The function *make_skin_surface_mesh_3<Polyhedron_3>* constructs a mesh isotopic to the skin surface based on the algorithm in [KV05]. It takes as input a range of weighted points and a shrink factor and outputs the mesh in a *Polyhedron_3* object. A number of subdivision steps might be applied to refine the mesh.

#include <CGAL/make_skin_surface_mesh_3.h>

void *mesh_skin_surface_3<Polyhedron_3>(Polyhedron_3 &p,*
WP_iterator begin,
WP_iterator end,
double shrink_factor=.5,
int nSubdivisions=0,
bool grow_balls=true)

Constructs a mesh of the skin surface defined by the weighted points and the shrink factor.
Precondition: *Polyhedron_3::HDS* can be used as the template argument of the *Polyhedron_incremental_builder_3<HDS>*.

CGAL::mesh_skin_surface_3<SkinSurface_3, Polyhedron_3>

Function

Definition

The function *mesh_skin_surface_3<SkinSurface_3, Polyhedron_3>* constructs a mesh isotopic to the skin surface based on the algorithm in [KV05]. It takes as input a *SkinSurface_3* object, which is a model of the *SkinSurface_3* concept and outputs the mesh in a *Polyhedron_3* object.

#include <CGAL/mesh_skin_surface_3.h>

void *make_skin_surface_mesh_3<SkinSurface_3,Polyhedron_3>(SkinSurface_3 skin_surface, Polyhedron_3 &p)*

Constructs a mesh of the *skin_surface* in *p*.
Precondition: *SkinSurface_3* is a model of the concept *SkinSurface_3* and *Polyhedron_3::HDS* can be used as the template argument of the *Polyhedron_incremental_builder_3<HDS>*.

Function

CGAL::subdivide_skin_surface_mesh_3<SkinSurface_3, Polyhedron_3>

Definition

The function *subdivide_skin_surface_mesh_3<SkinSurface_3, Polyhedron_3>* subdivides a skin surface mesh constructed by the function *mesh_skin_surface_3<SkinSurface_3, Polyhedron_3>*.

#include <CGAL/subdivide_skin_surface_mesh_3.h>

void subdivide_skin_surface_mesh_3<SkinSurface_3,Polyhedron_3>(SkinSurface_3 skin_surface,
Polyhedron_3 &p,
int nSubdiv = 1)

Subdivides the skin surface using *nSubdiv* 1-4 split operations (each triangle is split into four sub-triangles) and the new vertices are moved towards the skin surface.

Chapter 51

3D Mesh Generation

Pierre Alliez, Laurent Rineau, Stéphane Tayeb, Jane Tournois, Mariette Yvinec

Contents

51.1 Introduction

This package is devoted to the generation of isotropic simplicial meshes discretizing 3D domains. The domain to be meshed is a region of 3D space that has to be bounded. The region may be connected or composed of multiple components and/or subdivided in several subdomains.

Boundary and subdivision surfaces are either smooth or piecewise smooth surfaces, formed with planar or curved surface patches. Surfaces may exhibit 1-dimensional features (e.g. crease edges) and 0-dimensional features (e.g. singular points as corners tips, cusps or darts), that have to be fairly approximated in the mesh.

The output mesh is a 3-dimensional triangulation, including subcomplexes that approximate each input domain feature: subdomain, boundary surface patch or input domain feature with dimension 0 or 1. Thus, the output mesh includes a 3D submesh covering each subdomain, a surface mesh approximating each boundary or subdividing surface patch, a polyline approximation for each 1-dimensional feature and of course a vertex on each corner.

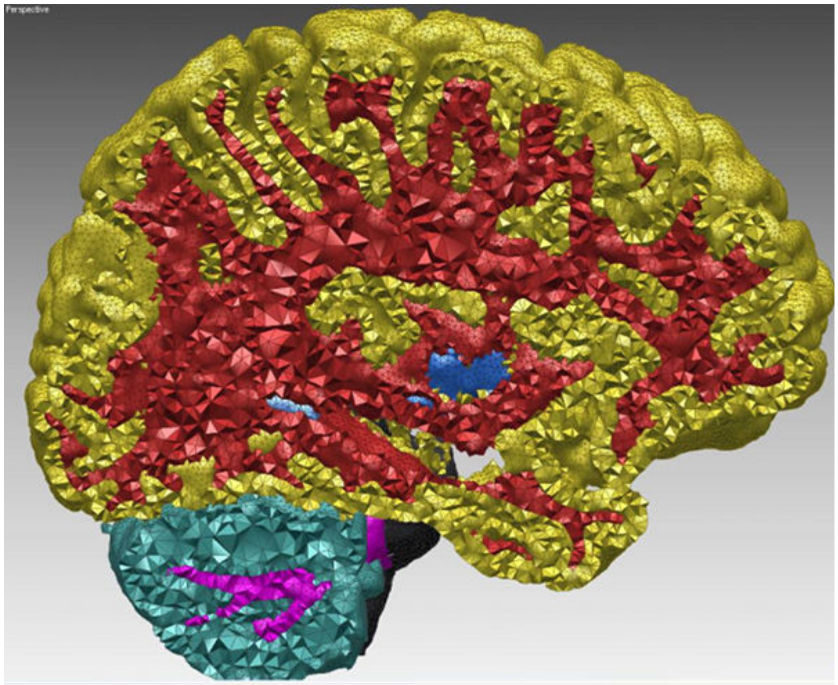

Figure 51.1: Cut-view of a multi-domain 3D mesh generated from a segmented image.

The main entry points of the package are two global functions that respectively generate and refine such meshes. The mesh generator is customized to output a mesh that fits as much as possible the user needs, for instance in terms of sizing field or with respect to some user customized quality criteria.

The meshing engine used in this mesh generator is based on Delaunay refinement [Che93, Rup95, She98b]. It uses the notion of restricted Delaunay triangulation to approximate 1-dimensional curve segments and surface patches [BO05]. Before the refinement, a mechanism of protecting balls is set up on 1-dimensional features, if any, to ensure a fair representation of those features in the mesh, and also to guarantee the termination of the refinement process, whatever may be the input geometry, in particular whatever small angles the boundary and subdivision surface patches may form [CDL07, CDR07]. The Delaunay refinement is followed by a mesh optimization phase to remove slivers and provide a good quality mesh.

Input domain

The domain to be meshed is assumed to be bounded and representable as a pure 3D complex. A 3D complex is a set of faces with dimension 0, 1, 2 and 3 such that all faces are pairwise interior disjoint, and the boundary of each face of the complex is the union of faces of the complex. The 3D complex is pure, meaning that each face is included in a face of dimension 3, so that the complex is entirely described by the set of its 3D faces and their subfaces. However the 3D complex needs not be connected. The set of faces with dimension lower or equal than 2 forms a 2D subcomplex which needs not be manifold, neither pure, nor connected: some 3D faces may have dangling 2D or 1D faces in their boundary faces.

In the rest of the documentation, we will refer to the input 3D complex as the input domain. The faces of the input domain with dimension 0, 1, 2 and 3 are called respectively *corners*, *curve segments*, *surface patches* and *subdomains* to clearly distinguish them from the faces of the mesh that are called vertices, edges, facets and cells.

Note that the input complex faces are not required to be linear nor smooth. Surface patches, for instance, may be smooth surface patches, or portions of surface meshes with boundaries. Curve segments may be for instance straight segments, curved segments or polylines. Each of those features will be accurately represented in the final mesh.

The 0 and 1-dimensional features of the input domain are usually singular points of the subdomain boundaries, however this is not required. Furthermore those features are not required to cover all the subdomains boundaries singularities but only those that need to be accurately represented in the final mesh. In the following, we say that a domain has *features* when it has 0 and 1-dimensional features that need to be accurately represented in the mesh, and we call those features *exposed features*. Therefore, a domain may be without features either because all boundary surface patches are smooth closed surfaces, or simply because the curves joining different surface patches and the singularities of those patches need not be accurately approximated in the final mesh.

Note also that input complex faces are not required to be connected. Faces of the input domain are identified by indexes. If a subdomain is not connected, its different components receive the same index. Likewise different surface patches, segment curves or corners may share the same index. Each connected component of a feature will be accurately represented in the final mesh. Note however that the occurrence of multiply connected faces in the input complex may affect the relevance of internal topological checks performed by the mesh generator. Also the mesh generator will not be able to apply different meshing criteria, e.g. different sizing field, for the different connected components of a single feature.

The domain is input to the mesh generation function, as a domain class, often called the oracle, that provides predicates and constructors related to the domain, the subdomains, the boundary surface patches and also the 0 and 1-dimensional exposed features, if any. Mainly, the oracle provides a predicate to test if a given query point belongs to the domain or not and to find in which subdomain it lies in the affirmative case. The domain class also provides predicates and constructors to test the intersection of a query line segment with the boundary surface patches and to build some intersection points if any. Lastly, if the input domain includes 1-dimensional exposed features, the domain class provides a way to construct sample points on these features.

The current implementation provides classes to represent domains bounded by isosurfaces of implicit functions, polyhedral domains and domains defined through 3D labeled images. Currently, 1-dimensional features may be defined as segments and polyline segments.

Output mesh

The resulting mesh is output as a subcomplex of a 3D Delaunay triangulation, in a class providing various iterators on mesh elements.

The 3D triangulation provides approximations of the subdomains, surface patches and curve segments and corners, according to the restricted Delaunay triangulation paradigm. This means that each subdomain is approximated by the union of the tetrahedral cells whose circumcenters are located inside the domain (or subdomain). Each surface patch is approximated by the union of the Delaunay mesh facets whose dual Voronoi edges intersect the surface patch. Such mesh facets are called *surface facets* in the following. The 1-dimensional exposed features are approximated by sequences of mesh edges and the 0-dimensional exposed features are represented by mesh vertices.

Delaunay Refinement

The mesh generation algorithm is mainly a Delaunay refinement process. The Delaunay refinement is preceded by a protecting phase to ensure an accurate representation of 1-dimensional features if any, and followed by an optimization phase to achieve a good quality mesh.

The Delaunay refinement process is driven by criteria concerning either the size and shape of mesh cells and surface facets. The refinement process terminates when there are no more mesh cells or surface facets violating the criteria.

The criteria are designed to achieve a nice spread of the mesh vertices while ensuring the termination of the refinement process. Those criteria may be somehow tuned to the user needs to achieve for instance the respect of a sizing field by mesh elements, some topological conditions on the representation of boundary surfaces in the mesh, and/or some error bound for the approximation of boundary surfaces. To some extend, the user may tune the Delaunay refinement to a prescribed trade-off between mesh quality and mesh density. The mesh density refers to the number of mesh vertices and cells, i.e. to the complexity of the mesh. The mesh quality referred to here is measured by the radius edge ratio of surface facets end mesh cells, where the radius edge ratio of a simplex (triangle or tetrahedron) is the the ratio between its circumradius and its shortest edge.

Protection of 0- and 1-dimensional exposed features

If the domain description includes 0 dimensional features, the corresponding points are inserted into the Delaunay triangulation from the start.

If the domain has 1-dimensional exposed features, the method of protecting balls [CDR07, CDL07] is used to achieve an accurate representation of those features in the mesh and to guarantee that the refinement process terminates whatever may be the dihedral angles formed by input surface patches incident to a given 1-feature or the angles formed by two 1-features incident to a 0-feature.

According to this method, the 1-dimensional features are sampled with points and covered by protecting balls centered on the sample points, in such a way that :
-no three balls intersect
-no pair of balls centered on different 1-features intersect.

The triangulation embedding the mesh is in fact a weighted Delaunay triangulation, and the triangulation is initialized by the insertion of all the protecting balls, regarded as weighted points. The Delaunay refinement process is then launched as before except that refinement points are no longer circumcenters but are weighted circumcenters. All Steiner vertices inserted by the refinement process are given a zero weight.

The method guarantees:
1) that each segment joining two successive centers on a 1-dimensional feature will stay in the triangulation, thus ensuring an accurate approximation of the 1-dimensional features.
2) that the refinement process will never try to insert a refinement point in the union of the protecting balls, which ensures the termination of the refinement process.

Optimization phase

Any tetrahedron that is quasi degenerate has a big radius edge ratio except those belonging to the family of slivers. A sliver is easily obtained as the convex hull of 4 points close to the equatorial circle of a 3D ball and roughly equally spread along this circle. The Delaunay refinement tracks tetrahedra with big radius edge ratio and therefore eliminates all kinds of badly shaped tetrahedra except slivers.

Therefore, at the end of the refinement process, some sliver shaped tetrahedra may occur in the mesh. The optimization phase aims at eliminating slivers.

The optimization phase is a succession of optimization processes, including possibly a Lloyd smoothing, an odt-smoothing, a perturber and an exuder.

The Lloyd and odt-smoother are global optimizers moving the mesh vertices to minimize a mesh energy. Those optimizers are described respectively in [DFG99, DW02] and in [Che04, ACSYD05]. In both cases the mesh energy is the *L1* error resulting from the interpolation of the function $f(x) = x^2$ by a piecewise linear function. In the case of the Lloyd smoother, the interpolation is linear in each Voronoi cell of the set of mesh vertices. In the case of the odt-smoother, the interpolation is linear in each cell of the Delaunay triangulation of the mesh vertices, hence the name odt which is an abbreviation for "optimal Delaunay triangulation".

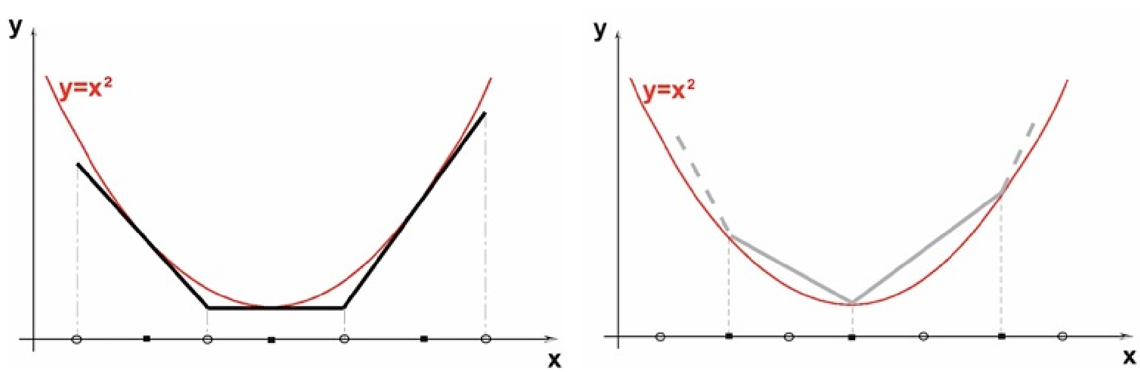

Figure 51.2: The one dimensional illustration of the mesh energy minimized by Lloyd (right) and ODT (left) smoothers.

The Lloyd optimizer is known to be blind to the occurrence of slivers in the mesh while the odt-smoother tends to chase them out. Both of them are global optimizers, meaning that they try to improve the whole mesh rather than focusing on the worst elements. However, both are empirically known to be very efficient as a preliminary step of optimization, as they tend to enhance the efficiency of the perturber and/or exuder applied next, see Figure 51.3

The perturber and the exuder focus on improving the worst mesh elements. The perturber [TSA09] improves the meshes by local changes in the vertices positions aiming to make sliver disappear. The exuder [CDE+00] chases the remaining slivers by re-weighting mesh vertices with optimal weights.

Each optimization process can be activated or not, and tuned according to the user requirements and the available time. By default, only the perturber and the exuder are activated.

Optimization processes are designed to improve mesh quality. However, beware that such an improvement is obtained by perturbing mesh vertices and modifying the mesh connectivity which has an impact on the strict compliance to the refinement criteria. Though a strict compliance to mesh criteria is granted at the end of the Delaunay refinement, this may no longer be true after some optimization processes. Also beware that the default behavior does involve some optimization processes.

51.2 Interface

The global functions

A 3D mesh generation process is launched through a call to one of the two following functions:

template <class C3T3, class MeshDomain_3, class MeshCriteria>
C3T3 make_mesh_3(MeshDomain_3 domain,

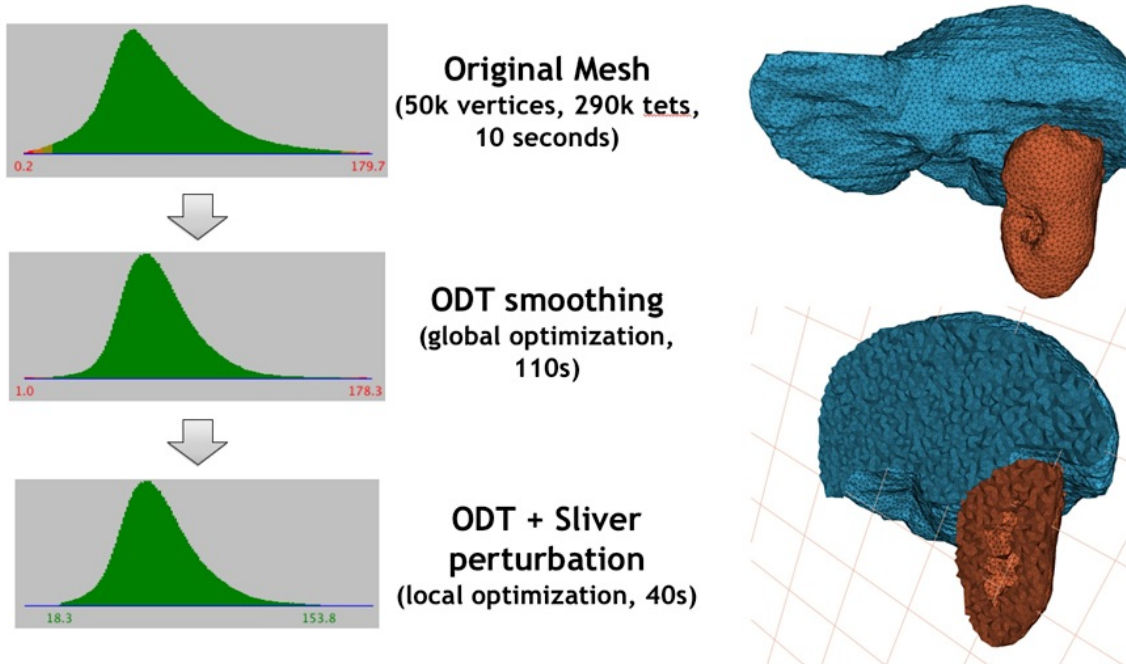

Figure 51.3: Compared effect of a global optimizer and the perturber. The left part shows the distribution of dihedral angles of mesh cells, right after Delaunay refinement (top), after some ODT smoothing (middle) and after perturbation (bottom). The numbers under the histograms give the measure in degrees of the smallest and biggest dihedral angles in the mesh.

MeshCriteria criteria,
parameters::internal::Features_options features = parameters::features(domain),
parameters::internal::Lloyd_options lloyd = parameters::no_lloyd(),
parameters::internal::Odt_options odt = parameters::no_odt(),
parameters::internal::Perturb_options perturb = parameters::perturb(),
parameters::internal::Exude_options exude = parameters::exude())

template <class C3T3, class MeshDomain_3, class MeshCriteria>
void refine_mesh_3(C3T3& c3t3,
MeshDomain_3 domain,
MeshCriteria criteria,
parameters::internal::Lloyd_options lloyd = parameters::no_lloyd(),
parameters::internal::Odt_options odt = parameters::no_odt(),
parameters::internal::Perturb_options perturb = parameters::perturb(),
parameters::internal::Exude_options exude = parameters::exude())

The function *make_mesh_3* generates from scratch a mesh of the input domain, while the function *refine_mesh_3* refines an existing mesh of the input domain. Note that as the protection of 0- and 1-dimensional features does not rely on Delaunay refinement, the function *refine_mesh_3* has no parameter to preserve features.

The data structure

The template parameter *C3T3* is required to be a model of the concept *MeshComplex_3InTriangulation_3*, a data structure devised to represent a three dimensional complex embedded in a 3D triangulation. In both functions, an instance of type *C3T3* is used to maintain the current approximating simplicial mesh and to represent the final 3D mesh at the end of the procedure. The type *C3T3* is required to provide a nested type *C3T3::Triangulation_3* for the 3D triangulation embedding the mesh. This triangulation is required to be a *CGAL::Regular_triangulation_3*. with vertex and cell base classes that are respectively models of the concepts *MeshVertexBase_3* and *MeshCellBase_3*.

The domain oracle and the features parameter

The template parameter *MeshDomain_3* is required to be a model of the concept *MeshDomain_3*. The argument *domain* of type *MeshDomain_3* is the sole link through which the domain to be discretized is known by the mesh generation algorithm.

This concept provides, among others, member functions to test whether or not a query segment intersects boundary surfaces, and to compute an intersection point in the affirmative. The *MeshDomain_3* concept adds member functions which given a query point tell whether the point lies inside or outside the domain and in which subdomain the point lies if inside.

If the domain description includes 0 and 1-dimensional features that have to be accurately represented in the final mesh, the template parameter *MeshDomain_3* is required to be of a model of the refined concept *MeshDomainWithFeatures_3*. Mainly the concept *MeshDomainWithFeatures_3* provides the incidence graph of 0, 1 and 2-dimensional features, and a member function to construct sample points on curve segments.

Using the parameter of type *Features*, the user whose domain is a model of *MeshDomainWithFeatures_3* can choose to have the corners and curve segments of the domain represented in the mesh or not. The type *Features* of this parameter is an internal undescribed type. The library provides functions to construct appropriate values of that type.

- *parameters::features(domain)* sets *features* according to the domain, i.e. 0 and 1-dimensional features are taken into account if *domain* is a *MeshDomainWithFeatures_3*
- *parameters::no_features()* prevents the representation of 0 and 1-dimensional features in the mesh. This is useful to get a smooth and rough approximation of a domain with features.

The meshing criteria

The template parameter *MeshCriteria* must be a model of the concept *MeshCriteria_3*, or a model of the refined concept *MeshCriteriaWithFeatures_3* if the domain has exposed features. The argument of type *MeshCriteria* passed to the mesh generator specifies the size and shape requirements for the tetrahedra in the mesh and for the triangles in the boundary surface mesh. These criteria condition the rules that drive the refinement process. At the end of the refinement process, mesh elements satisfy the criteria. This may not be strictly true anymore after the optimization phase, but this last phase is devised to only improve the mesh quality.

The criteria for surface facets are governed by the four following parameters:

- *facet_angle*. This parameter controls the shape of surface facets. Actually, it is a lower bound for the angle (in degree) of surface facets. When boundary surfaces are smooth, the termination of the meshing process is guaranteed if the angular bound is at most 30 degrees.

- *facet_size*. This parameter controls the size of surface facets. Actually, each surface facet has a surface Delaunay ball which is a ball circumscribing the surface facet and centered on the surface patch. The parameter *facet_size* is either a constant or a spatially variable scalar field, providing an upper bound for the radii of surface Delaunay balls.
- *facet_distance*. This parameter controls the approximation error of boundary and subdivision surfaces. Actually, it is either a constant or a spatially variable scalar field. It provides an upper bound for the distance between the circumcenter of a surface facet and the center of a surface Delaunay ball of this facet.
- *facet_topology*. This parameters controls the set of topological constraints which have to be verified by each surface facet. By default, each vertex of a surface facet has to be located on a surface patch, on a curve segment, or on a corner. It can also be set to check whether the three vertices of a surface facet belongs to the same surface patch. This has to be done cautiously, as such a criteria needs that each surface patches intersection is an input 1-dimensional feature.

The criteria for mesh cells are governed by two parameters:

- *cell_radius_edge_ratio*. This parameter controls the shape of mesh cells (but can't filter slivers, as we discussed earlier). Actually, it is an upper bound for the ratio between the circumradius of a mesh tetrahedron and its shortest edge. There is a theoretical bound for this parameter: the Delaunay refinement process is guaranteed to terminate for values of *cell_radius_edge_ratio* bigger than 2.
- *cell_size*. This parameter controls the size of mesh tetrahedra. It is either a scalar or a spatially variable scalar field. It provides an upper bound on the circumradii of the mesh tetrahedra.

Figure 51.4 shows how the mesh generation process behaves with respect to these parameters.

If the domain has 1-dimensional exposed features, the *criteria* includes a sizing field to guide the sampling of 1-dimensional features with protecting balls centers.

- *edge_size*. This constant or variable scalar field is used as an upper bound for the distance between two protecting ball centers that are consecutive on a 1-feature.

The optimization parameters

The four additional parameters are optimization parameters. They control which optimization processes are performed and allow the user to tune the parameters of the activated optimization processes. These parameters have internal types which are not described but the library provides global functions to generate appropriate values of these types:

- *parameters::lloyd()* and *parameters::no_lloyd()* activate and deactivate the Lloyd smoother.
- *parameters::odt()* and *parameters::no_odt()* activate and deactivate the odt-smoother.
- *parameters::perturb()* and *parameters::no_perturb()* activate and deactivate the perturber.
- *parameters::exude()* and *parameters::no_exude()* activate and deactivate the exuder.

These parameters are optional and can be passed in any order. If one parameter is not passed the default value is used. By default, only the perturber and the exuder are activated. Note that whatever may be the optimization

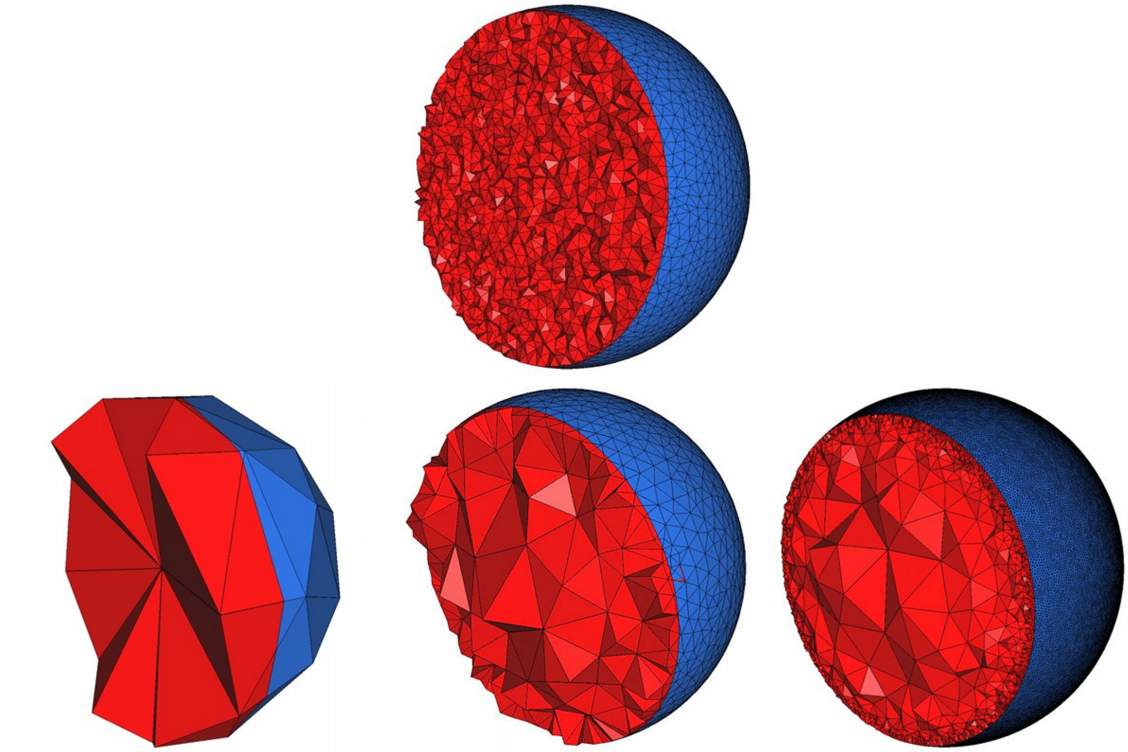

Figure 51.4: Top : the mesh is obtained using the parameters $(25, 0.15, 0.05)$ for the angular bound, radius bound and distance bound of surface facets and $(4, 0.2)$ for the radius-edge bound and radius bound of mesh cells. The result is a uniform mesh which contains tetrahedra of about the same size. Bottom left : the mesh is obtained by relaxing the *size bound* of tetrahedra and facets. The result is a small coarse mesh. Bottom middle : the mesh is obtained from the previous one by tightening the *distance bound* of surface facets to 0.01. The result is then a graded 3D mesh with a dense surface mesh achieving a precise approximation. Bottom right : the mesh is obtained from the previous one by fixing *radius bound* of surface facets to 0.01. The surface mesh is then denser to achieve the size bound.

processes activated by *make_mesh_3* or *refine_mesh_3*, they are always launched in the order that is a suborder of the following: *odt smoother*, *Lloyd smoother*, *perturber* and *exuder*.

The package also provides four global functions to launch each optimization process independently. These functions are useful for advanced experimentation on the efficiency of each optimization method. Note however that the exuder adds on mesh vertices weights that are conditioned by vertices positions. Therefore an exudation process should never be run before a smoother or a perturber. For a maximum efficiency, whatever may be the optimization processes activated, they should be launched in the order that is a suborder of the following: *odt-smoother*, *Lloyd-smoother*, *perturber*, *exuder*.

template< class C3T3, class MeshDomain_3 >
Mesh_optimization_return_code lloyd_optimize_mesh_3(C3T3& c3t3, MeshDomain_3 domain)

template< class C3T3, class MeshDomain_3 >
Mesh_optimization_return_code odt_optimize_mesh_3(C3T3& c3t3, MeshDomain_3 domain)

template< class C3T3, class MeshDomain_3 >
Mesh_optimization_return_code perturb_mesh_3(C3T3& c3t3, MeshDomain_3 domain)

template< class C3T3 >
Mesh_optimization_return_code *exude_mesh_3(C3T3& c3t3)*

Note that the global functions activating the optimization processes or launching those processes have themselves parameters (see details in reference pages) to tune the optimization process.

51.3 Examples

51.3.1 3D Domains Bounded by Isosurfaces

The following code produces a 3D mesh for a domain whose boundary surface is an isosurface defined by an implicit function. Figure 51.5 shows a cut view of the resulting mesh.

Note the use of named parameters (from Boost library) in the constructor of the *Mesh_criteria* instance.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/Mesh_triangulation_3.h>
#include <CGAL/Mesh_complex_3_in_triangulation_3.h>
#include <CGAL/Mesh_criteria_3.h>

#include <CGAL/Implicit_mesh_domain_3.h>
#include <CGAL/make_mesh_3.h>

// Domain
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::FT FT;
typedef K::Point_3 Point;
typedef FT (Function)(const Point&);
typedef CGAL::Implicit_mesh_domain_3<Function,K> Mesh_domain;

// Triangulation
typedef CGAL::Mesh_triangulation_3<Mesh_domain>::type Tr;
typedef CGAL::Mesh_complex_3_in_triangulation_3<Tr> C3t3;

// Criteria
typedef CGAL::Mesh_criteria_3<Tr> Mesh_criteria;

// To avoid verbose function and named parameters call
using namespace CGAL::parameters;

// Function
FT sphere_function (const Point& p)
{ return CGAL::squared_distance(p, Point(CGAL::ORIGIN))-1; }

int main()
{
  // Domain (Warning: Sphere_3 constructor uses squared radius !)
  Mesh_domain domain(sphere_function, K::Sphere_3(CGAL::ORIGIN, 2.));

  // Mesh criteria
```

```
  Mesh_criteria criteria(facet_angle=30, facet_size=0.1,
   facet_distance=0.025,
                              cell_radius_edge_ratio=2, cell_size=0.1);

  // Mesh generation
  C3t3 c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria);

  // Output
  std::ofstream medit_file("out.mesh");
  c3t3.output_to_medit(medit_file);

  return 0;
}
```

File: examples/Mesh_3/mesh_implicit_sphere.cpp

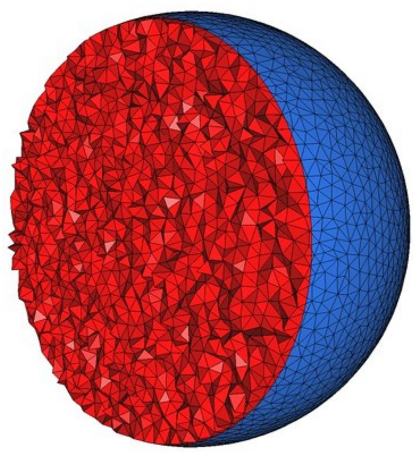

Figure 51.5: Cut view of a 3D mesh produced from an implicit domain

51.3.2 3D Polyhedral Domains

The following code produces a 3D mesh for a domain defined by polyhedral surfaces. Figure 51.6 shows the resulting mesh.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/Mesh_triangulation_3.h>
#include <CGAL/Mesh_complex_3_in_triangulation_3.h>
#include <CGAL/Mesh_criteria_3.h>

#include <CGAL/Polyhedral_mesh_domain_3.h>
#include <CGAL/make_mesh_3.h>
#include <CGAL/refine_mesh_3.h>

// IO
#include <CGAL/IO/Polyhedron_iostream.h>
```

```
// Domain
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Polyhedron_3<K> Polyhedron;
typedef CGAL::Polyhedral_mesh_domain_3<Polyhedron, K> Mesh_domain;

// Triangulation
typedef CGAL::Mesh_triangulation_3<Mesh_domain>::type Tr;
typedef CGAL::Mesh_complex_3_in_triangulation_3<Tr> C3t3;

// Criteria
typedef CGAL::Mesh_criteria_3<Tr> Mesh_criteria;

// To avoid verbose function and named parameters call
using namespace CGAL::parameters;

int main()
{
  // Create input polyhedron
  Polyhedron polyhedron;
  std::ifstream input("data/elephant.off");
  input >> polyhedron;

  // Create domain
  Mesh_domain domain(polyhedron);

  // Mesh criteria (no cell_size set)
  Mesh_criteria criteria(facet_angle=25, facet_size=0.15,
   facet_distance=0.008,
                         cell_radius_edge_ratio=3);

  // Mesh generation
  C3t3 c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria, no_perturb(),
   no_exude());

  // Output
  std::ofstream medit_file("out_1.mesh");
  c3t3.output_to_medit(medit_file);
  medit_file.close();

  // Set tetrahedron size (keep cell_radius_edge_ratio), ignore facets
  Mesh_criteria new_criteria(cell_radius_edge_ratio=3, cell_size=0.03);

  // Mesh refinement
  CGAL::refine_mesh_3(c3t3, domain, new_criteria);

  // Output
  medit_file.open("out_2.mesh");
  c3t3.output_to_medit(medit_file);

  return 0;
}
```

File: examples/Mesh_3/mesh_polyhedral_domain.cpp

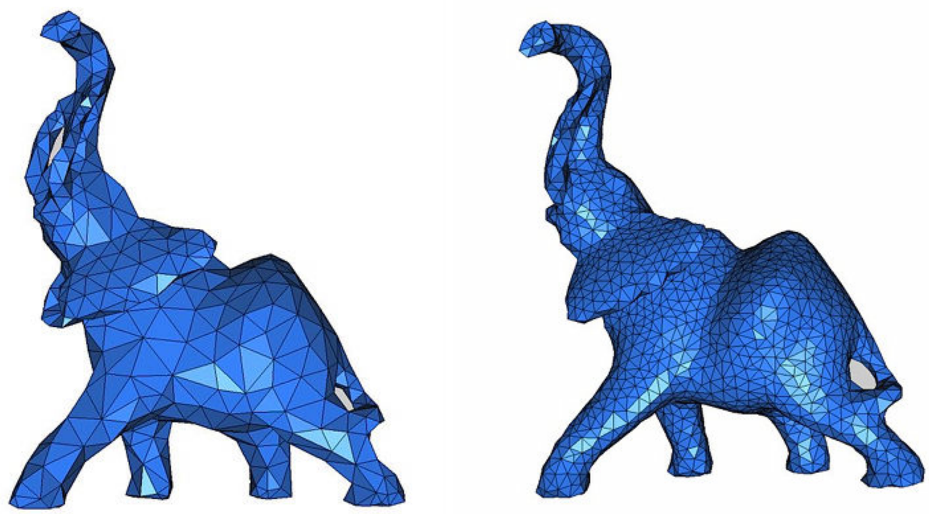

Figure 51.6: View of 3D meshes produced from a polyhedral domain. (i) is a view of file out_1.mesh and (ii) is a view of file out_2.mesh. Code from subsection 51.3.2 generates these files.

51.3.3 Domains From Segmented 3D Images

The following code produces a 3D mesh from a 3D image. The image is a segmented medical image in which each voxel is associated a label in accordance with the tissue the voxel belongs to. The domain is therefore a multi-domain where each subdomain corresponds to a specific tissue.

