adjustments for hidden data members in the true item type, such as linked-list pointers. Note that the user provides item types with the *Items* template argument, which may differ from the *Vertex*, *Halfedge*, and *Face* types defined in HalfedgeDS<Traits,Items,Alloc>. If they differ, they are derived from the user provided item types. We denote the user item types with *Vertex_base*, *Halfedge_base*, and *Face_base* in the following. The fully qualified name for *Vertex_base* would be for example – assuming that the type *Self* refers to the instantiated *HalfedgeDS* –

```
typedef typename Items::template Vertex_wrapper<Self,Traits> Vertex_wrapper;
typedef typename Vertex_wrapper::Vertex Vertex_base;
```

Implementing these functions relies on the fundamental assumption that an iterator (or handle) of the internally used container class can be constructed from a pointer of a contained item only. This is true and controlled by us for *CGAL::In_place_list*. It is true for the *std::vector* of major STL distributions, but not necessarily guaranteed. We might switch to an internal implementation if need arises.

static Vertex_handle	*HalfedgeDS::vertex_handle(Vertex_base* v)*
static Vertex_const_handle	*HalfedgeDS::vertex_handle(const Vertex_base* v)*
static Halfedge_handle	*HalfedgeDS::halfedge_handle(Halfedge_base* h)*
static Halfedge_const_handle	*HalfedgeDS::halfedge_handle(const Halfedge_base* h)*
static Face_handle	*HalfedgeDS::face_handle(Face_base* f)*
static Face_const_handle	*HalfedgeDS::face_handle(const Face_items* f)*

advanced

Creation

HalfedgeDS<Traits,Items,Alloc> hds; — empty halfedge data structure.

HalfedgeDS<Traits,Items,Alloc> hds(size_type v, size_type h, size_type f);

storage reserved for v vertices, h halfedges, and f faces.

HalfedgeDS<Traits,Items,Alloc> hds(hds2); — copy constructor.
Precondition: *hds2* contains no dangling handles.

HalfedgeDS<Traits,Items,Alloc>& $hds = hds2$ — assignment operator.
Precondition: *hds2* contains no dangling handles.

void *hds.reserve(size_type v, size_type h, size_type f)*

reserves storage for v vertices, h halfedges, and f faces. If all capacities are already greater or equal than the requested sizes nothing happens. Otherwise, *hds* will be resized and all handles, iterators and circulators invalidate.
Precondition: If resizing is necessary *hds* contains no dangling handles.

Access Member Functions

Size	*hds.size_of_vertices() const*	number of vertices.
Size	*hds.size_of_halfedges() const*	number of halfedges.
Size	*hds.size_of_faces() const*	number of faces.
Size	*hds.capacity_of_vertices() const*	space reserved for vertices.
Size	*hds.capacity_of_halfedges() const*	space reserved for halfedges.
Size	*hds.capacity_of_faces() const*	space reserved for faces.
size_t	*hds.bytes() const*	bytes used for *hds*.
size_t	*hds.bytes_reserved() const*	bytes reserved for *hds*.
allocator_type	*hds.get_allocator() const*	allocator object.

The following member functions return the non-mutable iterator if *hds* is declared const.

Vertex_iterator	*hds.vertices_begin()*	iterator over all vertices.
Vertex_iterator	*hds.vertices_end()*	
Halfedge_iterator	*hds.halfedges_begin()*	iterator over all halfedges

Halfedge_iterator	*hds.halfedges_end()*	
Face_iterator	*hds.faces_begin()*	iterator over all faces.
Face_iterator	*hds.faces_end()*	

Insertion

Note that the vertex-related and the face-related member functions may not be provided for a HalfedgeDS< Traits,Items,Alloc> that does not support vertices or faces respectively.

Vertex_handle *hds.vertices_push_back(const Vertex& v)*

appends a copy of v to *hds*. Returns a handle of the new vertex.

Halfedge_handle *hds.edges_push_back(const Halfedge& h, const Halfedge& g)*

appends a copy of h and a copy of g to *hds* and makes them opposite to each other. Returns a handle of the copy of h.

Halfedge_handle *hds.edges_push_back(const Halfedge& h)*

appends a copy of h and a copy of $h->opposite()$ to *hds* and makes them opposite to each other. Returns a handle of the copy of h.
Precondition: *h->opposite()* denotes a halfedge.

Face_handle *hds.faces_push_back(const Face& f)*

appends a copy of f to *hds*. Returns a handle of the new face.

Removal

Erasing single elements is optional and indicated with the type tag *Supports_removal*. The *pop_back* and the *clear* member functions are mandatory. If vertices or faces are not supported for a HalfedgeDS< Traits,Items,Alloc> the *pop_back* and the *clear* member functions must be provided as null operations.

void	*hds.vertices_pop_front()*	removes the first vertex if vertices are supported and *Supports_removal* $\equiv$ *CGAL::Tag_true*.
void	*hds.vertices_pop_back()*	removes the last vertex.
void	*hds.vertices_erase(Vertex_handle v)*	removes the vertex v if vertices are supported and *Supports_removal* $\equiv$ *CGAL::Tag_true*.

void *hds.vertices_erase(Vertex_handle first, Vertex_handle last)*

removes the range of vertices $[first, last)$ if vertices are supported and *Supports_removal* $\equiv$ *CGAL::Tag_true*.

void	*hds.edges_pop_front()*	removes the first two halfedges if *Supports_removal* $\equiv$ *CGAL::Tag_true*.
void	*hds.edges_pop_back()*	removes the last two halfedges.
void	*hds.edges_erase(Halfedge_handle h)*	removes the pair of halfedges *h* and *h->opposite()* if *Supports_removal* $\equiv$ *CGAL::Tag_true*.
void	*hds.edges_erase(Halfedge_handle first, Halfedge_handle last)*	
		removes the range of edges $[first, last)$ if *Supports_removal* $\equiv$ *CGAL::Tag_true*.
void	*hds.faces_pop_front()*	removes the first face if faces are supported and *Supports_removal* $\equiv$ *CGAL::Tag_true*.
void	*hds.faces_pop_back()*	removes the last face.
void	*hds.faces_erase(Face_handle f)*	removes the face *f* if faces are supported and *Supports_removal* $\equiv$ *CGAL::Tag_true*.
void	*hds.faces_erase(Face_handle first, Face_handle last)*	
		removes the range of faces $[first, last)$ if faces are supported and *Supports_removal* $\equiv$ *CGAL::Tag_true*.
void	*hds.vertices_clear()*	removes all vertices.
void	*hds.edges_clear()*	removes all halfedges.
void	*hds.faces_clear()*	removes all faces.
void	*hds.clear()*	removes all elements.

advanced

Operations with Border Halfedges

The following notion of *border halfedges* is particular useful where the halfedge data structure is used to model surfaces with boundary, i.e., surfaces with missing faces or open regions. Halfedges incident to an open region are called *border halfedges*. A halfedge is a *border edge* if the halfedge itself or its opposite halfedge is a border halfedge. The only requirement to work with border halfedges is that the *Halfedge* class provides a member function *is_border()* returning a *bool*. Usually, the halfedge data structure supports faces and the value of the default constructor of the face handle will indicate a border halfedge, but this may not be the only possibility. The *is_border()* predicate divides the edges into two classes, the border edges and the non-border edges. The following normalization reorganizes the sequential storage of the edges such that the non-border edges precede the border edges, and that for each border edge the latter of the two halfedges is a border halfedge (the first one might be a border halfedge too). The normalization stores the number of border halfedges, as well as the halfedge iterator where the border edges start at, within the halfedge data structure. These values will be invalid after further halfedge insertions or removals and changes in the border status of a halfedge. There is no automatic update required.

void *hds.normalize_border()*

sorts halfedges such that the non-border edges precede the border edges. For each border edge that is incident to a face, the halfedge iterator will reference the halfedge incident to the face right before the halfedge incident to the open region.

Size *hds.size_of_border_halfedges() const*

number of border halfedges. An edge with no incident face counts as two border halfedges.
Precondition: *normalize_border()* has been called and no halfedge insertion or removal and no change in border status of the halfedges have occurred since then.

Size *hds.size_of_border_edges() const*

number of border edges. If *size_of_border_edges()* is equal to *size_of_border_halfedges()* all border edges are incident to a face on one side and to an open region on the other side.
Precondition: *normalize_border()* has been called and no halfedge insertion or removal and no change in border status of the halfedges have occurred since then.

Halfedge_iterator *hds.border_halfedges_begin()*

halfedge iterator starting with the border edges. The range [*halfedges_begin(), border_halfedges_begin()*) denotes all non-border edges. The range [*border_halfedges_begin(), halfedges_end()*) denotes all border edges.
Precondition: *normalize_border()* has been called and no halfedge insertion or removal and no change in border status of the halfedges have occurred since then.