In the following example, the image is read from the file *liner.inr.gz* which is encoded in the format of the library Inrimage *http://inrimage.gforge.inria.fr/*. The resulting mesh is shown in Figure 51.7.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/Mesh_triangulation_3.h>
#include <CGAL/Mesh_complex_3_in_triangulation_3.h>
#include <CGAL/Mesh_criteria_3.h>

#include <CGAL/Labeled_image_mesh_domain_3.h>
#include <CGAL/make_mesh_3.h>
#include <CGAL/Image_3.h>

// Domain
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Labeled_image_mesh_domain_3<CGAL::Image_3,K> Mesh_domain;

// Triangulation
typedef CGAL::Mesh_triangulation_3<Mesh_domain>::type Tr;
typedef CGAL::Mesh_complex_3_in_triangulation_3<Tr> C3t3;

// Criteria
typedef CGAL::Mesh_criteria_3<Tr> Mesh_criteria;
```

```
// To avoid verbose function and named parameters call
using namespace CGAL::parameters;

int main()
{
  // Loads image
  CGAL::Image_3 image;
  image.read("data/liver.inr.gz");

  // Domain
  Mesh_domain domain(image);

  // Mesh criteria
  Mesh_criteria criteria(facet_angle=30, facet_size=6, facet_distance=4,
                         cell_radius_edge_ratio=3, cell_size=8);

  // Meshing
  C3t3 c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria);

  // Output
  std::ofstream medit_file("out.mesh");
  c3t3.output_to_medit(medit_file);

51.3.4 Using Variable Sizing Field

Sizing field as an analytical function

The following example shows how to use an analytical function as sizing field.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/Mesh_triangulation_3.h>
#include <CGAL/Mesh_complex_3_in_triangulation_3.h>
#include <CGAL/Mesh_criteria_3.h>

#include <CGAL/Implicit_mesh_domain_3.h>
#include <CGAL/make_mesh_3.h>

// Domain
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::FT FT;
typedef K::Point_3 Point;
typedef FT (Function)(const Point&);
typedef CGAL::Implicit_mesh_domain_3<Function,K> Mesh_domain;

// Triangulation
typedef CGAL::Mesh_triangulation_3<Mesh_domain>::type Tr;
typedef CGAL::Mesh_complex_3_in_triangulation_3<Tr> C3t3;

// Criteria
typedef CGAL::Mesh_criteria_3<Tr> Mesh_criteria;

// Sizing field
struct Spherical_sizing_field
{
  typedef ::FT FT;
  typedef Point Point_3;
  typedef Mesh_domain::Index Index;

  FT operator()(const Point_3& p, const int, const Index&) const
  {
    FT sq_d_to_origin = CGAL::squared_distance(p, Point(CGAL::ORIGIN));
    return CGAL::abs( CGAL::sqrt(sq_d_to_origin)-0.5 ) / 5. + 0.025;
  }
};

// To avoid verbose function and named parameters call
using namespace CGAL::parameters;

// Function
FT sphere_function (const Point& p)
{ return CGAL::squared_distance(p, Point(CGAL::ORIGIN))-1; }

int main()
{
  // Domain (Warning: Sphere_3 constructor uses squared radius !)
  Mesh_domain domain(sphere_function, K::Sphere_3(CGAL::ORIGIN, 2.));
```

```
  // Mesh criteria
  Spherical_sizing_field size;
  Mesh_criteria criteria(facet_angle=30, facet_size=0.1,
   facet_distance=0.025,
                         cell_radius_edge_ratio=2, cell_size=size);

  // Mesh generation
  C3t3 c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria, no_exude(),
   no_perturb());

  // Output
  std::ofstream medit_file("out.mesh");
  c3t3.output_to_medit(medit_file);

  return 0;
}
```

Different Sizing Field for Different Subdomains

The following example shows how to use different size for different organs in a 3D medical image.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/Mesh_triangulation_3.h>
#include <CGAL/Mesh_complex_3_in_triangulation_3.h>
#include <CGAL/Mesh_criteria_3.h>
#include <CGAL/Mesh_constant_domain_field_3.h>
```

```
#include <CGAL/Labeled_image_mesh_domain_3.h>
#include <CGAL/make_mesh_3.h>
#include <CGAL/Image_3.h>

// Domain
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Labeled_image_mesh_domain_3<CGAL::Image_3,K> Mesh_domain;

// Triangulation
typedef CGAL::Mesh_triangulation_3<Mesh_domain>::type Tr;
typedef CGAL::Mesh_complex_3_in_triangulation_3<Tr> C3t3;

// Criteria
typedef CGAL::Mesh_criteria_3<Tr> Mesh_criteria;
typedef CGAL::Mesh_constant_domain_field_3<Mesh_domain::R,
                                           Mesh_domain::Index>
   Sizing_field;

// To avoid verbose function and named parameters call
using namespace CGAL::parameters;

int main()
{
  // Loads image
  CGAL::Image_3 image;
  image.read("data/liver.inr.gz");

  // Domain
  Mesh_domain domain(image);

  // Sizing field: set global size to 8 and kidney size (label 127) to 3
  double kidney_size = 3.;
  int volume_dimension = 3;
  Sizing_field size(8);
  size.set_size(kidney_size, volume_dimension,
                domain.index_from_subdomain_index(127));

  // Mesh criteria
  Mesh_criteria criteria(facet_angle=30, facet_size=6, facet_distance=2,
                         cell_radius_edge_ratio=3, cell_size=size);

  // Meshing
  C3t3 c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria);

  // Output
  std::ofstream medit_file("out.mesh");
  c3t3.output_to_medit(medit_file);

  return 0;
}
```

51.3.5 Meshing Domains with Sharp Features

3D polyhedral domain with edges

The following example shows how to generate a mesh from a polyhedral surface. The output mesh conforms to the sharp features of the input surface.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/Mesh_triangulation_3.h>
#include <CGAL/Mesh_complex_3_in_triangulation_3.h>
#include <CGAL/Mesh_criteria_3.h>

#include <CGAL/Polyhedral_mesh_domain_with_features_3.h>
#include <CGAL/make_mesh_3.h>

// Domain
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Polyhedral_mesh_domain_with_features_3<K> Mesh_domain;

// Triangulation
typedef CGAL::Mesh_triangulation_3<Mesh_domain>::type Tr;
typedef CGAL::Mesh_complex_3_in_triangulation_3<
  Tr,Mesh_domain::Corner_index,Mesh_domain::Curve_segment_index> C3t3;

// Criteria
typedef CGAL::Mesh_criteria_3<Tr> Mesh_criteria;

// To avoid verbose function and named parameters call
using namespace CGAL::parameters;

int main()
{
```

```
  // Create domain
  Mesh_domain domain("data/fandisk.off");

  // Get sharp features
  domain.detect_features();

  // Mesh criteria
  Mesh_criteria criteria(edge_size = 0.025,
                         facet_angle = 25, facet_size = 0.05,
   facet_distance = 0.005,
                         cell_radius_edge_ratio = 3, cell_size = 0.05);

  // Mesh generation
  C3t3 c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria);

  // Output
  std::ofstream medit_file("out.mesh");
  c3t3.output_to_medit(medit_file);
}
```

File: examples/Mesh_3/mesh_polyhedral_domain_with_features.cpp

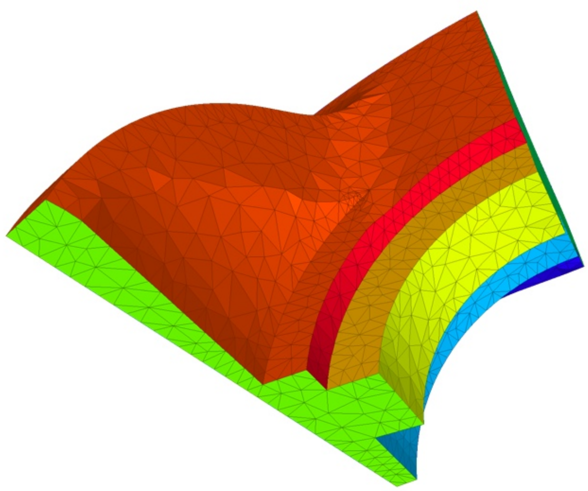

Figure 51.10: View of a 3D mesh with sharp features. Code from subsection 51.3.5 generates this mesh.

Implicit domain with 1D features

The following example shows how to generate a mesh from an implicit domain. We add by hand the intersection of the spheres as a sharp feature.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/Mesh_triangulation_3.h>
#include <CGAL/Mesh_complex_3_in_triangulation_3.h>
#include <CGAL/Mesh_criteria_3.h>
```

```
#include <CGAL/Implicit_mesh_domain_3.h>
#include <CGAL/Mesh_domain_with_polyline_features_3.h>
#include <CGAL/make_mesh_3.h>

// Kernel
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

// Domain
typedef K::FT FT;
typedef K::Point_3 Point;
typedef FT (Function)(const Point&);
typedef CGAL::Mesh_domain_with_polyline_features_3<
  CGAL::Implicit_mesh_domain_3<Function,K> >              Mesh_domain;

// Polyline
typedef std::vector<Point>        Polyline_3;
typedef std::list<Polyline_3>       Polylines;

// Triangulation
typedef CGAL::Mesh_triangulation_3<Mesh_domain>::type Tr;
typedef CGAL::Mesh_complex_3_in_triangulation_3<
  Tr,Mesh_domain::Corner_index,Mesh_domain::Curve_segment_index> C3t3;

// Criteria
typedef CGAL::Mesh_criteria_3<Tr> Mesh_criteria;

// To avoid verbose function and named parameters call
using namespace CGAL::parameters;

// Function
FT sphere_function1 (const Point& p)
{ return CGAL::squared_distance(p, Point(CGAL::ORIGIN))-2; }

FT sphere_function2 (const Point& p)
{ return CGAL::squared_distance(p, Point(2, 0, 0))-2; }

FT sphere_function (const Point& p)
{
  if(sphere_function1(p) < 0 || sphere_function2(p) < 0)
    return -1;
  else
    return 1;
}

#include <cmath>

int main()
{
  // Domain (Warning: Sphere_3 constructor uses squared radius !)
  Mesh_domain domain(sphere_function, K::Sphere_3(Point(1, 0, 0), 6.));

  // Mesh criteria
  Mesh_criteria criteria(edge_size = 0.15,
```

```
                             facet_angle = 25, facet_size = 0.15,
                             cell_radius_edge_ratio = 2, cell_size = 0.15);

  // Create edge that we want to preserve
  Polylines polylines (1);
  Polyline_3& polyline = polylines.front();

  for(int i = 0; i < 360; ++i)
  {
    Point p (1, std::cos(i*CGAL_PI/180), std::sin(i*CGAL_PI/180));
    polyline.push_back(p);
  }
  polyline.push_back(polyline.front()); // close the line

  // Insert edge in domain
  domain.add_features(polylines.begin(), polylines.end());

  // Mesh generation without feature preservation
  C3t3 c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria,
                                      CGAL::parameters::no_features());

  std::ofstream medit_file("out-no-protection.mesh");
  c3t3.output_to_medit(medit_file);
  medit_file.close();
  c3t3.clear();

  // Mesh generation with feature preservation
  c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria);

  // Output
  medit_file.open("out-with-protection.mesh");
  c3t3.output_to_medit(medit_file);
  medit_file.close();

  return 0;
}
```

File: examples/Mesh_3/mesh_two_implicit_spheres_with_balls.cpp

51.3.6 Tuning Mesh Optimization

In the previous examples, the mesh generation is launched through a call *make_mesh_3(domain,criteria)* with a minimal number of parameters. In such cases, the default optimization strategy is applied: after the Delaunay refinement process two optimization steps are performed, a perturbation and a sliver exudation. The following examples show how to disable default optimization steps and how to tune the parameters of optimization steps.

Disabling exudation and tuning perturbation

In this first example, we show how to disable the exudation step. The optimization phase after the refinement includes only a perturbation phase which is launched with no time bound and an objective of 10 degrees for the

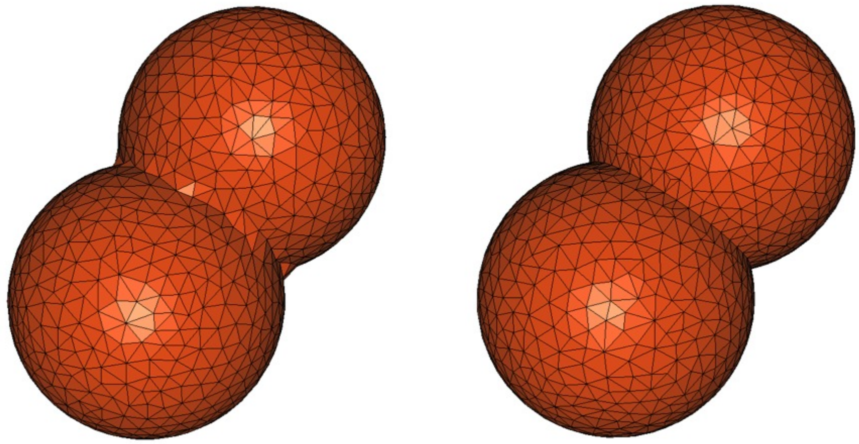

Figure 51.11: View of a 3D mesh with sharp features generated from two intersected implicit spheres. On the left, one can see the mesh without feature preservation, and on the right the mesh with feature preservation.

minimum dihedral angle of the mesh. The example shows two ways of achieving the same result. The first way issues a single call to *make_mesh_3* with the required optimization process activated and tuned. In the second way, *make_mesh_3* is first called without any optimization process and the resulting mesh is next optimized through a call to *perturb_mesh_3* with tuned parameters.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/Mesh_triangulation_3.h>
#include <CGAL/Mesh_complex_3_in_triangulation_3.h>
#include <CGAL/Mesh_criteria_3.h>

#include <CGAL/Labeled_image_mesh_domain_3.h>
#include <CGAL/make_mesh_3.h>
#include <CGAL/Image_3.h>

// Domain
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Labeled_image_mesh_domain_3<CGAL::Image_3,K> Mesh_domain;

// Triangulation
typedef CGAL::Mesh_triangulation_3<Mesh_domain>::type Tr;
typedef CGAL::Mesh_complex_3_in_triangulation_3<Tr> C3t3;

// Mesh Criteria
typedef CGAL::Mesh_criteria_3<Tr> Mesh_criteria;

// To avoid verbose function and named parameters call
using namespace CGAL::parameters;

int main()
{
  // Domain
  CGAL::Image_3 image;
  image.read("data/liver.inr.gz");
  Mesh_domain domain(image);
```

```
  // Mesh criteria
  Mesh_criteria criteria(facet_angle=30, facet_size=5,
    facet_distance=1.5,
                         cell_radius_edge_ratio=2, cell_size=7);

  // Mesh generation and optimization in one call (sliver_bound is the
  // targeted dihedral angle in degree)
  C3t3 c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria,
                                      no_exude(),
                                      perturb(sliver_bound=10,
    time_limit=15));

  // Mesh generation and optimization in several call
  C3t3 c3t3_bis = CGAL::make_mesh_3<C3t3>(domain, criteria,
                                          no_perturb(), no_exude());

  CGAL::perturb_mesh_3(c3t3_bis, domain, time_limit=15);

  // Output
  std::ofstream medit_file("out.mesh");
  c3t3.output_to_medit(medit_file);

  std::ofstream medit_file_bis("out_bis.mesh");
  c3t3_bis.output_to_medit(medit_file_bis);

  return 0;
}
```

File: examples/Mesh_3/mesh_optimization_example.cpp

Using Lloyd global optimization

In this second example, we show how to call the Lloyd optimization on the mesh, followed by a call to exudation. We set a time bound of 30s for the Lloyd optimization. We set a time bound of 10s and a sliver bound of 10 degrees for the exuder.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/Mesh_triangulation_3.h>
#include <CGAL/Mesh_complex_3_in_triangulation_3.h>
#include <CGAL/Mesh_criteria_3.h>

#include <CGAL/Labeled_image_mesh_domain_3.h>
#include <CGAL/make_mesh_3.h>
#include <CGAL/Image_3.h>

// Domain
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Labeled_image_mesh_domain_3<CGAL::Image_3,K> Mesh_domain;

// Triangulation
```

```
typedef CGAL::Mesh_triangulation_3<Mesh_domain>::type Tr;
typedef CGAL::Mesh_complex_3_in_triangulation_3<Tr> C3t3;

// Mesh Criteria
typedef CGAL::Mesh_criteria_3<Tr> Mesh_criteria;

// To avoid verbose function and named parameters call
using namespace CGAL::parameters;

int main()
{
  // Domain
  CGAL::Image_3 image;
  image.read("data/liver.inr.gz");
  Mesh_domain domain(image);

  // Mesh criteria
  Mesh_criteria criteria(facet_angle=30, facet_distance=1.2,
                         cell_radius_edge_ratio=2);

  // Mesh generation and optimization in one call
  C3t3 c3t3 = CGAL::make_mesh_3<C3t3>(domain, criteria,
                                      lloyd(time_limit=30),
                                      no_perturb(),
                                      exude(time_limit=10,
   sliver_bound=10));

  // Mesh generation and optimization in several call
  C3t3 c3t3_bis = CGAL::make_mesh_3<C3t3>(domain, criteria,
                                          no_perturb(), no_exude());

  CGAL::lloyd_optimize_mesh_3(c3t3_bis, domain, time_limit=30);
  CGAL::exude_mesh_3(c3t3_bis, sliver_bound=10, time_limit=10);

  // Output
  std::ofstream medit_file("out.mesh");
  c3t3.output_to_medit(medit_file);

  std::ofstream medit_file_bis("out_bis.mesh");
  c3t3_bis.output_to_medit(medit_file_bis);

  return 0;
}
```

51.4 Performances

We provide here some benchmarks of the performances of the mesh generation engine. The machine used is a PC running Linux64 with two Intel Xeon CPU X5450 clocked at 3.00 GHz with 32GB of RAM. The program has been compiled with g++ v4.3.2 with the -O3 option. Note that our implementation does not take advantage of multi-core architectures.

Those benchmarks have been done using CGAL v3.8.

51.4.1 Delaunay refinement

We study the refinement part of the mesh generation engine in this section. We give the CPU time (measured by *CGAL::Timer*) using the 3 provided oracles. In all experiments, we produce well shaped elements: we set the facet angle bound and the radius edge bound to their theoretical limit (resp. 30 degrees and 2). We also use the same uniform sizing field for facets and cells.

Implicit function

We mesh an analytical sphere of radius 1.

Size bound	vertices nb	facets nb	tetrahedra nb	CPU Time (s)	vertices/second
0.2	499	488	2,299	0.0240	20,800
0.1	3,480	2,046	18,756	0.146	23,800
0.05	25,556	8,274	149,703	1.50	17,000
0.025	195,506	33,212	1,194,727	17.4	11,200
0.0125	1,528,636	134,810	9,547,772	179	8,530

Polyhedral domain

We mesh a volume bounded by a closed triangulated surface made of about 50,000 vertices and 100,000 triangles. Picture 51.12 shows the mesh obtained when size is set to 0.005.

Size bound	vertices nb	facets nb	tetrahedra nb	CPU Time (s)	vertices/second
0.04	423	717	1,332	0.488	866
0.02	2,638	3,414	10,957	2.64	998
0.01	18,168	15,576	90,338	13.9	1,310
0.005	129,442	64,645	722,018	66.7	1,940
0.0025	967,402	263,720	5,756,491	348	2,780

3D image

We mesh image number 2 from the 3D-IRCADb-01[1] public database. The size of this image is 512x512x172 voxels (about 45M voxels). The size of the voxels is 0.78mm x 0.78mm x 1.6mm. Picture 51.13 shows the mesh obtained for size set to 4.

Size bound (mm)	vertices nb	facets nb	tetrahedra nb	CPU Time (s)	vertices/second
16	3,898	4,099	20,692	0.344	11,300
8	34,117	27,792	199,864	3.09	11,000
4	206,566	86,180	1,253,694	22.4	9,230
2	1,546,196	329,758	9,617,278	199	7,780

51.5 Design and Implementation History

Theoretical foundations

The CGAL mesh generation package implements a meshing engine based on the method of Delaunay refinement introduced by Chew [Che93] and Ruppert [Rup95] and pioneered in 3D by Shewchuk [She98b]. It uses the notion of restricted Delaunay triangulation to approximate 1-dimensional curved features and curved surface patches and rely on the work of Boissonnat and Oudot [BO05] and Oudot et al. [ORY05] to achieve accurate representation of boundary and subdividing surfaces in the mesh. The mechanism of protecting balls, used to ensure a fair representation of 1-dimensional features, if any, and the termination of the refinement process whatever may be the input geometry, in particular whatever small dihedral angles may form the boundary and subdivision surface patches, was pioneered by Cheng et al. [CDR07] and further experimented by Dey, Levine et al. [CDL07]. The optimization phase involves global optimization processes, a perturbation process and a sliver exudation process. The global optimizers are based on Lloyd smoothing [DFG99, DW02] and odt smoothing [Che04, ACSYD05], where odt means *optimal Delaunay triangulation*. The perturbation process is mainly based on the work of Tournois [Tou09] and Tournois et al. [TWAD09], while the exudation process is, the now famous, optimization by weighting described in Edelsbrunner et al. [CDE+00].

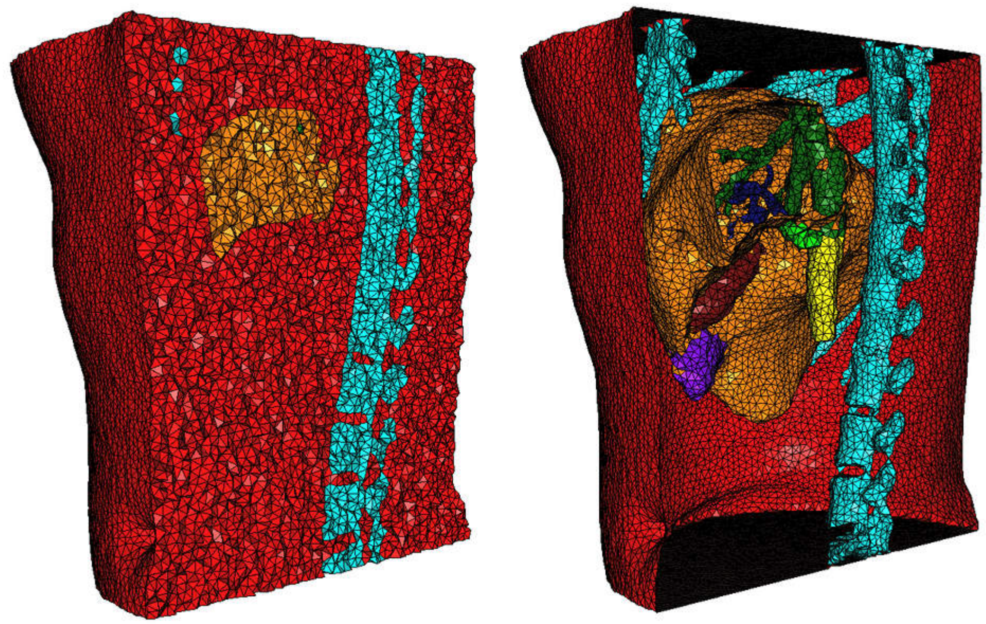

Figure 51.13: View of 3d image mesh generation result (size = 4).

Implementation history

Work on the package *Mesh_3* started during the PhD thesis of Laurent Rineau advised by Mariette Yvinec. A code prototype, together with a first version of design and specifications [RY07] came out of their collaboration.

From the beginning of 2009, most of the work has been performed by Stéphane Tayeb, in collaboration with Mariette Yvinec, Laurent Rineau, Pierre Alliez and Jane Tournois. First, Stéphane released the first public version of the package, implementing the specifications written by Laurent and Mariette.

The optimization processes are heavily based on the work of Jane Tournois and Pierre Alliez during the PhD of Jane advised by Pierre. The optimization phase was imported in the mesh generation package by Stéphane Tayeb and appeared first in release 3.6 of CGAL.

In collaboration with Laurent Rineau, Stéphane also added demos and examples. After some experiments on medical imaging data performed by Dobrina Boltcheva et al. [BYB09b, BYB09a], the handling of 1-dimensional features was worked out by Laurent Rineau, Stéphane Tayeb and Mariette Yvinec. It appeared first in the release 3.8 of CGAL.

Concept

MeshComplex_3InTriangulation_3

Definition

The concept MeshComplex_3InTriangulation_3 describes a data structure to represent and maintain a 3D complex embedded in a 3D triangulation. More precisely, the concept MeshComplex_3InTriangulation_3 is a minimal version designed to represent 3D complexes that have only faces with dimension 2 and 3. Embedded 3D complexes with faces of dimension 0, 1, 2 and 3, are more conveniently represented by the refined concept *MeshComplexWithFeatures_3InTriangulation_3*.

The data structure includes a 3D triangulation which is itself a 3D complex. To distinguish the faces of the embedded 3D complex from the faces of the triangulation, we call the faces of the embedded complex respectively *subdomains*, for 3D faces and *surface patches*, for 2D faces, while the triangulations faces are called respectively cells, facets, edges and vertices.

Each subdomain of the embedded 3D complex is a union of triangulation cells. Cells that belong to some subdomain are said to belong to the embedded complex. Each surface patch is a union of triangulation facets. Triangulation facets that belong to some surface patch are called surface facets. The concept MeshComplex_3InTriangulation_3 handles the marking and retrieval of the cells of the triangulation belonging to the subdomains and of the facets of the triangulation belonging to the surface patches. The concept MeshComplex_3InTriangulation_3 also includes an index type for vertices of the triangulation and attaches an integer, called the *dimension* to each vertex. When used by the meshing algorithm, the index and the dimension of each vertex are used to store respectively the lowest dimensional face of the input complex including the vertex and the dimension of this face.

In the 3D mesh generator, the concept MeshComplex_3InTriangulation_3 is used when the domain to be meshed has no feature with dimension 0 and 1. Such a data structure is used internally by the mesh generator to maintain the current approximation of each subdomain and each boundary surface patch. The data structure encodes the final mesh at the end of the meshing process.

Types

MeshComplex_3InTriangulation_3:: Triangulation

Type of the embedding 3D triangulation. This type must be a 3D regular triangulation of CGAL when used for 3D mesh generation.

typedef Triangulation::Vertex_handle
Vertex_handle; — Type *Vertex_handle* type of the triangulation.

typedef Triangulation::Cell_handle
Cell_handle; — The *Cell_handle* type of the triangulation.

typedef Triangulation::Facet
Facet; — The *Facet* type of the triangulation.

typedef Triangulation::Edge
Edge; — The *Edge* type of the triangulation.

typedef Triangulation::size_type
size_type; — Size type (unsigned integral type).

MeshComplex_3InTriangulation_3:: Subdomain_index

A type for indices of subdomains. This type must match the type *MeshDomain_3::Subdomain_index* when the concept is used for mesh generation.

MeshComplex_3InTriangulation_3:: Surface_patch_index

A type for indices of surface patches. This type must match the type *MeshDomain_3::Surface_patch_index* when the concept is used for mesh generation.

MeshComplex_3InTriangulation_3:: Index — A type for indexing vertices that belong to some surface patches or subdomains. This type must match the type *MeshDomain_3::Index* when the concept is used for mesh generation.

MeshComplex_3InTriangulation_3:: Cells_in_complex_iterator

An iterator type to visit the cells of the triangulation belonging to the 3D complex.

MeshComplex_3InTriangulation_3:: Facets_in_complex_iterator

An iterator type to visit the surface facets.

Creation

MeshComplex_3InTriangulation_3 c3t3;	Builds an empty 3D complex.
MeshComplex_3InTriangulation_3 c3t3(rhs);	Copy constructor. Embedded triangulation is duplicated.

MeshComplex_3InTriangulation_3&

	c3t3 = rhs	Assignment operator. Embedded triangulation is duplicated, and the former triangulation of *c3t3* is deleted.
void	*c3t3.swap(& rhs)*	Swaps *c3t3* and *rhs*.

Access Functions

Triangulation *c3t3.triangulation() const*

Returns a const reference to the triangulation.

advanced

Non const access

The responsibility of keeping a valid C3T3 belongs to the user when using advanced operations allowing a direct manipulation of the triangulation.

Triangulation&	*c3t3.triangulation()*	Returns a reference to the triangulation.

advanced

Modifiers

void *c3t3.add_to_complex(Cell_handle c, Subdomain_index index)*

Sets the cell *c* as a cell of the subdomain *index*.

void *c3t3.add_to_complex(Facet f, Surface_patch_index index)*

Adds the facet *f* as a facet of the surface patch *index*.)

void *c3t3.add_to_complex(Cell_handle c, int i, Surface_patch_index index)*

Same as above with *f=(c,i)*.

void *c3t3.remove_from_complex(Cell_handle c)*

Removes cell *c* from the embedded complex.

void *c3t3.remove_from_complex(Facet f)*

Removes facet *f* from the embedded complex.

void *c3t3.remove_from_complex(Cell_handle c, int i)*

Same as above with *f=(c,i)*.

void *c3t3.set_dimension(Vertex_handle v, int dimension)*

Sets the "dimension" of vertex *v*. The dimension is an integer attached to the vertex. When the concept MeshComplex_3InTriangulation_3 is used for mesh generation this integer is used to store the dimension of the lowest dimensional face of the input complex including the vertex.

void *c3t3.set_index(Vertex_handle v, Index index)*

Sets the index of a vertex.

Queries

Queries on the faces of the embedded complex.

size_type *c3t3.number_of_cells()*

Returns the number of cells that belong to the embedded complex.

size_type *c3t3.number_of_cells(Subdomain_index index)*

Returns the number of cells that belong to the subdomain of the embedded complex with index *index*.

size_type *c3t3.number_of_facets()*

Returns the number of facets that are surface facets, i. e. belong to some surface patch of the embedded complex.

size_type *c3t3.number_of_facets(Surface_patch_index index)*

Returns the number of facets that belong to the surface patch of the embedded complex with index *index*.

bool *c3t3.is_in_complex(Cell_handle c)*

Returns *true* iff the cell *c* belongs to the 3D complex.

bool *c3t3.is_in_complex(Facet f)*

Returns *true* iff the facet *f* belongs to the boundary 2D complex.

bool *c3t3.is_in_complex(Cell_handle c, int i)*

Same as above with *f=(c,i)*.

Queries on the identifier of the face complex including triangulation cells, facets and vertices.

Subdomain_index *c3t3.subdomain_index(Cell_handle c)*

Returns the index of the subdomain containing the cell *c*. The default subdomain index is returned if the cell *c* does not belong to the embedded complex.

Surface_patch_index *c3t3.surface_patch_index(Facet f)*

For a surface facet, returns the index of the surface patch containing the facet. The default *Surface_patch_index* value is returned if the facet is not a surface facet.

Surface_patch_index *c3t3.surface_patch_index(Cell_handle c, int i)*

Same as above with *f=(c,i)*.

int *c3t3.in_dimension(Vertex_handle v) const*

Returns the dimension of the vertex *v*.

Index *c3t3.index(Vertex_handle v) const*

Returns the index of the vertex *v*.

Traversal of the complex

The data structure provides iterators to visit the cells and facets of the complex. All those iterators are bidirectional and non mutable.

Cells_in_complex_iterator

c3t3.cells_in_complex_begin()

Returns a *Cell_in_complex_iterator* to visit the cells of the triangulation contained in the embedded complex.

Cells_in_complex_iterator

c3t3.cells_in_complex_end()

Returns the past-the-end iterator for the above iterator.

Cells_in_complex_iterator

c3t3.cells_in_complex_begin(Subdomain_index index)

Returns a *Cell_in_complex_iterator* to visit the cells of the triangulation which belong to the approximation of subdomain of index *index*.

Cells_in_complex_iterator

c3t3.cells_in_complex_end(Subdomain_index index)

Returns the past-the-end iterator for the above iterator.

Facets_in_complex_iterator

c3t3.facets_in_complex_begin()

Returns a *Facet_in_complex_iterator* to visit the facets in the surface patches of the embedded complexes.

Facets_in_complex_iterator

c3t3.facets_in_complex_end()

Returns the past-the-end iterator for the above iterator.

Facets_in_complex_iterator

c3t3.facets_in_complex_begin(Surface_patch_index index)

Returns a *Facet_in_complex_iterator* to visit the facets of the triangulation which which belong to the approximation of surface patch of index *index*.

Facets_in_complex_iterator

c3t3.facets_in_complex_end(Surface_patch_index index)

Returns the past-the-end iterator for the above iterator.

Concept

MeshComplexWithFeatures_3InTriangulation_3

Definition

The concept MeshComplexWithFeatures_3InTriangulation_3 describes a data structure to represent and maintain a 3D complex embedded in a 3D triangulation. The concept MeshComplexWithFeatures_3InTriangulation_3 refines the minimal concept *MeshComplex_3InTriangulation_3*, designed to represent 3D complexes having only faces with dimension 2 and 3. Therefore, the concept MeshComplexWithFeatures_3InTriangulation_3 may represent embedded complexes including *features*, i.e. faces with dimension 0 and 1.

The data structure includes a 3D triangulation which is itself a 3D complex. To distinguish the faces of the embedded 3D complex from the faces of the triangulation, we call respectively *subdomains*, *surface patches* *curve segments* and *corners* the faces of the complex with respective dimensions 3, 2, 1 and 0. The triangulations faces are called respectively cells, facets, edges and vertices.

Each subdomain of the embedded 3D complex is a union of triangulation cells. Likewise, each surface patch is a union of triangulation facets and each curve segment is a union of triangulation edges. The corners form a subset of the triangulation vertices. Note that subdomains, surface patches and and curved segments are not necessarily connected. Likewise each corner may be related to several mesh vertices. Triangulation facets that belong to some surface patch are called surface facets.

The concept MeshComplexWithFeatures_3InTriangulation_3 allows us to mark and retrieve the cells of the triangulation belonging to the subdomains, the facets of the triangulation belonging to surface patches, the edges belonging to curve segments and the vertices that are corners of the embedded complex.

Within the mesh generation functions, the concept MeshComplexWithFeatures_3InTriangulation_3 is the concept describing the data structure used to maintain the current approximation of the input domain. At the end of the meshing process, the data structure encodes the resulting mesh. In particular, each subdomain (resp. surface patch) of the input domain is then approximated by a subdomain (resp. a surface patch) of the embedded complex while the curve segments and corners represent the 1 and 0-dimensional features of the input complex.

Refines

MeshComplex_3InTriangulation_3

Types

MeshComplexWithFeatures_3InTriangulation_3:: Curve_segment_index

A type for indexes of curve segment. The type must match the type *MeshDomainWithFeatures_3::Curve_segment_index* when the concept is used for mesh generation.

MeshComplexWithFeatures_3InTriangulation_3:: Corner_index

A type for indexes of corners. The type must match the type *MeshDomainWithFeatures_3::Corner_index* when the concept is used for mesh generation.

MeshComplexWithFeatures_3InTriangulation_3:: Edges_in_complex_iterator

An iterator type to visit the edges of the triangulation belonging to curve segments.

MeshComplexWithFeatures_3InTriangulation_3:: Vertices_in_complex_iterator

An iterator type to visit the vertices of the triangulation that are corners of the embedded complex.

Modifiers

void *c3t3.add_to_complex(Edge e, Curve_segment_index index)*

Adds edge *e* as an element of the curve segment with index *index*.

void *c3t3.add_to_complex(Vertex_handle v1, Vertex_handle v2, Curve_segment_index index)*

Same as above with *e=(v1,v2)*.

void *c3t3.add_to_complex(Vertex_handle v, Corner_index index)*

Marks vertex *v* as a corner with index *index*.

void *c3t3.remove_from_complex(Edge e)*

Removes edge *e* from the embedded complex.

void *c3t3.remove_from_complex(Vertex_handle v1, Vertex_handle v2)*

Same as above with *e=(v1,v2)*.

void *c3t3.remove_from_complex(Vertex_handle v)*

Removes vertex *v* from the embedded complex.

Queries

Queries on the 1D complex and 0D complex.

size_type *c3t3.number_of_edges() const*

Returns the number of edges which belong to curve segments.

size_type *c3t3.number_of_edges(Curve_segment_index index) const*

Returns the number of edges which belong to curve segment with index *index*.

size_type *c3t3.number_of_corners() const*

Returns the number of vertices which are corners of the complex.

size_type *c3t3.number_of_corners(Corner_index index) const*

Returns the number of vertices which are corners of the complex with index *index*.

bool *c3t3.is_in_complex(Edge e) const*

Returns *true* iff edge *e* belongs to some curve segment.

bool *c3t3.is_in_complex(Vertex_handle v1, Vertex_handle v2) const*

Same as above with *e=(v1,v2)*.

bool *c3t3.is_in_complex(Vertex_handle v) const*

Returns *true* if vertex *v* is a corner.

Curve_segment_index

c3t3.curve_segment_index(Edge e)

Returns *Curve_segment_index* of edge *e*. The default *Curve_segment_index* value is returned if edge *e* does not belong to any curve segment.

Curve_segment_index

c3t3.curve_segment_index(Vertex_handle v1, Vertex_handle v2)

Same as above with *e=(v1,v2)*.

Corner_index *c3t3.corner_index(Vertex_handle v)*

Returns *Corner_index* of vertex *v*. The default *Corner_index* value is returned if vertex *v* is not a corner of the complex.

Traversal of the complex

Edges_in_complex_iterator

c3t3.edges_in_complex_begin() const

Returns an *Edges_in_complex_iterator* to visit the edges of the triangulation belonging to curve segments.

Edge_in_complex_iterator

c3t3.edges_in_complex_end() const

Returns the past-the-end iterator for the above iterator.

Edges_in_complex_iterator

c3t3.edges_in_complex_begin(Curve_segment_index index) const

Returns an *Edges_in_complex_iterator* to visit the edges of the triangulation belonging to curve segments of index *index*.

Edge_in_complex_iterator

c3t3.edges_in_complex_end(Curve_segment_index index) const

Returns the past-the-end iterator for the above iterator.

template <typename OutputIterator>
OutputIterator *c3t3.adjacent_vertices_in_complex(Vertex_handle v, OutputIterator out) const*

Fills *out* with the vertices of the triangulation that are adjacent to vertex *v* through an edge belonging to some curve segment. The value type of *out* must be *std::pair<Vertex_handle,Curve_segment_index>*.
Precondition: *c3t3.in_dimension(v) < 2*

Vertices_in_complex_iterator

c3t3.vertices_in_complex_begin() const

Returns a *Vertices_in_complex_iterator* to visit the vertices of the triangulation that are corners.

Vertices_in_complex_iterator

c3t3.vertices_in_complex_end() const

Returns the past-the-end iterator for the above iterator.

Vertices_in_complex_iterator

c3t3.vertices_in_complex_begin(Corner_index index) const

Returns a *Vertices_in_complex_iterator* to visit the vertices of the triangulation that are corners of index *index*.

Vertices_in_complex_iterator

c3t3.vertices_in_complex_end(Corner_index index) const

Returns the past-the-end iterator for the above iterator.

Concept

MeshDomain_3

Definition

The concept MeshDomain_3 describes the knowledge required on the object to be discretized. The concept MeshDomain_3 is the concept to be used when the input domain does not have 0 or 1-dimensional features that need to be accurately approximated by the mesh. In such a case, the queries issued by the meshing process concern only the faces of the input domain with dimension 3 and 2, that are respectively called *subdomains* and *surface patches*.

More specifically the concept MeshDomain_3 provides a method to localize a point with respect to the input domain and its subdomains. Moreover, as the concept *SurfaceMeshTraits_3*, it also provides predicates to test whether a query segment (or a ray, or a line) intersects the boundary of the domain or of the subdomains, and constructors to compute some intersection point if any. It also includes a method able to provide a small set of initial points on the boundary.

In the following we consider only proper intersection with the domain and subdomain boundaries. A segment, ray or line is said to intersect properly the domain boundary (resp. a subdomain boundary) if it includes points which are strictly inside and strictly outside the domain (resp. the subdomain).

Types

MeshDomain_3:: R	Geometric traits class. This type is defined to ensure compatibility with *CGAL::Kernel_traits<T>*.
MeshDomain_3:: Point_3	Point type.
MeshDomain_3:: Segment_3	Segment type.
MeshDomain_3:: Ray_3	Ray type.
MeshDomain_3:: Line_3	Line type.
typedef CGAL::Tag_false *Has_features;*	A type to distinguish *MeshDomain_3* models from *MeshDomainWithFeatures_3* models.
MeshDomain_3:: Subdomain_index	Type of indices for subdomains of the input domain. Must be a model of CopyConstructible, Assignable, DefaultConstructible and EqualityComparable. The default constructed value must match the label of the exterior of the domain (which contains at least the unbounded component).
MeshDomain_3:: Surface_patch_index	Type of indices for surface patches (boundaries and interfaces) of the input domain. Must be a model of CopyConstructible, Assignable, DefaultConstructible and EqualityComparable. The default constructed value must be the index value assigned to a non surface facet.
MeshDomain_3:: Index	Type of indices to be stored at mesh vertices to characterize the lowest dimensional face of the input complex on which the vertex lies. Must be a model of CopyConstructible, Assignable, DefaultConstructible and EqualityComparable.

typedef CGAL::cpp0x::tuple<Point_3, Index, int>

Intersection;	Return type of *Construct_intersection* queries. *int* represents the dimension of the lower dimensional face of the input complex on which the intersection point lies and *Index* is the index of this face.

MeshDomain_3:: Construct_initial_points	A function object to construct a set of initial points on the surface of the domain. Provides the following operators: *template<typename OutputIterator>* *OutputIterator operator()(OutputIterator pts)* *template<typename OutputIterator>* *OutputIterator operator()(int n, OutputIterator pts)* Those two operators output a set of (n) surface points to the output iterator *pts*, as objects of type *std::pair<Point_3, Index>*. If n is not given, the functor must provide enough points to initialize the mesh generation process.
MeshDomain_3:: Is_in_domain	A function object to query whether a point is in the input domain or not. In the positive case, it outputs the subdomain which includes the query point. Provides the operator: *boost::optional<Subdomain_index> operator()(Point_3 p)*
MeshDomain_3:: Do_intersect_surface	A function object which answers intersection queries between the surface patches of the domain and objects of type *Segment_3*, *Ray_3* or *Line_3*. Provides the operators: *boost::optional<Surface_patch_index> operator()(Segment_3 s)* *boost::optional<Surface_patch_index> operator()(Ray_3 r)* *boost::optional<Surface_patch_index> operator()(Line_3 l)* The return type of the operators tell whether or not the query intersects a surface patch. In the positive case, it provides (through operator*()) the *Surface_patch_index* of one of the intersected surface patches.
MeshDomain_3:: Construct_intersection	A function object to construct the intersection between an object of type *Segment_3*, *Ray_3* or *Line_3* and an interface. Provides the operators: *Intersection operator()(Segment_3 s)* *Intersection operator()(Ray_3 r)* *Intersection operator()(Line_3 l)* *Precondition*: do_intersect_surface(s/r/l) == true

Operations

The following functions give access to the function objects:

Construct_initial_points	
	domain.construct_initial_points_object()
Is_in_domain	*domain.is_in_domain_object()*
Do_intersect_surface	*domain.do_intersect_surface_object()*

Construct_intersection

domain.construct_intersection_object()

These methods are designed to convert indices:

Index	*domain.index_from_surface_patch_index(Surface_patch_index surface_patch_index)*	
		Returns the index to be stored at a vertex lying on the surface patch identified by *surface_patch_index*.
Index	*domain.index_from_subdomain_index(Subdomain_index subdomain_index)*	
		Returns the index to be stored at a vertex lying in the subdomain identified by *subdomain_index*.
Surface_patch_index	*domain.surface_patch_index(Index index)*	
		Returns the *Surface_patch_index* of the surface patch where lies a vertex with dimension 2 and index *index*.
Subdomain_index	*domain.subdomain_index(Index index)*	
		Returns the index of the subdomain containing a vertex with dimension 3 and index *index*.

MeshDomainWithFeatures_3

Concept

Definition

The concept MeshDomainWithFeatures_3 refines the concept *MeshDomain_3*. While the concept *MeshDomain_3* only exposes the 2-dimensional and 3-dimensional features of the domain through different queries, the concept MeshDomainWithFeatures_3 also exposes 0 and 1-dimensional features. The exposed features of the domain are respectively called subdomains, surface patches, curve segments and corners according to their respective dimensions 3,2,1 and 0.

Refines

MeshDomain_3

Types

typedef CGAL::Tag_true

Has_features;	A type to distinguish *MeshDomain_3* models from *MeshDomainWithFeatures_3* models.
MeshDomainWithFeatures_3:: FT	Numerical type.
MeshDomainWithFeatures_3:: Curve_segment_index	
	Type of indices for curve segments (1-dimensional features) of the input domain. Must be a model of CopyConstructible, Assignable, DefaultConstructible and LessThanComparable. The default constructed value must be the value of an edge which does not approximate a 1-dimensional feature of the input domain.
MeshDomainWithFeatures_3:: Corner_index	Type of indices for corners (i.e. 0-dimensional features) of the input domain. Must be a model of CopyConstructible, Assignable, DefaultConstructible and LessThanComparable.

Operations

Each connected component of a curve segment is assumed to be oriented. The orientation is defined by the ordering of the two incident corners at the origin and endpoint. Therefore it is possible to defined the signed geodesic distance between two ordered points on the same connected component of a curve segment. A cycle is a connected component of a curve segment incident to 0 or 1 corner.

Point_3 *md.construct_point_on_curve_segment(Point_3 p,*
Curve_segment_index ci,

FT d) const

Returns a point on the curve segment with index *ci* at signed geodesic distance *d* from point *p*.
Precondition: Point *p* is supposed to be on curve segment *ci*. If *d > 0*, the signed geodesic distance from *p* to the endpoint of the connected component of *ci* including *p*, should be greater than *d*. If *d < 0*, the signed geodesic distance from *p* to the origin of the connected component should be less than *d* from the origin of the connected component.

Note that *construct_point_on_curve segment* is assumed to return a uniquely defined point. Therefore it is not possible to handle as a single curve segment, a singular curve with several branches incident to the same point.

Queries

FT *md.geodesic_distance(Point_3 p, Point_3 q, Curve_segment_index ci) const*

Returns the signed geodesic distance between points *p* and *q* along the input curve segment with index *ci*.
Precondition: Points *p* and *q* belong to the same connected component of the curve segment with index *ci*.

CGAL::Sign *md.distance_sign_along_cycle(Point_3 p, Point_3 q, Point_3 r, Curve_segment_index ci) const*

Returns *CGAL::POSITIVE* if the signed geodesic distance from *p* to *q* on the way through *r* along cycle with index *ci* is positive, *CGAL::NEGATIVE* if the distance is negative, and *CGAL::ZERO* if *(p = q = r)*.
Precondition: Points *p*, *q* and *r* belongs to the same connected component of curve segment *ci* and this component is a cycle.

bool *md.is_cycle(Point_3 p, Curve_segment_index ci) const*

Returns *true* if the connected component of curve segment *ci* including point *p* is a cycle.

Retrieval of the input features and their incidences

template <typename OutputIterator>
OutputIterator *md.get_corners(OutputIterator corners) const*

Fills *corners* with the corners of the input domain. *corners* value type must be *std::pair<Corner_index,Point_3>*.

template <typename OutputIterator>

OutputIterator *md.get_curve_segments(OutputIterator curves) const*

Fills *curves* with the curve segments of the input domain. *curves* value type must be *CGAL::cpp0x::tuple<Curve_segment_index,std::pair<Point_3,Index>,std::pair<Point_3,Index> >*. If the curve segment corresponding to an entry in curves is not a cycle, the pair of associated points should belong to two corners incident on the curve segment. If it is a cycle, then the same *Point_3* should be given twice and must be any point on the cycle. The *Index* values associated to the points are their indices w.r.t. their dimension.

bool *md.are_incident_surface_patch_curve_segment(Surface_patch_index spi, Curve_segment_index csi)*

Returns *true* if the curve segment with index *csi* is incident to the surface patch with index *spi*.

bool *md.are_incident_surface_patch_corner(Surface_patch_index spi, Corner_index ci)*

Returns *true* if the corner with index *ci* is incident to the surface patch with index *spi*.

Indices converters

Index *md.index_from_curve_segment_index(Curve_segment_index curve_segment_index) const*

Returns the index to be stored at a vertex lying on the curve segment identified by *curve_segment_index*.

Curve_segment_index *md.curve_segment_index(Index index) const*

Returns the *Curve_segment_index* of the curve segment where lies a vertex with dimension 1 and index *index*.

Index *md.index_from_corner_index(Corner_index corner_index) const*

Returns the index to be stored at a vertex lying on the corner identified by *corner_index*.

Corner_index *md.corner_index(Index index) const*

Returns the *Corner_index* of the corner where lies a vertex with dimension 0 and index *index*.

MeshCriteria_3

Definition

The Delaunay refinement process involved in the template functions *make_mesh_3* and *refine_mesh_3* is guided by a set of elementary refinement criteria that concern either mesh tetrahedra or surface facets. The refinement criteria for tetrahedra are described through the concept *MeshCellCriteria_3* while the refinement criteria for surface facets are described by the concept *MeshFacetCriteria_3*. The concept MeshCriteria_3 encapsulates these concepts.

Types

MeshCriteria_3:: Facet_criteria	Functor that describes the criteria for surface facets. This type must be a model of the concept *MeshFacetCriteria_3*.
MeshCriteria_3:: Cell_criteria	Functor that describes the criteria for mesh tetrahedra. This type must be a model of the concept *MeshCellCriteria_3*.

Access Functions

Facet_criteria *criteria.facet_criteria_object()*

Returns the facet criteria.

Cell_criteria *criteria.cell_criteria_object()*

Returns the cell criteria.

MeshCellCriteria_3

Definition

The Delaunay refinement process involved in the template functions *make_mesh_3* and *refine_mesh_3* is guided by a set of elementary refinement criteria that concern either mesh tetrahedra or surface facets. The concept MeshCellCriteria_3 describes the types that handle the refinement criteria for mesh tetrahedra.

Types

MeshCellCriteria_3:: Cell_handle	Handle type for the cells of the triangulation. Must match the *Cell_handle* type in the triangulation type used by the mesh generation function.
MeshCellCriteria_3:: Cell_quality	Type representing the quality of a cell. Must be a model of CopyConstructible and LessThanComparable. Between two cells, the one which has the lower quality must have the lower *Cell_quality*.
MeshCellCriteria_3:: Is_cell_bad	Type representing if a cell is bad or not. Must be convertible to *bool*. If it converts to *true* then the cell is bad, otherwise the cell is good with regard to the criteria. In addition, an object of this type must contain an object of type *Cell_quality* if it represents a bad cell. *Cell_quality* must be accessible by *operator*()*. Note that *boost::optional< Cell_quality>* is a natural model of this concept.

Operations

Is_cell_bad   *cell_criteria(Cell_handle c)*

Returns *Is_cell_bad* value of cell *c*.

MeshFacetCriteria_3

Definition

The Delaunay refinement process involved in the template functions *make_mesh_3* and *refine_mesh_3* is guided by a set of elementary refinement criteria that concern either mesh tetrahedra or surface facets. The concept MeshFacetCriteria_3 describes the types that handle the refinement criteria for surface facets.

Types

MeshFacetCriteria_3:: Facet

Type for the facets of the triangulation. Must match the *Facet* type in the triangulation type used by the mesh generation function.

MeshFacetCriteria_3:: Cell_handle

Handle type for the cells of the triangulation. Must match the *Cell_handle* type in the triangulation type used by the mesh generation function.

MeshFacetCriteria_3:: Facet_quality

Type representing the quality of a facet. Must be a model of CopyConstructible and LessThanComparable. Between two facets, the one which has the lower quality must have the lower *Facet_quality*.

MeshFacetCriteria_3:: Is_facet_bad

Type representing if a facet is bad or not. This type must be convertible to *bool*. If it converts to *true* then the facet is bad, otherwise the facet is good with regard to the criteria.
In addition, an object of this type must contain an object of type *Facet_quality* if it represents a bad facet. *Facet_quality* must be accessible by *operator*()*. Note that *boost::optional<Facet_quality>* is a natural model of this concept

Operations

Is_facet_bad *facet_criteria(Facet f)*

Returns *Is_facet_bad* value of facet f.

Is_facet_bad *facet_criteria(Cell_handle c, int i)*

Same as above with *f=(c,i)*.

Has Models

MeshEdgeCriteria_3

Definition

The function object concept MeshEdgeCriteria_3 is designed to drive the process which samples the 1-dimensional features of the domain. It provides an upper bound for the distance between two protecting ball centers that are consecutive on a 1-feature.

Types

MeshEdgeCriteria_3:: Point_3	Point type. Must match the *Point_3* type in the triangulation type used by the mesh generation function.
MeshEdgeCriteria_3:: Edge	Type for edges of the triangulation. Must match the *Edge* type in the triangulation type used by the mesh generation function.
MeshEdgeCriteria_3:: FT	Numerical type.

Operations

bool *edge_criteria(Edge e)*

Returns *true* if edge *e* does not fulfill the criteria.

FT *edge_criteria.sizing_field(Point_3 p)*

Returns the value of the sizing field (i.e. the maximum edge length) at point *p*.

Has Models

Mesh_edge_criteria_3<Tr>

BisectionGeometricTraits_3

Concept

Definition

The concept BisectionGeometricTraits_3 describes a geometric traits class that provides the basic types and operations to implement a model of *MeshDomain_3* based solely on intersection detections. Points in the non-empty intersections are herein computed by bisection.

Such traits class is relevant when intersection detections can be performed efficiently. For instance, when bounding surfaces are implicitly described by a function (such as an isosurface of a 3D function from $\mathbb{R}^3$ to $\mathbb{R}$), the do-intersect predicate with a segment is computed by evaluations of the function values at both end points of the segment.

Types

BisectionGeometricTraits_3:: FT	Numerical type. Must be a model of *SqrtFieldNumberType* and constructible from a *double*.
BisectionGeometricTraits_3:: Point_3	The point type. Must have a constructor *Point_3(FT, FT, FT)*.
BisectionGeometricTraits_3:: Segment_3	Segment type.
BisectionGeometricTraits_3:: Ray_3	Ray type.
BisectionGeometricTraits_3:: Line_3	Line type.
BisectionGeometricTraits_3:: Vector_3	Vector type.
BisectionGeometricTraits_3:: Sphere_3	Sphere type.

BisectionGeometricTraits_3:: Compute_scalar_product_3

Function object providing the operator
FT operator()(Vector_3 v, Vector_3 w) which returns the scalar (inner) product of the two vectors *v* and *w*.

BisectionGeometricTraits_3:: Compute_squared_distance_3

Function object providing the operator
FT operator()(Point_3, Point_3) which returns the squared distance between two points.

BisectionGeometricTraits_3:: Compute_squared_radius_3

Function object providing the operator
FT operator()(Sphere_3 s) which returns the squared radius of *s*.

BisectionGeometricTraits_3:: Construct_center_3

Function object providing the operator
Point_3 operator()(Sphere_3 s) which returns the center of the sphere *s*.

BisectionGeometricTraits_3:: Construct_midpoint_3

Function object providing the operator
Point_3 operator()(Point_3 p, Point_3 q) which computes the midpoint of the segment *pq*.

BisectionGeometricTraits_3:: Construct_point_on_3

Function object providing the following operators:
Point_3 operator()(Line_3 l,int i); which returns an arbitrary point on *l*. It holds *point(i) == point(j)*, iff *i==j*. Furthermore, is directed from *point(i)* to *point(j)*, for all $i < j$.
Point_3 operator()(Ray_3 r,int i); which returns a point on *r*. *point(0)* is the source, *point(i)*, with $i > 0$, is different from the source.
Precondition: $i \geq 0$.
Point_3 operator()(Segment_3 s,int i); which returns either source or target of *s*: *point(0)* returns the source of *s*, *point(1)* returns the target of *s*. Parameter *i* is taken modulo 2, which gives easy access to the other end point.

BisectionGeometricTraits_3:: Construct_segment_3

Function object providing the operator
Segment_3 operator()(Point_3 p, Point_3 q); which returns a segment with source *p* and target *q*, directed from the source to the target.

BisectionGeometricTraits_3:: Construct_scaled_vector_3

Function object providing the operator
Vector_3 operator()(Vector_3 v, FT scale) which returns the vector *v* scaled by a factor *scale*.

BisectionGeometricTraits_3:: Construct_translated_point_3

Function object providing the operator
Point_3 operator()(Point_3 p, Vector_3 v) which returns the point obtained by translating *p* by the vector *v*.

BisectionGeometricTraits_3:: Construct_vector_3

Function object providing the operator
Vector_3 operator()(Point_3 a, Point_3 b) which returns the vector *b-a*.

BisectionGeometricTraits_3:: Has_on_bounded_side_3

Function object providing the operator
bool operator()(Sphere_3 s, Point_3 p); which returns true iff *p* lies on the bounded side of *s*.

Operations

The following functions give access to the predicate and construction objects:

Compute_scalar_product_3	*traits.compute_scalar_product_3_object()*
Compute_squared_distance_3	*traits.compute_squared_distance_3_object()*
Compute_squared_radius_3	*traits.compute_squared_radius_3_object()*
Construct_center_3	*traits.construct_center_3_object()*
Construct_midpoint_3	*traits.construct_midpoint_3_object()*
Construct_point_on_3	*traits.construct_point_on_3_object()*
Construct_scaled_vector_3	*traits.construct_scaled_vector_3_object()*
Construct_segment_3	*traits.construct_segment_3_object()*
Construct_translated_point_3	*traits.construct_translated_point_3_object()*
Construct_vector_3	*traits.construct_vector_3_object()*
Has_on_bounded_side_3	*traits.has_on_bounded_side_3_object()*

Has Models

Any CGAL Kernel.

Concept

IntersectionGeometricTraits_3

Definition

The concept IntersectionGeometricTraits_3 provides types and functors required to implement a model of *MeshDomain_3*, when the domain is described by a simplicial surface mesh forming its boundary. The concept IntersectionGeometricTraits_3 mainly provides the detection and construction of intersections between segments and triangles.

Types

IntersectionGeometricTraits_3:: Point_3	Point type.
IntersectionGeometricTraits_3:: Segment_3	Segment type.
IntersectionGeometricTraits_3:: Triangle_3	Triangle type.

IntersectionGeometricTraits_3:: Do_intersect_3

Function object that detects an intersection between a 3D segment and a 3D triangle. Provides the operators:
bool operator()(Segment_3 seg, Triangle_3 tr)
bool operator()(Triangle_3 tr, Segment_3 seg)
which return *true*, iff the triangle and the segment have a non empty intersection.

IntersectionGeometricTraits_3:: Intersect_3

Function object that constructs the intersection between a 3D segment and a 3D triangle. Provides the operators:
CGAL::Object operator()(Segment_3 seg, Triangle_3 tr)
CGAL::Object operator()(Triangle_3 tr, Segment_3 seg)
which computes as a *CGAL::Object* the intersection between the triangle and the segment. *CGAL::Object* is either a point, a segment or an empty object.

Operations

Do_intersect_3 *traits.do_intersect_3_object()*

Returns the intersection detection functor.

Intersect_3 *traits.intersect_3_object()*

Returns the intersection constructor.

Has Models

Any instantiation of *CGAL::Kernel* is a model of this traits concept.

Concept

LabeledImage_3

Definition

The concept LabeledImage_3 describes the requirements for the second template parameter of the class *Labeled_image_mesh_domain_3<Image,BGT>* which represents mesh domains defined by 3D labeled images. A 3D labeled image is a 3D array of elements of an integral type *Type*. *Type* can be *bool*, *char*, *short*, *int*, or *long* (signed or not). Such an array is associated to a 3D axis-aligned regular grid, in $\mathbb{R}^3$. A cell of this grid is denoted by *voxel*. A voxel is an iso-cuboid of size *vx()*, *vy()*, and *vz()*.

Types

LabeledImage_3:: Type	Type of voxel data. Must be an integral type.
LabeledImage_3:: RT	Ring number type.

Operations

int	*image.xdim()*	First dimension of the 3D array, i.e., the number of voxels along the x coordinate axis.
int	*image.ydim()*	Second dimension of the 3D array.
int	*image.zdim()*	Third dimension of the 3D array.
RT	*image.vx()*	Size of each voxel along x coordinate axis.
RT	*image.vy()*	Size of each voxel along y coordinate axis.
RT	*image.vz()*	Size of each voxel along z coordinate axis.
*const Type**	*image.data()*	Pointer to the first element of the 3D image. The size of the array must be *xdim()*×*ydim()*×*zdim()*.

Has Models

CGAL::Image_3<Kernel, T>, for any CGAL kernel *K* and any integral type *T*.

MeshCellBase_3

Definition

The concept MeshCellBase_3 describes the requirements for the *Cell* type of the triangulation used in the 3D mesh generation process. The type MeshCellBase_3 refines the concept *RegularTriangulationCellBase_3*. The concept MeshCellBase_3 includes a way to store and retrieve if a given cell of the triangulation is inside the domain or not and which subdomain it belongs to in case of a multi-domain.

Moreover, this concept adds four markers per cell to mark the facets of the triangulation that are surface facets, and four additional helper markers used in some operations to mark for instance the facets that have been visited.

This concept also provides storage for the centers of Delaunay surface balls. Each surface facet has a Delaunay surface ball, i. e. a circumscribing ball, centered on an input complex surface patch, and empty of triangulation vertices. In the following we call *surface center* of a surface facet, the center of its biggest Delaunay surface ball.

Refines

RegularTriangulationCellBase_3

Types

MeshCellBase_3:: Point — Point type, required to match the point type of the 3D triangulation in which the mesh is embedded.

MeshCellBase_3:: Subdomain_index; — Type of indices for cells of the input complex. Must match the type *MeshDomain_3::Subdomain_index*.

MeshCellBase_3:: Surface_patch_index; — Type of indices for surface patches of the input complex. Must match the type *MeshDomain_3::Surface_patch_index*.

Operations

Subdomain_index *cell.subdomain_index()*

Returns the index of the input subdomain that contains the cell *cell* of the triangulation.

void *cell.set_subdomain_index(Subdomain_index index)*

Sets the subdomain index of the cell.

bool *cell.is_facet_on_surface(int i)*

returns *true* iff *facet(i)* is a surface facet.

Surface_patch_index	*cell.surface_patch_index(int i)*
	returns *Surface_patch_index* of facet *i*.
void	*cell.set_surface_patch_index(int i, Surface_patch_index index)*
	sets *Surface_patch_index* of facet *i* to *index*.

bool	*cell.is_facet_visited(int i)*
	Returns *true* iff *facet(i)* has been visited.
void	*cell.set_facet_visited(int i, bool b)*
	Marks *facet(i)* as visited if *b* is *true* and non-visited otherwise.

Point	*cell.facet_surface_center(int i)*
	Returns a const reference to the surface center of *facet(i)*.
void	*cell.set_facet_surface_center(int i, Point p)*
	Sets point *p* as the surface center of *facet(i)*.

MeshVertexBase_3

Concept

Definition

The concept MeshVertexBase_3 describes the requirements for the *Vertex* type of the triangulation used by a 3D mesh generation process. The type MeshVertexBase_3 refines both the concept *RegularTriangulationVertexBase_3* and the concept *SurfaceMeshVertexBase_3*. It provides additional members to store and retrieve information about the location of the vertex with respect to the input domain describing the domain to be discretized. More specifically, the concept MeshVertexBase_3 provides read-write access to an integer representing the dimension of the lowest dimensional face of the input 3D complex on which the vertex lies, and to an index characteristic of this face.

Refines

RegularTriangulationVertexBase_3
SurfaceMeshVertexBase_3

Types

MeshVertexBase_3:: Index;	Index type. Must match the type *MeshDomain_3::Index*.
MeshVertexBase_3:: FT;	Numerical type.

Operations

int	*vertex.in_dimension() const*	
		Returns the dimension of the lowest dimensional face of the input 3D complex that contains the vertex.
void	*vertex.set_dimension(int)*	
		Sets the dimension of the lowest dimensional face of the input 3D complex that contains the vertex.
Index	*vertex.index()*	Returns the index of the lowest dimensional face of the input 3D complex that contains the vertex.
void	*vertex.set_index(Index)*	
		Sets the index of the lowest dimensional face of the input 3D complex that contains the vertex.

Internal

FT	*vertex.meshing_info() const*
void	*vertex.set_meshing_info(FT)*

These functions are used internally by mesh optimizers. The user is not encouraged to use them directly as they may change in the future.

MeshDomainField_3

Functor
Concept

Definition

The concept MeshDomainField_3 describes a scalar field which could be queried at any point of the space.

Types

MeshDomainField_3:: FT	Numerical type.
MeshDomainField_3:: Point_3	Point type.
MeshDomainField_3:: Index	Index type for points. Must match the type *MeshDomain_3::Index*.

Operations

The *operator()* returns the field value at a query point. The field value may depend on the query point location and/or on the input feature including the query point.

FT *msf(Point_3 p, int dimension, Index index)*

returns the value of the sizing field at the point *p*, assumed to be included in the input complex feature with dimension *dimension* and mesh vertex index *index*.

Concept

MeshPolyline_3

Definition

The concept MeshPolyline_3 implements a container of points designed to represent a polyline (i.e. a sequence of points). Types and functions provided in this concept are such as standard template library containers are natural models of this concept.

Types

MeshPolyline_3:: value_type	Point type. Must match the type *MeshDomain_3::Point_3*.
MeshPolyline_3:: const_iterator	A constant iterator on points. Must be a model of Bidirectional iterator and have *value_type* as value type.

Operations

const_iterator	*polyline.begin()*	Returns an iterator on the first point of the polyline.
const_iterator	*polyline.end()*	Returns the past-the-end iterator for the above iterator.

Has Models

std::vector<Kernel::Point_3> for any Kernel of CGAL is a natural model of this concept.

See Also

TriangleAccessor_3

Definition

The concept TriangleAccessor_3 represents an accessor to a triangulated polyhedral surface, intersection free and without boundaries.

Types

TriangleAccessor_3:: Triangle_3	Triangle type. Must be a model of DefaultConstructible and CopyConstructible.
TriangleAccessor_3:: Triangle_iterator	Triangle iterator type. Must be a model of InputIterator.
TriangleAccessor_3:: Triangle_handle	Handle to a *Triangle_3*. Must be constructible from *Triangle_iterator*. It may be *Triangle_Iterator* itself.
TriangleAccessor_3:: Polyhedron	Polyhedron type.

Operations

Triangle_iterator *ta.triangles_begin(Polyhedron p)*

Returns a *Triangle_iterator* to visit the triangles of polyhedron *p*.

Triangle_iterator *ta.triangles_end(Polyhedron p)*

Returns the past-the-end iterator for the above iterator.

Triangle_3 *ta.triangle(Triangle_handle h)*

Returns a *Triangle_3* object from handle *h*.

Has Models

Triangle_accessor_3<Polyhedron_3<K>,K>

Class

CGAL::Mesh_complex_3_in_triangulation_3<Tr,CornerIndex,CurveSegmentIndex>

Definition

The class *Mesh_complex_3_in_triangulation_3<Tr,CornerIndex,CurveSegmentIndex>* implements a data structure to store the 3D restricted Delaunay triangulation used by a mesh generation process.

This class is a model of the concept *MeshComplexWithFeatures_3InTriangulation_3*.

Parameters

The template parameter *Tr* can be instantiated with any 3D regular triangulation of CGAL provided that its vertex and cell base class are models of the concepts *MeshVertexBase_3* and *MeshCellBase_3*, respectively.

The template parameter *CornerIndex* is the type of the indices for corners and the template parameter *CurveSegmentIndex* is the type of the indices for curves segments. They must match the *Corner_index* and *Curve_segment_index* types of the model of the *MeshDomainWithFeatures_3* concept used for mesh generation.

Those two last template parameters defaults to *int*, so that they can be ignored if the domain used for mesh generation does not include 0 and 1-dimensionnal features (i.e is a model of the concept *MeshDomain_3*).

#include <CGAL/Mesh_complex_3_in_triangulation_3.h>

Is Model for the Concepts

MeshComplexWithFeatures_3InTriangulation_3

Types

typedef Tr::Vertex::Index

Index; Index type.

typedef Tr::Cell::Surface_patch_index

Surface_patch_index; Surface index type.

typedef Tr::Cell::Subdomain_index

Subdomain_index; Subdomain index type.

typedef CornerIndex *Corner_index;* *Corner_index* type.

typedef CurveSegmentIndex

Curve_segment_index;

Curve_segment_index type.

Operations

void *c3t3.output_to_medit(std::ofstream& os)*

Outputs the mesh to *os* in medit format.

Class

CGAL::Mesh_triangulation_3<MD,Gt>

Definition

The class *Mesh_triangulation_3<MD,Gt>* provides a default triangulation to be used as the 3D triangulation of a mesh generation process.

#include <CGAL/Mesh_triangulation_3.h>

Parameters

Template parameter *MD* stands for a model of *MeshDomain_3*.

Template parameter *Gt* stands for a model of *RegularTriangulationTraits_3* and defaults to *Kernel_traits<MD> ::Kernel*.

Types

Mesh_triangulation_3<MD,Gt>:: type	*CGAL::Regular_triangulation_3* type whose vertex and cell classes are respectively *Mesh_vertex_base_3<MD,Gt>* and *Mesh_cell_base_3<MD,Gt>*.

CGAL::Mesh_vertex_base_3<MD,Gt,Vb>

Class

Definition

The class *Mesh_vertex_base_3<MD,Gt,Vb>* is a model of the concept *MeshVertexBase_3*. It is designed to serve as vertex base class for the 3D triangulation used in a 3D mesh generation process.

Parameters

The template parameter *MD* provides the types of indices used to identify the faces of the input complex. It must be a model of the concept *MeshDomain_3*.

The template parameter *Gt* is the geometric traits class. It must be a model of the concept *RegularTriangulationTraits_3*.

The third parameter *Vb* is the vertex base class. It has to be a model of the concept *TriangulationVertexBase_3* and defaults to *Triangulation_vertex_base_3<Gt>*.

CGAL::Mesh_criteria_3<Tr>

Class

Definition

The class *Mesh_criteria_3<Tr>* is a model of both concepts *MeshCriteria_3* and *MeshCriteriaWithFeatures_3*. It gathers the refinement criteria for mesh tetrahedra and surface facets where surface facets are facets in the mesh approximating the domain surface patches. In addition, for domain with exposed 1-dimensional features, the class *Mesh_criteria_3<Tr>* handles the definition of a sizing field to guide the discretization of 1-dimensional features.

#include <CGAL/Mesh_criteria_3.h>

Parameters

The parameter *Tr* has to be instantiated with the type used for *C3T3::Triangulation*, where *C3T3* is the model of *MeshComplex_3InTriangulation_3* used in the mesh generation process, and *C3T3::Triangulation* its nested triangulation type.

Is Model for the Concepts

MeshCriteria_3

Types

typedef Mesh_edge_criteria_3<Tr>

Edge_criteria; The criteria for edges.

typedef Mesh_facet_criteria_3<Tr>

Facet_criteria; The criteria for facets.

typedef Mesh_cell_criteria_3<Tr>

Cell_criteria; The criteria for cells.

Creation

Mesh_criteria_3<Tr> mc(Facet_criteria facet_criteria, Cell_criteria cell_criteria);

Construction from facet and cell criteria. The edge criteria are ignored in this case.

Mesh_criteria_3<Tr> mc(Edge_criteria edge_criteria,
Facet_criteria facet_criteria,
Cell_criteria cell_criteria)

Construction from edge, facet and cell criteria.

template<typename FT, typename ...Fieldi>
Mesh_criteria_3<Tr> mc(Field1 parameters::edge_size = ignored,
FT parameters::facet_angle = ignored,
Field2 parameters::facet_size = ignored,
Field3 parameters::facet_distance = ignored,
Mesh_facet_topology parameters::facet_topology = CGAL::FACET_VERTICES_ON_SURFACE,
FT parameters::cell_radius_edge_ratio = ignored,
Field4 parameters::cell_size = ignored)

Construction from criteria parameters. This constructor uses named parameters (from *Boost.Parameter*) for convenient criteria construction. See a complete description of these parameters below.

The template parameter *FT* should be a model of concept *FieldType*. The template parameters *Fieldi* ($i \in \{1..4\}$) should be either a model of the concept *FieldType* or a model of the concept *MeshDomainField_3*.

The parameters are named parameters and can be passed in any order provided their name is given (see example below). The name of each parameter is the one that is written in the description of the function (e.g. *parameters::facet_size*).

The description of each parameter is as follows:

-*edge_size*: a scalar field (resp. a constant) providing a space varying (resp. a uniform) upper bound for the lengths of curve segment edges.

-*facet_angle*: a lower bound for the angles (in degrees) of the surface mesh facets.
-*facet_size*: a scalar field (resp. a constant) describing a space varying (resp. a uniform) upper-bound or for the radii of the surface Delaunay balls.
-*facet_distance*: a scalar field (resp. a constant) describing a space varying (resp. a uniform) upper bound for the same distance.
-*facet_topology*: the set of topological constraints which have to be verified by each surface facet. The default value is *CGAL::FACET_VERTICES_ON_SURFACE*. See *Mesh_facet_topology* manual page to get all possible values.

-*cell_radius_edge_ratio*: an upper bound for the radius-edge ratio of the mesh tetrahedra.
-*cell_size*: a scalar field (resp. a constant) describing a space varying (resp. a uniform) upper-bound for the circumradii of the mesh tetrahedra.

Note that each size or distance parameter can be specified using two ways: either as scalar field or as a numerical value when the field is uniform.

Each parameter has a special default value *ignored* which means that the corresponding criteria will be ignored. Numerical sizing or distance values, as well as scalar fields should be given in the unit used for coordinates of points in the mesh domain class of the mesh generation process.

Example

```
// Create a Mesh_criteria_3<Tr> object with all cell and facet parameters
    set
Mesh_criteria_3<Tr> criteria (parameters::facet_angle=30,
                              parameters::facet_size=1,
                              parameters::facet_distance=0.1,
```

```
                                parameters::cell_radius_edge_ratio=2,
                                parameters::cell_size=1.5);

// Create a Mesh_criteria_3<Tr> object with size ignored (note that the
    order changed)
Mesh_criteria_3<Tr> criteria (parameters::cell_radius_edge_ratio=2,
                                parameters::facet_angle=30,
                                parameters::facet_distance=0.1);
```

CGAL::Mesh_cell_criteria_3<Tr>

Definition

The class *Mesh_cell_criteria_3<Tr>* is a model of *MeshCellCriteria_3*. It provides, for the mesh tetrahedra, a uniform shape criteria and a sizing field which may be a uniform or variable field.

#include <CGAL/Mesh_cell_criteria_3.h>

Parameters

The parameter *Tr* must be identical to the nested type *Triangulation* of the instance used as model of *MeshComplex_3InTriangulation_3*.

Is Model for the Concepts

MeshCellCriteria_3

Types

typedef Tr::FT	*FT;*	Numerical type

Creation

Mesh_cell_criteria_3<Tr> mcc(FT radius_edge_bound, FT radius_bound);

Returns an object to serve as default criteria for cells. The argument *radius_edge_bound* is the upper bound for the radius-edge ratio of the tetrahedra. The argument *radius_bound* is a uniform upper bound for the circumradii of the tetrahedra in the mesh. See section 51.1 for further details. Note that if one parameter is set to 0, then its corresponding criteria is ignored.

template<class SizingField>
Mesh_cell_criteria_3<Tr> mcc(FT radius_edge_bound, SizingField radius_bound);

Returns an object to serve as default criteria for facets. The type *SizingField* must be a model of the concept *MeshDomainField_3*. The behavior and semantic of the arguments are the same as above, except that the radius bound parameter is a functional instead of a constant.

CGAL::Mesh_facet_criteria_3<Tr>

Functor
Class

Definition

The class *Mesh_facet_criteria_3<Tr>* is a model of *MeshFacetCriteria_3*. It provides a uniform bound for the shape criterion, a uniform or variable sizing field for the size criterion and/or a uniform or variable distance field for the approximation error criterion.

#include <CGAL/Mesh_facet_criteria_3.h>

Parameters

The parameter *Tr* must be identical to the nested type *Triangulation* of the instance used as model of *MeshComplex_3InTriangulation_3*.

Is Model for the Concepts

MeshFacetCriteria_3

Types

typedef Tr::Geom_traits::FT

FT;	Numerical type

Creation

Mesh_facet_criteria_3<Tr> mfc(FT angle_bound,
FT radius_bound,
FT distance_bound,
Mesh_facet_topology topology = FACET_VERTICES_ON_SURFACE)

Returns an object to serve as criteria for facets. The argument *angle_bound* is the lower bound for the angle in degrees of the surface mesh facets. The argument *radius_bound* is a uniform upper bound for the radius of the surface Delaunay balls. The argument *distance_bound* is an upper bound for the center-center distances of the surface mesh facets. *topology* is the set of topological constraints which have to be verified by each surface facet. See section 51.1 for further details. Note that if one parameter is set to 0, then its corresponding criteria is ignored.

template <class SizingField, class DistanceField>
Mesh_facet_criteria_3<Tr> mfc(FT angle_bound,
SizingField radius_bound,
DistanceField distance_bound,

Mesh_facet_topology topology = FACET_VERTICES_ON_SURFACE)

Returns an object to serve as criteria for facets. The types *SizingField* and *DistanceField* must be models of the concept *MeshDomainField_3*. The behavior and semantic of the arguments are the same as above, except that the radius and distance bound parameters are functionals instead of constants.

MeshEdgeCriteria_3

Types

typedef Tr::Geom_traits::FT

FT;	Numerical type.

Creation

Mesh_edge_criteria_3<Tr> mec(FT length_bound);

Returns an object to serve as criteria for edges. The argument *length_bound* is an upper bound for the length of the edges which are used to discretize the curve segments. Note that if one parameter is set to 0, then its corresponding criteria is ignored.

template <class SizingField>
Mesh_edge_criteria_3<Tr> mec(SizingField length_bound);

Returns an object to serve as criteria for edges. The type *SizingField* must be a model of concept *MeshDomainField_3*. The behavior and semantic of the argument are the same as above, except that the length parameter is a functional instead of a constant.

Functor
Class

CGAL::Mesh_constant_domain_field_3<Gt,Index>

Definition

The class *Mesh_constant_domain_field_3<Gt,Index>* is a model of concept *MeshDomainField_3*. It provides a constant field accessible using queries on 3D-points.

The class *Mesh_constant_domain_field_3<Gt,Index>* can also be customized through *set_size()* operations to become a piecewise constant field, i.e. a sizing field with a constant size on each subpart of the domain.

#include <CGAL/Mesh_constant_domain_field_3.h>

Parameters

The parameter *Gt* is the geometric traits class. It must match the type *Triangulation::Geom_traits*, where *Triangulation* is the nested type of the model of *MeshComplex_3InTriangulation_3* used in the meshing process.

The parameter *Index* is the type of index of the vertices of the triangulation. It must match the type *Index* of the model of *MeshDomain_3* used in the meshing process.

Is Model for the Concepts

MeshDomainField_3

Types

typedef Gt::FT	*FT;*	Numerical type.
typedef Gt::Point_3	*Point_3;*	Point type.
typedef Index	*Index;*	Type of index of the vertices of the triangulation.

Creation

Mesh_constant_domain_field_3<Gt,Index> mcf(FT size);

Builds a constant domain field with size *size*.

Operations

void	*mcf.set_size(FT size, int dimension, Index index)*

Sets the size such as *operator()* will return size *size* at any query point of dimension *dimension* and index *index*.

CGAL::Implicit_mesh_domain_3<Function,BGT>

Class

Definition

The class *Implicit_mesh_domain_3<Function,BGT>* implements a domain whose bounding surface is described implicitly as the zero level set of a function. The domain to be discretized is assumed to be the domain where the function has negative values. This class is a model of the concept *MeshDomain_3*.

Parameters

Parameter *BGT* is a geometric traits which provides the basic operations to implement intersection tests and computations through a bisection method. This parameter must be instantiated with a model of the concept *BisectionGeometricTraits_3*.

Parameter *Function* provides the definition of the function. This parameter stands for a model of the concept *ImplicitFunction* described in the surface mesh generation package. The number types *Function::FT* and *BGT::FT* are required to match.

The constructor of *Implicit_mesh_domain_3<Function,BGT>* takes as argument a bounding sphere which is required to circumscribe the surface and to have its center inside the domain. This domain constructs intersection points between the surface and segments/rays/lines by bisection. It needs an *error_bound* such that the bisection process is stopped when the query segment is smaller than the error bound. The *error_bound* passed as argument to the domain constructor is a relative error bound expressed as a ratio to the bounding sphere radius.

#include <CGAL/Implicit_mesh_domain_3.h>

Is Model for the Concepts

MeshDomain_3

Creation

Implicit_mesh_domain_3<Function,BGT> domain(Function f, BGT::Sphere_3 bounding_sphere, BGT::FT error_bound = FT(1e-3))

f is the object of type *Function* that represents the implicit surface.
bounding_sphere is a bounding sphere of the implicit surface. The value of f at the sphere center c must be negative: $f(c) < 0$.
error_bound is the relative error bound used to compute intersection points between the implicit surface and query segments. The bisection is stopped when the length of the intersected segment is less than the product of *error_bound* by the radius of *bounding_sphere*.

CGAL::Polyhedral_mesh_domain_3<Polyhedron,IGT,TriangleAccessor>

Class

Definition

The class *Polyhedral_mesh_domain_3<Polyhedron,IGT,TriangleAccessor>* implements a domain whose boundary is a simplicial polyhedral surface. This surface must be closed and free of intersection. This class is a model of the concept *MeshDomain_3*.

Parameters

The parameter *Polyhedron* stands for the type of the input polyhedral surface. The only requirements for this type is that the triangles of the surfaces must be accessible through an object of the class *TriangleAccessor*.

The parameter *IGT* stands for a geometric traits class providing the types and functors required to implement the intersection tests and intersection computations for polyhedral boundary surfaces. This parameter has to be instantiated with a model of the concept *IntersectionGeometricTraits_3*.

The parameter *TriangleAccessor* provides access to the triangles of the input polyhedral surface. It must be a model of the concept *TriangleAccessor_3*. It defaults to *Triangle_accessor_3<Polyhedron,IGT>*. The type *IGT::Triangle_3* must be identical to the type *TriangleAccessor::Triangle_3*.

#include <CGAL/Polyhedral_mesh_domain_3.h>

Is Model for the Concepts

MeshDomain_3

Creation

Polyhedral_mesh_domain_3<Polyhedron,IGT,TriangleAccessor> domain(Polyhedron polyhedron);

Construction from a polyhedral surface.

Class

CGAL::Polyhedral_mesh_domain_with_features_3<IGT>

Definition

The class *Polyhedral_mesh_domain_with_features_3<IGT>* implements a domain whose boundary is a simplicial polyhedral surface. This surface must be closed and free of intersection. It is a model of the concept *MeshDomainWithFeatures_3*. It also provides a member function to automatically detect sharp features from the input polyhedral surface.

Parameters

The parameter *IGT* stands for a geometric traits class providing the types and functors required to implement the intersection tests and intersection computations for polyhedral boundary surfaces. This parameter has to be instantiated with a model of the concept *IntersectionGeometricTraits_3*.