Concept

HalfedgeDSFace

Definition

The concept HalfedgeDSFace defines the requirements for the local *Face* type in the *HalfedgeDS* concept. It is also required in the *Face_wrapper<Refs,Traits>* member class template of an items class, see the *HalfedgeDSItems* concept.

A face optionally stores a reference to an incident halfedge that points to the face. A type tag indicates whether the related member functions are supported. Figure 26.3 depicts the relationship between a halfedge and its incident halfedges, vertices, and faces.

For the protection of the integrity of the data structure classes such as *CGAL::Polyhedron_3* are allowed to redefine the modifying member functions to be private. In order to make them accessible for the halfedge data structure they must be derived from a base class *Base* where the modifying member functions are still public. (The protection can be bypassed by the user, but not by accident.)

Types

HalfedgeDSFace:: HalfedgeDS	instantiated *HalfedgeDS* ($\equiv$ *Refs*).
HalfedgeDSFace:: Base	base class that allows modifications.
HalfedgeDSFace:: Vertex	model of *HalfedgeDSVertex*.
HalfedgeDSFace:: Halfedge	model of *HalfedgeDSHalfedge*.
HalfedgeDSFace:: Vertex_handle	handle to vertex.
HalfedgeDSFace:: Halfedge_handle	handle to halfedge.
HalfedgeDSFace:: Face_handle	handle to face.
HalfedgeDSFace:: Vertex_const_handle	
HalfedgeDSFace:: Halfedge_const_handle	
HalfedgeDSFace:: Face_const_handle	
HalfedgeDSFace:: Supports_face_halfedge	*CGAL::Tag_true* or *CGAL::Tag_false*.

Creation

HalfedgeDSFace f;	default constructor.

Operations available if *Supports_face_halfedge* $\equiv$ *CGAL::Tag_true*

Halfedge_handle	f*.halfedge()*	
Halfedge_const_handle	f*.halfedge() const*	incident halfedge that points to f.
void	f*.set_halfedge(Halfedge_handle h)*	sets incident halfedge to h.

HalfedgeDSHalfedge

Definition

The concept HalfedgeDSHalfedge defines the requirements for the local *Halfedge* type in the *HalfedgeDS* concept. It is also required in the *Halfedge_wrapper<Refs,Traits>* member class template of an items class, see the *HalfedgeDSItems* concept.

A halfedge is an oriented edge between two vertices. It is always paired with a halfedge pointing in the opposite direction. The *opposite()* member function returns this halfedge of opposite orientation. The *next()* member function points to the successor halfedge along the face – or if the halfedge is a border halfedge – along the open region. A halfedge optionally stores a reference to the previous halfedge along the face, a reference to an incident vertex, and a reference to an incident face. Type tags indicate whether the related member functions are supported. Figure 26.3 depicts the relationship between a halfedge and its incident halfedges, vertices, and faces.

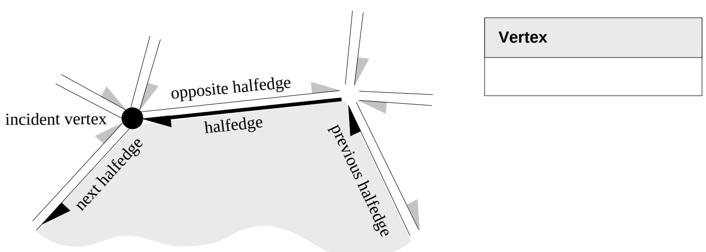

Figure 26.3: The three classes *Vertex*, *Halfedge*, and *Face* of the halfedge data structure. Member functions with shaded background are mandatory. The others are optionally supported.

For the protection of the integrity of the data structure classes such as *CGAL::Polyhedron_3* are allowed to redefine the modifying member functions to be private. In order to make them accessible for the halfedge data structure they must be derived from a base class *Base* where the modifying member functions are still public. Even more protection is provided for the *set_opposite()* member function. The base class *Base_base* provides access to it. (The protection could be bypassed also by an user, but not by accident.)

Types

HalfedgeDSHalfedge:: HalfedgeDS	instantiated *HalfedgeDS* ($\equiv$ *Refs*).
HalfedgeDSHalfedge:: Base	base class that allows modifications.
HalfedgeDSHalfedge:: Base_base	base class to access *set_opposite()*.
HalfedgeDSHalfedge:: Vertex	model of *HalfedgeDSVertex*.
HalfedgeDSHalfedge:: Face	model of *HalfedgeDSFace*.
HalfedgeDSHalfedge:: Vertex_handle	handle to vertex.
HalfedgeDSHalfedge:: Halfedge_handle	handle to halfedge.
HalfedgeDSHalfedge:: Face_handle	handle to face.
HalfedgeDSHalfedge:: Vertex_const_handle	
HalfedgeDSHalfedge:: Halfedge_const_handle	
HalfedgeDSHalfedge:: Face_const_handle	
HalfedgeDSHalfedge:: Supports_halfedge_prev	*CGAL::Tag_true* or *CGAL::Tag_false*.

HalfedgeDSHalfedge:: Supports_halfedge_vertex	~
HalfedgeDSHalfedge:: Supports_halfedge_face	~

Creation

HalfedgeDSHalfedge h;	default constructor.

Operations

Halfedge_handle	*h.opposite()*	
Halfedge_const_handle	*h.opposite() const*	the opposite halfedge.
void	*h.set_opposite(Halfedge_handle h)*	sets opposite halfedge to *h*.
Halfedge_handle	*h.next()*	
Halfedge_const_handle	*h.next() const*	the next halfedge around the face.
void	*h.set_next(Halfedge_handle h)*	sets next halfedge to *h*.
bool	*h.is_border() const*	is true if *h* is a border halfedge.

Operations available if *Supports_halfedge_prev* ≡ *CGAL::Tag_true*

Halfedge_handle	*h.prev()*	
Halfedge_const_handle	*h.prev() const*	the previous halfedge around the face.
void	*h.set_prev(Halfedge_handle h)*	sets prev halfedge to *h*.

Operations available if *Supports_halfedge_vertex* ≡ *CGAL::Tag_true*

Vertex_handle	*h.vertex()*	
Vertex_const_handle	*h.vertex() const*	the incident vertex of *h*.
void	*h.set_vertex(Vertex_handle v)*	sets incident vertex to *v*.

Operations available if *Supports_halfedge_face* ≡ *CGAL::Tag_true*

Face_handle	*h.face()*	
Face_const_handle	*h.face() const*	the incident face of *h*. If *h* is a border halfedge the result is default construction of the handle.
void	*h.set_face(Face_handle f)*	sets incident face to *f*.

Concept

HalfedgeDSItems

Definition

The concept HalfedgeDSItems wraps the three item types – vertex, halfedge, and face – for a halfedge data structure. A HalfedgeDSItems contains three member class templates named *Vertex_wrapper*, *Halfedge_wrapper*, and *Face_wrapper*, each with two template parameters, *Refs* and *Traits*. *Refs* requires an instantiated halfedge data structure *HalfedgeDS* as argument, *Traits* is a geometric traits class supplied by the class that uses the halfedge data structure as internal representation. *Traits* is not used by the halfedge data structure itself. These three member class templates provide a local type named *Vertex*, *Halfedge*, and *Face* respectively. The requirements on these types are described on page 1856, page 1852, and page 1850 respectively.

Types

HalfedgeDSItems:: Vertex_wrapper<Refs,Traits>::Vertex	model of *HalfedgeDSVertex*.
HalfedgeDSItems:: Halfedge_wrapper<Refs,Traits>::Halfedge	model of *HalfedgeDSHalfedge*.
HalfedgeDSItems:: Face_wrapper<Refs,Traits>::Face	model of *HalfedgeDSFace*.

CGAL::HalfedgeDS_face_base<Refs> . . . . page 1868

Example

The following example shows the canonical implementation of the *CGAL::HalfedgeDS_min_items* class. It uses the base classes for the item types that are provided in the library.

```
struct HalfedgeDS_min_items {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef CGAL::HalfedgeDS_vertex_min_base< Refs>   Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef CGAL::HalfedgeDS_halfedge_min_base< Refs> Halfedge;
```

```
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef CGAL::HalfedgeDS_face_min_base< Refs>     Face;
    };
};
```

See page 1873 for an example implementation of the *CGAL::HalfedgeDS_items_2* class.

HalfedgeDSVertex

Definition

The concept HalfedgeDSVertex defines the requirements for the local *Vertex* type in the *HalfedgeDS* concept. It is also required in the *Vertex_wrapper<Refs,Traits>* member class template of an items class, see the *HalfedgeDSItems* concept.

A vertex optionally stores a reference to an incident halfedge that points to the vertex. A type tag indicates whether the related member functions are supported. Figure 26.3 depicts the relationship between a halfedge and its incident halfedges, vertices, and faces.

For the protection of the integrity of the data structure classes such as *CGAL::Polyhedron_3* are allowed to redefine the modifying member functions to be private. In order to make them accessible for the halfedge data structure they must be derived from a base class *Base* where the modifying member functions are still public. (The protection could be bypassed by an user, but not by accident.)

Types

HalfedgeDSVertex:: HalfedgeDS	instantiated *HalfedgeDS* ($\equiv$ *Refs*).
HalfedgeDSVertex:: Base	base class that allows modifications.
HalfedgeDSVertex:: Halfedge	model of *HalfedgeDSHalfedge*.
HalfedgeDSVertex:: Face	model of *HalfedgeDSFace*.
HalfedgeDSVertex:: Vertex_handle	handle to vertex.
HalfedgeDSVertex:: Halfedge_handle	handle to halfedge.
HalfedgeDSVertex:: Face_handle	handle to face.
HalfedgeDSVertex:: Vertex_const_handle	
HalfedgeDSVertex:: Halfedge_const_handle	
HalfedgeDSVertex:: Face_const_handle	
HalfedgeDSVertex:: Supports_vertex_halfedge	*CGAL::Tag_true* or *CGAL::Tag_false*.

Creation

HalfedgeDSVertex v;	default constructor.

Operations available if *Supports_vertex_halfedge* $\equiv$ *CGAL::Tag_true*

Halfedge_handle	*v.halfedge()*	
Halfedge_const_handle	*v.halfedge() const*	incident halfedge that points to *v*.
void	*v.set_halfedge(Halfedge_handle h)*	sets incident halfedge to *h*.

Class

CGAL::HalfedgeDS_const_decorator<HDS>

Definition

The classes *CGAL::HalfedgeDS_items_decorator<HDS>*, *CGAL::HalfedgeDS_decorator<HDS>*, and *CGAL::HalfedgeDS_const_decorator<HDS>* provide additional functions to examine and to modify a halfedge data structure *HDS*. The class *CGAL::HalfedgeDS_items_decorator<HDS>* provides additional functions for vertices, halfedges, and faces of a halfedge data structure without knowing the containing halfedge data structure. The class *CGAL::HalfedgeDS_decorator<HDS>* stores a reference to the halfedge data structure and provides functions that modify the halfedge data structure, for example Euler-operators. The class *CGAL::HalfedgeDS_const_decorator<HDS>* stores a const reference to the halfedge data structure. It contains non-modifying functions, for example the test for validness of the data structure.

All these additional functions take care of the different capabilities a halfedge data structure may have or may not have. The functions evaluate the type tags of the halfedge data structure to decide on the actions. If a particular feature is not supported nothing is done. Note that for example the creation of new halfedges is mandatory for all halfedge data structures and will not appear here again.

#include <CGAL/HalfedgeDS_const_decorator.h>

Inherits From

CGAL::HalfedgeDS_items_decorator<HDS> . . . . page 1875

Creation

HalfedgeDS_const_decorator<HDS> D(const HDS& hds);

keeps internally a const reference to *hds*.

Validness Checks

A halfedge data structure has no definition of validness of its own, but a useful set of tests is defined with the following levels:

Level 0 The number of halfedges is even. All pointers except the vertex pointer and the face pointer for border halfedges are unequal to their respective default construction value. For all halfedges h: The opposite halfedge is different from h and the opposite of the opposite is equal to h. The next of the previous halfedge is equal to h. For all vertices v: the incident vertex of the incident halfedge of v is equal to v. The halfedges around v starting with the incident halfedge of v form a cycle. For all faces f: the incident face of the incident halfedge of f is equal to f. The halfedges around f starting with the incident halfedge of f form a cycle. Redundancies among internal variables are tested, e.g., that iterators enumerate as many items as the related size value indicates.

Level 1 All tests of level 0. For all halfedges h: The incident vertex of h exists and is equal to the incident vertex of the opposite of the next halfedge. The incident face (or hole) of h is equal to the incident face (or hole) of the next halfedge.

Level 2 All tests of level 1. The sum of all halfedges that can be reached through the vertices must be equal to the number of all halfedges, i.e., all halfedges incident to a vertex must form a single cycle.

Level 3 All tests of level 2. The sum of all halfedges that can be reached through the faces must be equal to the number of all halfedges, i.e., all halfedges surrounding a face must form a single cycle (no holes in faces).

Level 4 All tests of level 3 and *normalized_border_is_valid*.

bool

D.is_valid(bool verbose = false, int level = 0) const

returns *true* if the halfedge data structure *hds* is valid with respect to the *level* value as defined above. If *verbose* is *true*, statistics are written to *cerr*.

bool

D.normalized_border_is_valid(bool verbose = false) const

returns *true* if the border halfedges are in normalized representation, which is when enumerating all halfedges with the halfedge iterator the following holds: The non-border edges precede the border edges. For border edges, the second halfedge is a border halfedge. (The first halfedge may or may not be a border halfedge.) The halfedge iterator *border_halfedges_begin()* denotes the first border edge. If *verbose* is *true*, statistics are written to *cerr*.

CGAL::HalfedgeDS_decorator<HDS> . . . . page 1860

Example

The following program fragment illustrates the implementation of a *is_valid()* member function for a simplified polyhedron class. We assume here that the level three check is the appropriate default for polyhedral surfaces.

```
namespace CGAL {
    template <class Traits>
    class Polyhedron {
        typedef HalfedgeDS_default<Traits> HDS;
        HDS hds;
    public:
        // ...
        bool is_valid( bool verb = false, int level = 0) const {
            Verbose_ostream verr(verb);
            verr << "begin Polyhedron::is_valid( verb=true, level = " <<
   level
                 << "):" << std::endl;
            HalfedgeDS_const_decorator<HDS> decorator(hds);
            bool valid = decorator.is_valid( verb, level + 3);
            // further checks ...
        }
    };
}
```

Class

CGAL::HalfedgeDS_decorator<HDS>

Definition

The classes *CGAL::HalfedgeDS_items_decorator<HDS>*, *CGAL::HalfedgeDS_decorator<HDS>*, and *CGAL::HalfedgeDS_const_decorator<HDS>* provide additional functions to examine and to modify a halfedge data structure *HDS*. The class *CGAL::HalfedgeDS_items_decorator<HDS>* provides additional functions for vertices, halfedges, and faces of a halfedge data structure without knowing the containing halfedge data structure. The class *CGAL::HalfedgeDS_decorator<HDS>* stores a reference to the halfedge data structure and provides functions that modify the halfedge data structure, for example Euler-operators. The class *CGAL::HalfedgeDS_const_decorator<HDS>* stores a const reference to the halfedge data structure. It contains non-modifying functions, for example the test for validness of the data structure.

All these additional functions take care of the different capabilities a halfedge data structure may have or may not have. The functions evaluate the type tags of the halfedge data structure to decide on the actions. If a particular feature is not supported nothing is done. Note that for example the creation of new halfedges is mandatory for all halfedge data structures and will not appear here again.

#include <CGAL/HalfedgeDS_decorator.h>

Inherits From

CGAL::HalfedgeDS_items_decorator<HDS> . . . . page 1875

Creation

HalfedgeDS_decorator<HDS> D(HDS& hds);	keeps internally a reference to *hds*.

Creation of New Items

Vertex_handle	*D.vertices_push_back(Vertex v)*	appends a copy of *v* to *hds* if vertices are supported. Returns a handle of the new vertex, or *Vertex_handle()* otherwise.
Face_handle	*D.faces_push_back(Face f)*	appends a copy of *f* to *hds* if faces are supported. Returns a handle of the new face, or *Face_handle()* otherwise.

Creation of New Composed Items

Halfedge_handle	*D.create_loop()*	returns handle of a halfedge from a newly created loop in *hds* consisting of a single closed edge, one vertex and two faces (if supported respectively).
Halfedge_handle	*D.create_segment()*	returns a halfedge from a newly created segment in *hds* consisting of a single open edge, two vertices and one face (if supported respectively).