#include <CGAL/Polyhedral_mesh_domain_with_features_3.h>

Is Model for the Concepts

MeshDomainWithFeatures_3

Inherits From

CGAL::Mesh_domain_with_polyline_features_3<CGAL::Polyhedral_mesh_domain_3<CGAL::Mesh_polyhedron_3<IGT>::type,IGT> >

Types

Polyhedral_mesh_domain_with_features_3<IGT>:: FT

Numerical type.

Creation

template <typename Polyhedron>
Polyhedral_mesh_domain_with_features_3<IGT> md(Polyhedron p);

Constructs a *Polyhedral_mesh_domain_with_features_3* from a *Polyhedron*. The only requirement on type *Polyhedron* is that *CGAL::Mesh_polyhedron_3<IGT>::type* should be constructible from *Polyhedron*. No feature detection is done at this level. Note that a copy of *p* will be done.

Polyhedral_mesh_domain_with_features_3<IGT> md(std::string filename);

Constructs a *Polyhedral_mesh_domain_with_features_3* from an off file. No feature detection is done at this level.

Operations

void *md.detect_features(FT angle_bound=120)*

Detects sharp features of the internal polyhedron and inserts them in as features of the domain. *angle_bound* gives the maximum dihedral angle (in degrees) between two triangles of the internal polyhedron which is used to consider that the edge between those triangles is a feature edge.

Class

CGAL::Labeled_image_mesh_domain_3<Image,BGT>

Definition

The class *Labeled_image_mesh_domain_3<Image,BGT>* implements a domain described by a 3D labeled image. A 3D labeled image is a grid of voxels, where each voxel is associated with an index (a subdomain index) characterizing the subdomain in which the voxel lies. This class is a model of the concept *MeshDomain_3*. The domain to be discretized is the union of voxels that have an non-default index (different from the default constructed value of the type *Image::Type*).

This class includes a member function that provides, by interpolation, the subdomain index of any query point. An intersection between a segment and bounding surfaces is detected when both segment endpoints are associated with different values of subdomain indices. The intersection is then constructed by bisection. The bisection stops when the query segment is shorter than a given error bound e. This error bound is given by $e{=}d{\times}bound$ where d is the length of the diagonal of the bounding box (in world coordinates) and *bound* is the argument passed to the constructor of *Labeled_image_mesh_domain_3<Image,BGT>*.

Parameters

Parameter *Image* is the type of the input image. This parameter must be a model of the concept *LabeledImage_3*.

Parameter *BGT* is a geometric traits class which provides the basic operations to implement intersection tests and intersection computations through a bisection method. This parameter must be instantiated with a model of the concept *BisectionGeometricTraits_3*.

#include <CGAL/Labeled_image_mesh_domain_3.h>

Is Model for the Concepts

MeshDomain_3

Creation

Labeled_image_mesh_domain_3<Image,BGT> domain(Image image, BGT::FT error_bound = FT(1e-3));

Construction from an image. The parameter *error_bound* is relative to the size of the image.

CGAL::Mesh_domain_with_polyline_features_3<MeshDomain_3>

Class

Definition

The class *Mesh_domain_with_polyline_features_3<MeshDomain_3>* is designed to allow the user to add some 0- and 1-dimensional features into any model of the *MeshDomain_3* concept. The 1-dimensional features are described as polylines whose endpoints are the added corners.

Parameters

The template parameter *MeshDomain_3* is the type of the domain which should be extended. It has to be a model of the *MeshDomain_3* concept.

#include <CGAL/Mesh_domain_with_polyline_features_3.h>

Is Model for the Concepts

MeshDomainWithFeatures_3

Inherits From

MeshDomain_3

Types

typedef int	*Corner_index;*	*Corner_index* type.
typedef int	*Curve_segment_index;*	*Curve_segment_index* type.

Creation

template <typename ...T>
Mesh_domain_with_polyline_features_3<MeshDomain_3> md(T ...t);

Constructor. Forwards the arguments to the constructor of the base class.

Operations

template <typename InputIterator>
void *md.add_features(InputIterator begin, InputIterator beyond)*

Add 1-dimensional features in the domain. *InputIterator* value type must be a model of the concept *MeshPolyline_3*.

template <typename InputIterator>
void *md.add_features_and_incidences(InputIterator begin, InputIterator beyond)*

Add 1-dimensional features in the domain with their incidences with 2-dimensional features of the domain. The *InputIterator* value type must be *std::pair<Polyline, std::pair< InputSurfacePatchIndexIterator, InputSurfacePatchIndexIterator>* > where *Polyline* must be a model of the concept *MeshPolyline_3* and the internal pair gives a range on surface patches indices which are incident to the polyline.

CGAL::make_mesh_3

Definition

The function *make_mesh_3* is a 3D mesh generator. It produces simplicial meshes which discretize 3D domains.

The mesh generation algorithm is a Delaunay refinement process followed by an optimization phase. The criteria driving the Delaunay refinement process may be tuned to achieve the user needs with respect to the size of mesh elements, the accuracy of boundaries approximation, etc.

The optimization phase is a sequence of optimization processes, including possibly a Lloyd smoothing, an odt-smoothing, a perturber and an exuder. Each optimization process can be activated or not, according to the user requirements and available time. By default, only the perturber and the exuder are activated. Note that the benefits of the exuder will be lost if the mesh is further refined afterward.

The function outputs the mesh to an object which provides iterators to traverse the resulting mesh data structure or can be written to a file (see 51.3).

```
template <class C3T3, class MeshDomain_3, class MeshCriteria>
C3T3    make_mesh_3( MeshDomain_3 domain,
                     MeshCriteria criteria,
                     parameters::internal::Features_options features = parameters::features(domain),
                     parameters::internal::Lloyd_options lloyd = parameters::no_lloyd(),
                     parameters::internal::Odt_options odt = parameters::no_odt(),
                     parameters::internal::Perturb_options perturb = parameters::perturb(),
                     parameters::internal::Exude_options exude = parameters::exude())
```

Parameters

Parameter *C3T3* is required to be a model of the concept *MeshComplex_3InTriangulation_3*. This is the return type.

The type *C3T3* is in particular required to provide a nested type *C3T3::Triangulation* for the 3D triangulation embedding the mesh. The vertex and cell base classes of the triangulation *C3T3::Triangulation* are required to be models of the concepts *MeshVertexBase_3* and *MeshCellBase_3* respectively.

Template parameter *MeshDomain_3* is required to be a model of the concept *MeshDomain_3*, or of the refined concept *MeshDomainWithFeatures_3* if the domain has corners and curve segments that need to be accurately represented in the mesh. The argument *domain* is the sole link through which the domain to be discretized is known by the mesh generation algorithm.

The parameter *features* allows the user to specify if 0 and 1-dimensional features actually have to be taken into account or not when the domain is a model of *MeshDomainWithFeatures_3*. The type *Features* of this parameter is an internal undescribed type. The library provides functions to construct appropriate values of that type.

- *parameters::features(domain)* sets *features* according to the domain, i.e. 0 and1-dimensional features are taken into account if *domain* is a *MeshDomainWithFeatures_3*. This is the default behavior if parameter *features* is not specified.

- *parameters::no_features()* prevents the representation of 0 and 1-dimensional features in the mesh.

The template parameter *MeshCriteria* has to be a model of the concept *MeshCriteria_3*, or a model of the refined concept *MeshCriteriaWithFeatures_3* if the domain has exposed features. The argument *criteria* of type *MeshCriteria* specifies the size and shape requirements for mesh tetrahedra and surface facets. These criteria form the rules which drive the refinement process. All mesh elements satisfy those criteria at the end of the refinement process. In addition, if the domain has features, the argument *criteria* provides a sizing field to guide the discretization of 1-dimensional exposed features.

The four additional parameters are optimization parameters. They control which optimization processes are performed and allow the user to tune the parameters of the optimization processes. We do not describe the types of optimization parameters as they are internal types. The package defines two global functions for each optimization parameter to generate appropriate value of this parameter.

- *parameters::lloyd()* and *parameters::no_lloyd()* are designed to trigger or not a call to *lloyd_optimize_mesh_3* function and to set the parameters of this optimizer. If one parameter is not set, the default value of *lloyd_optimize_mesh_3* is used for this parameter.
- *parameters::odt()* and *parameters::no_odt()* are designed to trigger or not a call to *odt_optimize_mesh_3* function and to set the parameters of this optimizer If one parameter is not set, the default value of *odt_optimize_mesh_3* is used for this parameter.
- *parameters::perturb()* and *parameters::no_perturb()* are designed to trigger or not a call to *perturb_mesh_3* function and to set the parameters of this optimizer. If one parameter is not set, the default value of *perturb_mesh_3* is used for this parameter, except for the time bound which is set to be equal to the refinement CPU time.
- *parameters::exude()* and *parameters::no_exude()* are designed to trigger or not a call to *exude_mesh_3* function and to override to set the parameters of this optimizer. If one parameter is not set, the default value of *exude_mesh_3* is used for this parameter, except for the time bound which is set to be equal to the refinement CPU time.

The optimization parameters can be passed in random order. If one parameter is not passed, its default value is used. The default values are *no_lloyd()*, *no_odt()*, *perturb()* and *exude()*.

Note that whatever may be the optimization processes activated, they are always launched in the order that is a suborder of the following (see user manual for further details): *lloyd*, *odt*, *perturb*, *exude*.

Also beware, that optimization of the mesh is obtained by perturbing mesh vertices and modifying the mesh connectivity and that this has an impact on the strict compliance to the refinement criteria. Though a strict compliance to mesh criteria is granted at the end of the Delaunay refinement, this may no longer be true after some optimization processes. Also beware that the default behavior does involve some optimization processes.

Function

CGAL::refine_mesh_3

Definition

The function *refine_mesh_3* is a 3D mesh generator. It produces simplicial meshes which discretize 3D domains.

The mesh generation algorithm is a Delaunay refinement process followed by an optimization phase. The criteria driving the Delaunay refinement process may be tuned to achieve the user needs with respect to the size of mesh elements, the accuracy of boundaries approximation, etc.

The optimization phase is a succession of optimization processes, including possibly a Lloyd smoothing, an odt-smoothing, a perturber and an exuder. Each optimization process can be activated or not, according to the user requirements and available time. By default, only the perturber and the exuder are activated. Note that the benefits of the exuder will be lost if the mesh is further refined afterward.

template <class C3T3, class MeshDomain_3, class MeshCriteria>
void refine_mesh_3(C3T3& c3t3,
MeshDomain_3 mesh_domain,
MeshCriteria mesh_criteria,
parameters::internal::Lloyd_options lloyd = parameters::no_lloyd(),
parameters::internal::Odt_options odt = parameters::no_odt(),
parameters::internal::Perturb_options perturb = parameters::perturb(),
parameters::internal::Exude_options exude = parameters::exude())

advanced

The function template *refine_mesh_3* may be used to refine a previously computed mesh, e.g.:

C3T3 c3t3 = CGAL::make_mesh_3<C3T3>(domain,criteria);
CGAL::refine_mesh_3(c3t3, domain, new_criteria);

Please note that we guarantee the result if and only if the domain does not change from one refinement to the next one.

advanced

Parameters

Parameter *C3T3* is required to be a model of the concept *MeshComplex_3InTriangulation_3*. The argument *c3t3* is passed by reference as this object is modified by the refinement process. As the refinement process only adds points to the triangulation, all vertices of the triangulation of *c3t3* remain in the mesh during the refinement process. Object *c3t3* can be used to insert specific points in the domain to ensure that they will be contained in the final triangulation.

The type *C3T3* is in particular required to provide a nested type *C3T3::Triangulation* for the 3D triangulation embedding the mesh. The vertex and cell base classes of the triangulation *C3T3::Triangulation* are required to be models of the concepts *MeshVertexBase_3* and *MeshCellBase_3* respectively.

Template parameter *MeshDomain_3* is required to be a model of the concept *MeshDomain_3* or of the refined concept *MeshDomainWithFeatures_3* if 0 and 1-dimensional features of the input complex have to be accurately represented in the mesh. The argument *domain* is the sole link through which the domain to be discretized is known by the mesh generation algorithm.

The template parameter *MeshCriteria* has to be a model of the concept *MeshCriteria_3*, or a model of the refined concept *MeshCriteriaWithFeatures_3* if the domain has exposed features. The argument *criteria* of type *MeshCriteria* specifies the size and shape requirements for mesh tetrahedra and surface facets. These criteria form the rules which drive the refinement process. All mesh elements satisfy those criteria at the end of the refinement process. In addition, if the domain has features, the argument *criteria* provides a sizing field to guide the discretization of 1-dimensional exposed features.

The four additional parameters are optimization parameters. They control which optimization processes are performed and allow the user to tune the parameters of the optimization processes. We do not describe the types of optimization parameters as they are internal types. The package defines two global functions for each optimization parameter to generate appropriate value of this parameter.

- *parameters::lloyd()* and *parameters::no_lloyd()* are designed to trigger or not a call to *lloyd_optimize_mesh_3* function and to set the parameters of this optimizer. If one parameter is not set, the default value of *lloyd_optimize_mesh_3* is used for this parameter.
- *parameters::odt()* and *parameters::no_odt()* are designed to trigger or not a call to *odt_optimize_mesh_3* function and to set the parameters of this optimizer If one parameter is not set, the default value of *odt_optimize_mesh_3* is used for this parameter.
- *parameters::perturb()* and *parameters::no_perturb()* are designed to trigger or not a call to *perturb_mesh_3* function and to set the parameters of this optimizer. If one parameter is not set, the default value of *perturb_mesh_3* is used for this parameter, except for the time bound which is set to be equal to the refinement CPU time.
- *parameters::exude()* and *parameters::no_exude()* are designed to trigger or not a call to *exude_mesh_3* function and to override to set the parameters of this optimizer. If one parameter is not set, the default value of *exude_mesh_3* is used for this parameter, except for the time bound which is set to be equal to the refinement CPU time.

The optimization parameters can be passed in random order. If one parameter is not passed, its default value is used. The default values are *no_lloyd()*, *no_odt()*, *perturb()* and *exude()*. Note that whatever may be the optimization processes activated, they are always launched in the order that is a suborder of the following (see user manual for further details): *lloyd*, *odt*, *perturb*, *exude*.

Beware that optimization of the mesh is obtained by perturbing mesh vertices and modifying the mesh connectivity and that this has an impact on the strict compliance to the refinement criteria. Though a strict compliance to mesh criteria is granted at the end of the Delaunay refinement, this may no longer be true after some optimization processes. Also beware that the default behavior does involve some optimization processes.

CGAL::exude_mesh_3

Function

Definition

The function *exude_mesh_3* performs a sliver exudation process on a Delaunay mesh.

The sliver exudation process consists in turning the Delaunay triangulation into a weighted Delaunay triangulation and optimizing the weights of vertices in such a way that slivers disappear and the quality of the mesh improves.

#include <CGAL/exude_mesh_3.h>

template<typename C3T3>
Mesh_optimization_return_code

exude_mesh_3(C3T3& c3t3,
double parameters::time_limit=0,
double parameters::sliver_bound=0)

Precondition: *time_limit* ≥ 0 and $0 \leq$ *sliver_bound* ≤ 180

Parameters

Parameter *C3T3* is required to be a model of the concept *MeshComplex_3InTriangulation_3*. The argument *c3t3*, passed by reference, provides the initial mesh and is modified by the algorithm to represent the final optimized mesh.

The function has two optional parameters which are named parameters (we use the Boost.Parameter library). Therefore, when calling the function, the parameters can be provided in any order provided that the names of the parameters are used (see example at the bottom of this page).

- Parameter *time_limit*, whose name is *parameters::time_limit*, is used to set up, in seconds, a CPU time limit after which the optimization process is stopped. This time is measured using the *CGAL::Timer* class. The default value is *0* and means that there is no time limit.
- Parameter *sliver_bound*, whose name is *parameters::sliver_bound*, is designed to give, in degree, a targeted lower bound on dihedral angles of mesh cells. The exudation process considers in turn all the mesh cells that have a smallest dihedral angle less than *sliver_bound* and tries to make them disappear by weighting their vertices. The optimization process stops when every cell in the mesh achieves this quality. The default value is *0* and means that there is no targeted bound : the exuder then runs as long as it can improve the smallest dihedral angles of the set of cells incident to some vertices.

Return Values

The function *exude_mesh_3* returns a value of type *Mesh_optimization_return_code* which is:

- *BOUND_REACHED* when the targeted bound for the smallest dihedral angle in the mesh is reached.

- *TIME_LIMIT_REACHED* when the time limit is reached.
- *CANT_IMPROVE_ANYMORE* when exudation process stops because it can no longer improve the smallest dihedral angle of the set of cells incident to some vertex in the mesh.

Example

```
// Exude without sliver_bound, using at most 10s CPU time
exude_mesh_3(c3t3, parameters::time_limit=10);
```

CGAL::perturb_mesh_3

Definition

The function *perturb_mesh_3* is a mesh optimizer that improves the quality of a Delaunay mesh by changing the mesh vertices positions.

The perturber tries to improve the dihedral angles of the worst cells in the mesh degree by degree: the step number n is considered as successful if after this step the worst tetrahedron of the mesh has a minimal dihedral angle larger than n degrees. The perturber exits if this is not the case.

#include <CGAL/perturb_mesh_3.h>

```
template<typename C3T3, typename MeshDomain_3>
Mesh_optimization_return_code

                perturb_mesh_3( C3T3& c3t3,
                                MeshDomain_3 domain,
                                double parameters::time_limit=0,
                                double parameters::sliver_bound=0)
```

Precondition: $time\_limit \geq 0$ and $0 \leq sliver\_bound \leq 180$

Parameters

Parameter *C3T3* is required to be a model of the concept *MeshComplex_3InTriangulation_3*. The argument *c3t3*, passed by reference, provides the initial mesh and is modified by the algorithm to represent the final optimized mesh.

Parameter *MeshDomain_3* is required to be a model of the concept *MeshDomain_3*. The argument *domain* must be the *MeshDomain_3* object used to create the *c3t3* parameter.

The function has two optional parameters which are named parameters (we use the Boost.Parameter library). Therefore, when calling the function, the parameters can be provided in any order provided that the names of the parameters are used (see example at the bottom of this page).

- Parameter *time_limit* whose name is *parameters::time_limit*, is used to set up, in seconds, a CPU time limit after which the optimization process is stopped. This time is measured using *CGAL::Timer*. The default value is *0* and means that there is no time limit.
- Parameter *sliver_bound*, whose name is *parameters::sliver_bound*, is designed to give, in degree, a targeted lower bound on dihedral angles of mesh cells. The function *perturb_mesh_3* runs as long as steps are successful and step number *sliver_bound* (after which the worst tetrahedron in the mesh has a smallest angle larger than *sliver_bound* degrees) has not been reached. The default value is *0* and means that there is no targeted bound: the perturber then runs as long as steps are successful.

Return Values

The function *perturb_mesh_3* returns a value of type *Mesh_optimization_return_code* which is:

- *BOUND_REACHED* when the targeted bound for the smallest dihedral angle in the mesh is reached.
- *TIME_LIMIT_REACHED* when the time limit is reached.
- *CANT_IMPROVE_ANYMORE* when the perturbation process stops because the last step is unsuccessful.

Example

```
// Perturb until every dihedral angle of the mesh is >= 10 degrees
// No time bound is set
perturb_mesh_3(c3t3, domain, parameters::sliver_bound=10);
```

CGAL::lloyd_optimize_mesh_3

Definition

The function *lloyd_optimize_mesh_3* is a mesh optimization process based on the minimization of a global energy function.

In *lloyd_optimize_mesh_3*, the minimized global energy may be interpreted as the L^1-norm of the error achieved when the function x^2 is interpolated on the mesh domain using a piecewise linear function which is linear in each cell of the Voronoi diagram of the mesh vertices.

The optimizer *lloyd_optimize_mesh_3* works in iterative steps. At each iteration, mesh vertices are moved into positions that bring to zero the energy gradient and the Delaunay triangulation is updated. Vertices on the mesh boundaries are handled in a special way so as to preserve an accurate representation of the domain boundaries.

#include <CGAL/lloyd_optimize_mesh_3.h>

```
template<typename C3T3, typename MeshDomain_3>
Mesh_optimization_return_code

        lloyd_optimize_mesh_3( C3T3& c3t3,
                               MeshDomain_3 domain,
                               double parameters::time_limit=0,
                               std::size_t parameters::max_iteration_number=0,
                               double parameters::convergence=0.02,
                               double parameters::freeze_bound = 0.01)
```

Precondition: *time_limit* ≥ 0 and $0 \leq$ *convergence* ≤ 1 and $0 \leq$ *freeze_bound* ≤ 1

Parameters

Parameter *C3T3* is required to be a model of the concept *MeshComplex_3InTriangulation_3*. The argument *c3t3*, passed by reference, provides the initial mesh and is modified by the algorithm to represent the final optimized mesh.

Parameter *MeshDomain_3* is required to be a model of the concept *MeshDomain_3*. The argument *domain* must be the *MeshDomain_3* object used to create the *c3t3* parameter.

The function has four optional parameters which are named parameters (we use the Boost.Parameter library). Therefore, when calling the function, the parameters can be provided in any order provided that the names of the parameters are used (see example at the bottom of this page).

- Parameter *time_limit*, whose name is *parameters::time_limit*, is used to set up, in seconds, a CPU time limit after which the optimization process is stopped. This time is measured using *CGAL::Timer*. The default value is *0* and means that there is no time limit.
- Parameter *max_iteration_number*, whose name is *parameters::max_iteration_number*, sets a limit on the number of performed iterations. The default value of *0* means that there is no limit on the number of performed iterations.

- Parameter *convergence*, whose name is *parameters::convergence*, is a stopping criterion based on convergence: the optimization process is stopped, when at the last iteration, the displacement of any vertex is less than a given percentage of the length of the shortest edge incident to that vertex. The parameter *convergence* gives the threshold ratio.
- Parameter *freeze_bound*, whose name is *parameters::freeze_bound*, is designed to reduce running time of each optimization iteration. Any vertex that has a displacement less than a given percentage of the length of its shortest incident edge, is frozen (i.e. is not relocated). The parameter *freeze_bound* gives the threshold ratio. At each iteration, any vertex that moves, unfreezes all its incident vertices.

Return Values

The function *lloyd_optimize_mesh_3* returns a value of type *Mesh_optimization_return_code* which is:

- *TIME_LIMIT_REACHED* when the time limit is reached.
- *MAX_ITERATION_NUMBER_REACHED* when *lloyd_optimize_mesh_3* stops because it has performed *max_iteration_number* iterations.
- *CONVERGENCE_REACHED* when *lloyd_optimize_mesh_3* stops because the convergence criterion is achieved.

Example

```
// Lloyd-smoothing until convergence reaches 0.01, freezing vertices
   which
// move less than 0.001*shortest_incident_edge_length
lloyd_optimize_mesh_3(c3t3, domain, parameters::convergence=0.01,
                      parameters::freeze_bound=0.001);
```

CGAL::odt_optimize_mesh_3

Function

Definition

The function *odt_optimize_mesh_3* is a mesh optimization process based on the minimization of a global energy function.

In *odt_optimize_mesh_3*, the minimized global energy may be interpreted as the L^1-norm of the error achieved when the function x^2 is interpolated on the mesh domain using a piecewise linear function which is linear in each mesh cell.

The optimizer *odt_optimize_mesh_3* works in iterative steps. At each iteration, mesh vertices are moved into positions that bring to zero the energy gradient and the Delaunay triangulation is updated. Vertices on the mesh boundaries are handled in a special way so as to preserve an accurate representation of the domain boundaries.

#include <CGAL/odt_optimize_mesh_3.h>

```
template<typename C3T3, typename MeshDomain_3>
Mesh_optimization_return_code

                    odt_optimize_mesh_3( C3T3& c3t3,
                                         MeshDomain_3 domain,
                                         double parameters::time_limit=0,
                                         std::size_t parameters::max_iteration_number=0,
                                         double parameters::convergence=0.02,
                                         double parameters::freeze_bound = 0.01)
```

Precondition: *time_limit* ≥ 0 and $0 \leq$ *convergence* ≤ 1 and $0 \leq$ *freeze_bound* ≤ 1

Parameters

Parameter *C3T3* is required to be a model of the concept *MeshComplex_3InTriangulation_3*. The argument *c3t3*, passed by reference, provides the initial mesh and is modified by the algorithm to represent the final optimized mesh.

Parameter *MeshDomain_3* is required to be a model of the concept *MeshDomain_3*. The argument *domain* must be the *MeshDomain_3* object used to create the *c3t3* parameter.

The function has four optional parameters which are named parameters (we use the Boost.Parameter library). Therefore, when calling the function, the parameters can be provided in any order provided that the names of the parameters are used (see example at the bottom of this page).

- Parameter *time_limit*, whose name is *parameters::time_limit*, is used to set up, in seconds, a CPU time limit after which the optimization process is stopped. This time is measured using *CGAL::Timer*. The default value is *0* and means that there is no time limit.
- Parameter *max_iteration_number*, whose name is *parameters::max_iteration_number*, sets a limit on the number of performed iterations. The default value of *0* means that there is no limit on the number of performed iterations.

- Parameter *convergence*, whose name is *parameters::convergence*, is a stopping criterion based on convergence: the optimization process is stopped, when at the last iteration, the displacement of any vertex is less than a given percentage of the length the shortest edge incident to that vertex. The parameter *convergence* gives the threshold ratio.

- Parameter *freeze_bound*, whose name is *parameters::freeze_bound*, is designed to reduce running time of each optimization iteration. Any vertex that has a displacement less than a given percentage of the length of its shortest incident edge, is frozen (i.e. is not relocated). The parameter *freeze_bound* gives the threshold ratio. At each iteration, any vertex that moves, unfreezes the neighboring vertices.

Return Values

The function *odt_optimize_mesh_3* returns a value of type *Mesh_optimization_return_code* which is:

- *TIME_LIMIT_REACHED* when the time limit is reached.

- *MAX_ITERATION_NUMBER_REACHED* when *odt_optimize_mesh_3* stops because it has performed *max_iteration_number* iterations.

- *CONVERGENCE_REACHED* when *odt_optimize_mesh_3* stops because the convergence criterion is achieved.

Example

```
// 100 iterations of Odt-smoothing
odt_optimize_mesh_3(c3t3, domain, parameters::max_iteration_number=100,
                         parameters::convergence=0);
```

CGAL::parameters::features

Definition

The function *parameters::features* provides a value of internal type *Features* to specify if 0 and 1-dimensional features have to be taken into account. The provided value is a default value that triggers the representation of corners and curve segments in the mesh when the domain is a model of *MeshDomainWithFeatures_3*.

#include <CGAL/refine_mesh_3.h>

% parameters::internal::Features_options

parameters::features()

Provides a *Features_options* value such that 0 and 1-dimensional input features are taken into account if domain is a model of the refined concept *MeshDomainWithFeatures_3*.

See Also

CGAL::make_mesh_3 . . . . page 3217,
CGAL::refine_mesh_3 . . . . page 3220,
CGAL::parameters::no_features . . . . page 3232.

Function

CGAL::parameters::no_features

Definition

The function *parameters::no_features* allows the user to prevent the handling of 0 and 1 dimensional features. This is useful when the domain is a model of *MeshDomainWithFeatures_3* and the user does not want corners and curve segments to be accurately represented in the mesh.

#include <CGAL/refine_mesh_3.h>

parameters::internal::Features_options

parameters::no_features()

Return a *Features_options* value that prevents the mesh generator to take into account 0 and 1-dimensional input features.

CGAL::parameters::exude

Function

Definition

The function *parameters::exude* allows the user to trigger a call to *exude_mesh_3* in the *make_mesh_3* and *refine_mesh_3* mesh generation functions. It also allows the user to pass parameters to the optimization function *exude_mesh_3* through these mesh generation functions.

#include <CGAL/refine_mesh_3.h>

parameters::internal::Exude_options

parameters::exude(double parameters::time_limit = 0,
double parameters::sliver_bound = 0)

Parameters

The parameters are named parameters. They are the same (i.e. they have the same name and the same default values) as the parameters of *exude_mesh_3* function. See its manual page for further details.

Example

```
// Mesh generation with an exudation step
C3t3 c3t3 = make_mesh_3<c3t3>(domain, criteria, parameters::exude());
refine_mesh_3(c3t3, domain, criteria,
    parameters::exude(parameters::time_limit=10));
```

Function

CGAL::parameters::no_exude

Definition

The function *parameters::no_exude* allows the user to tell the mesh generation functions *make_mesh_3* and *refine_mesh_3* that no exudation must be done.

#include <CGAL/refine_mesh_3.h>

parameters::internal::Exude_options

parameters::no_exude()

Example

```
// Mesh generation without exudation
C3t3 c3t3 = make_mesh_3<c3t3>(domain, criteria, parameters::no_exude());
```

CGAL::parameters::perturb

Definition

The function *parameters::perturb* allows the user to trigger a call to *perturb_mesh_3* in *make_mesh_3* and *refine_mesh_3* mesh generation functions. It also allows the user to pass parameters to the optimization function *perturb_mesh_3* through these mesh generation functions.

#include <CGAL/refine_mesh_3.h>

parameters::internal::Perturb_options

parameters::perturb(double parameters::time_limit = 0,
double parameters::sliver_bound = 0)

Parameters

The parameters are named parameters. They are the same (i.e. they have the same name and the same default values) as the parameters of *perturb_mesh_3* function. See its manual page for further details.

Example

```
// Mesh generation with a perturbation step
C3t3 c3t3 = make_mesh_3<c3t3>(domain, criteria, parameters::perturb());
refine_mesh_3(c3t3, domain, criteria,
   parameters::perturb(parameters::time_limit=10));
```

Function

Function

CGAL::parameters::no_perturb

Definition

The function *parameters::no_perturb* allows the user to tell mesh generation global functions *make_mesh_3* and *refine_mesh_3* that no perturbation must be done.

#include <CGAL/refine_mesh_3.h>

parameters::internal::Perturb_options

parameters::no_perturb()

Parameters

This function takes no parameter.

Example

```
// Mesh generation without perturbation
C3t3 c3t3 = make_mesh_3<c3t3>(domain, criteria,
    parameters::no_perturb());
```

CGAL::parameters::lloyd

Definition

The function *parameters::lloyd* allows the user to trigger a call of *lloyd_optimize_mesh_3* in the mesh generation functions *make_mesh_3* and *refine_mesh_3*. It also allows the user to pass parameters to the optimization function *lloyd_optimize_mesh_3* through these mesh generation functions.

#include <CGAL/refine_mesh_3.h>

parameters::internal::Lloyd_options

parameters::lloyd(double parameters::time_limit = 0,
std::size_t parameters::max_iteration_number = 0,
double parameters::convergence = 0.02,
double parameters::freeze_bound = 0.01)

Parameters

The parameters are named parameters. They are the same (i.e. they have the same name and the same default values) as the parameters of the *lloyd_optimize_mesh_3* function. See its manual page for further details.

Example

```
// Mesh generation with lloyd optimization step
C3t3 c3t3 = make_mesh_3<c3t3>(domain, criteria, parameters::lloyd());
refine_mesh_3(c3t3, domain, criteria,
   parameters::lloyd(parameters::time_limit=10));
```

CGAL::Mesh_optimization_return_code

Definition

The enum *Mesh_optimization_return_code* is the output of the global mesh optimization functions. This output corresponds to mesh optimization process termination reasons. Note that depending on what parameters have been set to the optimizer, each return value may represent a failure or a success.

#include <CGAL/Mesh_optimization_return_code.h>

enum Mesh_optimization_return_code { *BOUND_REACHED = 0,*
TIME_LIMIT_REACHED,
CANT_IMPROVE_ANYMORE,
CONVERGENCE_REACHED,
MAX_ITERATION_NUMBER_REACHED}

Values

The following values are defined:

- *BOUND_REACHED*: The given lower bound on mesh quality is reached.
- *TIME_LIMIT_REACHED*: The given time limit is reached.
- *CANT_IMPROVE_ANYMORE*: Mesh could not be improved anymore.
- *CONVERGENCE_REACHED*: The given convergence bound is reached.
- *MAX_ITERATION_NUMBER_REACHED*: The given maximum iteration number is reached.

Enum

CGAL::Mesh_facet_topology

Definition

The enum *Mesh_facet_topology* is designed to tell which constraints have to be checked on each surface facet during the mesh refinement process.

#include <CGAL/Mesh_facet_topology.h>

enum Mesh_facet_topology { *FACET_VERTICES_ON_SURFACE = 1,*
FACET_VERTICES_ON_SAME_SURFACE_PATCH,
FACET_VERTICES_ON_SAME_SURFACE_PATCH_WITH_ADJACENCY_CHECK}

Values

The following values are defined:

- *FACET_VERTICES_ON_SURFACE*: Each vertex of the facet have to be on the surface, on a curve segment, or on a corner.
- *FACET_VERTICES_ON_SAME_SURFACE_PATCH*: The three vertices of a facet belonging to a surface patch *s* have to be on the same surface patch *s*, on a curve segment or on a corner.
- *FACET_VERTICES_ON_SAME_SURFACE_PATCH_WITH_ADJACENCY_CHECK*: The three vertices of a facet belonging to a surface patch *s* have to be on the same surface patch *s*, or on a curve segment incident to the surface patch *s* or on a corner incident to the surface patch *s*.

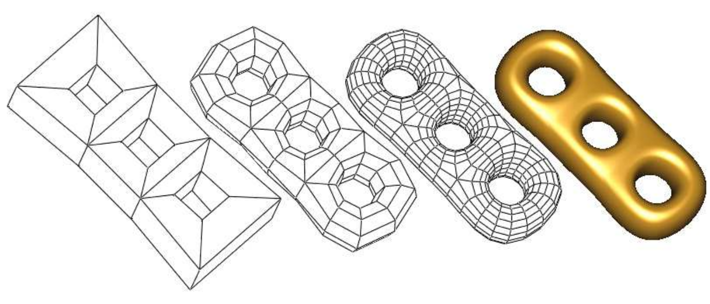
Geometry Processing

Chapter 52

3D Surface Subdivision Methods

Le-Jeng Andy Shiue

Contents



52.1 Introduction

Subdivision methods are simple yet powerful ways to generate smooth surfaces from arbitrary polyhedral meshes. Unlike spline-based surfaces (e.g NURBS) or other numeric-based modeling techniques, users of subdivision methods do not need the mathematical knowledge of the subdivision methods. The natural intuition of the geometry suffices to control the subdivision methods.

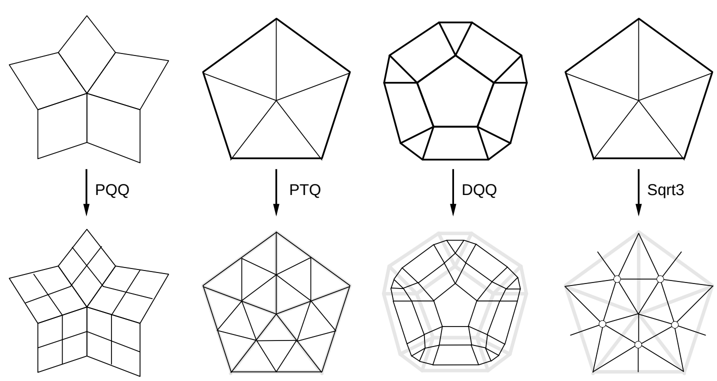
Subdivision_method_3, designed to work on the class *Polyhedron_3*, aims to be easy to use and to extend. *Subdivision_method_3* is not a class, but a namespace which contains four popular subdivision methods and their refinement functions. These include Catmull-Clark, Loop, Doo-Sabin and $\sqrt{3}$ subdivisions. Variations of these methods can be easily extended by substituting the geometry computation of the refinement host.

52.2 Subdivision Method

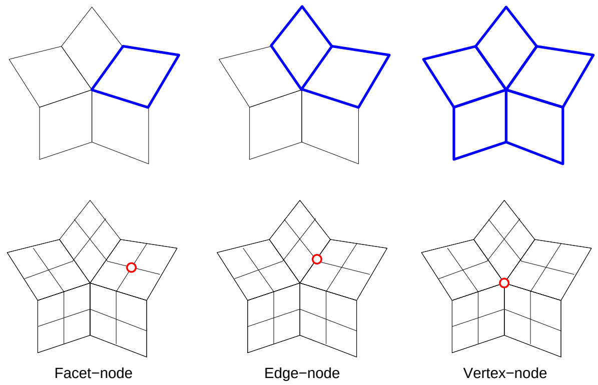
In this chapter, we explain some fundamentals of subdivision methods. We focus only on the topics that help you to understand the design of the package. [WW02] has details on subdivision methods. Some terminology introduced in this section will be used again in later sections. If you are only interested in using a specific subdivision method, Section 52.3 gives a quick tutorial on Catmull-Clark subdivision.

A subdivision method recursively refines a coarse mesh and generates an ever closer approximation to a smooth surface. The coarse mesh can have arbitrary shape, but it has to be a 2-manifold. In a 2-manifold, every interior point has a neighborhood homeomorphic to a 2D disk. Subdivision methods on non-manifolds have been developed, but are not considered in *Subdivision_method_3*. The chapter teaser shows the steps of Catmull-Clark subdivision on a CAD model. The coarse mesh is repeatedly refined by a quadrisection pattern, and new points are generated to approximate a smooth surface.

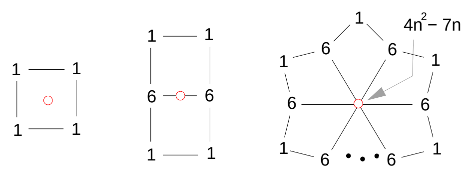
Many refinement patterns are used in practice. *Subdivision_method_3* supports the four most popular patterns, and each of them is used by Catmull-Clark[CC78], Loop, Doo-Sabin and $\sqrt{3}$ subdivision (left to right in the figure). We name these patterns by their topological characteristics instead of the associated subdivision methods. PQQ indicates the *P*rimal *Q*uadtrateral *Q*uadrisection. PTQ indicates the *P*rimal *T*riangle *Q*uadrisection. DQQ indicates the *D*ual *Q*uadtrateral *Q*uadrisection. $\sqrt{3}$ indicates the converging speed of the triangulation toward the subdivision surface.



The figure demonstrates these four refinement patterns on the 1-disk of a valence-5 vertex/facet. Refined meshes are shown below the source meshes. Points on the refined mesh are generated by averaging neighbor points on the source mesh. A graph, called *stencil*, determines the source neighborhood whose points contribute to the position of a refined point. A refinement pattern usually defines more than one stencil. For example, the PQQ refinement has a vertex-node stencil, which defines the 1-ring of an input vertex; an edge-node stencil, which defines the 1-ring of an input edge; and a facet-node stencil, which defines an input facet. The stencils of the PQQ refinement are shown in the following figure. The blue neighborhoods in the top row indicate the corresponding stencils of the refined nodes in red.



Stencils with weights are called *geometry masks*. A subdivision method defines a geometry mask for each stencil, and generates new points by averaging source points weighted by the mask. Geometry masks are carefully chosen to meet requirements of certain surface smoothness and shape quality. The geometry masks of Catmull-Clark subdivision are shown below.



The weights shown here are unnormalized, and n is the valence of the vertex. The generated point, in red, is computed by a summation of the weighted points. For example, a Catmull-Clark facet-node is computed by the summation of $1/4$ of each point on its stencil.

A stencil can have an unlimited number of geometry masks. For example, a facet-node of PQQ refinement may be computed by the summation of $1/5$ of each stencil node instead of $1/4$. Although it is legal in *Subdivision_method_3* to have any kind of geometry mask, the result surfaces may be odd, not smooth, or not even exist. [WW02] explains the details on designing masks for a quality subdivision surface.