Removal of Elements

The following member functions do *not* update affected incidence relations except if mentioned otherwise.

void	*D.vertices_pop_front()*	removes the first vertex if vertices are supported. *Requirement*: *Supports_removal* $\equiv$ *CGAL::Tag_true*.
void	*D.vertices_pop_back()*	removes the last vertex if vertices are supported.
void	*D.vertices_erase(Vertex_handle v)*	removes the vertex v if vertices are supported. *Requirement*: *Supports_removal* $\equiv$ *CGAL::Tag_true*.
void	*D.vertices_erase(Vertex_handle first, Vertex_handle last)*	removes the range $[first, last)$ if vertices are supported. *Requirement*: *Supports_removal* $\equiv$ *CGAL::Tag_true*.
void	*D.faces_pop_front()*	removes the first face if faces are supported. *Requirement*: *Supports_removal* $\equiv$ *CGAL::Tag_true*.
void	*D.faces_pop_back()*	removes the last face if faces are supported.
void	*D.faces_erase(Face_handle f)*	removes the face f if faces are supported. *Requirement*: *Supports_removal* $\equiv$ *CGAL::Tag_true*.
void	*D.faces_erase(Face_handle first, Face_handle last)*	removes the range $[first, last)$ if faces are supported. *Requirement*: *Supports_removal* $\equiv$ *CGAL::Tag_true*.
void	*D.erase_face(Halfedge_handle h)*	removes the face incident to h from *hds* and changes all halfedges incident to the face into border edges or removes them from the halfedge data structure if they were already border edges. If this creates isolated vertices they get removed as well. See *make_hole(h)* for a more specialized variant. *Precondition*: *h->is_border() == false*. *Requirement*: If faces are supported, *Supports_removal* $\equiv$ *CGAL::Tag_true*.
void	*D.erase_connected_component(Halfedge_handle h)*	removes the vertices, halfedges, and faces that belong to the connected component of h. *Precondition*: For all halfedges g in the connected component *g.next() != Halfedge_handle()*. *Requirement*: *Supports_removal* $\equiv$ *CGAL::Tag_true*.
unsigned int	*D.keep_largest_connected_components(unsigned int nb_components_to_keep)*	Erases the small connected components and the isolated vertices. Keep *nb_components_to_keep* largest connected components. Returns the number of connected components erased (ignoring isolated vertices). *Requirement*: supports vertices, halfedges, and removal operation.

Modifying Functions (For Border Halfedges)

void *D.make_hole(Halfedge_handle h)*

removes the face incident to *h* from *hds* and creates a hole.
Precondition: *h != Halfedge_handle()* and *!(h->is_border())*.
Requirement: If faces are supported, *Supports_removal* ≡ *CGAL::Tag_true*.

Halfedge_handle *D.fill_hole(Halfedge_handle h)*

fills the hole incident to *h* with a new face from *hds*. Returns *h*.
Precondition: *h != Halfedge_handle()* and *h->is_border()*.

Halfedge_handle *D.fill_hole(Halfedge_handle h, Face f)*

fills the hole incident to *h* with a copy of face f. Returns *h*.
Precondition: *h != Halfedge_handle()* and *h->is_border()*.

Halfedge_handle *D.add_face_to_border(Halfedge_handle h, Halfedge_handle g)*

extends the surface with a new face from *hds* into the hole incident to *h* and *g*. It creates a new edge connecting the vertex denoted by *g* with the vertex denoted by *h* and fills this separated part of the hole with a new face, such that the new face is incident to *g*. Returns the new halfedge that is incident to the new face.
Precondition: *h != Halfedge_handle()*, *g != Halfedge_handle()*, *h->is_border()*, *g->is_border()* and *g* can be reached along the hole starting with *h*.

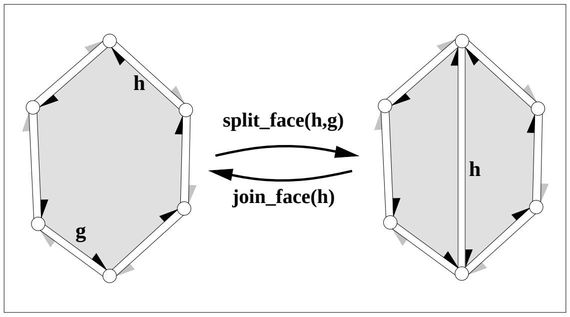
Halfedge_handle *D.add_face_to_border(Halfedge_handle h, Halfedge_handle g, Face f)*

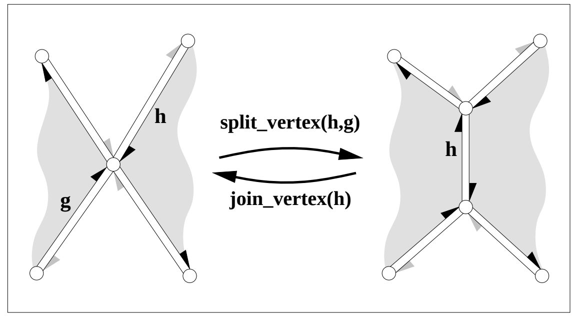
extends the surface with a copy of face f into the hole incident to *h* and *g*. It creates a new edge connecting the tip of *g* with the tip of *h* and fills this separated part of the hole with a copy of face f, such that the new face is incident to *g*. Returns the new halfedge that is incident to the new face.
Precondition: *h != Halfedge_handle()*, *g != Halfedge_handle()*, *h->is_border()*, *g->is_border()* and *g* can be reached along the hole starting with *h*.

Modifying Functions (Euler Operators)

The following Euler operations modify consistently the combinatorial structure of the halfedge data structure. The geometry remains unchanged. Note that well known graph operations are also captured with these Euler operators, for example an edge contraction is equal to a *join_vertex()* operation, or an edge removal to *join_face()*.

Given a halfedge data structure *hds* and a halfedge handle *h* four special applications of the Euler operators are worth mentioning: *split_vertex(h,h)* results in an antenna emanating from the tip of *h*; *split_vertex(h,h->next()->opposite())* results in an edge split of the halfedge *h->next* with a new vertex in-between; *split_face(h,h)* results in a loop directly following *h*; and *split_face(h,h->next())* results in a bridge parallel to the halfedge *h->next* with a new face in-between.





Halfedge_handle   *D.split_face(Halfedge_handle h, Halfedge_handle g)*

splits the face incident to *h* and *g* into two faces with a new diagonal between the two vertices denoted by *h* and *g* respectively. The second (new) face obtained from *hds* is a copy of the first face. Returns *h->next()* after the operation, i.e., the new diagonal. The new face is to the right of the new diagonal, the old face is to the left. The time is proportional to the distance from *h* to *g* around the face.

Halfedge_handle   *D.join_face(Halfedge_handle h)*

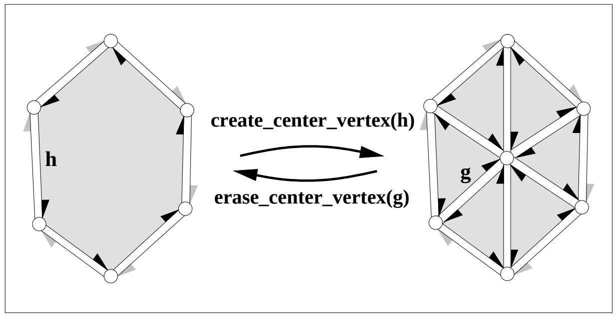
joins the two faces incident to *h*. The face incident to *h->opposite()* gets removed from *hds*. Both faces might be holes. Returns the predecessor of *h* around the face. The invariant *join_face(split_face(h, g))* returns *h* and keeps the data structure unchanged. The time is proportional to the size of the face removed and the time to compute *h->prev()*.
Requirement: *Supports_removal* $\equiv$ *CGAL::Tag_true*.

Halfedge_handle   *D.split_vertex(Halfedge_handle h, Halfedge_handle g)*

splits the vertex incident to *h* and *g* into two vertices and connects them with a new edge. The second (new) vertex obtained from *hds* is a copy of the first vertex. Returns *h->next()->opposite()* after the operation, i.e., the new edge in the orientation towards the new vertex. The time is proportional to the distance from *h* to *g* around the vertex.

Halfedge_handle   *D.join_vertex(Halfedge_handle h)*

joins the two vertices incident to *h*. The vertex denoted by *h->opposite()* gets removed by *hds*. Returns the predecessor of *h* around the vertex, i.e., *h->opposite()->prev()*. The invariant *join_vertex(split_vertex(h, g))* returns *h* and keeps the polyhedron unchanged. The time is proportional to the degree of the vertex removed and the time to compute *h->prev()* and *h->opposite()->prev()*.
Requirement: *Supports_removal* $\equiv$ *CGAL::Tag_true*.

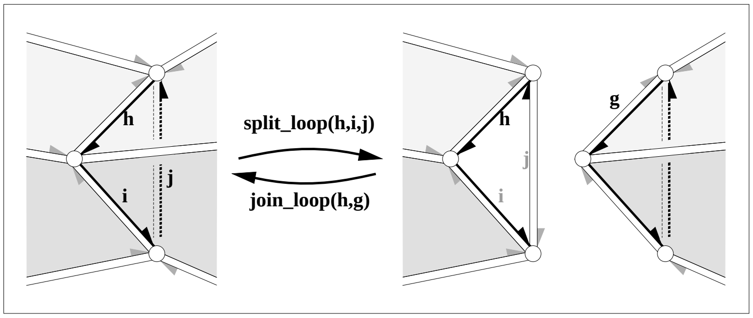


Halfedge_handle *D.create_center_vertex(Halfedge_handle h)*

barycentric triangulation of *h->face()*. Creates a new vertex, a copy of *h->vertex()*, and connects it to each vertex incident to *h->face()* splitting *h->face()* into triangles. *h* remains incident to the original face, all other triangles are copies of this face. Returns the halfedge *h->next()* after the operation, i.e., a halfedge pointing to the new vertex. The time is proportional to the size of the face.
Precondition: *h* is not a border halfedge.

Halfedge_handle *D.erase_center_vertex(Halfedge_handle g)*

reverses *create_center_vertex*. Erases the vertex pointed to by *g* and all incident halfedges thereby merging all incident faces. Only *g->face()* remains. The neighborhood of *g->vertex()* may not be triangulated, it can have larger faces. Returns the halfedge *g->prev()*. Thus, the invariant *h* == *erase_center_vertex(create_center_vertex(h))* holds if *h* is not a border halfedge. The time is proportional to the sum of the size of all incident faces.
Precondition: None of the incident faces of *g->vertex()* is a hole. There are at least two distinct faces incident to the faces that are incident to *g->vertex()*. (This prevents the operation from collapsing a volume into two faces glued together with opposite orientations, such as would happen with any vertex of a tetrahedron.)
Requirement: *Supports_removal* $\equiv$ *CGAL::Tag_true*.



Halfedge_handle *D.split_loop(Halfedge_handle h, Halfedge_handle i, Halfedge_handle j)*

cuts the halfedge data structure into two parts along the cycle (h,i,j). Three new vertices (one copy for each vertex in the cycle) and three new halfedges (one copy for each halfedge in the cycle), and two new triangles are created. h,i,j will be incident to the first new triangle. The return value will be the halfedge incident to the second new triangle which is the copy of *h-opposite()*.
Precondition: h,i,j denote distinct, consecutive vertices of the halfedge data structure and form a cycle: i.e., *h->vertex() == i->opposite()->vertex()*, ..., *j->vertex() == h->opposite()->vertex()*.

Halfedge_handle *D.join_loop(Halfedge_handle h, Halfedge_handle g)*

glues the boundary of the two faces denoted by *h* and *g* together and returns *h*. Both faces and the vertices along the face denoted by *g* gets removed. Both faces may be holes. The invariant *join_loop(h, split_loop(h, i, j))* returns *h* and keeps the data structure unchanged.
Precondition: The faces denoted by *h* and *g* are different and have equal degree (i.e., number of edges).
Requirement: *Supports_removal* $\equiv$ *CGAL::Tag_true*.

Validness Checks

These operations are the same as for *CGAL::HalfedgeDS_const_decorator<HDS>*. See their documentation on page 1858.

bool *D.is_valid(bool verbose = false, int level = 0) const*

bool *D.normalized_border_is_valid(bool verbose = false) const*

Miscellaneous

void *D.inside_out()* reverses face orientations.
Precondition: *is_valid()* of level three.

Example

The following program fragment illustrates the implementation of the Euler operator *split_vertex()* for a simplified polyhedron class.

```
template <class Traits>
namespace CGAL {
    class Polyhedron {
        typedef HalfedgeDS_default<Traits> HDS;
        HDS hds;
    public:
        // ...
        Halfedge_handle split_vertex( Halfedge_handle h, Halfedge_handle
    g) {
            HalfedgeDS_decorator<HDS> D(hds);
            // Stricter preconditions than for HalfedgeDS only.
            CGAL_precondition( D.get_vertex(h) == D.get_vertex(g));
            CGAL_precondition( h != g);
            return D.split_vertex( h, g);
        }
    };
}
```

CGAL::HalfedgeDS_default<Traits,HalfedgeDSItems,Alloc>

Definition

template < class Traits,
class HalfedgeDSItems = CGAL::HalfedgeDS_items_2,
class Alloc = CGAL_ALLOCATOR(int)>
class HalfedgeDS_default;

The class *HalfedgeDS_default<Traits,HalfedgeDSItems,Alloc>* is a model for the *HalfedgeDS* concept. The second template parameter *HalfedgeDSItems* has a default argument *CGAL::HalfedgeDS_items_2*. The third template parameter *Alloc* uses the CGAL default allocator as default setting. *HalfedgeDS_default< Traits,HalfedgeDSItems,Alloc>* is a list-based representation with bidirectional iterators that supports removal.

#include <CGAL/HalfedgeDS_default.h>

Is Model for the Concepts

HalfedgeDS<Traits,Items,Alloc> . . . . page 1843

Types

typedef bidirectional_iterator_tag	*iterator_category;*
typedef CGAL::Tag_true	*Supports_removal;*

CGAL::HalfedgeDS_decorator<HDS> . . . . page 1860
CGAL::HalfedgeDS_const_decorator<HDS> . . . . page 1858

Implementation

Currently, *HalfedgeDS_default<Traits,HalfedgeDSItems,Alloc>* is derived from *CGAL::HalfedgeDS_list< Traits>*. The copy constructor and the assignment operator need $O(n)$ time with n the total number of vertices, halfedges, and faces. The former suboptimal implementation with an $O(n \log n)$ runtime has been replaced with a faster implementation based on hashing for the pointer lookup.

Class

CGAL::HalfedgeDS_face_base<Refs>

Definition

The class *HalfedgeDS_face_base<Refs>* is a model of the *HalfedgeDSFace* concept. *Refs* is an instantiation of a *HalfedgeDS*. The template declaration of *HalfedgeDS_face_base<Refs>* has three parameters with some defaults that allow to select various flavors of faces. The declaration is best explained with the two following declarations, essentially hiding an implementation dependent default setting:

template <class Refs, class T = CGAL::Tag_true>
class HalfedgeDS_face_base;

template <class Refs, class T, class Plane>
class HalfedgeDS_face_base;

HalfedgeDS_face_base<Refs> defines a face including a reference to an incident halfedge.

CGAL::HalfedgeDS_face_base<Refs,CGAL::Tag_false> is a face without a reference to an incident halfedge. It is empty besides the required type definitions. It can be used for deriving own faces. See also *CGAL::HalfedgeDS_face_min_base<Refs>*.

CGAL::HalfedgeDS_face_base<Refs,CGAL::Tag_true,Plane> is a face with a reference to an incident halfedge and it stores a plane equation of type *Plane*. It can be used as a face for a model of the *PolyhedronItems_3* concept.

CGAL::HalfedgeDS_face_base<Refs,CGAL::Tag_false,Plane> is a face without a reference to an incident halfedge and it stores a plane equation of type *Plane*. It can be used as a face for a model of the *PolyhedronItems_3* concept.

#include <CGAL/HalfedgeDS_face_base.h>

Is Model for the Concepts

HalfedgeDSFace . . . . page 1850

Types

HalfedgeDS_face_base<Refs>:: Plane	plane type for three argument version.

Creation

HalfedgeDS_face_base<Refs> f;	default constructor.
HalfedgeDS_face_base<Refs> f(Plane pln);	initialized with plane *pln*.

Operations

Plane&	*f.plane()*
const Plane&	*f.plane() const*

CGAL::HalfedgeDS_halfedge_base<Refs>

Class

Definition

The class *HalfedgeDS_halfedge_base<Refs>* is a model of the *HalfedgeDSHalfedge* concept. *Refs* is an instantiation of a *HalfedgeDS*. The full declaration states four template parameters:

```
template < class Refs,
           class Tag_prev   = CGAL::Tag_true,
           class Tag_vertex = CGAL::Tag_true,
           class Tag_face   = CGAL::Tag_true>
class HalfedgeDS_halfedge_base;
```

If *Tag_prev* ≡ *CGAL::Tag_true* a reference to the previous halfedge is supported.

If *Tag_vertex* ≡ *CGAL::Tag_true* an incident vertex is supported.

If *Tag_face* ≡ *CGAL::Tag_true* an incident face is supported.

In all cases, a reference to the next halfedge and to the opposite halfedge is supported.

#include <CGAL/HalfedgeDS_halfedge_base.h>

Is Model for the Concepts

HalfedgeDSHalfedge . . . . page 1852

Creation

CGAL::HalfedgeDS_items_2

Class

Definition

The class *HalfedgeDS_items_2* is a model of the *HalfedgeDSItems* concept. It uses the default types for vertices, halfedges, and faces that declare all incidences supported by a *HalfedgeDS*. The vertex also contains a point of type *Traits::Point_2*, where *Traits* is the template argument of the corresponding *HalfedgeDS*.