52.3 A Quick Example: Catmull-Clark Subdivision

Assuming you are familiar with *Polyhedron_3*, you can integrate *Subdivision_method_3* into your program without much effort.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Subdivision_method_3.h>
#include <iostream>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>

typedef CGAL::Simple_cartesian<double>     Kernel;
typedef CGAL::Polyhedron_3<Kernel>         Polyhedron;

using namespace std;
using namespace CGAL;
```

```
int main(int argc, char** argv) {
  if (argc != 2) {
    cout << "Usage: CatmullClark_subdivision d < filename" << endl;
    cout << "       d: the depth of the subdivision (0 < d < 10)" <<
   endl;
    cout << "       filename: the input mesh (.off)" << endl;
    return 0;
  }

  int d = argv[1][0] - '0';

  Polyhedron P;
  cin >> P; // read the .off

  Subdivision_method_3::CatmullClark_subdivision(P,d);

  cout << P; // write the .off

  return 0;
}
```

File: examples/Subdivision_method_3/CatmullClark_subdivision.cpp

This example demonstrates the use of the Catmull-Clark subdivision method on a *Polyhedron_3*. The polyhedron is restricted in the Cartesian space, where most subdivision applications are designed to work. There is only one line deserving a detailed explanation:

```
Subdivision_method_3::CatmullClark_subdivision(P,d);
```

Subdivision_method_3 specifies the namespace of our subdivision functions. *CatmullClark_subdivision(P,d)* computes the Catmull-Clark subdivision surface of the polyhedron *P* after *d* iterations of the refinements. The polyhedron *P* is passed by reference, and is modified (i.e. subdivided) by the subdivision function.

This example shows how to subdivide a simple *Polyhedron_3* with *Subdivision_method_3*. An application-defined polyhedron might use a specialized kernel and/or a specialized internal container. There are two major restrictions on the application-defined polyhedron to work with *Subdivision_method_3*.

- *Point_3* is type-defined by the kernel. Without *Point_3* and the associated operations being defined, *Subdivision_method_3* can not know how to compute and store the new vertex points.
- The primitives (such as vertices, halfedges and facets) in the internal container are sequentially ordered (e.g. *std::vector* and *std::list*). This implies that the iterators traverse the primitives in the order of their creations/insertions.

Section 52.5 gives detailed explanations on those two restrictions.

52.4 Catmull-Clark Subdivision

Subdivision_method_3 is designed to allow customization of the subdivision methods. This section explains the implementation of the Catmull-Clark subdivision function in *Subdivision_method_3*. The implementation demonstrates the customization of the PQQ refinement to Catmull-Clark subdivision.

When a subdivision method is developed, a refinement pattern is chosen, and then a set of geometry masks are developed to position the new points. There are three key components to implement a subdivision method:

- a mesh data structure that can represent arbitrary 2-manifolds,
- a process that refines the mesh data structure,
- and the geometry masks that compute the new points.

E. Catmull and J. Clark picked the PQQ refinement for their subdivision method, and developed a set of geometry masks to generate (or more precisely, to approximate) the B-spline surface from the control mesh. *Subdivision_method_3* provides a function that glues all three components of the Catmull-Clark subdivision method.

```
template <class Polyhedron_3, template <typename> class Mask>
void PQQ(Polyhedron_3& p, Mask<Polyhedron_3> mask, int depth)
```

Polyhedron_3 is a generic mesh data structure for arbitrary 2-manifolds. *PQQ()*, which refines the control mesh *p*, is a *refinement host* that uses a policy class *Mask<Polyhedron_3>* as part of it geometry computation. During the refinement, *PQQ()* computes and assigns new points by cooperating with the *mask*. To implement Catmull-Clark subdivision, *Mask*, the *geometry policy*, has to realize the geometry masks of Catmull-Clark subdivision. *depth* specifies the iterations of the refinement on the control mesh.

To implement the geometry masks, we need to know how a refinement host communicates with its geometry masks. The PQQ refinement defines three stencils, and hence three geometry masks are required for Catmull-Clark subdivision. The following class defines the interfaces of the stencils for the PQQ refinement.

```
template <class Polyhedron_3>
class PQQ_stencil_3 {
  void facet_node(Facet_handle facet, Point_3& pt);
  void edge_node(Halfedge_handle edge, Point_3& pt);
  void vertex_node(Vertex_handle vertex, Point_3& pt);
};
```

Each class function in *PQQ_stencil_3* computes a new point based on the neighborhood of the primitive handle, and assigns the new point to *Point_3& pt*.

We realize each class function with the geometry masks of Catmull-Clark subdivision.

```
template <class Polyhedron_3>
class CatmullClark_mask_3 {
  void facet_node(Facet_handle facet, Point_3& pt) {
    Halfedge_around_facet_circulator hcir = facet->facet_begin();
    int n = 0;
    Point_3 p(0,0,0);
    do {
      p = p + (hcir->vertex()->point() - ORIGIN);
      ++n;
    } while (++hcir != facet->facet_begin());
    pt = ORIGIN + (p - ORIGIN)/FT(n);
  }
  void edge_node(Halfedge_handle edge, Point_3& pt) {
    Point_3 p1 = edge->vertex()->point();
    Point_3 p2 = edge->opposite()->vertex()->point();
```

```
    Point_3 f1, f2;
    facet_node(edge->facet(), f1);
    facet_node(edge->opposite()->facet(), f2);
    pt = Point_3((p1[0]+p2[0]+f1[0]+f2[0])/4,
                 (p1[1]+p2[1]+f1[1]+f2[1])/4,
                 (p1[2]+p2[2]+f1[2]+f2[2])/4 );
  }
  void vertex_node(Vertex_handle vertex, Point_3& pt) {
    Halfedge_around_vertex_circulator vcir = vertex->vertex_begin();
    int n = circulator_size(vcir);

    FT Q[] = {0.0, 0.0, 0.0}, R[] = {0.0, 0.0, 0.0};
    Point_3& S = vertex->point();

    Point_3 q;
    for (int i = 0; i < n; i++, ++vcir) {
      Point_3& p2 = vcir->opposite()->vertex()->point();
      R[0] += (S[0]+p2[0])/2;
      R[1] += (S[1]+p2[1])/2;
      R[2] += (S[2]+p2[2])/2;
      facet_node(vcir->facet(), q);
      Q[0] += q[0];
      Q[1] += q[1];
      Q[2] += q[2];
    }
    R[0] /= n;    R[1] /= n;    R[2] /= n;
    Q[0] /= n;    Q[1] /= n;    Q[2] /= n;

    pt = Point_3((Q[0] + 2*R[0] + S[0]*(n-3))/n,
                 (Q[1] + 2*R[1] + S[1]*(n-3))/n,
                 (Q[2] + 2*R[2] + S[2]*(n-3))/n );
  }
};
```

This example shows the default implementation of Catmull-Clark masks in *Subdivision_method_3*. This default implementation assumes the *types* (such as *Point_3* and *Facet_handle*) are defined within *Polyhedron_3*. *CatmullClark_mask_3* is designed to work on a *Polyhedron_3* with the *Cartesian* kernel. You may need to rewrite the geometry computation to match the kernel geometry of your application.

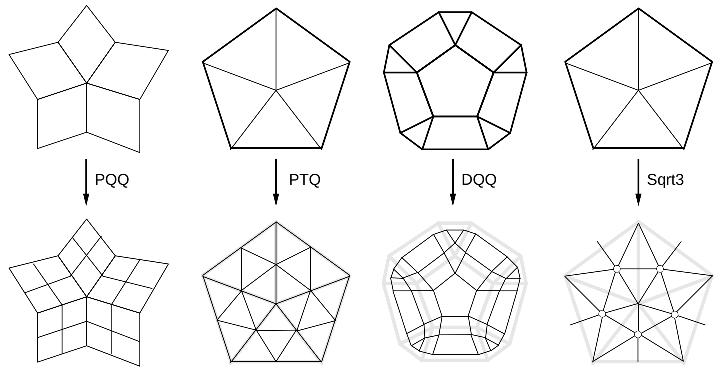
To invoke the Catmull-Clark subdivision method, we call *PQQ()* with the Catmull-Clark masks we just defined.

```
PQQ(p, CatmullClark_mask_3<Polyhedron_3>(), depth);
```

Loop, Doo-Sabin and $\sqrt{3}$ subdivisions are implemented in the similar process: pick a refinement host and implement the geometry policy. The key of developing your own subdivision method is implementing the right combination of the refinement host and the geometry policy. It is explained in the next two sections.

52.5 Refinement Host

A refinement host is a template function of a polyhedron class and a geometry mask class. It refines the input polyhedron, and computes new points through the geometry masks. *Subdivision_method_3* supports four refinement hosts: primal quadrilateral quadrisection (PQQ), primal triangle quadrisection (PTQ), dual quadrilateral quadrisection (DQQ) and $\sqrt{3}$ triangulation. Respectively, they are used by Catmull-Clark, Loop, Doo-Sabin and $\sqrt{3}$ subdivision.



```
namespace Subdivision_method_3 {
  template <class Polyhedron_3, template <typename> class Mask>
  void PQQ(Polyhedron_3& p, Mask<Polyhedron_3> mask, int step);

  template <class Polyhedron_3, template <typename> class Mask>
  void PTQ(Polyhedron_3& p, Mask<Polyhedron_3> mask, int step);

  template <class Polyhedron_3, template <typename> class Mask>
  void DQQ(Polyhedron_3& p, Mask<Polyhedron_3> mask, int step)

  template <class Polyhedron_3, template <typename> class Mask>
  void Sqrt3(Polyhedron_3& p, Mask<Polyhedron_3> mask, int step)
}
```

The polyhedron class is a specialization of *Polyhedron_3*, and the mask is a policy class realizing the geometry masks of the subdivision method.

A refinement host refines the input polyhedron, maintains the stencils (i.e., the mapping between the control mesh and the refined mesh), and calls the geometry masks to compute the new points. In *Subdivision_method_3*, refinements are implemented as a sequence of connectivity operations (mainly Euler operations). The order of the connectivity operations plays a key role when maintaining stencils. By matching the order of the source submeshes to the refined vertices, no flag in the primitives is required to register the stencils. It avoids the data dependency of the refinement host on the polyhedron class. To make the ordering trick work, the polyhedron class must have a sequential container, such as a vector or a linked-list, as the internal storage. A sequential container guarantees that the iterators of the polyhedron always traverse the primitives in the order of their insertions. Non-sequential structures such as trees or maps do not provide the required ordering, and hence can not be used with *Subdivision_method_3*.

Although *Subdivision_method_3* does not require flags to support the refinements and the stencils, it still needs to know how to compute and store the geometry data (i.e. the points). *Subdivision_method_3* expects that the typename *Point_3* is defined in the geometry kernel of the polyhedron (i.e. the *Polyhedron_3::Traits::Kernel*). A point of the type *Point_3* is returned by the geometry policy and is then assigned to the new vertex. The geometry policy is explained in next section.

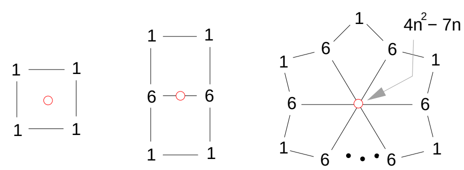
Refinement hosts *PQQ* and *DQQ* work on a general polyhedron, and *PTQ* and *Sqrt3* work on a triangulated polyhedron. The result of *PTQ* and *Sqrt3* on a non-triangulated polyhedron is undefined. *Subdivision_method_3* does not verify the precondition of the mesh characteristics before the refinement.

For details of the refinement implementation, interested users should refer to [SP05].

52.6 Geometry Policy

A geometry policy defines a set of geometry masks. Each geometry mask is realized as a member function that computes new points of the subdivision surface.

Each geometry mask receives a primitive handle (e.g. *Halfedge_handle*) of the control mesh, and returns a *Point_3* to the subdivided vertex. The function collects the vertex neighbors of the primitive handle (i.e. nodes on the stencil), and computes the new point based on the neighbors and the mask (i.e. the stencil weights).



This figure shows the geometry masks of Catmull-Clark subdivision. The weights shown here are unnormalized, and *n* is the valence of the vertex. The new points are computed by the summation of the weighted points on their stencils. Following codes show an implementation of the geometry mask of the facet-node. The complete listing of a Catmull-Clark geometry policy is in the Section 52.4.

```
template <class Polyhedron_3>
class CatmullClark_mask_3 {
  void facet_node(Facet_handle facet, Point_3& pt) {
    Halfedge_around_facet_circulator hcir = facet->facet_begin();
    int n = 0;
    Point_3 p(0,0,0);
    do {
      p = p + (hcir->vertex()->point() - ORIGIN);
      ++n;
    } while (++hcir != facet->facet_begin());
    pt = ORIGIN + (p - ORIGIN)/FT(n);
  }
}
```

In this example, the computation is based on the assumption that the *Point_3* is the *CGAL::Point_3*. It is an assumption, but not a restriction. You are allowed to use any point class as long as it is defined as the *Point_3* in your polyhedron. You may need to modify the geometry policy to support the computation and the assignment of the specialized point. This extension is not unusual in graphics applications. For example, you might want to subdivide the texture coordinates for your subdivision surface.

The refinement host of Catmull-Clark subdivision requires three geometry masks for polyhedrons without open boundaries: a vertex-node mask, an edge-node mask, and a facet-node mask. To support polyhedrons with boundaries, a border-node mask is also required. The border-node mask for Catmull-Clark subdivision is listed below, where *ept* returns the new point splitting *edge* and *vpt* returns the new point on the vertex pointed by *edge*.

```
  void border_node(Halfedge_handle edge, Point_3& ept, Point_3& vpt) {
    Point_3& ep1 = edge->vertex()->point();
    Point_3& ep2 = edge->opposite()->vertex()->point();
    ept = Point_3((ep1[0]+ep2[0])/2, (ep1[1]+ep2[1])/2,
   (ep1[2]+ep2[2])/2);
```

```
    Halfedge_around_vertex_circulator vcir = edge->vertex_begin();
    Point_3& vp1  = vcir->opposite()->vertex()->point();
    Point_3& vp0  = vcir->vertex()->point();
    Point_3& vp_1 = (--vcir)->opposite()->vertex()->point();
    vpt = Point_3((vp_1[0] + 6*vp0[0] + vp1[0])/8,
                  (vp_1[1] + 6*vp0[1] + vp1[1])/8,
                  (vp_1[2] + 6*vp0[2] + vp1[2])/8 );
  }
```

The mask interfaces of all four refinement hosts are listed below. *DQQ_stencil_3* and *Sqrt3_stencil_3* do not have the border-node stencil because the refinement hosts of DQQ and $\sqrt{3}$ refinements do not support global boundaries in the current release. This might be changed in the future releases.

```
template <class Polyhedron_3>
class PQQ_stencil_3 {
  void facet_node(Facet_handle, Point_3&);
  void edge_node(Halfedge_handle, Point_3&);
  void vertex_node(Vertex_handle, Point_3&);

  void border_node(Halfedge_handle, Point_3&, Point_3&);
};

template <class Polyhedron_3>
class PTQ_stencil_3 {
  void edge_node(Halfedge_handle, Point_3&);
  void vertex_node(Vertex_handle, Point_3&);

  void border_node(Halfedge_handle, Point_3&, Point_&);
};

template <class Polyhedron_3>
class DQQ_stencil_3 {
public:
  void corner_node(Halfedge_handle edge, Point_3& pt);
};

template <class Polyhedron_3>
class Sqrt3_stencil_3 {
public:
  void vertex_node(Vertex_handle vertex, Point_3& pt);
};
```

The source codes of *CatmullClark_mask_3*, *Loop_mask_3*, *DooSabin_mask_3*, and *Sqrt3_mask_3* are the best sources of learning these stencil interfaces.

52.7 The Four Subdivision Methods

Subdivision_method_3 supports Catmull-Clark, Loop, Doo-Sabin and $\sqrt{3}$ subdivisions by specializing their respective refinement hosts. They are designed to work on a *Polyhedron_3*. If your application uses a polyhedron with a specialized geometry kernel, you need to specialize the refinement host with a geometry policy based on that kernel.

```
namespace Subdivision_method_3 {
  template <class Polyhedron_3>
  void CatmullClark_subdivision(Polyhedron_3& p, int step = 1) {
    PQQ(p, CatmullClark_mask_3<Polyhedron_3>(), step);
  }

  template <class Polyhedron_3>
  void Loop_subdivision(Polyhedron_3& p, int step = 1) {
    PTQ(p, Loop_mask_3<Polyhedron_3>() , step);
  }

  template <class Polyhedron_3>
  void DooSabin_subdivision(Polyhedron_3& p, int step = 1) {
    DQQ(p, DooSabin_mask_3<Polyhedron_3>(), step);
  }

  template <class Polyhedron_3>
  void Sqrt3_subdivision(Polyhedron_3& p, int step = 1) {
    Sqrt3(p, Sqrt3_mask_3<Polyhedron_3>(), step);
  }
}
```

The following example demonstrates the use of Doo-Sabin subdivision on a polyhedral mesh.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Subdivision_method_3.h>

#include <iostream>

#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>

typedef CGAL::Simple_cartesian<double>     Kernel;
typedef CGAL::Polyhedron_3<Kernel>         Polyhedron;

using namespace std;
using namespace CGAL;

int main(int argc, char **argv) {
  if (argc != 2) {
    cout << "Usage: DooSabin_subdivision d < filename" << endl;
    cout << "       d: the depth of the subdivision (0 < d < 10)" <<
   endl;
    cout << "       filename: the input mesh (.off)" << endl;
    return 0;
  }

  int d = argv[1][0] - '0';

  Polyhedron P;
  cin >> P; // read the .off

  Subdivision_method_3::DooSabin_subdivision(P,d);
```

```
  cout << P; // write the .off

  return 0;
}
```

File: examples/Subdivision_method_3/DooSabin_subdivision.cpp

52.8 Other Subdivision Methods

Subdivision_method_3 supports four practical subdivision methods on a Cartesian *Polyhedron_3*. More subdivision methods can be supported through the specialization of refinement hosts with custom geometry masks. The following example develops a subdivision method generating an improved Loop subdivision surface.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Subdivision_method_3.h>

#include <cstdio>
#include <iostream>

#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>

typedef CGAL::Simple_cartesian<double>     Kernel;
typedef CGAL::Polyhedron_3<Kernel>         Polyhedron;

using namespace std;
using namespace CGAL;

// ======================================================================
template <class Poly>
class WLoop_mask_3 {
  typedef Poly                                              Polyhedron;

  typedef typename Polyhedron::Vertex_iterator              Vertex_iterator;
  typedef typename Polyhedron::Halfedge_iterator            Halfedge_iterator;
  typedef typename Polyhedron::Facet_iterator               Facet_iterator;

  typedef typename Polyhedron::Halfedge_around_facet_circulator

    Halfedge_around_facet_circulator;
  typedef typename Polyhedron::Halfedge_around_vertex_circulator

    Halfedge_around_vertex_circulator;

  typedef typename Polyhedron::Traits                       Traits;
  typedef typename Traits::Kernel                           Kernel;

  typedef typename Kernel::FT                               FT;
  typedef typename Kernel::Point_3                          Point;
  typedef typename Kernel::Vector_3                         Vector;
```

```
public:
  void edge_node(Halfedge_iterator eitr, Point& pt) {
    Point& p1 = eitr->vertex()->point();
    Point& p2 = eitr->opposite()->vertex()->point();
    Point& f1 = eitr->next()->vertex()->point();
    Point& f2 = eitr->opposite()->next()->vertex()->point();

    pt = Point((3*(p1[0]+p2[0])+f1[0]+f2[0])/8,
               (3*(p1[1]+p2[1])+f1[1]+f2[1])/8,
               (3*(p1[2]+p2[2])+f1[2]+f2[2])/8 );
  }
  void vertex_node(Vertex_iterator vitr, Point& pt) {
    double R[] = {0.0, 0.0, 0.0};
    Point& S = vitr->point();

    Halfedge_around_vertex_circulator vcir = vitr->vertex_begin();
    std::size_t n = circulator_size(vcir);
    for (std::size_t i = 0; i < n; i++, ++vcir) {
      Point& p = vcir->opposite()->vertex()->point();
      R[0] += p[0];     R[1] += p[1];   R[2] += p[2];
    }
    if (n == 6) {
      pt = Point((10*S[0]+R[0])/16, (10*S[1]+R[1])/16,
   (10*S[2]+R[2])/16);
    } else if (n == 3) {
      double B = (5.0/8.0 - std::sqrt(3+2*std::cos(6.283/n))/64.0)/n;
      double A = 1-n*B;
      pt = Point((A*S[0]+B*R[0]), (A*S[1]+B*R[1]), (A*S[2]+B*R[2]));
    } else {
      double B = 3.0/8.0/n;
      double A = 1-n*B;
      pt = Point((A*S[0]+B*R[0]), (A*S[1]+B*R[1]), (A*S[2]+B*R[2]));
    }
  }
  void border_node(Halfedge_iterator eitr, Point& ept, Point& vpt) {
    Point& ep1 = eitr->vertex()->point();
    Point& ep2 = eitr->opposite()->vertex()->point();
    ept = Point((ep1[0]+ep2[0])/2, (ep1[1]+ep2[1])/2, (ep1[2]+ep2[2])/2);

    Halfedge_around_vertex_circulator vcir = eitr->vertex_begin();
    Point& vp1  = vcir->opposite()->vertex()->point();
    Point& vp0  = vcir->vertex()->point();
    Point& vp_1 = (--vcir)->opposite()->vertex()->point();
    vpt = Point((vp_1[0] + 6*vp0[0] + vp1[0])/8,
                (vp_1[1] + 6*vp0[1] + vp1[1])/8,
                (vp_1[2] + 6*vp0[2] + vp1[2])/8 );
  }
};

int main(int argc, char **argv) {
  if (argc != 2) {

    cout << "       d: the depth of the subdivision (0 < d < 10)" <<
   endl;
```

```
    cout << "        filename: the input mesh (.off)" << endl;
    return 0;
  }

  int d = argv[1][0] - '0';

  Polyhedron P;
  cin >> P; // read the .off

  Subdivision_method_3::PTQ(P, WLoop_mask_3<Polyhedron>(), d);

  cout << P; // write the .off

  return 0;
}
```

File: examples/Subdivision_method_3/Customized_subdivision.cpp

The points generated by the geometry mask are semantically required to converge to a smooth surface. This is the requirement imposed by the theory of the subdivision surface. *Subdivision_method_3* does not enforce this requirement, nor will it verify the smoothness of the subdivided mesh. *Subdivision_method_3* guarantees the topological properties of the subdivided mesh. A genus-n 2-manifold is assured to be subdivided into a genus-n 2-manifold. But when specialized with ill-designed geometry masks, *Subdivision_method_3* may generate a surface that is odd, not smooth, or not even exist.

3D Surface Subdivision Methods Reference Manual

Le-Jeng Andy Shiue

Subdivision methods recursively refine the control mesh (i.e. the input mesh) and generate points approximating the limit surface. Designed to work on the class *Polyhedron_3*, *Subdivision_method_3* aims to be easy to use and to extend. *Subdivision_method_3* is not a class, but a namespace which consists of four popular subdivision methods and their refinement hosts. Supported subdivision methods include Catmull-Clark, Loop, Doo-Sabin and $\sqrt{3}$ subdivisions. Their respective refinement hosts are PQQ, PTQ, DQQ and $\sqrt{3}$ refinements. Variations of those methods can be easily extended by substituting the geometry computation of the refinement host.

CGAL::Subdivision_method_3

Definition

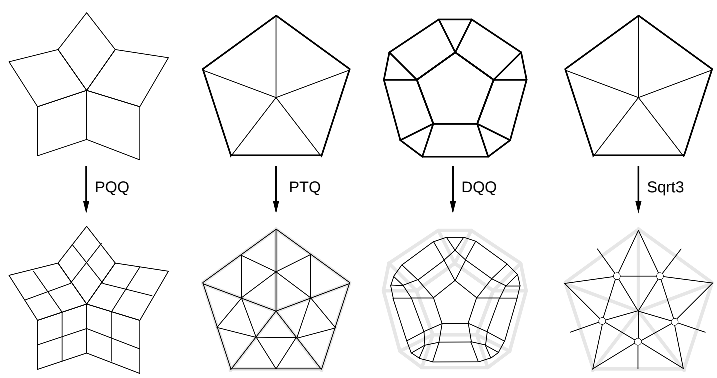
A subdivision method recursively refines a coarse mesh and generates an ever closer approximation to a smooth surface. *Subdivision_method_3* consists of four subdivision methods and their refinement hosts. Each refinement host is a template function of a polyhedron class and a geometry policy class. It refines the connectivity of the control mesh and computes the geometry of the refined mesh. The geometry computation is dedicated to the custom geometry policy. A geometry policy consists of functions that compute the new point based on the subdivision stencil. A stencil defines the footprint (a submesh of the control mesh) of a new point.

The four supported refinement hosts are the primal quadrilateral quadrisection (PQQ), the primal triangle quadrisection (PTQ), the dual quadrilateral quadrisection (DQQ), and the $\sqrt{3}$ triangulation. These refinements are respectively used in Catmull-Clark, Loop, Doo-Sabin and $\sqrt{3}$ subdivision.

#include <CGAL/Subdivision_method_3.h>

Refinement Host

A refinement host is a template function of a polyhedron class and a geometry mask class. It refines the input polyhedron, and computes new points through the geometry masks. *Subdivision_method_3* supports four refinement hosts: *PQQ*, *PTQ*, *DQQ* and *Sqrt3*.



template <class Polyhedron_3, template <typename> class Mask>
void PQQ(Polyhedron_3& p, Mask<Polyhedron_3> mask, int step = 1)

applies the PQQ refinement on the control mesh *p step* times. The geometry of the refined mesh is computed by the geometry policy *mask*. This function overwrites the control mesh *p* with the refined mesh.

template <class Polyhedron_3, template <typename> class Mask>
void PTQ(Polyhedron_3& p, Mask<Polyhedron_3> mask, int step = 1)

applies the PTQ refinement on the control mesh *p step* times, where *p* contains only triangle facets. The geometry of the refined mesh is computed by the geometry policy *mask*. This function overwrites the control mesh *p* with the refined mesh. The result of a non-triangle mesh *p* is undefined.

template <class Polyhedron_3, template <typename> class Mask>
void *DQQ(Polyhedron_3& p, Mask<Polyhedron_3> mask, int step = 1)*

applies the DQQ refinement on the control mesh *p* *step* times. The geometry of the refined mesh is computed by the geometry policy *mask*. This function overwrites the control mesh *p* with the refined mesh.

template <class Polyhedron_3, template <typename> class Mask>
void *Sqrt3(Polyhedron_3& p, Mask<Polyhedron_3> mask, int step = 1)*

applies the $\sqrt{3}$ triangulation on the control mesh *p* *step* times, where *p* contains only triangle facets. The geometry of the refined mesh is computed by the geometry policy *mask*. This function overwrites the control mesh *p* with the refined mesh. The result of a non-triangle mesh *p* is undefined.

Subdivision Method

template <class Polyhedron_3>
void *CatmullClark_subdivision(Polyhedron_3& p, int step = 1)*

applies Catmull-Clark subdivision *step* times on the control mesh *p*. This function overwrites the control mesh *p* with the subdivided mesh.

template <class Polyhedron_3>
void *Loop_subdivision(Polyhedron_3& p, int step = 1)*

applies Loop subdivision *step* times on the control mesh *p*. This function overwrites the control mesh *p* with the subdivided mesh.

template <class Polyhedron_3>
void *DooSabin_subdivision(Polyhedron_3& p, int step = 1)*

applies Doo-Sabin subdivision *step* times on the control mesh *p*. This function overwrites the control mesh *p* with the subdivided mesh.

template <class Polyhedron_3>
void *Sqrt3_subdivision(Polyhedron_3& p, int step = 1)*

applies $\sqrt{3}$ subdivision *step* times on the control mesh *p*. This function overwrites the control mesh *p* with the subdivided mesh.

Example

This example program subdivides a polyhedral mesh with Catmull-Clark subdivision.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Subdivision_method_3.h>
#include <iostream>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>

typedef CGAL::Simple_cartesian<double>     Kernel;
typedef CGAL::Polyhedron_3<Kernel>         Polyhedron;

using namespace std;
using namespace CGAL;

int main(int argc, char** argv) {
  if (argc != 2) {
    cout << "Usage: CatmullClark_subdivision d < filename" << endl;
    cout << "       d: the depth of the subdivision (0 < d < 10)" <<
   endl;
    cout << "       filename: the input mesh (.off)" << endl;
    return 0;
  }

  int d = argv[1][0] - '0';

  Polyhedron P;
  cin >> P; // read the .off

  Subdivision_method_3::CatmullClark_subdivision(P,d);

  cout << P; // write the .off

  return 0;
}
```

PQQMask_3

Required member functions for the PQQMask_3 concept. This policy concept of geometric computations is used in *CGAL::Subdivision_method_3::PQQ<Polyhedron_3, Mask>*.

Operations

void *mask.facet_node(Facet_handle facet, Point_3& pt)*

computes the facet-point *pt* based on the neighborhood of the facet *f*.

void *mask.edge_node(Edge_handle e, Point_3& pt)*

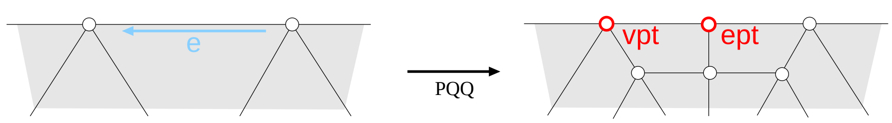
computes the edge-point *pt* based on the neighborhood of the edge *e*.

void *mask.vertex_node(Vertex_handle v, Point_3& pt)*

computes the vertex-point *pt* based on the neighborhood of the vertex *v*.

void *mask.border_node(Halfedge_handle e, Point_3& ept, Point_3& vpt)*

computes the edge-point *ept* and the vertex-point *vpt* based on the neighborhood of the border edge *e*.



Has Models

PTQMask_3

Required member functions for the PTQMask_3 concept. This policy concept of geometric computations is used in *CGAL::Subdivision_method_3::PTQ<Polyhedron_3, Mask>*.

Operations

void *mask.edge_node(Edge_handle e, Point_3& pt)*

computes the edge-point *pt* based on the neighborhood of the edge *e*.

void *mask.vertex_node(Vertex_handle v, Point_3& pt)*

computes the vertex-point *pt* based on the neighborhood of the vertex *v*.

void *mask.border_node(Halfedge_handle e, Point_3& ept, Point_3& vpt)*

computes the edge-point *ept* and the vertex-point *vpt* based on the neighborhood of the border edge *e*.

Concept

Class

CGAL::CatmullClark_mask_3<Polyhedron_3>

Definition

A stencil determines a source neighborhood whose points contribute to the position of a refined point. The geometry mask of a stencil specifies the computation on the nodes of the stencil. *CatmullClark_mask_3<Polyhedron_3>* implements the geometry masks of Catmull-Clark subdivision on a *Polyhedron_3<Cartesian>*.

#include <CGAL/Subdivision_mask_3.h>

Parameters

The full template declaration of *CatmullClark_mask_3<Polyhedron_3>* states one template parameter:

template < class Polyhedron_3> class CatmullClark_mask_3;

The only parameter requires a *Polyhedron_3* as the argument. The *Polyhedron_3* should be specialized with the *Cartesian* kernel, which defines the *Point_3* for the vertices.

Creation

CatmullClark_mask_3<Polyhedron_3> CC; default constructor.

Stencil functions

void CC.facet_node(Facet_handle f, Point_3& pt)

computes the Catmull-Clark facet-point *pt* of the facet *f*.

void CC.edge_node(Edge_handle e, Point_3& pt)

computes the Catmull-Clark edge-point *pt* of the edge *e*.

void CC.vertex_node(Vertex_handle v, Point_3& pt)

computes the Catmull-Clark vertex-point *pt* of the vertex *v*.

void CC.border_node(Halfedge_handle e, Point_3& ept, Point_3& vpt)

computes the Catmull-Clark edge-point *ept* and the Catmull-Clark vertex-point *vpt* of the border edge *e*.

Class

CGAL::Loop_mask_3<Polyhedron_3>

Definition

A stencil determines a source neighborhood whose points contribute to the position of a refined point. The geometry mask of a stencil specifies the computation on the nodes of the stencil. *Loop_mask_3<Polyhedron_3>* implements the geometry masks of Loop subdivision on a triangulated *Polyhedron_3<Cartesian>*.

#include <CGAL/Subdivision_mask_3.h>

Parameters

The full template declaration of *Loop_mask_3<Polyhedron_3>* states one template parameter:

template < class Polyhedron_3> class Loop_mask_3;

The only parameter requires a *Polyhedron_3* as the argument. The *Polyhedron_3* should be specialized with the *Cartesian* kernel, which defines the *Point_3* for the vertices.

Creation

Loop_mask_3<Polyhedron_3> L; default constructor.

Stencil functions

void *L.edge_node(Edge_handle e, Point_3& pt)*

computes the Loop edge-point *pt* of the edge *e*.

void *L.vertex_node(Vertex_handle v, Point_3& pt)*

computes the Loop vertex-point *pt* of the vertex *v*.

void *L.border_node(Halfedge_handle e, Point_3& ept, Point_3& vpt)*

computes the Loop edge-point *ept* and the Loop vertex-point *vpt* of the border edge *e*.

CGAL::DooSabin_mask_3<Polyhedron_3>

Class

Definition

A stencil determines a source neighborhood whose points contribute to the position of a refined point. The geometry mask of a stencil specifies the computation on the nodes of the stencil. *DooSabin_mask_3<Polyhedron_3>* implements the geometry masks of Doo-Sabin subdivision on a *Polyhedron_3<Cartesian>*.

#include <CGAL/Subdivision_mask_3.h>

Parameters

The full template declaration of *DooSabin_mask_3<Polyhedron_3>* states one template parameter:

template < class Polyhedron_3> class DooSabin_mask_3;

The only parameter requires a *Polyhedron_3* as the argument. The *Polyhedron_3* should be specialized with the *Cartesian* kernel, which defines the *Point_3* for the vertices.

Creation

DooSabin_mask_3<Polyhedron_3> DS; default constructor.

Stencil functions

void *DS.corner_node(Halfedge_handle he, Point_3& pt)*

computes the Doo-Sabin point *pt* of the vertex pointed by the halfedge *he*.

CGAL::Sqrt3_mask_3<Polyhedron_3>

Definition

A stencil determines a source neighborhood whose points contribute to the position of a refined point. The geometry mask of a stencil specifies the computation on the nodes of the stencil. *Sqrt3_mask_3<Polyhedron_3>* implements the geometry masks of $\sqrt{3}$ subdivision on a triangulated *Polyhedron_3<Cartesian>*.

#include <CGAL/Subdivision_mask_3.h>

Parameters

The full template declaration of *Sqrt3_mask_3<Polyhedron_3>* states one template parameter:

template < class Polyhedron_3> class Sqrt3_mask_3;

The only parameter requires a *Polyhedron_3* as the argument. The *Polyhedron_3* should be specialized with the *Cartesian* kernel, which defines the *Point_3* for the vertices.

Creation

Sqrt3_mask_3<Polyhedron_3> S; default constructor.

Stencil functions

void *S.facet_node(Facet_handle f, Point_3& pt)*

computes the $\sqrt{3}$ facet-point *pt* of the facet *f*.

void *S.vertex_node(Vertex_handle v, Point& pt)*

computes the $\sqrt{3}$ vertex-point *pt* of the vertex *v*.

Chapter 53

Triangulated Surface Mesh Simplification

Fernando Cacciola

Contents

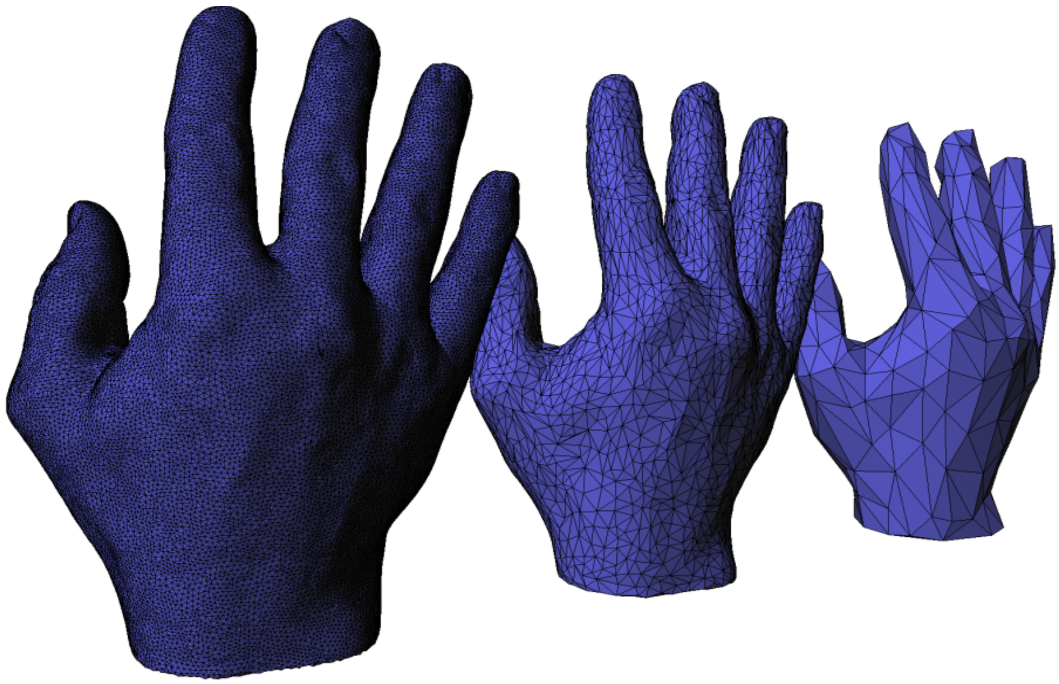
53.1 Introduction

Surface mesh simplification is the process of reducing the number of faces used in the surface while keeping the overall shape, volume and boundaries preserved as much as possible. It is the opposite of subdivision.

The algorithm presented here can simplify any *oriented 2-manifold surface*, with any number of connected components, with or without boundaries (border or holes) and handles (arbitrary genus), using a method known as *edge collapse*. Roughly speaking, the method consists of iteratively replacing an edge with a single vertex, removing 2 triangles per collapse.

Edges are collapsed according to a priority given by a user-supplied *cost* function, and the coordinates of the replacing vertex are determined by another user-supplied *placement* function. The algorithm terminates when a user-supplied *stop predicate* is met, such as reaching the desired number of edges.

The algorithm implemented here is generic in the sense that it does not require the surface to be of a particular type. Instead, it defines the concept of a *EdgeCollapsableMesh*, which presents the surface as being a halfedge data structure, and any surface that is a model of that concept can be simplified. The concept is defined not in terms of a monolithic class, but in terms of a set of functions and traits, making it easy to adapt any concrete



surface type, even if it is not a halfedge data structure at all. In particular, the concept definition follows the design of the Boost Graph Library (BGL) [SLL02].

The design is *policy-based* (http://en.wikipedia.org/wiki/Policy-based_design), meaning that you can customize some aspects of the process by passing a set of *policy objects*. Each policy object specifies a particular aspect of the algorithm, such as how edges are selected and where the replacement vertex is placed. All policies have a sensible default. Furthermore, the API uses the so-called *named-parameters* technique which allows you to pass only the relevant parameters, in any order, omitting those parameters whose default is appropriate.

53.2 Overview of the Simplification Process

The free function that implements the simplification algorithm takes not only the surface and the desired stop predicate but a number of additional parameters which control and monitor the simplification process. This section briefly describes the process in order to set the background for the discussion of the parameters to the algorithm.

There are two slightly different ”edge” collapse operations. One is known as *edge-collapse* while the other is known as *halfedge-collapse*. Given an edge ’e’ joining vertices ’w’ and ’v’, the edge-collapse operation replaces ’e’,’w’ and ’v’ for a new vertex ’r’, while the halfedge-collapse operation pulls ’v’ into ’w’, dissapearing ’e’ and leaving ’w’ in place. In both cases the operation removes the edge ’e’ along with the 2 triangles adjacent to it.

This package uses the halfedge-collapse operation, which is implemented by removing, additionally, 1 vertex (’v’) and 2 edges, one per adjacent triangle. It optionally moves the remaining vertex (’w’) into a new position, called *placement*, in which case the net effect is the same as in the edge-collapse operation.