#include <CGAL/HalfedgeDS_items_2.h>

Is Model for the Concepts

HalfedgeDSItems . . . . page 1854

CGAL::HalfedgeDS_halfedge_base<Refs> . . . . page 1871
CGAL::HalfedgeDS_face_base<Refs> . . . . page 1868

Example

The following example shows the canonical implementation of the *HalfedgeDS_items_2* class. It uses the base classes for the item types that are provided in the library.

```
struct HalfedgeDS_items_2 {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef typename Traits::Point_2 Point;
        typedef CGAL::HalfedgeDS_vertex_base< Refs, Tag_true, Point>
   Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef CGAL::HalfedgeDS_halfedge_base< Refs> Halfedge;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef CGAL::HalfedgeDS_face_base< Refs> Face;
    };
};
```

The following example shows a class definition for a new items class derived from the *HalfedgeDS_items_2* class. It replaces the *Face_wrapper* with a new definition of a face that contains a member variable for color. The new face makes use of the face base class provided in the library.

```
// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
    My_face() {}
    My_face( CGAL::Color c) : color(c) {}
};

// An items type using my face.
struct My_items : public CGAL::HalfedgeDS_items_2 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};
```

CGAL::HalfedgeDS_items_decorator<HDS>

Class

Definition

The classes *CGAL::HalfedgeDS_items_decorator<HDS>*, *CGAL::HalfedgeDS_decorator<HDS>*, and *CGAL::HalfedgeDS_const_decorator<HDS>* provide additional functions to examine and to modify a halfedge data structure *HDS*. The class *CGAL::HalfedgeDS_items_decorator<HDS>* provides additional functions for vertices, halfedges, and faces of a halfedge data structure without knowing the containing halfedge data structure. The class *CGAL::HalfedgeDS_decorator<HDS>* stores a reference to the halfedge data structure and provides functions that modify the halfedge data structure, for example Euler-operators. The class *CGAL::HalfedgeDS_const_decorator<HDS>* stores a const reference to the halfedge data structure. It contains non-modifying functions, for example the test for validness of the data structure.

All these additional functions take care of the different capabilities a halfedge data structure may have or may not have. The functions evaluate the type tags of the halfedge data structure to decide on the actions. If a particular feature is not supported nothing is done. Note that for example the creation of new halfedges is mandatory for all halfedge data structures and will not appear here again.

#include <CGAL/HalfedgeDS_items_decorator.h>

Types

HalfedgeDS_items_decorator<HDS>:: HalfedgeDS	halfedge data structure.
HalfedgeDS_items_decorator<HDS>:: Traits	traits class.
HalfedgeDS_items_decorator<HDS>:: Vertex	vertex type of *HalfedgeDS*.
HalfedgeDS_items_decorator<HDS>:: Halfedge	halfedge type of *HalfedgeDS*.
HalfedgeDS_items_decorator<HDS>:: Face	face type of *HalfedgeDS*.

HalfedgeDS_items_decorator<HDS>:: Vertex_handle
HalfedgeDS_items_decorator<HDS>:: Halfedge_handle
HalfedgeDS_items_decorator<HDS>:: Face_handle
HalfedgeDS_items_decorator<HDS>:: Vertex_iterator
HalfedgeDS_items_decorator<HDS>:: Halfedge_iterator
HalfedgeDS_items_decorator<HDS>:: Face_iterator

The respective *const_handle*'s and *const_iterator*'s are available as well.

HalfedgeDS_items_decorator<HDS>:: size_type
HalfedgeDS_items_decorator<HDS>:: difference_type
HalfedgeDS_items_decorator<HDS>:: iterator_category

HalfedgeDS_items_decorator<HDS>:: Supports_vertex_halfedge
HalfedgeDS_items_decorator<HDS>:: Supports_halfedge_prev
HalfedgeDS_items_decorator<HDS>:: Supports_halfedge_vertex
HalfedgeDS_items_decorator<HDS>:: Supports_halfedge_face
HalfedgeDS_items_decorator<HDS>:: Supports_face_halfedge
HalfedgeDS_items_decorator<HDS>:: Supports_removal

Creation

HalfedgeDS_items_decorator<HDS> D;	default constructor.

Access Functions

Halfedge_handle	*D.get_vertex_halfedge(Vertex_handle v)*	returns the incident halfedge of *v* if supported, *Halfedge_handle()* otherwise.
Vertex_handle	*D.get_vertex(Halfedge_handle h)*	returns the incident vertex of *h* if supported, *Vertex_handle()* otherwise.
Halfedge_handle	*D.get_prev(Halfedge_handle h)*	returns the previous halfedge of *h* if supported, *Halfedge_handle()* otherwise.
Halfedge_handle	*D.find_prev(Halfedge_handle h)*	returns the previous halfedge of *h*. Uses the *prev()* method if supported or performs a search around the face using *next()*.
Halfedge_handle	*D.find_prev_around_vertex(Halfedge_handle h)*	returns the previous halfedge of *h*. Uses the *prev()* method if supported or performs a search around the vertex using *next()*.
Face_handle	*D.get_face(Halfedge_handle h)*	returns the incident face of *h* if supported, *Face_handle()* otherwise.
Halfedge_handle	*D.get_face_halfedge(Face_handle f)*	returns the incident halfedge of *f* if supported, *Halfedge_handle()* otherwise.

Corresponding member functions for *const_handle*'s are provided as well.

Modifying Functions (Composed)

void	*D.close_tip(Halfedge_handle h) const*	makes *h->opposite()* the successor of *h*.
void	*D.close_tip(Halfedge_handle h, Vertex_handle v) const*	makes *h->opposite()* the successor of *h* and sets the incident vertex of *h* to *v*.
void	*D.insert_tip(Halfedge_handle h, Halfedge_handle v) const*	inserts the tip of the edge *h* into the halfedges around the vertex pointed to by *v*. Halfedge *h->opposite()* is the new successor of *v* and *h->next()* will be set to *v->next()*. The vertex of *h* will be set to the vertex *v* refers to if vertices are supported.
void	*D.remove_tip(Halfedge_handle h) const*	removes the edge *h->next()->opposite()* from the halfedge circle around the vertex referred to by *h*. The new successor halfedge of *h* will be *h->next()->opposite()->next()*.

void *D.insert_halfedge(Halfedge_handle h, Halfedge_handle f) const*

inserts the halfedge *h* between *f* and *f->next()*. The face of *h* will be the one *f* refers to if faces are supported.

void *D.remove_halfedge(Halfedge_handle h) const*

removes edge *h->next()* from the halfedge circle around the face referred to by *h*. The new successor of *h* will be *h->next()->next()*.

void *D.set_vertex_in_vertex_loop(Halfedge_handle h, Vertex_handle v) const*

loops around the vertex incident to *h* and sets all vertex pointers to *v*.
Precondition: *h != Halfedge_handle()*.

void *D.set_face_in_face_loop(Halfedge_handle h, Face_handle f) const*

loops around the face incident to *h* and sets all face pointers to *f*.
Precondition: *h != Halfedge_handle()*.

Halfedge_handle *D.flip_edge(Halfedge_handle h) const*

performs an edge flip. It returns *h* after rotating the edge *h* one vertex in the direction of the face orientation.
Precondition: *h != Halfedge_handle()* and both incident faces of *h* are triangles.

Modifying Functions (Primitives)

void *D.set_vertex_halfedge(Vertex_handle v, Halfedge_handle g) const*

sets the incident halfedge of *v* to *g*.

void *D.set_vertex_halfedge(Halfedge_handle h) const*

sets the incident halfedge of the vertex incident to *h* to *h*.

void *D.set_vertex(Halfedge_handle h, Vertex_handle v) const*

sets the incident vertex of *h* to *v*.

void *D.set_prev(Halfedge_handle h, Halfedge_handle g) const*

sets the previous link of *h* to *g*.

void *D.set_face(Halfedge_handle h, Face_handle f) const*

sets the incident face of *h* to *f*.

void *D.set_face_halfedge(Face_handle f, Halfedge_handle g) const*

sets the incident halfedge of *f* to *g*.

void *D.set_face_halfedge(Halfedge_handle h) const*

sets the incident halfedge of the face incident to *h* to *h*.

See Also

Example

The following program fragment illustrates how a refined halfedge class for a polyhedron can make use of the *find_prev()* member function to implement a *prev()* member function that works regardless of whether the halfedge data structure *HDS* provides a *prev()* member function for its halfedges or not. In the case that not, the implementation given here runs in time proportional to the size of the incident face. For const-correctness a second implementation with signature *Halfedge_const_handle prev() const;* is needed.