Naturally, the surface that results from an edge collapse deviates from the initial surface by some amount, and since the goal of simplification is to reduce the number of triangles while retaining the overall look of the surface as much as possible, it is necessary to measure such a deviation. Some methods attempt to measure the total deviation from the initial surface to the completely simplified surface, for example, by tracking an accumulated error while keeping a history of the simplification changes. Other methods, like the one implemented in this package, attempt to measure only the *cost* of each individual edge collapse (the local deviation introduced by a single simplification step) and plan the entire process as a sequence of steps of increasing cost.

Global error tracking methods produce highly accurate simplifications but take up a lot of additional space. Cost-driven methods, like the one in this package, produce slightly less accurate simplifications but take up much less additional space, even none in some cases.

The cost-driven method implemented in this package is mainly based on [LT98, LT99], with contributions from [HDD^{+}93], [GH97] and [DEGN99].

The algorithm proceeds in two stages. In the first stage, called *collection stage*, an initial *collapse cost* is assigned to each and every edge in the surface. Then in the second stage, called *collapsing stage*, edges are processed in order of increasing cost. Some processed edges are collapsed while some are just discarded. Collapsed edges are replaced by a vertex and the collapse cost of all the edges now incident on the replacement vertex is recalculated, affecting the order of the remaining unprocessed edges.

Not all edges selected for processing are collapsed. A processed edge can be discarded right away, without being collapsed, if it doesn't satisfy certain topological and geometric conditions.

The algorithm presented in [GH97] contracts (collapses) arbitrary vertex pairs and not only edges by considering certain vertex pairs as forming a pseudo-edge and proceeding to collapse both edges and pseudo-edges in the same way as in [LT98, LT99] (which is the algorithm implemented here). However, contracting an arbitrary vertex-pair may result in a non-manifold surface, but the current state of this package can only deal with manifold surfaces, thus, it can only collapse edges. That is, this package cannot be used as a framework for vertex contraction.

53.3 Cost Strategy

The specific way in which the collapse cost and vertex placement is calculated is called the *cost strategy*. The user can choose different strategies in the form of policies and related parameters, passed to the algorithm.

The current version of the package provides a set of policies implementing two strategies: the Lindstrom-Turk strategy, which is the default, and a strategy consisting of an edge-length cost with an optional midpoint placement (much faster but less accurate).

53.3.1 Lindstrom-Turk Cost and Placement Strategy

The main characteristic of the strategy presented in [LT98, LT99] is that the simplified surface is not compared at each step with the original surface (or the surface at a previous step) so there is no need to keep extra information, such as the original surface or a history of the local changes. Hence the name *memoryless* simplification.

At each step, all remaining edges are potential candidates for collapsing and the one with the lowest cost is selected.

The cost of collapsing an edge is given by the position chosen for the vertex that replaces it.

The replacement vertex position is computed as the solution to a system of 3 linearly-independent linear equality constraints. Each constraint is obtained by minimizing a quadratic objective function subject to the previously computed constraints.

There are several possible candidate constraints and each is considered in order of importance. A candidate constraint might be *incompatible* with the previously accepted constraints, in which case it is rejected and the next constraint is considered.
Once 3 constraints have been accepted, the system is solved for the vertex position.

The first constraints considered preserves the shape of the surface boundaries (in case the edge profile has boundary edges). The next constraints preserve the total volume of the surface. The next constraints, if needed, optimize the local changes in volume and boundary shape. Lastly, if a constraint is still needed (because the ones previously computed were incompatible), a third (and last) constraint is added to favor equilateral triangles over elongated triangles.

The cost is then a weighted sum of the shape, volume and boundary optimization terms, where the user specifies the unit *weighting unit factor* for each term.

The local changes are computed independently for each edge using only the triangles currently adjacent to it at the time when the edge is about to be collapsed, that is, after all previous collapses. Thus, the transitive path of minimal local changes yields at the end a global change reasonably close to the absolute minimum.

53.3.2 Cost Strategy Policies

The cost strategy used by the algorithm is selected by means of two policies: *GetPlacement* and *GetCost*.

The *GetPlacement* policy is called to compute the new position for the remaining vertex after the halfedge-collapse. It returns an optional value, which can be absent, in which case the remaining vertex is kept in its place.

The *GetCost* policy is called to compute the cost of collapsing an edge. This policy uses the placement to compute the cost (which is an error measure) and determines the ordering of the edges.

The algorithm maintains an internal data structure (a mutable priority queue) which allows each edge to be processed in increasing cost order. Such a data structure requires some per-edge additional information, such as the edge's cost. If the record of per-edge additional information occupies N bytes of storage, simplifying a surface of 1 million edges (a normal size) requires 1 million times N bytes of additional storage. Thus, to minimize the amount of additional memory required to simplify a surface only the cost is attached to each edge and nothing else.

But this is a tradeoff: the cost of a collapse is a function of the placement (the new position chosen for the remaining vertex) so before *GetCost* is called for each and every edge, *GetPlacement* must also be called to obtain the placement parameter to the cost function. But that placement, which is a 3D Point, is not attached to each and every edge since that would easily *triple* the additional storage requirement.

On the one hand, this dramatically saves on memory but on the other hand is a processing waste because when an edge is effectively collapsed, *GetPlacement* must be called *again* to know were to move the remaining vertex.

Earlier prototypes shown that attaching the placement to the edge, thus avoiding one redundant call to the placement function after the edge collapsed, has little impact on the total running time. This is because the cost of an each edge is not just computed once but changes several times during the process so the placement function must be called several times just as well. Caching the placement can only avoid the very last call, when the edge is collapsed, but not all the previous calls which are needed because the placement (and cost) changes.

53.4 API

53.4.1 API Overview

Since the algorithm is free from robustness issues there is no need for exact predicates nor constructions and *Simple_cartesian*<*double*> can be used safely. [1]

The simplification algorithm is implemented as the free template function *CGAL::Surface_mesh_simplification::edge_collapse*. The function has two mandatory and several optional parameters.

Mandatory Parameters

There are two main parameters to the algorithm: the surface to be simplified (in-place) and the stop predicate.

The surface to simplify must be a model of the *EdgeCollapsableMesh* concept. Many concrete surface types, such as *CGAL::Polyhedron_3* with only triangular faces, become models of that concept via a technique known as *external adaptation*, which is described in [SLL02] and this BGL web page: `http://www.boost.org/libs/graph/doc/leda_conversion.html`

External adaptation is a way to add an interface to an object without coercing the type of the object (which happens when you adapt it by means of a wrapper). That is, the formal parameter to the *edge_collapse* function that implements the simplification is the concrete surface object itself, not an adaptor which delegates the functionality to the concrete type.

The stop predicate is called after each edge is selected for processing, *before* it is classified as collapsible or not (thus before it is collapsed). If the stop predicate returns *true* the algorithm terminates.

Optional Named Parameters

The notion of *named parameters* was also introduced in the BGL. You can read about it in [SLL02] or the following site: `http://www.boost.org/libs/graph/doc/bgl_named_params.html`. Named parameters allow the user to specify only those parameters which are really needed, by name, making the parameter ordering unimportant.

Say there is a function *f()* that takes 3 parameters called *name*, *age* and *gender*, and you have variables *n,a and g* to pass as parameters to that function. Without named parameters, you would call it like this: *f(n,a,g)*, but with named parameters, you call it like this: *f(name(n).age(a).gender(g))*.

That is, you give each parameter a name by wrapping it into a function whose name matches that of the parameter. The entire list of named parameters is really a composition of function calls separated by a dot (.). Thus, if the function takes a mix of mandatory and named parameters, you use a comma to separate the last non-named parameter from the first named parameters, like this:

f(non_named_par0, non_named_pa1, name(n).age(a).gender(g))

When you use named parameters, the ordering is irrelevant, so this: *f(name(n).age(a).gender(g))* is equivalent to this: *f(age(a).gender(g).name(n))*, and you can just omit any named parameter that has a default value.

[1] In the current version, 3.3, the LindstromTurk policies are not implemented for homogeneous coordinates, so a cartesian kernel must be used.

int r = edge_collapse(surface
                     ,stop_predicate
                     ,vertex_index_map(vimap)
                       .edge_index_map(eimap)
                       .edge_is_border_map(ebmap)
                       .get_cost(cf)
                       .get_placement(pf)
                       .visitor(vis)
                     );
```

53.4.2 Examples

Example Using a Default Polyhedron

The following example illustrates the simplest of the cases. It uses an ordinary polyhedron and only one of the optional parameters. The unspecified cost strategy defaults to Lindstrom-Turk.

```
#include <iostream>
#include <fstream>

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>

// Adaptor for Polyhedron_3
#include <CGAL/Surface_mesh_simplification/HalfedgeGraph_Polyhedron_3.h>

// Simplification function
#include <CGAL/Surface_mesh_simplification/edge_collapse.h>

// Stop-condition policy
#include
    <CGAL/Surface_mesh_simplification/Policies/Edge_collapse/Count_stop_predicate.h>
```

```
typedef CGAL::Simple_cartesian<double> Kernel;
typedef CGAL::Polyhedron_3<Kernel> Surface;

namespace SMS = CGAL::Surface_mesh_simplification ;

int main( int argc, char** argv )
{
  Surface surface;

  std::ifstream is(argv[1]) ; is >> surface ;

  // This is a stop predicate (defines when the algorithm terminates).
  // In this example, the simplification stops when the number of
   undirected edges
  // left in the surface drops below the specified number (1000)
  SMS::Count_stop_predicate<Surface> stop(1000);

  // This the actual call to the simplification algorithm.
  // The surface and stop conditions are mandatory arguments.
  // The index maps are needed because the vertices and edges
  // of this surface lack an "id()" field.
  int r = SMS::edge_collapse
            (surface
            ,stop

   ,CGAL::vertex_index_map(boost::get(CGAL::vertex_external_index,surface))
                  .edge_index_map  (boost::get(CGAL::edge_external_index
    ,surface))
            );

  std::cout << "\nFinished...\n" << r << " edges removed.\n"
            << (surface.size_of_halfedges()/2) << " final edges.\n" ;

  std::ofstream os( argc > 2 ? argv[2] : "out.off" ) ; os << surface ;

  return 0 ;
}

// EOF //
```

File: examples/Surface_mesh_simplification/edge_collapse_polyhedron.cpp

Example Using an Enriched Polyhedron

The following example is equivalent to the previous example but using an enriched polyhedron whose halfedges support an *id* field to store the edge index needed by the algorithm. It also shows how to explicitly specify a cost strategy (other than the default) and how to use a visitor object to track the simplification process.

```
#include <iostream>
#include <fstream>
```

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>

// Adaptor for Polyhedron_3
#include <CGAL/Surface_mesh_simplification/HalfedgeGraph_Polyhedron_3.h>

// Simplification function
#include <CGAL/Surface_mesh_simplification/edge_collapse.h>

// Visitor base
#include <CGAL/Surface_mesh_simplification/Edge_collapse_visitor_base.h>

// Extended polyhedron items which include an id() field
#include <CGAL/Polyhedron_items_with_id_3.h>

// Stop-condition policy
#include
   <CGAL/Surface_mesh_simplification/Policies/Edge_collapse/Count_ratio_stop_predicate.h>

// Non-default cost and placement policies
#include
   <CGAL/Surface_mesh_simplification/Policies/Edge_collapse/Midpoint_and_length.h>

typedef CGAL::Simple_cartesian<double> Kernel;

typedef Kernel::Point_3 Point ;

//
// Setup an enriched polyhedron type which stores an id() field in the
   items
//
typedef CGAL::Polyhedron_3<Kernel,CGAL::Polyhedron_items_with_id_3>
   Surface;

typedef Surface::Halfedge_handle Halfedge_handle ;
typedef Surface::Vertex_handle   Vertex_handle ;

namespace SMS = CGAL::Surface_mesh_simplification ;

typedef SMS::Edge_profile<Surface> Profile ;

// The following is a Visitor that keeps track of the simplification
   process.
// In this example the progress is printed real-time and a few statistics
    are
// recorded (and printed in the end).
//
struct Stats
{
  Stats()
    : collected(0)
    , processed(0)
```

```
    , collapsed(0)
    , non_collapsable(0)

Triangulated Surface Mesh Simplification

Reference Manual

This chapter introduces the concepts and classes of the triangulated surface mesh simplification package. The packages provides a policy-based algorithm for the simplification of triangulated surface meshes by iterative edge-collapsing.

EdgeCollapsableMesh

Concept

Definition

The concept EdgeCollapsableMesh describes the requirements for the type of triangulated surface mesh that can be passed to the simplification algorithm.

The surface must be structurally equivalent to a polyhedral surface having only triangular faces. It can have any number of connected components, boundaries (borders and holes) and handles (arbitrary genus).

Refines

HalfedgeGraph

Valid Expressions

The mesh simplification algorithm requires the free function *collapse_triangulation_edge*.

template<class EdgeCollapsableMesh>
typename boost::graph_traits<EdgeCollapsableMesh>::vertex_descriptor

halfedge_collapse(typename boost::graph_traits<EdgeCollapsableMesh>::edge_descriptor const& ue, EdgeCollapsableMesh& mesh)

Collapses the undirected edge *(v0v1,v1v0)* replacing it with *v0* or *v1*, as described in the following paragraph.
Precondition: This function requires *mesh* to be an oriented 2-manifold with or without boundaries. Furthermore, the undirected edge *(v0v1,v1v0)* must satisfy the *link condition* [DEGN99], which guarantees that the surface is also 2-manifold after the edge collapse.

Let *v0* be the source and *v1* be the target vertices of *v0v1*.

For $e \in \{$ *v0v1,v1v0* $\}$, let *en* and *ep* be the next and previous edges, that is *en* = *next_edge(e, mesh)*, *ep* = *prev_edge(e,mesh)*, and let *eno* and *epo* be their opposite edges, that is *eno* = *opposite_edge(en, mesh)* and *epo* = *opposite_edge(ep,mesh)*.

Then, after the collapse of *(v0v1,v1v0)* the following holds:

- The edge *e* is no longer in *mesh*.
- One of $\{$*v0,v1*$\}$ is no longer in *mesh* while the other remains. [2] Let *vgone* be the removed vertex and *vkept* be the remaining vertex.
- If *e* was a border edge, that is *get(is_border, e, mesh) == true*, then *next_edge(ep) == en*, and *prev_edge(en) == ep*.
- If *e* was not a border edge, that is *get(is_border, e, mesh) == false*, then *ep* and *epo* are no longer in *mesh* while *en* and *eno* are kept in *mesh*.

[2] Even though it would appear that v0 can always be the vertex being removed, there is a case when removing the edge *e requires v1* to be removed as well. See figure 53.5.

- For all edges *ie* in *in_edges(vgone,mesh)*, *target(ie,mesh) == vkept* and *source(opposite_edge(ie),mesh) == vkept*.
- No other incidence information has changed in *mesh*.

The function returns vertex *vkept* (which can be either *v0* or *v1*).

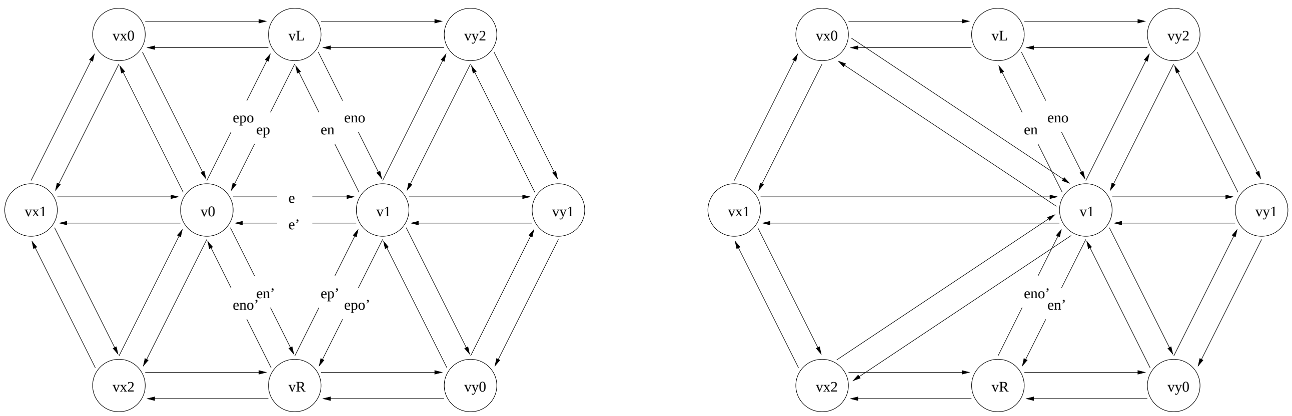

Figure 53.1: General case. The following mesh elements are removed: triangles $(v0, v1, vL)$ and $(v1, v0, vR)$, edges (e, e'), (ep, epo) and (ep', epo'), and vertex $v0$.

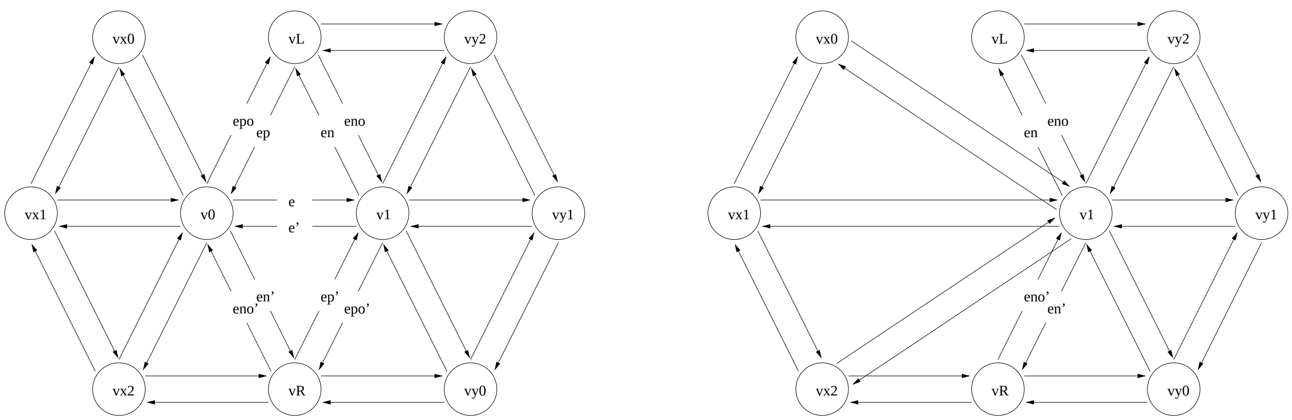

Figure 53.2: When the collapsing edge is not itself a border, but is incident upon a border edge that is removed, the operation is the same as in the general case.

Has Models

CGAL::Polyhedron_3<Traits> . . . . page 1795
(If it has only triangular faces, and via *External Adaptation*, which is described in [SLL02] and this BGL web page: `http://www.boost.org/libs/graph/doc/leda_conversion.html`).

See Also

boost::graph_traits< CGAL::Polyhedron_3<Traits> > . . . . page 4282
CGAL::halfedge_graph_traits< CGAL::Polyhedron_3<Traits> > . . . . page 4286

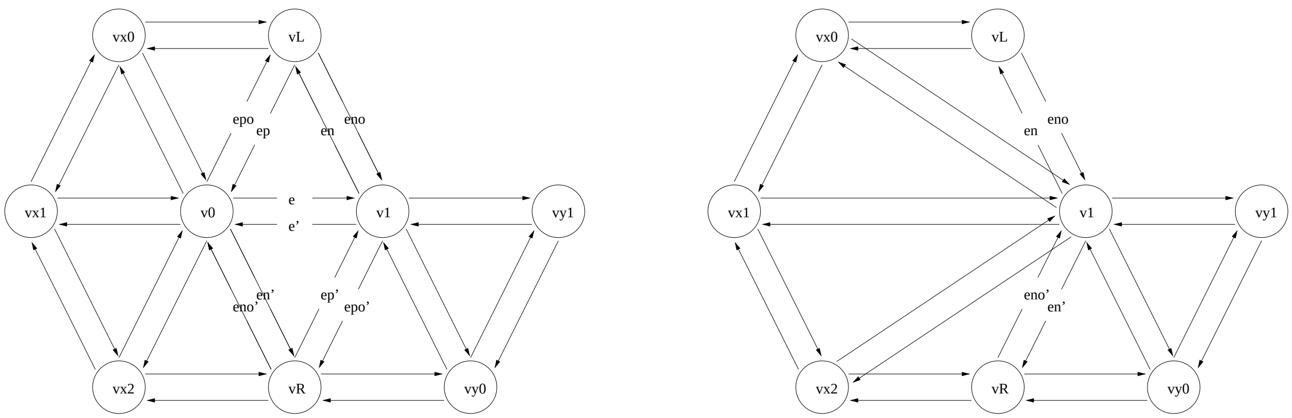

Figure 53.3: When the collapsing edge is not itself a border, but is incident upon a border edge that is *not* removed, the operation is still the same as in the general case.

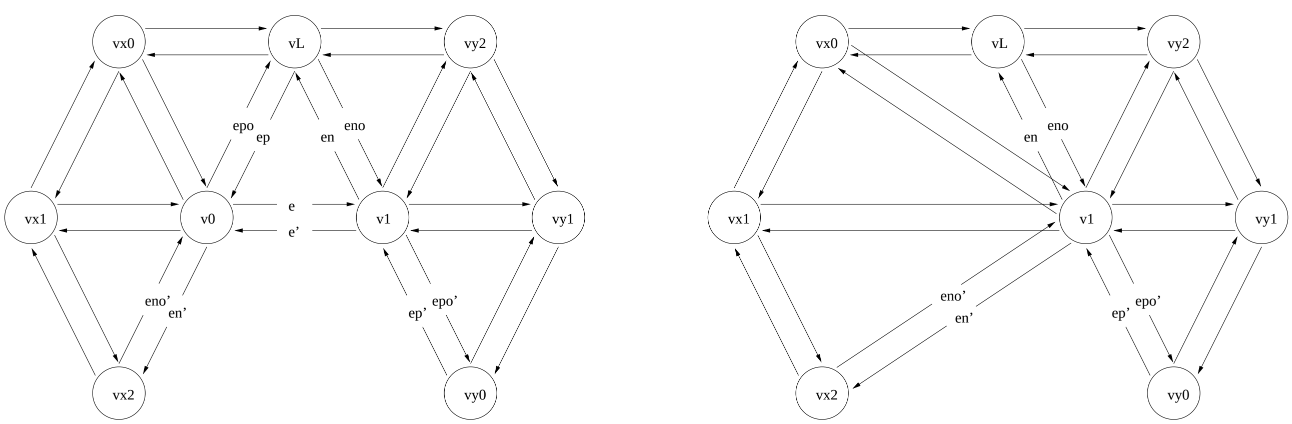

Figure 53.4: When the collapsing edge is itself a border, only 1 triangle is removed. Thus, even if (ep', epo') exists, it's not removed.

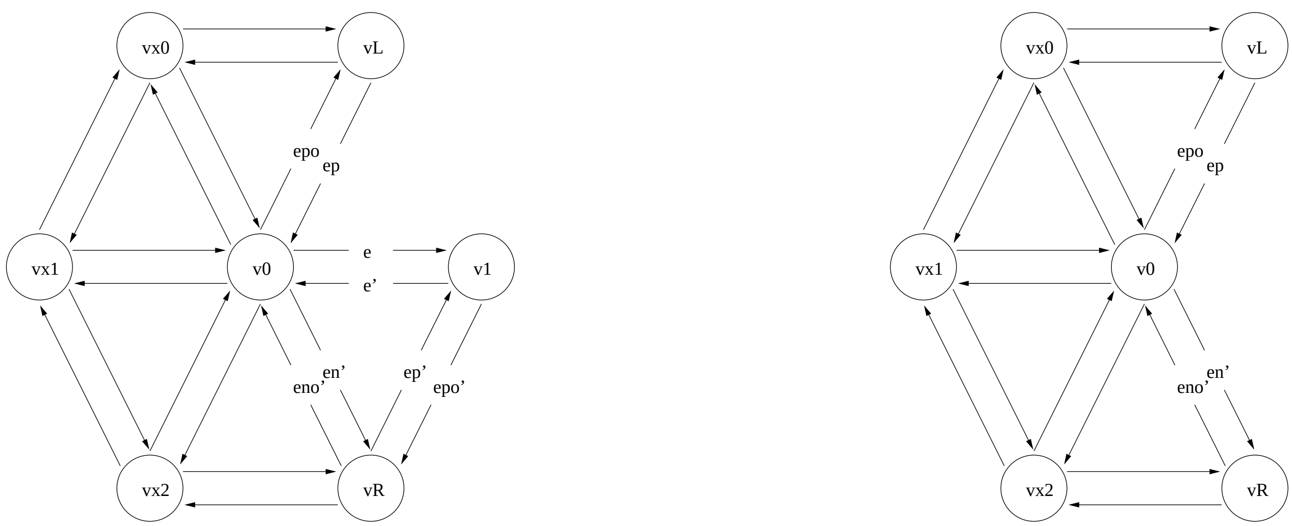

Figure 53.5: This figure illustrates the single exceptional case when removing $(v0, v1)$ neccesarily implies removing $(v1)$, thus $(v0)$ remains.

EdgeProfile

Concept

Definition

The concept EdgeProfile describes the requirements for a data structure that caches the local topology and geometry in the surroundings of an undirected edge.

This profile is used by the stop, cost and placement policies.

Types

EdgeProfile:: ECM		The type of the surface to simplify. Must be a model of the *EdgeCollapsableMesh* concept.
typename boost::graph_traits<ECM>::vertex_descriptor		
	vertex_descriptor;	A BGL vertex descriptor representing a vertex of the surface.
typename boost::graph_traits<ECM>::edge_descriptor		
	edge_descriptor;	A BGL edge descriptor representing an edge of the surface.
typename CGAL::halfedge_graph_traits<ECM>::Point		
	Point;	The point type for the surface vertex. Must be a model of *Point_3*.

Access Functions

vertex_descriptor	*ep.v0() const*	One of vertices of the edge to be collapsed.
vertex_descriptor	*ep.v1() const*	The other vertex of the edge to be collapsed.
edge_descriptor	*ep.v0_v1() const*	One of the directed edges corresponding to the undirected edge being collapsed.
edge_descriptor	*ep.v1_v0() const*	The other directed edge corresponding to the undirected edge being collapsed.
Point	*ep.p0() const*	The point of vertex $v0$.
Point	*ep.p1() const*	The point of vertex $v1$.
vertex_descriptor	*ep.vL() const*	If $v0v1$ belongs to a finite face (is not a border edge) the third vertex of that triangular face, a *null descriptor* otherwise.
edge_descriptor	*ep.v_1vL() const*	If $v0v1$ belongs to a finite face (is not a border edge) the directed edge from $v1$ to vL, a *null descriptor* otherwise.
edge_descriptor	*ep.vL_v0() const*	If $v0v1$ belongs to a finite face (is not a border edge) the directed edge from vL to $v0$, a *null descriptor* otherwise.
vertex_descriptor	*ep.vR() const*	If $v1v0$ belongs to a finite face (is not a border edge) the third vertex of that triangular face, a *null descriptor* otherwise.
edge_descriptor	*ep.v0_vR() const*	If $v1v0$ belongs to a finite face (is not a border edge) the directed edge from $v0$ to vR, a *null descriptor* otherwise.
edge_descriptor	*ep.vR_v1() const*	If $v1v0$ belongs to a finite face (is not a border edge) the directed edge from vR to $v1$, a *null descriptor* otherwise.

std::vector<vertex_descriptor>

	ep.link() const	The unique sequence of the vertices around $v0v1$ in topological order (*ccw* or *ccw* depending on the relative ordering of *v0* and *v1* in the profile).

std::vector<edge_descriptor>

	ep.border_edges() const	
		The unique collection of the border directed edges incident upon $v0$ and $v1$.
bool	*ep.left_face_exits() const*	
		Indicates if *v0v1* belongs to a finite face of the mesh (i.e, *v0v1* is not a border edge).
bool	*ep.right_face_exits() const*	
		Indicates if *v0v1* belongs to a finite face of the mesh (i.e, *v1v0* is not a border edge).

Has Models

CGAL::Surface_mesh_simplification::Edge_profile<ECM> . . . . page 3304

StopPredicate

Definition

The concept StopPredicate describes the requirements for the predicate which indicates if the simplification process must finish.

Types

StopPredicate:: ECM	The type of the surface to simplify. Must be a model of the *EdgeCollapsableMesh* concept.
StopPredicate:: FT	A field type representing the collapse cost
StopPredicate:: size_type	An integer type representing the number of edges
StopPredicate:: Profile	The type of the edge profile cache. Must be a model of the *EdgeProfile* concept.

Operations

bool *sp.operator()(FT const& current_cost,*
Profile const& profile,
size_type initial_count,
size_type current_count) const

This predicate is called each time an edge is selected for processing, before it is collapsed.
current_cost is the cost of the selected edge.
initial_count and *current_count* are the number of initial and current edges.

If the return value is *true* the simplification terminates before processing the edge, otherwise it continues normally.

Has Models

CGAL::Surface_mesh_simplification::Count_stop_predicate<ECM> . . . . page 3305
CGAL::Surface_mesh_simplification::Count_ratio_stop_predicate<ECM> . . . . page 3306

Functor
Concept

GetCost

Definition

The concept GetCost describes the requirements for the *policy function object* which gets the *collapse cost* of an edge.

The cost returned is a *boost::optional* value (i.e. it can be absent). An *absent* cost indicates that the edge should not be collapsed. This could be the result of a computational limitation (such as overflow), or can be intentionally returned to prevent the edge from being collapsed.

Refines

DefaultConstructible
CopyConstructible

Types

GetCost:: Profile		The type of the edge profile cache. Must be a model of the *EdgeProfile* concept.
GetCost:: FT		A field type representing the collapse cost
typename CGAL::halfedge_graph_traits<ECM>::Point		
	Point;	The point type for the surface vertex. Must be a model of *Point_3*.
boost::optional<FT>	*result_type;*	The type of the result (an optional cost value).

Operations

result_type *gc.operator()(Profile const& edge_profile, boost::optional<Point> const& placement) const*

Computes and returns the cost of collapsing the edge (represented by its profile), using the calculated placement.

Has Models

CGAL::Surface_mesh_simplification::Edge_length_cost<ECM> . . . . page 3307
CGAL::Surface_mesh_simplification::LindstromTurk_cost<ECM> . . . . page 3309

GetPlacement

Functor
Concept

Definition

The concept GetPlacement describes the requirements for the *policy function object* which gets the *collapse placement* of an edge, that is, the new position of the vertex that remains after a halfedge-collapse operation.

The placement returned is a *boost::optional* value (i.e., it can be absent). An absent result indicates that the remaining vertex must be kept in place, not moved to a new position.

Refines

DefaultConstructible
CopyConstructible

Types

GetPlacement:: Profile		The type of the edge profile cache. Must be a model of the *EdgeProfile* concept.
typename CGAL::halfedge_graph_traits<ECM>::Point		
	Point;	The point type for the surface vertex. Must be a model of *Point_3*.
boost::optional<Point>		
	result_type;	The type of the result (an optional point).

Operations

result_type *gp.operator()(Profile const& edge_profile) const*

Computes and returns the placement, that is, the position of the vertex which replaces the collapsing edge (represented by its profile).

Has Models

CGAL::Surface_mesh_simplification::Midpoint_placement<ECM> . . . . page 3308
CGAL::Surface_mesh_simplification::LindstromTurk_placement<ECM> . . . . page 3310

Concept

EdgeCollapseSimplificationVisitor

Definition

The concept EdgeCollapseSimplificationVisitor describes the requirements for the *visitor object* which is used to track the edge collapse simplification algorithm.

The several callbacks given as member functions in the visitor are called from certain places in the algorithm implementation.

Types

EdgeCollapseSimplificationVisitor:: ECM	The type of the surface to simplify. Must be a model of the *EdgeCollapsableMesh* concept.
EdgeCollapseSimplificationVisitor:: FT	A field type representing the collapse cost
EdgeCollapseSimplificationVisitor:: Profile	The type of the edge profile cache. Must be a model of the *EdgeProfile* concept.
typename CGAL::halfedge_graph_traits<ECM>::Point	
Point;	The point type for the surface vertex. Must be a model of *Point_3*.
EdgeCollapseSimplificationVisitor:: size_type	An integer type representing the number of edges

Operations

void *v.OnStarted(ECM& surface)*

Called before the algorithm starts.

void *v.OnFinished(ECM& surface)*

Called after the algorithm finishes.

void *v.OnStopConditionReached(ECM& surface)*

Called when the *StopPredicate* returned *true* (but not if the algorithm terminates because the surface could not be simplified any further).

void *v.OnCollected(Profile profile, boost::optional<FT> cost)*

Called during the *collecting phase* (when a cost is assigned to the edges), for each edge collected.

void *v.OnSelected(Profile profile,*
boost::optional<FT> cost,
size_type initial_count,
size_type current_count)

Called during the *processing phase* (when edges are collapsed), for each edge that is selected.
This method is called before the algorithm checks if the edge is collapsable.
cost indicates the current collapse cost for the edge. If absent (meaning that it could not be computed) the edge will not be collapsed.
initial_count and *current_count* refer to the number of edges.

void *v.OnCollapsing(Profile profile, boost::optional<Point> placement)*

Called when an edge is about to be collapsed and replaced by a vertex whose position is **placement*.
If *placement* is absent (meaning that it could not be computed) the edge will not be collapsed.

void *v.OnNonCollapsable(Profile profile)*

Called for each selected edge which cannot be collapsed because doing so would change the topological type of the surface (turn it into a non-manifold for instance).

Function

CGAL::Surface_mesh_simplification::edge_collapse

Definition

The function *Surface_mesh_simplification::edge_collapse* simplifies in-place a triangulated surface mesh by iteratively collapsing edges.

#include <CGAL/Surface_mesh_simplification/edge_collapse.h>

template<class EdgeCollapsableMesh,class StopPredicate, class P, class T, class R>
int *edge_collapse(EdgeCollapsableMesh& surface,*
StopPredicate should_stop,
sms_named_params<P,T,R> named_parameters)

Simplifies *surface* in-place by collapsing edges, and returns the number of edges effectively removed.

Non-named parameters

surface is the surface to simplify. It must be a model of the *EdgeCollapsableMesh* concept.

should_stop is the stop-condition policy. It must be a model of the *StopPredicate* concept.

Named parameters

named_parameters holds the list of all the additional parameters used by the *edge_collapse* function (including default parameters).

The named parameters list is a composition of function calls separated by a dot (.) where the name of each function matches the name of an argument and wraps the actual parameter.

This is an example with 2 arguments:

vertex_index_map(the_actual_vertex_index_map).edge_index_map(the_actual_edge_index_map)

the_actual_vertex_index_map and *the_actual_edge_index_map* are the actual parameters, while *vertex_index_map()* and *edge_index_map()* are wrapper functions used to designate each formal argument.

All named parameters have default values so you only need to compose those for which the default is inappropriate. Furthermore, since each actual parameter is wrapped in a function whose name designates the formal argument, the order of named parameters in the list is totally irrelevant.

In the following subsections, each named parameter is documented as a helper function. The argument to each helper function is the actual parameter to *edge_collapse()*, while the name of the helper function designates which formal argument it is.

vertex_index_map(VertexIndexMap vpm)

Maps each vertex in the surface into an unsigned integer number in the range *[0,num_vertices(surface))*.

VertexIndexMap must be a ReadablePropertyMap whose *key_type* is *boost::graph_traits<EdgeCollapsableMesh const>::vertex_descriptor* and whose *value_type* is *boost::graph_traits<EdgeCollapsableMesh>::size_type*,

Default: the property map obtained by calling *get(vertex_index,surface)*, which requires the surface vertices to have an *id()* member properly initialized to the required value.
If the vertices don't have such an *id()*, you must pass some property map explicitly. An external property map can be easily obtained by calling *get(vertex_external_index,surface)*. This constructs on the fly, and returns, a property map which non-intrusively associates a proper id with each vertex.

edge_index_map(EdgeIndexMap eim)

Maps each *directed* edge in the surface into an unsigned integer number in the range *[0,num_edges(surface))*.

EdgeIndexMap must be a ReadablePropertyMap whose *key_type* is *boost::graph_traits<EdgeCollapsableMesh const>::edge_descriptor* and whose *value_type* is *boost::graph_traits<EdgeCollapsableMesh>::size_type*

Default: the property map obtained by calling *get(edge_index,surface)*, which requires the surface edges to have an *id()* member properly initialized to the require value.
If the edges don't have such an *id()*, you must pass some property map explicitly. An external property map can be easily obtained by calling *get(edge_external_index,surface)*. This constructs on the fly, and returns, a property map which non-intrusively associates a proper id with each edge.

edge_is_border_map(EdgeIsBorderMap ebm)

Maps each *directed* edge in the surface into a Boolean value which indicates if the edge belongs to the boundary of the surface (facing the outside). *EdgeIsBorderMap* must be a ReadablePropertyMap whose *key_type* is *boost::graph_traits<EdgeCollapsableMesh const>::edge_descriptor* and whose *value_type* is *bool*.

Default: the property map obtained by calling *get(edge_is_border,surface)*.

get_cost(GetCost gc)

The policy which returns the collapse cost for an edge.
The type of *gc* must be a model of the *GetCost* concept.

Default: *CGAL::Surface_mesh_simplification::LindstromTurk_cost<EdgeCollapsableMesh>*.

get_placement(GetPlacement gp)

The policy which returns the placement (position of the replacemet vertex) for an edge.
The type of *gp* must be a model of the *GetPlacement* concept.

Default: *CGAL::Surface_mesh_simplification::LindstromTurk_placement<EdgeCollapsableMesh>*

visitor(EdgeCollapseSimplificationVisitor v)

The visitor that is called by the *edge_collapse* function in certain points to allow the user to track the simplification process.
The type of *v* must be a model of the *EdgeCollapseSimplificationVisitor* concept.

Default: an implementation-defined dummy visitor.

If you wish to provide your own visitor, you can derive from: *CGAL::Surface_mesh_simplification::Edge_collapse_visitor_base*<*EdgeCollapsableMesh*> and override only the callbacks you are interested in.

All these functions naming parameters are defined in *namespace CGAL*. Being non-member functions, they could clash with equally named functions in some other namespace. If that happens, simply qualify the *first* [3] named parameter with *CGAL::*, as shown in the examples in the user manual.

Semantics

The simplification process continues until the *should_stop* policy returns *true* or the surface cannot be simplified any further due to topological constraints.

get_cost and *get_placement* are the policies which control the *cost-strategy*, that is, the order in which edges are collapsed and the remaining vertex is re-positioned.

visitor is used to keep track of the simplification process. It has several member functions which are called at certain points in the simplification code.

[3] The second and subsequent named parameters shall not be qualified as they are member functions

CGAL::Surface_mesh_simplification::Edge_collapse_visitor_base< ECM>

Class

Definition

The class *Surface_mesh_simplification::Edge_collapse_visitor_base<ECM>* provides a base class for models of the *EdgeCollapseSimplificationVisitor* concept. It has one template argument: the type of surface being simplified, which must be a model of the *EdgeCollapsableMesh* concept.

This base class implements all of the visitor's callbacks. This way, users need only override the callbacks they are interested in. The callbacks *are not virtual* because this is not a dynamically polymorphic base class and the derived visitor will never be used polymorphically at runtime (is perfectly fine to override and hide a non-virtual method in the context of the static polymorphism used in the simplification algorithm).

Chapter 54

Planar Parameterization of Triangulated Surface Meshes

Laurent Saboret, Pierre Alliez and Bruno Lévy

Contents

54.1 Introduction

Parameterizing a surface amounts to finding a one-to-one mapping from a suitable domain to the surface. A good mapping is the one which minimizes either angle distortions (conformal parameterization) or area distortions (equiareal parameterization) in some sense. In this package, we focus on parameterizing triangulated surfaces which are homeomorphic to a disk, and on piecewise linear mappings onto a planar domain.

Although the main motivation behind the first parameterization methods was the application to texture mapping, it is now frequently used for mapping more sophisticated modulation signals (such as normal, transparency, reflection or light modulation maps), fitting scattered data, re-parameterizing spline surfaces, repairing CAD models, approximating surfaces and remeshing.

This CGAL package implements some of the state-of-the-art surface parameterization methods, such as least squares conformal maps, discrete conformal map, discrete authalic parameterization, Floater mean value coordinates or Tutte barycentric mapping. These methods mainly distinguish by the distortion they minimize (angles vs. areas), by the constrained border onto the planar domain (convex polygon vs. free border) and by the guarantees provided in terms of bijective mapping.

The package proposes currently an interface with *CGAL::Polyhedron_3<Traits>* data structure.

Since parameterizing meshes require efficient representation of sparse matrices and efficient iterative or direct linear solvers, we provide a unified interface to a linear solver library (EIGEN), and propose a separate package devoted to OpenNL sparse linear solver.

Note that linear solvers commonly use double precision floating point numbers. Therefore, this package is intended to be used with a CGAL Cartesian kernel with doubles.

The intended audience of this package is researchers, developers or students developing algorithms around parameterization of triangle meshes for geometry processing as well as for signal mapping on triangulated surfaces.

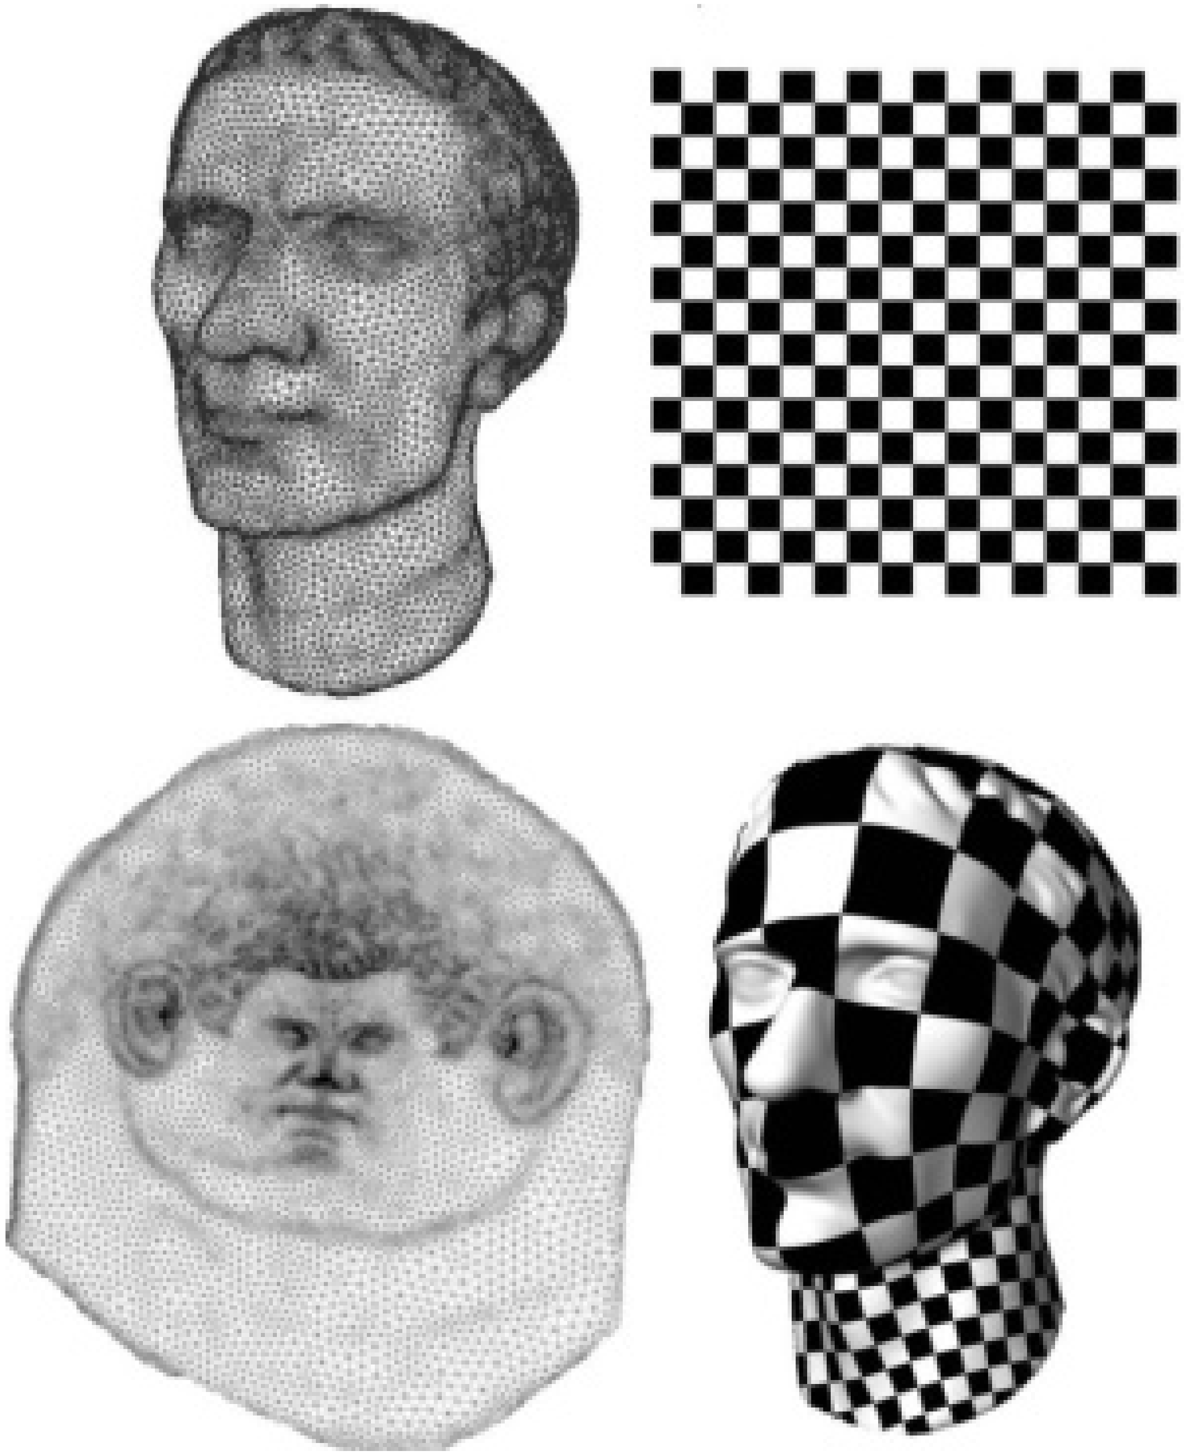

Figure 54.1: Texture mapping via Least Squares Conformal Maps parameterization. Top: original mesh and texture. Bottom: parameterized mesh (left: parameter space, right: textured mesh).

54.2 Basics

54.2.1 Default Surface Parameterization

From the user point of view, the simplest entry point to this package is the following function:

Parameterizer_traits_3<ParameterizationMesh_3>::Error_code

parameterize(ParameterizationMesh_3 & mesh)

Compute a one-to-one mapping from a 3D triangle surface mesh to a 2D circle, using Floater Mean Value Coordinates algorithm. A one-to-one piecewise linear mapping is guaranteed. The result is a pair of (u,v) parameter coordinates for each vertex of the input mesh.
Preconditions: mesh must be a triangle mesh surface with one connected component.

The function *CGAL::parameterize()* applies a default surface parameterization method: Floater Mean Value Coordinates [Flo03a], with an arc-length circular border parameterization, and using OpenNL sparse linear solver [Lev05]. The *ParameterizationMesh_3* concept defines the input meshes handled by *CGAL::parameterize()*. See Section 54.2.2. The result is stored into the (u,v) fields of the mesh halfedges.

Note: *CGAL::Parameterizer_traits_3<ParameterizationMesh_3>* is the (pure virtual) superclass of all surface parameterizations and defines the error codes.

54.2.2 Input Mesh for parameterize()

The input meshes handled *directly* by *CGAL::parameterize()* must be models of *ParameterizationMesh_3*, triangulated, 2-manifold, oriented, and homeomorphic to discs (possibly with holes).

Note: *ParameterizationMesh_3* is a general concept to access a polyhedral mesh. It is optimized for the *Surface_mesh_parameterization* package only in the sense that it defines the accessors to fields specific to the parameterization domain (*index*, *u*, *v*, *is_parameterized*). The extra constraints needed by the surface parameterization methods (triangulated, 2-manifold, homeomorphic to a disc) are not part of the concept and are checked at runtime.

This package provides a model of the *ParameterizationMesh_3* concept to access *CGAL::Polyhedron_3<Traits>* :
CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron_3_>

We will see later that *CGAL::parameterize()* can support *indirectly* meshes that are not topological disks.

54.2.3 Default Parameterization Example

Simple_parameterization.cpp applies the default parameterization to a *CGAL::Polyhedron_3<Traits>* mesh (must be a topological disk). Eventually, it extracts the result from halfedges and prints it.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
```

```
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/Parameterization_polyhedron_adaptor_3.h>
#include <CGAL/parameterize.h>

#include <iostream>
#include <fstream>

//
    ----------------------------------------------------------------------------
// Private types
//
    ----------------------------------------------------------------------------

typedef CGAL::Cartesian<double>             Kernel;
typedef CGAL::Polyhedron_3<Kernel>          Polyhedron;

//
    ----------------------------------------------------------------------------

 // Output
 //***************************************

 // Raw output: dump (u,v) pairs
 Polyhedron::Vertex_const_iterator pVertex;
 for (pVertex = mesh.vertices_begin();
     pVertex != mesh.vertices_end();
```

```
        pVertex++)
    {
        // (u,v) pair is stored in any halfedge
        double u = mesh_adaptor.info(pVertex->halfedge())->uv().x();
        double v = mesh_adaptor.info(pVertex->halfedge())->uv().y();
        std::cout << "(u,v) = (" << u << "," << v << ")" << std::endl;
    }

    return EXIT_SUCCESS;
}
```