Note also the use of the static member function *halfedge_handle()* of the halfedge data structure. It converts a pointer to the halfedge into a halfedge handle. This conversion encapsulates possible adjustments for hidden data members in the true halfedge type, such as linked-list pointers.

```
struct Polyhedron_halfedge {
    // ...
    Halfedge_handle  prev() {
        CGAL::HalfedgeDS_items_decorator<HDS> decorator;
        return decorator.find_prev( HDS::halfedge_handle(this));
    }
};
```

CGAL::HalfedgeDS_min_items

Class

Definition

The class *HalfedgeDS_min_items* is a model of the *HalfedgeDSItems* concept. It defines types for vertices, halfedges, and faces that declare the minimal required incidences for a *HalfedgeDS*, which are the *next()* and the *opposite()* member function for halfedges.

#include <CGAL/HalfedgeDS_min_items.h>

Is Model for the Concepts

Example

The following example shows the canonical implementation of the *CGAL::HalfedgeDS_min_items* class. It uses the base classes for the item types that are provided in the library.

```
struct HalfedgeDS_min_items {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef CGAL::HalfedgeDS_vertex_min_base< Refs>   Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef CGAL::HalfedgeDS_halfedge_min_base< Refs> Halfedge;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef CGAL::HalfedgeDS_face_min_base< Refs>     Face;
    };
};
```

Class

CGAL::HalfedgeDS_list<Traits,HalfedgeDSItems,Alloc>

Definition

The class *HalfedgeDS_list<Traits,HalfedgeDSItems,Alloc>* is a model for the *HalfedgeDS* concept. *HalfedgeDS_list<Traits,HalfedgeDSItems,Alloc>* is a list-based representation with bidirectional iterators that supports removal.

#include <CGAL/HalfedgeDS_list.h>

Is Model for the Concepts

HalfedgeDS<Traits,Items,Alloc> . . . . page 1843

Types

typedef bidirectional_iterator_tag	*iterator_category;*
typedef CGAL::Tag_true	*Supports_removal;*

Operations

Besides operations required from the concept *HalfedgeDS<Traits,Items,Alloc>*, this class supports additionally:

void *hds.vertices_splice(Vertex_iterator target, Self &source, Vertex_iterator first, Vertex_iterator last)*

inserts elements in the range [*first, last*) before position *target* and removes the elements from *source*. It takes constant time if &*source* == &*hds*; otherwise, it takes linear time in the size of the range.
Precondition: [*first, last*) is a valid range in *source*. *target* is not in the range [*first, last*).

void *hds.halfedges_splice(Halfedge_iterator target,*
Self &source,
Halfedge_iterator first,
Halfedge_iterator last)

inserts elements in the range [*first, last*) before position *target* and removes the elements from *source*. It takes constant time if &*source* == &*hds*; otherwise, it takes linear time in the size of the range.
Precondition: [*first, last*) is a valid range in *source*. *target* is not in the range [*first, last*).

void *hds.faces_splice(Face_iterator target, Self &source, Face_iterator first, Face_iterator last)*

inserts elements in the range [*first, last*) before position *target* and removes the elements from *source*. It takes constant time if &*source* == &*hds*; otherwise, it takes linear time in the size of the range.
Precondition: [*first, last*) is a valid range in *source*. *target* is not in the range [*first, last*).

Implementation

HalfedgeDS_list<Traits,HalfedgeDSItems,Alloc> uses internally the *CGAL::In_place_list* container class. The copy constructor and the assignment operator need $O(n)$ time with n the total number of vertices, halfedges, and faces. The former suboptimal implementation with an $O(n \log n)$ runtime has been replaced with a faster implementation based on hashing for the pointer lookup.

CGAL_ALLOCATOR(int) is used as default argument for the *Alloc* template parameter.

Class

CGAL::HalfedgeDS_vector<Traits,HalfedgeDSItems,Alloc>

Definition

The class *HalfedgeDS_vector<Traits,HalfedgeDSItems,Alloc>* is a model for the *HalfedgeDS* concept. *HalfedgeDS_vector<Traits,HalfedgeDSItems,Alloc>* is a vector-based representation with random access iterators that does not support removal.

#include <CGAL/HalfedgeDS_vector.h>

Is Model for the Concepts

HalfedgeDS<Traits,Items,Alloc> . . . . page 1843

Types

typedef random_access_iterator_tag	*iterator_category;*
typedef CGAL::Tag_false	*Supports_removal;*

CGAL::HalfedgeDS_const_decorator<HDS> . . . . page 1858

Implementation

HalfedgeDS_vector<Traits,HalfedgeDSItems,Alloc> uses internally the STL *std::vector* container class. We require that we can create a *std::vector::iterator* from a pointer. If this will not be true any longer for any major STL distribution we might switch to an internal implementation of a vector.

The capacity is restricted to the reserved size. Allocations are not possible beyond the capacity without calling reserve again. All handles and iterators are invalidated upon a reserve call that increases the capacity.

CGAL_ALLOCATOR(int) is used as default argument for the *Alloc* template parameter.

CGAL::HalfedgeDS_vertex_base<Refs>

Class

Definition

The class *HalfedgeDS_vertex_base<Refs>* is a model of the *HalfedgeDSVertex* concept. *Refs* is an instantiation of a *HalfedgeDS*. The template declaration of *HalfedgeDS_vertex_base<Refs>* has three parameters with some defaults that allow to select various flavors of vertices. The declaration is best explained with the two following declarations, essentially hiding an implementation dependent default setting:

template <class Refs, class T = CGAL::Tag_true>
class HalfedgeDS_vertex_base;

template <class Refs, class T, class Point>
class HalfedgeDS_vertex_base;

HalfedgeDS_vertex_base<Refs> defines a vertex including a reference to an incident halfedge.

CGAL::HalfedgeDS_vertex_base<Refs,CGAL::Tag_false> is a vertex without a reference to an incident halfedge. It is empty besides the required type definitions. It can be used for deriving own vertex implementations. See also *CGAL::HalfedgeDS_vertex_min_base<Refs>*.

CGAL::HalfedgeDS_vertex_base<Refs,CGAL::Tag_true,Point> is a vertex with a reference to an incident halfedge and it stores a point of type *Point*. It can be used as a vertex for a model of the *PolyhedronItems_3* concept.

CGAL::HalfedgeDS_vertex_base<Refs,CGAL::Tag_false,Point> is a vertex without a reference to an incident halfedge and it stores a point of type *Point*. It can be used as a vertex for a model of the *PolyhedronItems_3* concept.

#include <CGAL/HalfedgeDS_vertex_base.h>

Is Model for the Concepts

HalfedgeDSVertex . . . . page 1856

Types

HalfedgeDS_vertex_base<Refs>:: Point	point type for three argument version.

Creation

HalfedgeDS_vertex_base<Refs> v;	default constructor.
HalfedgeDS_vertex_base<Refs> v(Point p);	initialized with point *p*.

Operations

Point&	*v.point()*
const Point&	*v.point() const*

Chapter 27

Combinatorial Maps

Guillaume Damiand

Contents

27.1 Introduction

A *d*-dimensional combinatorial map is a data structure representing an orientable subdivided *d*-dimensional object obtained by taking *d*D cells, and allowing to glue *d*D cells along *(d-1)*D cells. It provides a description of all the cells of the subdivision (for example vertices and edges), together with incidence and adjacency relationships. This package is a generalization of the halfedge data structure to higher dimension.[1]

We denote *i*-cell for an *i*-dimensional cell (for example in 3D, 0-cells are *vertices*, 1-cells are *edges*, 2-cells are *facets*, and 3-cells are *volumes*). A *boundary relation* is defined on these cells, giving for each *i*-cell *c* the set of *(i-1)*-cells contained in the boundary of *c*. Two cells *c1* and *c2* are *incident* if there is a path of cells, starting from the cell of biggest dimension to the other cell, such that each cell of the path (except the first one) belongs to the boundary of the previous cell in the path. Two *i*-cells *c3* and *c4* are *adjacent* if there is an *(i-1)*-cell incident to both *c3* and *c4*. You can see an example of a 2D object and a 3D object in Figure 27.1 showing some cells of the subdivision and some adjacency and incidence relations.