File: examples/Surface_mesh_parameterization/Simple_parameterization.cpp

54.2.4 Enhanced parameterize() function

This package provides a second *CGAL::parameterize()* entry point where the user can specify a parameterization method:

Parameterizer_traits_3<ParameterizationMesh_3>::Error_code

parameterize(ParameterizationMesh_3 & mesh,
ParameterizerTraits_3 parameterizer)

Compute a one-to-one mapping from a 3D triangle surface 'mesh' to a simple 2D domain. The mapping is piecewise linear on the triangle mesh. The result is a pair (u,v) of parameter coordinates for each vertex of the input mesh. One-to-one mapping may be guaranteed or not, depending on the chosen *ParametizerTraits_3* algorithm.
Preconditions: 'mesh' must be a triangle surface mesh with one connected component, and the mesh border must be mapped onto a convex polygon (for fixed border parameterizations).

54.2.5 Introduction to the Package Concepts

The ParameterizerTraits_3 concept

This CGAL package implements some of the state-of-the-art surface parameterization methods, such as Least Squares Conformal Maps, Discrete Conformal Map, Discrete Authalic Parameterization, Floater Mean Value Coordinates or Tutte Barycentric Mapping. These methods are provided as models of the *ParameterizerTraits_3* concept. See Section 54.3.

Each of these surface parameterization methods is templated by the input mesh type, a border parameterization and a solver:

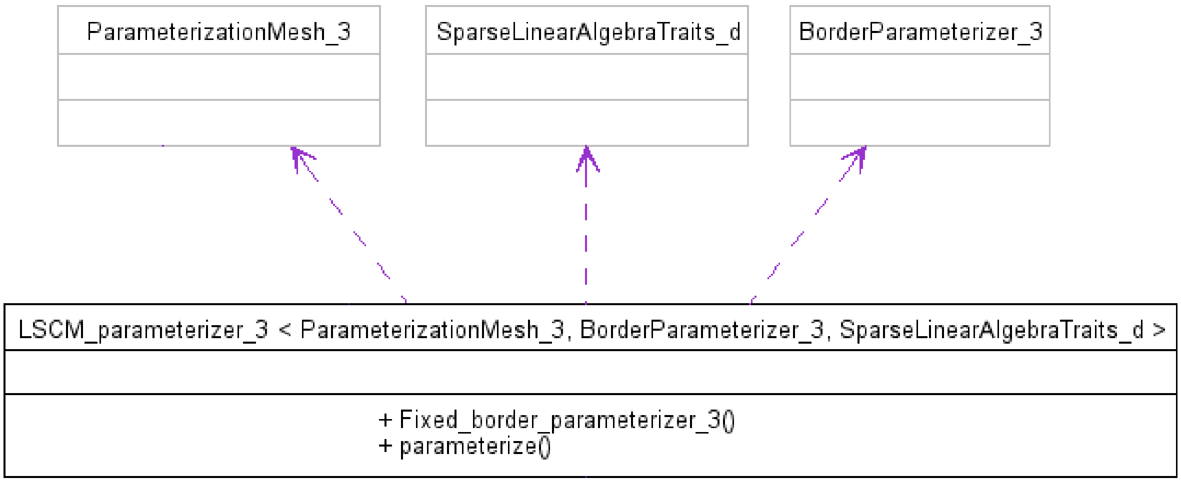

Figure 54.2: A parameterizer UML class diagram (simplified).

The BorderParameterizer_3 concept

Parameterization methods for borders are used as traits classes modifying the behavior of *ParameterizerTraits_3* models. They are provided as models of the *BorderParameterizer_3* concept. See Sections 54.3.1 and 54.3.2.

The SparseLinearAlgebraTraits_d concept

This package solves sparse linear systems using solvers which are models of *SparseLinearAlgebraTraits_d*. See Section 54.4.

The ParameterizationMesh_3 and ParameterizationPatchableMesh_3 Concepts

As described in Section 54.2.2 the input meshes handled by *CGAL::parameterize()* must be models of the *ParameterizationMesh_3* concept. The surface parameterization methods provided by this package only support surfaces which are homeomorphic to disks, possibly with holes. Nevertheless meshed with arbitrary topology and number of connected components can be parameterized, provided that the user specifies a *cut graph* (an oriented list of vertices) which is the border of a topological disc. If no cut graph is specified as input, the longest border of the input mesh is taken by default, the others being considered as holes.

For this purpose, the *CGAL::Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>* class is responsible for *virtually* cutting a patch into a *ParameterizationPatchableMesh_3* mesh. The resulting patch is a topological disk (if the input cutting path is correct) and provides a *ParameterizationMesh_3* interface. It can be used as parameter for the function *CGAL::parameterize()*.

ParameterizationPatchableMesh_3 inherits from *ParameterizationMesh_3*, thus is a concept for a 3D surface mesh. *ParameterizationPatchableMesh_3* adds the ability to support patches and virtual seams. *Patches* are a subset of a 3D mesh. *Virtual seams* behave as if the surface was cut along a cut graph. More information is provided in Section 54.5.

54.3 Surface Parameterization Methods

This CGAL package implements some of the state-of-the-art surface parameterization methods, such as Least Squares Conformal Maps, Discrete Conformal Map, Discrete Authalic Parameterization, Floater Mean Value Coordinates or Tutte Barycentric Mapping. These methods are provided as models of the *ParameterizerTraits_3* concept.

54.3.1 Fixed Border Surface Parameterizations

Fixed Border Surface Parameterizations need a set of constraints: two (u,v) coordinates for each vertex along the border. Such border parameterizations are described in Section 54.3.1.

Tutte Barycentric Mapping

CGAL::Barycentric_mapping_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

The Barycentric Mapping parameterization method has been introduced by Tutte [Tut63]. In parameter space, each vertex is placed at the barycenter of its neighbors to achieve the so-called convex combination condition. This algorithm amounts to solve one sparse linear solver for each set of parameter coordinates, with a #vertices x #vertices sparse and symmetric positive definite matrix (if the border vertices are eliminated from the linear system). A coefficient (i, j) of the matrix is set to 1 for an edge linking the vertex v_i to the vertex v_j, to minus the degree of the vertex v_i for a diagonal element, and to 0 for any other matrix entry. Although a bijective mapping is guaranteed when the border is convex, this method does not minimize angles nor areas distortion.

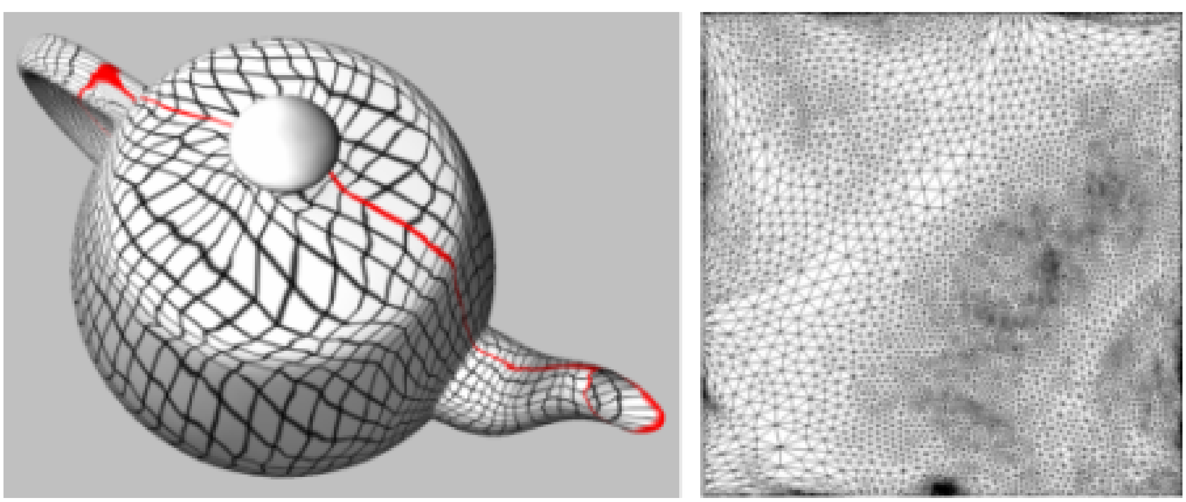

Figure 54.3: Left: Tutte barycentric mapping parameterization (the red line depicts the cut graph). Right: parameter space.

Discrete Conformal Map

CGAL::Discrete_conformal_map_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

Discrete conformal map parameterization has been introduced by Eck et al. to the graphics community [EDD+95]. It attempts to lower angle deformation by minimizing a discrete version of the Dirichlet energy as derived by Pinkall and Polthier [PP93]. A one-to-one mapping is guaranteed only when the two following conditions are fulfilled: the barycentric mapping condition (each vertex in parameter space is a convex combination if its neighboring vertices), and the border is convex. This method solves two #vertices x #vertices sparse linear systems. The matrix (the same for both systems) is sparse and symmetric definite positive (if the border vertices are eliminated from the linear system and if the mesh contains no hole), thus can be efficiently solved using dedicated linear solvers.

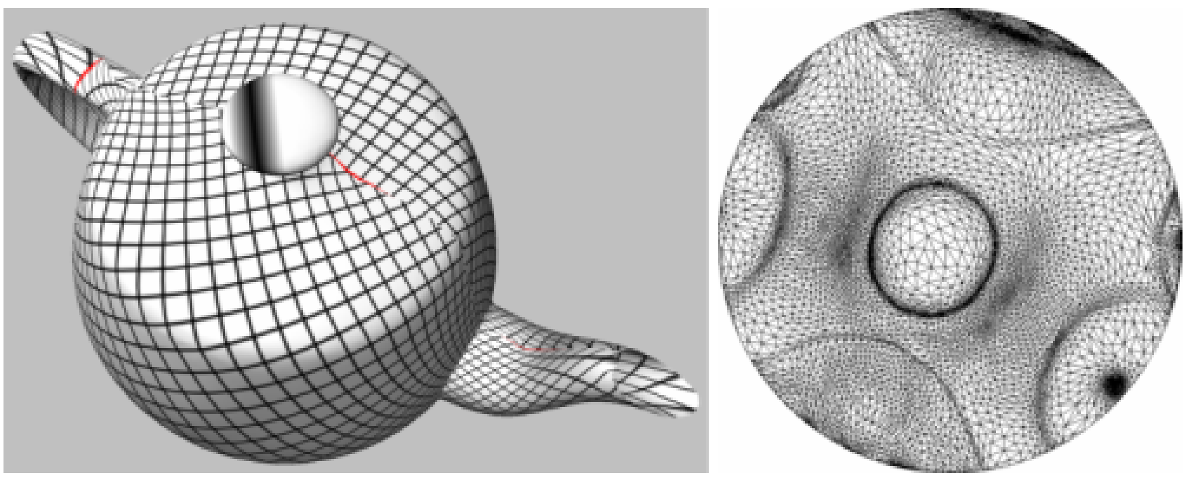

Figure 54.4: Left: discrete conformal map. Right: parameter space.

Floater Mean Value Coordinates

CGAL::Mean_value_coordinates_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

The mean value coordinates parameterization method has been introduced by Floater [Flo03a]. Each vertex in parameter space is optimized so as to be a convex combination of its neighboring vertices. The barycentric coordinates are this time unconditionally positive, by deriving an application of the mean theorem for harmonic functions. This method is in essence an approximation of the discrete conformal maps, with a guaranteed one-to-one mapping when the border is convex. This method solves two #vertices x #vertices sparse linear systems. The matrix (the same for both systems) is asymmetric.

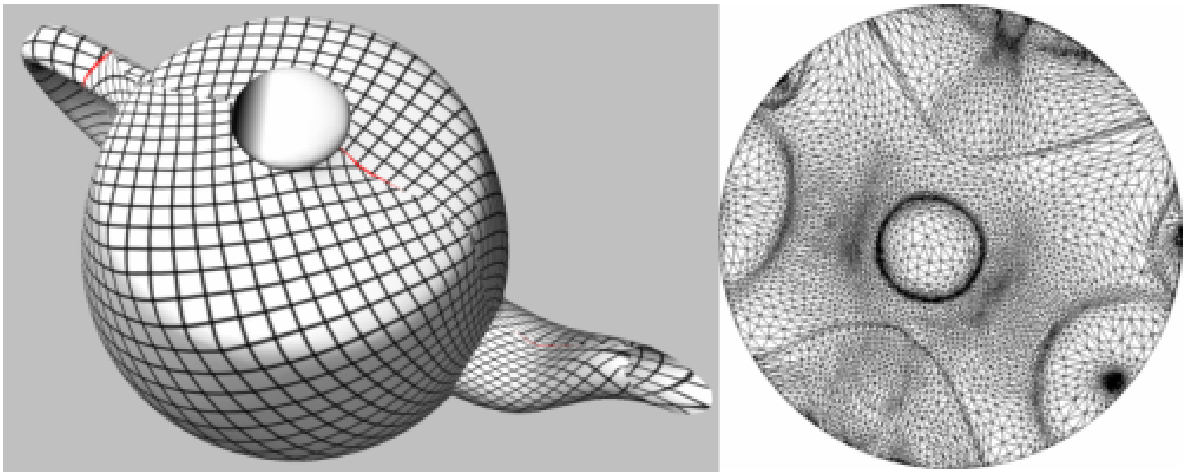

Figure 54.5: Floater Mean Value Coordinates

Discrete Authalic parameterization

CGAL::Discrete_authalic_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

The discrete authalic parameterization method has been introduced by Desbrun et al. [DMA02]. It corresponds to a weak formulation of an area-preserving method, and in essence locally minimizes the area distortion. A one-to-one mapping is guaranteed only if the convex combination condition is fulfilled and the border is convex. This method solves two #vertices x #vertices sparse linear systems. The matrix (the same for both systems) is asymmetric.

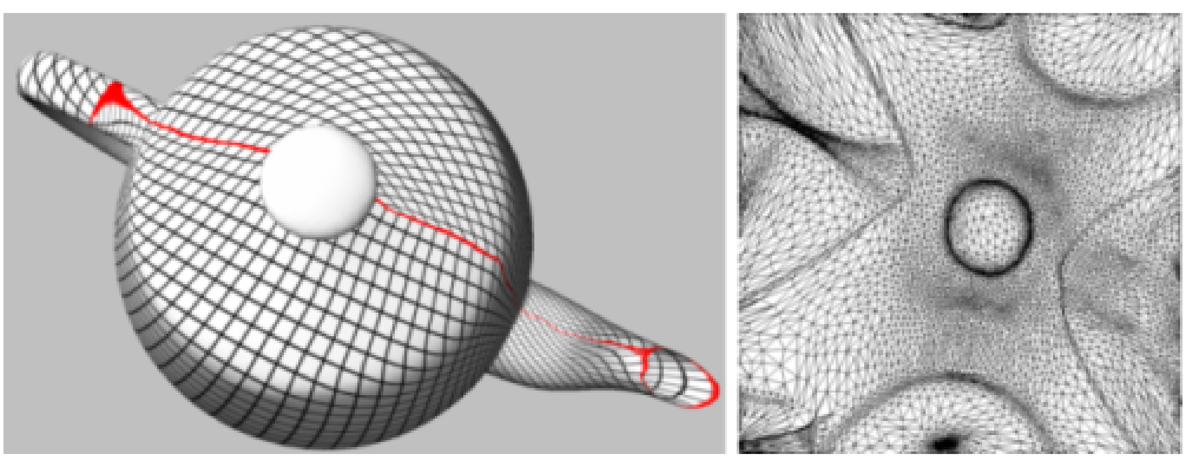

Figure 54.6: Discrete Authalic Parameterization

Border Parameterizations for Fixed Methods

Parameterization methods for borders are used as traits classes modifying the behavior of *ParameterizerTraits_3* models. They are provided as models of the *BorderParameterizer_3* concept. Border parameterizations for fixed border surface parameterizations are a family of methods to define a set of constraints, namely two u, v coordinates for each vertex along the border.

- The user can select a border parameterization among two commonly used methods: uniform or arc-length parameterization.

  Usage:

  Uniform border parameterization is more stable, although it gives poor visual results. The arc-length border parameterization is used by default.

- One convex shape specified by one shape among two standard ones: a circle or a square.

  Usage:

  The circular border parameterization is used by default as it corresponds to the simplest convex shape. The square border parameterization is commonly used for texture mapping.

CGAL::Circular_border_arc_length_parameterizer_3<ParameterizationMesh_3>
CGAL::Circular_border_uniform_parameterizer_3<ParameterizationMesh_3>
CGAL::Square_border_arc_length_parameterizer_3<ParameterizationMesh_3>
CGAL::Square_border_uniform_parameterizer_3<ParameterizationMesh_3>

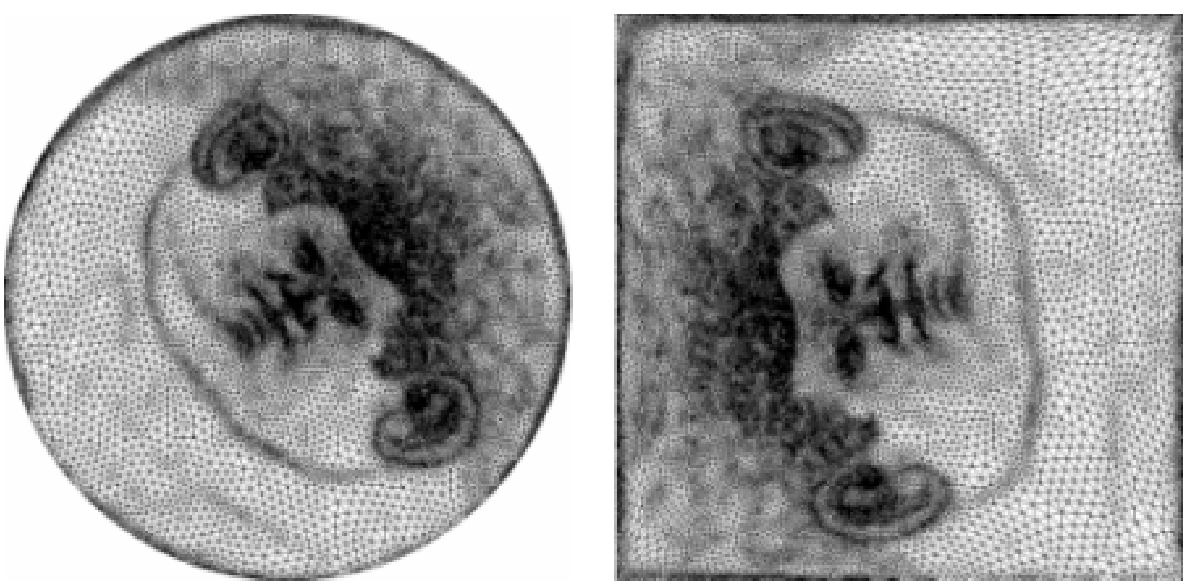

Figure 54.7: Left: Julius Cesar mask parameterization with Authalic/circular border. Right: Julius Cesar mask's image with Floater/square border.

54.3.2 Free Border Surface Parameterizations

Least Squares Conformal Maps

CGAL::LSCM_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

The Least Squares Conformal Maps (LSCM) parameterization method has been introduced by Lévy et al. [LPRM02]. It corresponds to a conformal method with a free border (at least two vertices have to be constrained to obtain a unique solution), which allows further lowering of the angle distortion. A one-to-one mapping is not guaranteed by this method. It solves a (2 × #triangles) × #vertices sparse linear system in the least squares sense, which implies solving a symmetric matrix.

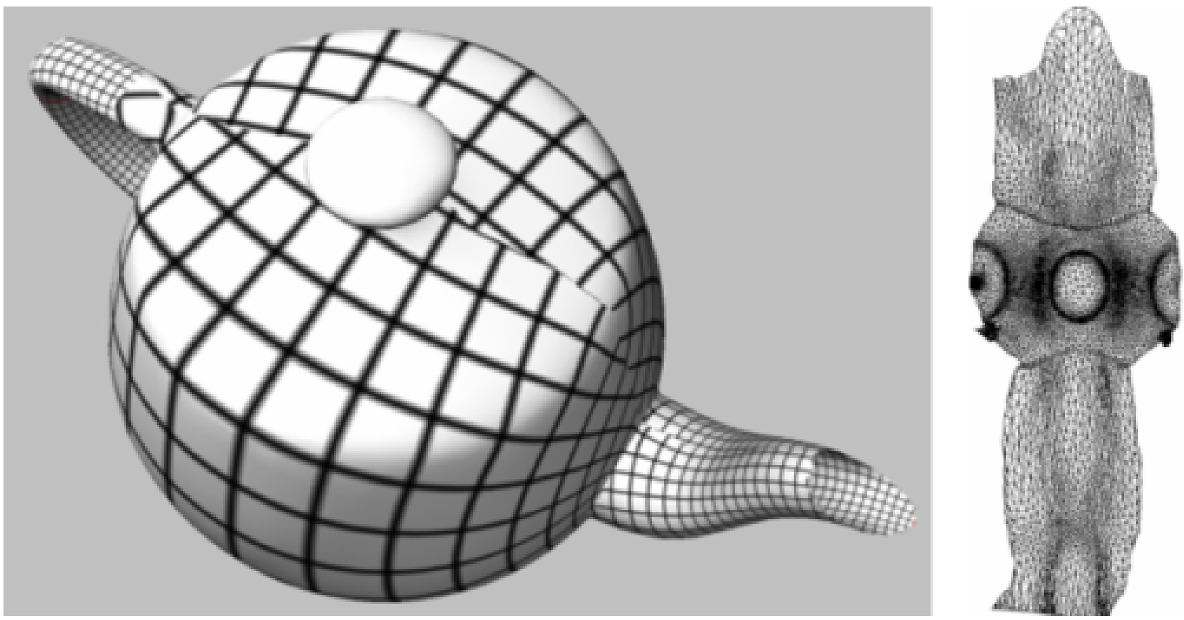

Figure 54.8: Least squares conformal maps.

Border Parameterizations for Free Methods

Parameterization methods for borders are used as traits classes modifying the behavior of *ParameterizerTraits_3* models. They are provided as models of the *BorderParameterizer_3* concept. The border parameterizations associated to free border surface parameterization methods define only two constraints: the pinned vertices.

- *CGAL::Two_vertices_parameterizer_3<ParameterizationMesh_3>*

  Usage:

  CGAL::Two_vertices_parameterizer_3<ParameterizationMesh_3> is the default free border parameterization, and is the only one available in the current version of this package.

54.3.3 Discrete Authalic Parameterization Example

Authalic_parameterization.cpp computes a Discrete Authalic parameterization over a *CGAL::Polyhedron_3< Traits>* mesh. Specifying a specific surface parameterization instead of the default one means using the second parameter of *CGAL::parameterize()*. The differences with the first example *Simple_parameterization.cpp* are:

```
#include <CGAL/Discrete_authalic_parameterizer_3.h>

...

//***************************************
// Discrete Authalic Parameterization
//***************************************

typedef
   CGAL::Discrete_authalic_parameterizer_3<Parameterization_polyhedron_adaptor>
                                                    Parameterizer;

Parameterizer::Error_code err = CGAL::parameterize(mesh_adaptor,
   Parameterizer());

...
```

54.3.4 Square Border Arc Length Parameterization Example

Square_border_parameterization.cpp computes a Floater mean value coordinates parameterization with a square border arc length parameterization. Specifying a specific border parameterization instead of the default one means using the second parameter of *CGAL::Mean_value_coordinates_parameterizer_3< ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>*. The differences with the first example *Simple_parameterization.cpp* are:

```
#include <CGAL/Square_border_parameterizer_3.h>

...

//***************************************
// Floater Mean Value Coordinates parameterization
// with square border
//***************************************

// Square border parameterizer
typedef
   CGAL::Square_border_arc_length_parameterizer_3<Parameterization_polyhedron_adaptor>

   Border_parameterizer;

// Floater Mean Value Coordinates parameterizer with square border
typedef
   CGAL::Mean_value_coordinates_parameterizer_3<Parameterization_polyhedron_adaptor,

   Border_parameterizer>
```

```
                                                    Parameterizer;

Parameterizer::Error_code err = CGAL::parameterize(mesh_adaptor,
    Parameterizer());

...
```

54.4 Sparse Linear Algebra

Parameterizing triangle meshes requires both efficient representation of sparse matrices and efficient iterative or direct linear solvers. We provide links to EIGEN library and include a separate package devoted to OpenNL sparse linear solver.

54.4.1 List of Solvers

We provide an interface to several sparse linear solvers, as models of the *SparseLinearAlgebraTraits_d* concept:

- An interface to sparse solvers from the OPENNL library [Lev05] is provided through classes *OpenNL::DefaultLinearSolverTraits<COEFFTYPE, MATRIX, VECTOR, SOLVER>* and *OpenNL::SymmetricLinearSolverTraits<COEFFTYPE, MATRIX, VECTOR, SOLVER>*. The OpenNL library version shipped with CGAL is a lightweight default sparse linear solver. It does not support large systems, but it is portable and supports exact number types.
- An interface to all sparse solvers from the Eigen (Page 28) library is provided through the class *CGAL::Eigen_solver_traits<T>*. This solver traits class can be used for an iterative or a direct, symmetric or general sparse solvers. The EIGEN solver to be used must be given as template parameter.

54.4.2 EIGEN Solver Example

The example *examples/Surface_mesh_parameterization/Eigen_parameterization.cpp* computes the default parameterization method (Floater mean value coordinates with a circular border), but specifically instantiates an EIGEN solver. Specifying a specific solver instead of the default one (OpenNL) means using the third parameter of *CGAL::Mean_value_coordinates_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>*. The differences with the first example *examples/Surface_mesh_parameterization/Simple_parameterization.cpp* are:

```
#include <CGAL/Eigen_solver_traits.h>

...

//***************************************
// Floater Mean Value Coordinates parameterization
// (circular border) with Eigen solver
//***************************************

// Circular border parameterizer (the default)
```

```
typedef
    CGAL::Circular_border_arc_length_parameterizer_3<Parameterization_polyhedron_adaptor>
                                                              Border_parameterizer;
// Eigen solver
typedef CGAL::Eigen_solver_traits<>                          Solver;

// Floater Mean Value Coordinates parameterization
// (circular border) with Eigen solver
typedef
    CGAL::Mean_value_coordinates_parameterizer_3<Parameterization_polyhedron_adaptor,

    Border_parameterizer,
                                                                   Solver>
                                                              Parameterizer;

Parameterizer::Error_code err = CGAL::parameterize(mesh_adaptor,
    Parameterizer());

...
```

54.5 Cutting a Mesh

54.5.1 Computing a Cut Graph

All surface parameterization methods proposed in this package only deal with meshes which are homeomorphic (topologically equivalent) to discs. Nevertheless meshes with arbitrary topology and number of connected components car be parameterized, provided that the user specifies a cut graph (an oriented list of vertices), which is the border of a topological disc. If no cut graph is provided as input, the longest border already in the input mesh is taken as default border, all other borders being considered as holes. Note that only the inside part (i.e., one connected component) of the given border is parameterized.

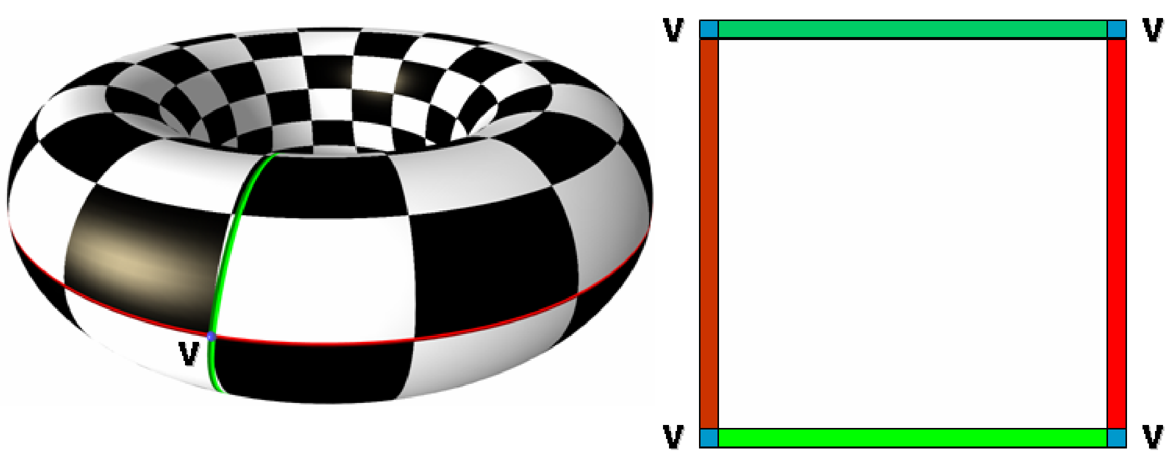

Figure 54.9: Cut Graph

This package does not provide any algorithm to transform an arbitrary mesh into a topological disk, the user being responsible for generating such a cut graph. Nevertheless, we provide in *polyhedron_ex_parameterization.cpp* a simple cutting algorithm for the sake of completeness.

54.5.2 Applying a Cut

The surface parameterization classes in this package only *directly* support surfaces which are homeomorphic to disks (models of *ParameterizationMesh_3*). This software design simplifies the implementation of all new parameterization methods.

The *CGAL::Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>* class is responsible for *virtually* cutting a patch in a *ParameterizationPatchableMesh_3* mesh. The resulting patch is a topological disk (if the cut graph is correct) and provides a *ParameterizationMesh_3* interface. It can be used as parameter of *CGAL::parameterize()*.

ParameterizationPatchableMesh_3 inherits from concept *ParameterizationMesh_3*, thus is a concept for a 3D surface mesh. *ParameterizationPatchableMesh_3* adds the ability to support patches and virtual seams. *Patches* are a subset of a 3D mesh. *Virtual seams* behave exactly as if the surface was cut along a certain graph.

The *ParameterizationMesh_3* interface with the Polyhedron is both a model of *ParameterizationMesh_3* and *ParameterizationPatchableMesh_3*:
CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron_3_>

Note that this class is a decorator which adds *on the fly* the necessary fields to unmodified CGAL data structures (using STL maps). For better performances, it is recommended to use CGAL data structures enriched with the proper fields. See *Polyhedron_ex* class in *polyhedron_ex_parameterization.cpp* example.