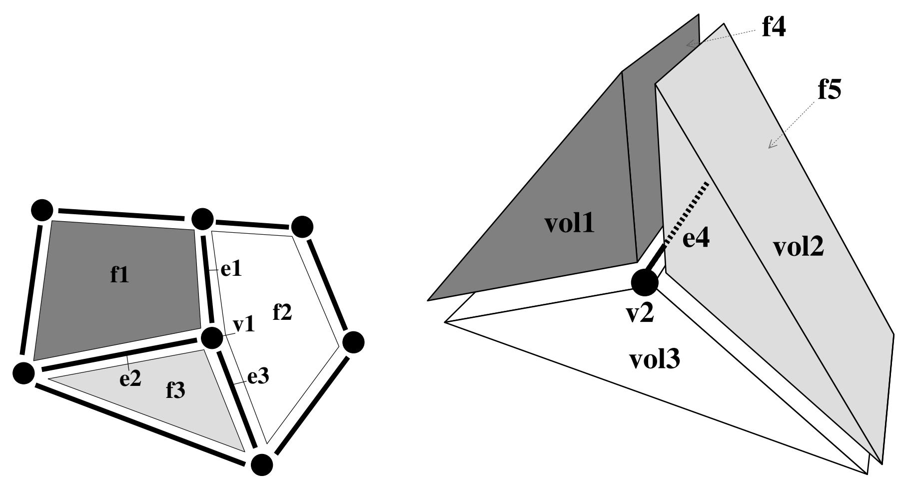

Figure 27.1: Example of subdivided objects that can be described by combinatorial maps. **Left**: A 2D object composed of three facets (2-cells), named *f1*, *f2* and *f3*, nine edges (1-cells) and seven vertices (0-cells). *f1* and *f2* are adjacent along edge *e1*, thus *e1* is incident both to *f1* and *f2*. Vertex *v1* is incident to edge *e1*, thus *v1* is incident to *f1* and *f2* by transitivity. **Right**: A 3D object (only partially represented for vertices and edges) composed of three volumes (3-cells), named *vol1*, *vol2* and *vol3*, twelve facets (2-cells) (there is one facet *f4* between *vol1* and *vol2*, and similarly between *vol1* and *vol3* and *vol2* and *vol3*), sixteen edges (1-cells), and eight vertices (0-cells). *vol1* and *vol2* are adjacent along facet *f4*, thus *f4* is incident both to *vol1* and *vol2*. Edge *e4* is incident to the three facets between *vol1* and *vol2*, *vol1* and *vol3*, and *vol2* and *vol3*. *e4* is also incident to the three volumes by transitivity.

A combinatorial map is an edge-centered data structure describing the cells and the incidence and adjacency relations, using only one basic element called *dart*, and a set of *pointers* between these darts. A dart can be thought as a part of an oriented edge (1-cell), together with a part of incident cells of dimensions 0, 2, 3,. . . , *d*. When a dart *d0* describes a part of an *i*-cell *c*, we say that *d0 belongs* to *c*, and that *c contains d0*. Let us look at the example in Figure 27.2 showing the 2D and 3D combinatorial maps describing the two objects given in Figure 27.1.

First let us start in 2D (Figure 27.2 (Left)). Facet *f1* is described by four darts. These darts are linked together with pointers. Starting from a dart and following a β_1 pointer, we get to a dart which belongs to the same facet

[1] A 2D combinatorial map is equivalent to a halfedge data structure: there is a one-to-one mapping between elements of both data structures, halfedges corresponding to darts.

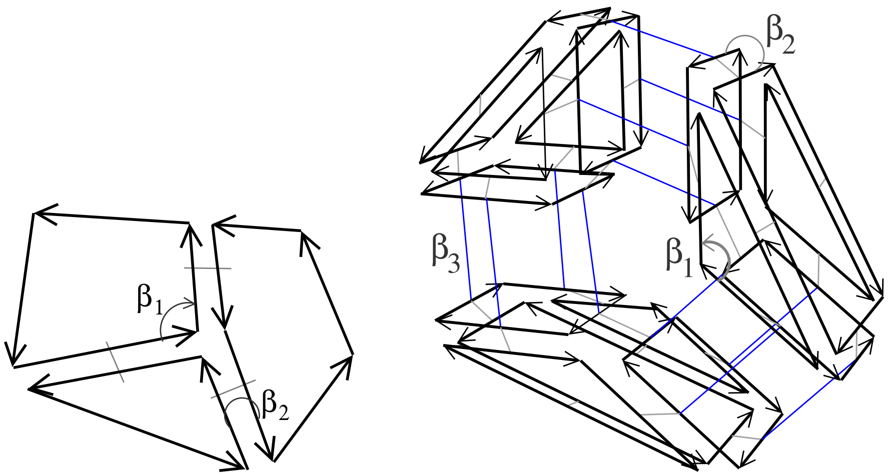

Figure 27.2: Combinatorial maps representing the objects given in Figure 27.1. **Left**: The 2D combinatorial map which contains 12 darts. **Right**: The 3D combinatorial map which contains 54 darts (18 for each volume).

but to the next edge (1-cell, which explains the index 1 of β_1). Starting from any dart and following β_1 pointers, we can reach exactly all the darts describing the facet. Starting from a dart and following a β_2 pointer, we get to a dart which belongs to the same edge but to the neighboring facet (2-cell, which explains the index 2 of β_2). Starting from any dart and following β_2 pointers, we can reach exactly all the darts describing the edge (in 2D one or two darts).

Things are slightly different for vertices. Indeed, each β_i points to a dart belonging to a different i-cell, but also to a different 0-cell (vertex). This is so because two linked darts have opposite orientations. For this reason, starting from any dart belonging to a vertex v, we have to follow β_2 then β_1 to reach exactly the darts describing the vertex v. In fact, by composing two β_is, we always obtain a dart belonging to the same vertex (if we do not start by following a β_1 pointer).

The main interest of combinatorial map definition based on darts and β_i pointers is to be able to increase the dimension "only" by adding new pointers. We can verify this fact by studying the 3D example (Figure 27.2 (Right)). In addition to β_1 and β_2 of the 2D case, there is a new pointer β_3.

If we take a closer look at the central edge *e4* shown in Figure 27.3 (Left), we can see that it is described by six darts linked together. Starting from a dart and following a β_3 pointer, we get to a dart which belongs to the same edge, to the same facet, but to the neighboring volume (a 3-cell, which explains the index 3 in β_3). Similarly, starting from a dart and following a β_2 pointer, we get to a dart which belongs to the same edge, to the same volume, but to the neighboring facet (2-cell). Starting from any of these six darts and following β_2 and β_3 pointers, we can reach exactly the six darts describing edge *e4*.

For facets, by following a β_1 pointer, we get to a dart which belongs to the same facet, to the same volume, but to the next edge (1-cell, which explains the index 1 of β_1). Starting from any dart and following β_1 and β_3 pointers, we can reach exactly all the darts describing the facet (see Figure 27.3 (Right)). For volumes, starting from any dart and following β_1 and β_2 pointers, we can reach exactly all the darts describing the volume.

For vertices, we have to follow β_2 then β_1, and β_3 then β_1 to reach exactly the darts describing the vertex v. Indeed, as in 2D, we have to compose two β_is to obtain a dart belonging to the same vertex (if we do not start by following a β_1 pointer).

In some cases, the general rule that by following a β_i we get a dart which belongs to the neighboring i-cell is not true, as for example for darts belonging to the boundary of the represented object. For example, in Figure 27.1 (Left), any dart *d0* that does not belong to edge *e1*, *e2* and *e3* belongs to a 2-cell, and there is no neighboring

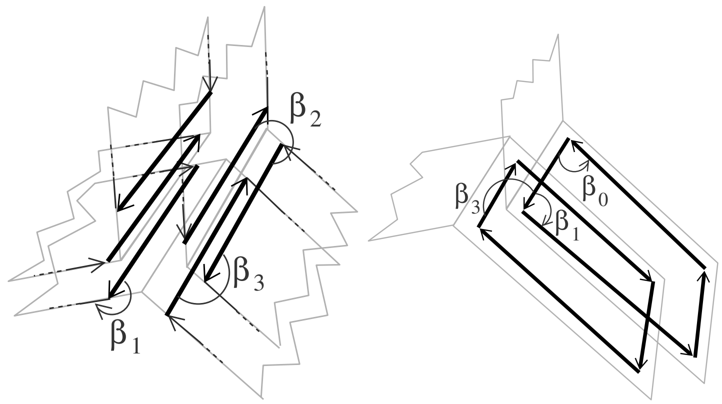

Figure 27.3: Two zooms on the 3D combinatorial map given in Figure 27.2 (Right). **Left**: Zoom around the central edge *e4* which details the six darts belonging to the edge. **Right**: Zoom around the facet between volumes *vol2* and *vol3* which details the eight darts belonging to the facet.

facet along the edge containing *d0*. Another example is in Figure 27.1 (Right), for any dart *d0* that belongs to facet *f5*. *d0* belongs to volume *vol2*, but there is no neighboring volume along this facet. The general rule is also not true for unbounded cells. For example if we remove a dart in Figure 27.2 (Left), we obtain an unbounded facet having a dart without next dart for β_1, and if we remove a facet in Figure 27.2 (Right), we obtain an unbounded volume having some darts without neighboring facet for β_2. In such a case, there is a particular value called $\varnothing$ used to describe that a dart *d0* is not linked to another dart in dimension *i*.