54.5.3 Cutting a Mesh Example

Mesh_cutting_parameterization.cpp virtually cuts a *CGAL::Polyhedron_3<Traits>* mesh to make it a topological disk, then applies the default parameterization:

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/Parameterization_polyhedron_adaptor_3.h>
#include <CGAL/parameterize.h>
#include <CGAL/Parameterization_mesh_patch_3.h>

#include <iostream>
#include <fstream>

//
    ----------------------------------------------------------------------------
// Private types
//
    ----------------------------------------------------------------------------

typedef CGAL::Cartesian<double>             Kernel;
typedef CGAL::Polyhedron_3<Kernel>          Polyhedron;
```

```
// Polyhedron adaptor
typedef CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron>

   Parameterization_polyhedron_adaptor;

// Type describing a border or seam as a vertex list
typedef std::list<Parameterization_polyhedron_adaptor::Vertex_handle>
                                                    Seam;

//
   ----------------------------------------------------------------------------
// Private functions
//
   ----------------------------------------------------------------------------

// If the mesh is a topological disk, extract its longest border,
// else compute a very simple cut to make it homeomorphic to a disk.
// Return the border of this region (empty on error)
//
// CAUTION: this cutting algorithm is very naive. Write your own!
static Seam cut_mesh(Parameterization_polyhedron_adaptor& mesh_adaptor)
{
    // Helper class to compute genus or extract borders
    typedef
   CGAL::Parameterization_mesh_feature_extractor<Parameterization_polyhedron_adaptor>
                                                    Mesh_feature_extractor;

    Seam seam;              // returned list

    // Get reference to Polyhedron_3 mesh
    Polyhedron& mesh = mesh_adaptor.get_adapted_mesh();

    // Extract mesh borders and compute genus
    Mesh_feature_extractor feature_extractor(mesh_adaptor);
    int nb_borders = feature_extractor.get_nb_borders();
    int genus = feature_extractor.get_genus();

    // If mesh is a topological disk
    if (genus == 0 && nb_borders > 0)
    {
        // Pick the longest border
        seam = feature_extractor.get_longest_border();
    }
    else // if mesh is *not* a topological disk, create a virtual cut
    {

```

File: examples/Surface_mesh_parameterization/Mesh_cutting_parameterization.cpp

54.6 Output

Parameterization methods compute (u,v) fields for each vertex of the input mesh, with the seam vertices being virtually duplicated (thanks to *CGAL::Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>*). To support this duplication, *CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron_3_>* stores the result in the (u,v) fields of the input mesh halfedges. A (u,v) pair is computed for each inner vertex (i.e. its halfedges share the same (u,v) pair), while a (u,v) pair is computed for each border halfedge. The user has to iterate over the mesh halfedges to get the result. Note that (u,v) fields do not exist in *CGAL::Polyhedron_3<Traits>*, thus the output traversal is specific to the way the (u,v) fields are implemented by the adaptor.

54.6.1 EPS Output Example

Complete_parameterization_example.cpp is a complete parameterization example which outputs the resulting parameterization to a EPS file. It gets the (u,v) fields computed by a parameterization method over a *CGAL::Polyhedron_3<Traits>* mesh with a *CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron_3_>* adaptor:

```
#include <CGAL/basic.h> // include basic.h before testing #defines

#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/Parameterization_polyhedron_adaptor_3.h>
#include <CGAL/parameterize.h>
#include <CGAL/Discrete_authalic_parameterizer_3.h>
#include <CGAL/Square_border_parameterizer_3.h>
#include <CGAL/Parameterization_mesh_patch_3.h>

#include <CGAL/Eigen_solver_traits.h>

#include <iostream>
#include <fstream>

54.7 Complexity and Guarantees

54.7.1 Parameterization Methods and Guarantees

- Fixed boundaries
  - One-to-one mapping
    Tutte's theorem guarantees a one-to-one mapping provided that the weights are all positive and the border convex. It is the case for Tutte barycentric mapping and Floater mean value coordinates. It is not always the case for discrete conformal map (cotangents) and discrete authalic parameterization.
  - Non-singularity of the matrix
    Geshorgin's theorem guarantees the convergence of the solver if the matrix is diagonal dominant. This is the case with positive weights (Tutte barycentric mapping and Floater mean value coordinates).
- Free boundaries
  - One-to-one mapping
    No guarantee is provided by LSCM (both global overlaps and triangle flips can occur).
  - Non-singularity of the matrix
    For LSCM, the matrix of the system is the Gram matrix of a matrix with maximal rank, and is therefore non-singular (Gram theorem).

54.7.2 Precision

Two algorithms of this package construct the sparse linear system(s) using trigonometric functions, and are this incompatible with exact arithmetic:

- Floater mean value coordinates
- Circular border parameterization

On the other hand, linear solvers commonly use double precision floating point numbers.
OpenNL's BICGSTAB solver (accessible through the *OpenNL::DefaultLinearSolverTraits<COEFFTYPE, MATRIX, VECTOR, SOLVER>* interface) is the only solver supported by this package which computes exact results, when used with an exact arithmetic. This package is intended to be used mainly with a CGAL Cartesian kernel with doubles.

OpenNL's BICGSTAB Solver with an Exact Arithmetic

The BICGSTAB conjugate gradient is in disguise a direct solver. In a nutshell, it computes a vector basis orthogonal with respect to the matrix, and the coordinates of the solution in this vector basis. Each iteration computes one component of the basis and one coordinate, therefore the algorithm converges to the solution in n iterations, where n is the dimension of the matrix. More precisely, it is shown to converge in k iteration, where k is the number of distinct eigenvalues of the matrix.

Solvers with a Floating Point Arithmetic

OpenNL's BICGSTAB example:

When inexact numerical types are used (e.g. doubles), accumulated errors slow down convergence (in practice, it requires approximately $5k$ iterations to converge). The required number of iterations depends on the eigenvalues of the matrix, and these eigenvalues depend on the shape of the triangles. The optimum is when the triangles are equilateral (then the solver converges in less than 10 iterations). The worst case is obtained when the mesh has a large number of skinny triangles (near-singular Jacobian matrix of the triangle). In this case, the spectrum of the matrix is wide (many different eigenvalues), and the solver requires nearly $5n$ iterations to converge.

54.7.3 Algorithmic Complexity

In this package, we focus on piecewise linear mappings onto a planar domain. All surface parameterization methods are based on solving one (or two) sparse linear system(s). The algorithmic complexity is dominated by the resolution of the sparse linear system(s).

OpenNL's BICGSTAB example:

At each iteration, the operation of highest complexity is the product between the sparse-matrix and a vector. The sparse matrix has a fixed number of non-zero coefficients per row, therefore the matrix / vector product has $O(n)$ complexity. Since convergence is reached after k iterations, the complexity is $O(k.n)$ (where k is the number of distinct eigenvalues of the matrix). Therefore, best case complexity is $O(n)$ (equilateral triangles), and worst case complexity is $O(n^2)$ (skinny triangles).

54.8 Software Design

54.8.1 Global Function parameterize()

This package's entry point is:

```
// Compute a one-to-one mapping from a 3D triangle surface 'mesh' to a
// 2D circle, using Floater Mean Value Coordinates algorithm.
// A one-to-one mapping is guaranteed.
template <class ParameterizationMesh_3>
typename Parameterizer_traits_3<ParameterizationMesh_3>::Error_code
parameterize(ParameterizationMesh_3& mesh)  // 3D mesh, model of
    ParameterizationMesh_3 concept
{
```

```
    Mean_value_coordinates_parameterizer_3<ParameterizationMesh_3>
   parameterizer;
    return parameterizer.parameterize(mesh);
}

// Compute a one-to-one mapping from a 3D triangle surface 'mesh' to a
// simple 2D domain.
// One-to-one mapping may be guaranteed or not,
// depending on the chosen ParametizerTraits_3 algorithm.
template <class ParameterizationMesh_3, class ParameterizerTraits_3>
typename Parameterizer_traits_3<ParameterizationMesh_3>::Error_code
parameterize(ParameterizationMesh_3& mesh,          // 3D mesh, model of
    ParameterizationMesh_3
             ParameterizerTraits_3 parameterizer)   // Parameterization
    method for 'mesh'
{
    return parameterizer.parameterize(mesh);
}
```

You may notice that these global functions simply call the parameterize() method of a *ParameterizerTraits_3* object. The purpose of these global functions is:

- to be consistent with other CGAL algorithms that are also provided as global functions, e.g. *CGAL::convex_hull_2()*,
- to provide a default parameterization method (Floater Mean Value Coordinates), which wouldn't be possible with a direct call to an object's method.

You may also wonder why there is not just one *CGAL::parameterize()* function with a default *ParameterizerTraits_3* argument equal to *CGAL::Mean_value_coordinates_parameterizer_3< ParameterizationMesh_3>*. The reason is simply that this is not allowed by the C++ standard (see [C++98], paragraph 14.1/9).

54.8.2 No Common Parameterization Algorithm

ParameterizerTraits_3 models modify the behavior of the global function *CGAL::parameterize()* - hence the *Traits* in the name. On the other hand, *ParameterizerTraits_3* models do not modify the behavior of a common parameterization algorithm - as you might expect.

In this package, we focus on triangulated surfaces that are homeomorphic to a disk and on piecewise linear mappings onto planar domains. A consequence is that the skeleton of all parameterization methods of this package is the same:

- Allocate a sparse linear system $A.X = B$
- Parameterize the mesh border and initialize B
- Parameterize the inner points of the mesh and set A coefficients
- Solve the system

It is tempting to make the parameterization method a traits class that modifies the behavior of a common parameterization algorithm. On the other hand, there are several differences among methods:

- Fixed border methods need to parameterize all border vertices, while free border methods parameterize only two vertices.
- Some methods create symmetric definite positive systems, which may be solved more efficiently than general systems.
- Most parameterization methods use two #vertices x #vertices systems, where Least Squares Conformal Maps uses one (2 * #triangles) x #vertices system.
- Most parameterization methods invert the A matrix, when Least Squares Conformal Maps solves the system in the least squares sense.

Therefore, the software design chosen is:

- Each *ParameterizerTraits_3* model implements its own version of the parameterization algorithm as a parameterize() method.
- Each *ParameterizerTraits_3* model has template arguments defining the border parameterization and sparse linear solver to use, with default values adapted to the method.
- Code factorization is achieved using a class hierarchy and (few) virtual methods.

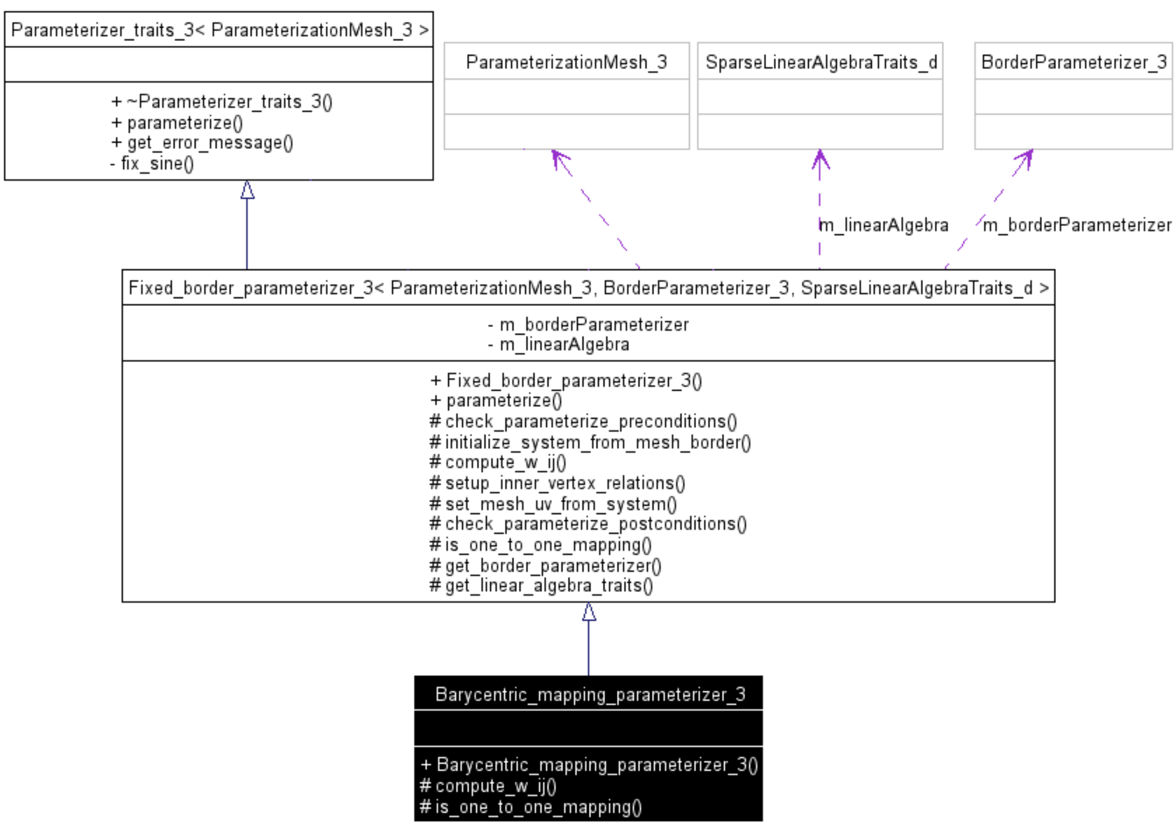

Figure 54.10: A parameterizer UML class diagram (main types and methods only)

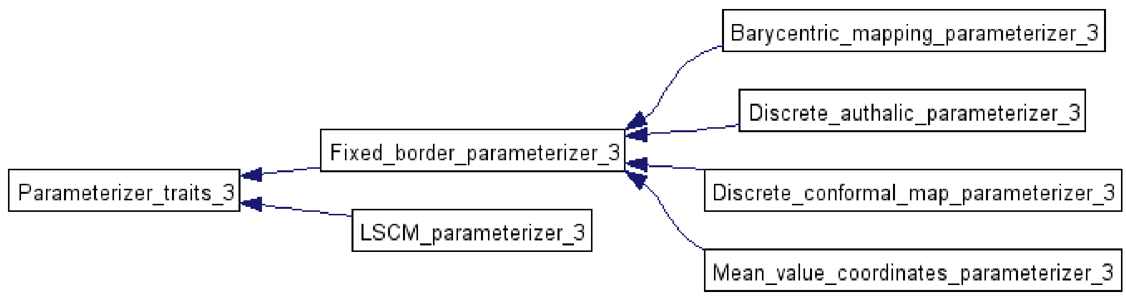

Figure 54.11: Surface parameterizer classes hierarchy

Note: *CGAL::Parameterizer_traits_3<ParameterizationMesh_3>* is the (pure virtual) superclass of all surface parameterization classes.

54.8.3 Fixed_border_parameterizer_3 Class

Linear fixed border parameterization algorithms are very close. They mainly differ by the energy that they try to minimize, i.e. by the value of the w_{ij} coefficient of the A matrix, for v_i and v_j neighbor vertices of the mesh [FH05]. One consequence is that most of the code of the fixed border methods is factorized in the *CGAL::Fixed_border_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>* class.

Subclasses:

- must provide *BorderParameterizer_3* and *SparseLinearAlgebraTraits_d* default template parameters that make sense,
- must implement *compute_w_ij*() to compute w_{ij} = (i, j) coefficient of matrix A for v_j neighbor vertex of v_i,
- may implement an optimized version of *is_one_to_one_mapping*().

See *CGAL::Barycentric_mapping_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>* class as an example.

54.8.4 Border Parameterizations

Border Parameterizations are models of the *BorderParameterizer_3* concept. To simplify the implementation, *BorderParameterizer_3* models know only the *ParameterizationMesh_3* mesh class. They do not know the parameterization algorithm or the sparse linear solver used.

54.8.5 ParameterizationMesh_3 and ParameterizationPatchableMesh_3 Concepts

All parameterization methods are templated by the kind of mesh they are applied on. The mesh type must be a model of *ParameterizationMesh_3*.

The purpose of such a model is to:

1. Support several kind of meshes.
2. Hide the implementation of extra fields specific to the parameterization domain (*index*, *u*, *v*, *is_parameterized*).
3. Handle in the mesh type the complexity of *virtually* cutting a mesh to make it homeomorphic to a disk (instead of duplicating this code in each parameterization method).

Two options are possible for 1) and 2):

- Pass to all classes and methods a mesh pointer, a traits class to manipulate it, and accessors to the extra field arrays. This is the choice of the Boost Graph Library with *boost::graph_traits<>* and the property maps.
- Pass to all classes and methods an object that points to the actual mesh and knows how to access to its fields. This is the Adaptor concept [GHJV95].

The current design of this package uses the second option, which is simpler. Of course, we may decide at some point to switch to the first one to reach a deeper integration of CGAL with Boost.

Point 3) is solved by class *CGAL::Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>*, which takes care of *virtually* cutting a patch in a *ParameterizationPatchableMesh_3* mesh, to make it appear as a topological disk with a *ParameterizationMesh_3* interface. *ParameterizationPatchableMesh_3* inherits from concept *ParameterizationMesh_3* and adds the ability to support patches and virtual seams.

This mainly means that:

- vertices can be tagged as inside or outside the patch to parameterize,
- the fields specific to parameterizations (*index*, *u*, *v*, *is_parameterized*) can be set *per corner* (which is a more general way of saying *per half-edge*).

54.8.6 SparseLinearAlgebraTraits_d Concept

This package solves sparse linear systems using solvers which are models of *SparseLinearAlgebraTraits_d*.

SparseLinearAlgebraTraits_d is a sub-concept of the *LinearAlgebraTraits_d* concept in *Kernel_d*. The goal is to adapt easily code written for dense matrices to sparse ones, and vice-versa.

54.8.7 Cutting a Mesh

In this package, we focus on triangulated surfaces that are homeomorphic to a disk.

Computing a cutting path that transforms a closed mesh of arbitrary genus into a topological disk is a research topic on its own. This package does not intend to cover this topic at the moment.

54.9 Extending the Package and Reusing Code

54.9.1 Reusing Mesh Adaptors

ParameterizationMesh_3 defines a concept to access to a general polyhedral mesh. It is optimized for the *Surface_mesh_parameterization* package only in the sense that it defines the accessors to fields specific to the parameterization domain (*index*, *u*, *v*, *is_parameterized*).

It may be easily generalized.

54.9.2 Reusing Sparse Linear Algebra

The *SparseLinearAlgebraTraits_d* concept and the traits classes for EIGEN and OpenNL are independent of the rest of the *Surface_mesh_parameterization* package, and may be reused by CGAL developers for other purposes.

54.9.3 Adding New Parameterization Methods

Implementing a new fixed border linear parameterization is easy. Most of the code of the fixed border methods is factorized in the *CGAL::Fixed_border_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>* class. Subclasses must mainly implement a *compute_w_ij*() method which computes each $w_{ij} = (i, j)$ coefficient of the matrix A for v_j neighboring vertices of v_i.

Although implementing a new free border linear parameterization method is more challenging, the Least Squares Conformal Maps parameterization method provides a good starting point.

Implementing *non* linear parameterizations is a natural extension to this package, although only the mesh adaptors can be reused.

54.9.4 Adding New Border Parameterization Methods

Implementing a new border parameterization method is easy. Square, circular and two-points border parameterizations are good starting points.

54.9.5 Mesh Cutting

Obviously, this package would benefit of having robust algorithms which transform arbitrary meshes into topological disks.

Planar Parameterization of Triangulated Surface Meshes
Reference Manual

Laurent Saboret, Pierre Alliez and Bruno Lévy

Parameterizing a surface amounts to finding a one-to-one mapping from a suitable domain to the surface. A good mapping is the one which minimizes either angle or area distortions in some sense. In this package, we focus on triangulated surfaces that are homeomorphic to a disk and on piecewise linear mappings into a planar domain.

54.10 Classified Reference Pages

Main Function

Concepts

Surface Parameterization Methods

This CGAL package implements some of the state-of-the-art parameterization methods:

- Fixed border:
  - Tutte Barycentric Mapping [Tut63]. One-to-one mapping is guaranteed for convex border.
  - Floater Mean Value Coordinates [Flo03a]. One-to-one mapping is guaranteed for convex border.

– Discrete Conformal Map [EDD+95]. Conditionally guaranteed if all weights are positive and border is convex.
– Discrete Authalic parameterization [DMA02]. Conditionally guaranteed if all weights are positive and border is convex.

- Free border:
  – Least Squares Conformal Maps [LPRM02].

Border Parameterization Methods

Border parameterization methods define a set of constraints (a constraint specifies two (u,v) coordinates for each instance of a vertex along the border).

This package implements all common border parameterization methods:

- For fixed border methods:
  – the user can select a border parameterization among two common methods: uniform or arc-length parameterizations.
  – one convex shape specified by:
    ∗ one shape among a set of standard ones (circle, square).
- For free border methods: at least two constraints (the pinned vertices).

Mesh

The general definition of input meshes handled *directly* by *CGAL::parameterize()* is:

- Model of *ParameterizationMesh_3*.
- Triangulated.
- 2-manifold.
- Oriented.
- Homeomorphic to a disc (may have holes).

This package provides a model of the *ParameterizationMesh_3* concept to access *CGAL::Polyhedron_3<Traits>* :
CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron_3_>

The meshes supported *indirectly* by the package can be of any genus and have any number of connected components. If it is not a topological disc, the input mesh has to come with a description of a cutting path (an oriented list of vertices) which is the border of a topological disc. If no cutting path is given as input, we assume that the surface border is the longest border already in the input mesh (the other borders will be considered as holes).

The *CGAL::Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>* class is responsible for *virtually* cutting a patch in a *ParameterizationPatchableMesh_3* mesh. The resulting patch is a topological disk (if the input cutting path is correct) and provides a *ParameterizationMesh_3* interface. It can be used as parameter of *CGAL::parameterize()*.

Note that this way the user is responsible for cutting a closed mesh of arbitrary genus (even a topological disc with an intricate seam cut), as long as this condition is fulfilled.

The package provides an interface with *CGAL::Polyhedron_3<Traits>*:

Output

A (u,v) pair is computed for each inner vertex (i.e. its halfedges share the same (u,v) pair), while a (u,v) pair is computed for each border halfedge. The user must iterate over the mesh halfedges to get the result.

Sparse Linear Algebra

Since parameterizing meshes requires efficient representation of sparse matrices and efficient iterative or direct linear solvers, we provide an interface to several sparse linear solvers:

- EIGEN 3.1 (or greater) is the library recommended by CGALfor solving sparse systems.
- OpenNL (authored by Bruno Lévy) is shipped with CGALand is the default solver.

OpenNL::DefaultLinearSolverTraits<COEFFTYPE, MATRIX, VECTOR, SOLVER> in OpenNL package
OpenNL::SymmetricLinearSolverTraits<COEFFTYPE, MATRIX, VECTOR, SOLVER> in OpenNL package

Helper Classes

Checks and Assertions

The package performs the next checks:

For *fixed* border parameterizations:

- Preconditions:
  - check that the border is mapped onto a convex polygon.
  - check that the input mesh is triangular.
  - check that the input mesh is a surface with one connected component.
- Postconditions:
  - check one-to-one mapping.

For *free* border parameterizations:

- Preconditions:
  - check that the input mesh is triangular.
  - check that the input mesh is a surface with one connected component.
- Postconditions:
  - check one-to-one mapping.

Assertions are optional checks. The assertion flags for the package use *SURFACE_MESH_PARAMETERIZATION* in their names (*e.g.*, *CGAL_SURFACE_MESH_PARAMETERIZATION_NO_ASSERTIONS*).

Class

CGAL::Barycentric_mapping_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

Definition

The class *Barycentric_mapping_parameterizer_3* implements Tutte Barycentric Mapping algorithm [Tut63]. This algorithm is also called *Tutte Uniform Weights* by other authors.

One-to-one mapping is guaranteed if the surface's border is mapped to a convex polygon.

This class is a Strategy [GHJV95] called by the main parameterization algorithm *Fixed_border_parameterizer_3::parameterize*(). It provides default *BorderParameterizer_3* and *SparseLinearAlgebraTraits_d* template parameters that make sense. It implements *compute_w_ij*() to compute *w_ij* = (i, j) coefficient of matrix A for j neighbor vertex of i based on Tutte Barycentric Mapping method. It implements an optimized version of *is_one_to_one_mapping*().

#include <CGAL/Barycentric_mapping_parameterizer_3.h>

Inherits From

Fixed_border_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

Is Model for the Concepts

Model of the *ParameterizerTraits_3* concept.

Design Pattern

Barycentric_mapping_parameterizer_3 class is a Strategy [GHJV95]: it implements a strategy of surface parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

template<class *ParameterizationMesh_3*, class *BorderParameterizer_3* = *Circular_border_arc_length_parameterizer_3<ParameterizationMesh_3>*, class *SparseLinearAlgebraTraits_d* = *OpenNL::DefaultLinearSolverTraits<typename ParameterizationMesh_3::NT>*>
class *Barycentric_mapping_parameterizer_3*;

Parameters:
ParameterizationMesh_3: 3D surface mesh. *BorderParameterizer_3*: Strategy to parameterize the surface border. *SparseLinearAlgebraTraits_d*: Traits class to solve a sparse linear system. Note: the system is **not** symmetric because *Fixed_border_parameterizer_3* does not remove (yet) border vertices from the system.

Creation

Barycentric_mapping_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d> param(Border_param border_param = Border_param(),

S

LA sparse_la = Sparse_LA())

Constructor.
Parameters:
border_param: Object that maps the surface's border to 2D space. *sparse_la*: Traits object to access a sparse linear system.

Operations

virtual NT *param.compute_w_ij(Adaptor, Vertex_const_handle, Vertex_around_vertex_const_circulator) [protected, virtual]*

Compute *w_ij* = (i, j) coefficient of matrix A for j neighbor vertex of i.
Tutte Barycentric Mapping algorithm is the most simple one: *w_ij* = 1 for j neighbor vertex of i.

virtual bool *param.is_one_to_one_mapping(Adaptor, Matrix, Vector, Vector) [protected, virtual]*

Check if 3D -> 2D mapping is one-to-one.
Theorem: one-to-one mapping is guaranteed if all *w_ij* coefficients are > 0 (for j vertex neighbor of i) and if the surface border is mapped onto a 2D convex polygon. All *w_ij* coefficients = 1 (for j vertex neighbor of i), thus mapping is guaranteed if the surface border is mapped onto a 2D convex polygon.

Concept

BorderParameterizer_3

Definition

BorderParameterizer_3 is a concept of class that parameterizes a given type of mesh, *Adaptor*, which is a model of the *ParameterizationMesh_3* concept.

Implementation note: To simplify the implementation, *BorderParameterizer_3* models know only the *ParameterizationMesh_3* class. They do not know the parameterization algorithm requirements or the kind of sparse linear system used.

Design Pattern

BorderParameterizer_3 models are Strategies [GHJV95]: they implement a strategy of border parameterization for models of *ParameterizationMesh_3*.

Types

BorderParameterizer_3:: Adaptor	Export *ParameterizationMesh_3* template parameter.
BorderParameterizer_3:: Error_code	The various errors detected by this package.

Creation

Construction and destruction are undefined.

Operations

Error_code	*bp.parameterize_border(Adaptor& mesh)*	
		Assign to mesh's border vertices a 2D position (i.e. a (u, v) pair) on border's shape. Mark them as *parameterized*. Return false on error.
bool	*bp.is_border_convex()*	
		Indicate if border's shape is convex.

CGAL::Circular_border_arc_length_parameterizer_3< ParameterizationMesh_3>

Class

Definition

Circular_border_arc_length_parameterizer_3 is the default border parameterizer for fixed border parameterization methods.

This class parameterizes the border of a 3D surface onto a circle, with an arc-length parameterization: (u, v) values are proportional to the length of border edges. *Circular_border_parameterizer_3* implements most of the border parameterization algorithm. This class implements only *compute_edge_length*() to compute a segment's length.

#include <CGAL/Circular_border_parameterizer_3.h>

CGAL::Circular_border_parameterizer_3<ParameterizationMesh_3>

Class

Definition

This is the base class of strategies that parameterize the border of a 3D surface onto a circle. *Circular_border_parameterizer_3* is a pure virtual class, thus cannot be instantiated. It implements most of the algorithm. Subclasses just have to implement *compute_edge_length*() to compute a segment's length.

Implementation note: To simplify the implementation, *BorderParameterizer_3* models know only the *ParameterizationMesh_3* class. They do not know the parameterization algorithm requirements or the kind of sparse linear system used.

#include <CGAL/Circular_border_parameterizer_3.h>

Is Model for the Concepts

Model of the *BorderParameterizer_3* concept (although you cannot instantiate this class).

Design Pattern

BorderParameterizer_3 models are Strategies [GHJV95]: they implement a strategy of border parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

template<class *ParameterizationMesh_3*>
class *Circular_border_parameterizer_3*;

Types

Circular_border_parameterizer_3<ParameterizationMesh_3>:: Adaptor

Export *ParameterizationMesh_3* template parameter.

Creation

Operations

Parameterizer_traits_3<Adaptor>::Error_code

bp.parameterize_border(Adaptor& mesh)

Assign to mesh's border vertices a 2D position (i.e. a (u, v) pair) on border's shape. Mark them as *parameterized*.

bool	*bp.is_border_convex()*	
		Indicate if border's shape is convex.
virtual double	*bp.compute_edge_length(Adaptor mesh, Vertex_const_handle source, Vertex_const_handle target) [protected, pure virtual]*	
		Compute the length of an edge.

Class

CGAL::Discrete_authalic_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

Definition

The class *Discrete_authalic_parameterizer_3* implements the Discrete Authalic Parameterization algorithm [DMA02]. This method is sometimes called *DAP* or just *Authalic parameterization*.

DAP is a weak area-preserving parameterization. It is a compromise between area-preserving and angle-preserving.

One-to-one mapping is guaranteed if surface's border is mapped onto a convex polygon.

This class is a Strategy [GHJV95] called by the main parameterization algorithm *Fixed_border_parameterizer_3::parameterize*(). *Discrete_authalic_parameterizer_3*: It provides default *BorderParameterizer_3* and *SparseLinearAlgebraTraits_d* template parameters that make sense. It implements *compute_w_ij*() to compute *w_ij* = (i, j) coefficient of matrix A for j neighbor vertex of i based on Discrete Authalic Parameterization algorithm.

Class

CGAL::Discrete_conformal_map_parameterizer_3< ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

Definition

The class *Discrete_conformal_map_parameterizer_3* implements the Discrete Conformal Map (DCM) parameterization [EDD+95]. This algorithm is also called *Discrete Conformal Parameterization (DCP)*, *Discrete Harmonic Map* or *Fixed Conformal Parameterization* by other authors.

This is a conformal parameterization, i.e. it attempts to preserve angles.

One-to-one mapping is guaranteed if surface's border is mapped onto a convex polygon.

This class is a Strategy [GHJV95] called by the main parameterization algorithm *Fixed_border_parameterizer_3::parameterize*(). It provides default *BorderParameterizer_3* and *SparseLinearAlgebraTraits_d* template parameters that make sense. It implements *compute_w_ij*() to compute *w_ij* = (i, j) coefficient of matrix A for j neighbor vertex of i based on Discrete Conformal Map method.

Class

CGAL::Fixed_border_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

Definition

The class *Fixed_border_parameterizer_3* is the base class of fixed border parameterization methods (Tutte, Floater, ...).

One-to-one mapping is guaranteed if surface's border is mapped onto a convex polygon.

This class is a pure virtual class, thus cannot be instantiated. Anyway, it implements most of the parameterization algorithm parameterize(). Subclasses are Strategies [GHJV95] that modify the behavior of this algorithm: They provide *BorderParameterizer_3* and *SparseLinearAlgebraTraits_d* template parameters that make sense. They implement *compute_w_ij*() to compute *w_ij* = (i, j) coefficient of matrix A for j neighbor vertex of i. They may implement an optimized version of *is_one_to_one_mapping*().

#include <CGAL/Fixed_border_parameterizer_3.h>

Inherits From

Parameterizer_traits_3<ParameterizationMesh_3>

Is Model for the Concepts

Model of the *ParameterizerTraits_3* concept (although you cannot instantiate this class).

Design Pattern

Fixed_border_parameterizer_3 class is a Strategy [GHJV95]: it implements (part of) a strategy of surface parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

template<class *ParameterizationMesh_3*, class *BorderParameterizer_3* = *Circular_border_arc_length_parameterizer_3<ParameterizationMesh_3>*, class *SparseLinearAlgebraTraits_d* = *OpenNL::DefaultLinearSolverTraits<typename ParameterizationMesh_3::NT>*>
class *Fixed_border_parameterizer_3*;

Types

Fixed_border_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>:: Border_param

Export *BorderParameterizer_3* template parameter.

Fixed_border_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>:: Sparse_LA

Export *SparseLinearAlgebraTraits_d* template parameter.

Creation

Fixed_border_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d> param(Border_param border_param = Border_param(), Sparse_LA sparse_la = Sparse_LA())

Constructor.
Parameters:
border_param: Object that maps the surface's border to 2D space. *sparse_la*: Traits object to access a sparse linear system.

Operations

Error_code *param.parameterize(Adaptor& mesh)*

Compute a one-to-one mapping from a triangular 3D surface *mesh* to a piece of the 2D space. The mapping is linear by pieces (linear in each triangle). The result is the (u, v) pair image of each vertex of the 3D surface.
Preconditions:
mesh must be a surface with one connected component. *mesh* must be a triangular mesh. The mesh border must be mapped onto a convex polygon.

Error_code *param.check_parameterize_preconditions(Adaptor& mesh) [protected, virtual]*

Check parameterize() preconditions: *mesh* must be a surface with one connected component. *mesh* must be a triangular mesh. The mesh border must be mapped onto a convex polygon.

void *param.initialize_system_from_mesh_border(Matrix& A, Vector& Bu, Vector& Bv, Adaptor mesh)*

Initialize A, Bu and Bv after border parameterization. Fill the border vertices' lines in both linear systems: *u = constant* and *v = constant*.
Preconditions:
Vertices must be indexed. A, Bu and Bv must be allocated. Border vertices must be parameterized.

virtual NT *param.compute_w_ij(Adaptor mesh, Vertex_const_handle main_vertex_v_i, Vertex_around_vertex_const_circulator neighbor_vertex_v_j) [protected, pure virtual]*

Compute *w_ij* = (i, j) coefficient of matrix A for j neighbor vertex of i. Implementation note: Subclasses must at least implement *compute_w_ij*().

Error_code *param.setup_inner_vertex_relations(Matrix& A, Vector& Bu, Vector& Bv, Adaptor mesh, Vertex_const_handle vertex) [protected, virtual]*

Compute the line i of matrix A for i inner vertex: call *compute_w_ij*() to compute the A coefficient *w_ij* for each neighbor *v_j*. compute *w_ii* = - sum of *w_ijs*.
Preconditions:
Vertices must be indexed. Vertex i musn't be already parameterized. Line i of A must contain only zeros.

void *param.set_mesh_uv_from_system(Adaptor& mesh, Vector Xu, Vector Xv)*

Copy Xu and Xv coordinates into the (u, v) pair of each surface vertex.

Error_code *param.check_parameterize_postconditions(Adaptor mesh, Matrix A, Vector Bu, Vector Bv) [protected, virtual]*

Check parameterize() postconditions: 3D -> 2D mapping is one-to-one.

bool *param.is_one_to_one_mapping(Adaptor mesh, Matrix A, Vector Bu, Vector Bv) [protected, virtual]*

Check if 3D -> 2D mapping is one-to-one. The default implementation checks each normal.

Border_param& *param.get_border_parameterizer()*

Get the object that maps the surface's border onto a 2D space.

Sparse_LA& *param.get_linear_algebra_traits()*

Get the sparse linear algebra (traits object to access the linear system).

SparseLinearAlgebraTraits_d::Matrix

Concept

Definition

SparseLinearAlgebraTraits_d::Matrix is a concept of a sparse matrix class.

Refines

LinearAlgebraTraits_d::Matrix

Types

Matrix:: NT

Creation

Matrix M(int dimension);	Create a square matrix initialized with zeros.
Matrix M(int rows, int columns);	Create a rectangular matrix initialized with zeros.

Operations

int *M.row_dimension() const*

Return the matrix number of rows.

int *M.column_dimension() const*

Return the matrix number of columns.

NT *M.get_coef(int row, int column) const*

Read access to a matrix coefficient.
Preconditions:
0 <= row < *row_dimension*(). 0 <= column < *column_dimension*().

void *M.add_coef(int row, int column, NT value)*

Write access to a matrix coefficient: *a_ij* <- *a_ij* + val.
Preconditions:
0 <= row < *row_dimension*(). 0 <= column < *column_dimension*().

void *M.set_coef(int row, int column, NT value, bool new_coef = false)*

Write access to a matrix coefficient: *a_ij* <- val.
Optimization: Caller can optimize this call by setting *new_coef* to true if the coefficient does not already exist in the matrix.
Preconditions:
0 <= i < *row_dimension*(). 0 <= j < *column_dimension*().

CGAL::Mean_value_coordinates_parameterizer_3< ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

Definition

The class *Mean_value_coordinates_parameterizer_3* implements Floater Mean Value Coordinates parameterization [Flo03a]. This method is sometimes called simply *Floater parameterization*.

This is a conformal parameterization, i.e. it attempts to preserve angles.

One-to-one mapping is guaranteed if the surface's border is mapped to a convex polygon.

This class is a Strategy [GHJV95] called by the main parameterization algorithm *Fixed_border_parameterizer_3::parameterize*(). It provides default *BorderParameterizer_3* and *SparseLinearAlgebraTraits_d* template parameters that make sense. It implements *compute_w_ij*() to compute *w_ij* = (i, j) coefficient of matrix A for j neighbor vertex of i based on Floater Mean Value Coordinates parameterization. It implements an optimized version of *is_one_to_one_mapping*().

#include <CGAL/Mean_value_coordinates_parameterizer_3.h>

Inherits From

Fixed_border_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

Is Model for the Concepts

Model of the *ParameterizerTraits_3* concept.

Design Pattern

Mean_value_coordinates_parameterizer_3 class is a Strategy [GHJV95]: it implements a strategy of surface parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

template<class *ParameterizationMesh_3*, class *BorderParameterizer_3* = *Circular_border_arc_length_parameterizer_3<ParameterizationMesh_3>*, class *SparseLinearAlgebraTraits_d* = *OpenNL::DefaultLinearSolverTraits<typename ParameterizationMesh_3::NT>*>
class *Mean_value_coordinates_parameterizer_3*;

Creation

Mean_value_coordinates_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d> param(Border_param border_param = Border_param(),

LA sparse_la = Sparse_LA())

Constructor.
Parameters:
border_param: Object that maps the surface's border to 2D space. *sparse_la*: Traits object to access a sparse linear system.

Operations

virtual NT *param.compute_w_ij(Adaptor mesh, Vertex_const_handle main_vertex_v_i, Vertex_around_vertex_const_circulator neighbor_vertex_v_j)*
[protected, virtual]

Compute *w_ij* = (i, j) coefficient of matrix A for j neighbor vertex of i.

virtual bool *param.is_one_to_one_mapping(Adaptor, Matrix, Vector, Vector) [protected, virtual]*

Check if 3D -> 2D mapping is one-to-one.
Theorem: one-to-one mapping is guaranteed if all *w_ij* coefficients are > 0 (for j vertex neighbor of i) and if the surface border is mapped onto a 2D convex polygon. Floater formula above implies that *w_ij* > 0 (for j vertex neighbor of i), thus mapping is guaranteed if the surface border is mapped onto a 2D convex polygon.

Concept

ParameterizationMesh_3

Definition

ParameterizationMesh_3 is a concept for a 3D surface mesh. Its main purpose is to allow the parameterization methods to access meshes in a uniform manner.

A *ParameterizationMesh_3* surface consists of vertices, facets and an incidence relation on them. No notion of edge is requested. Vertices represent points in 3d-space. Facets are planar polygons without holes defined by the circular sequence of vertices along their border. The surface itself can have holes. The vertices along the border of a hole are called *border vertices*. A surface is *closed* if it contains no border vertices.

The surface must be an oriented 2-manifold with border vertices, i.e. the neighborhood of each point on the surface is either homeomorphic to a disc or to a half disc, except for vertices where many holes and surfaces with border can join.

ParameterizationMesh_3 defines the types, data and methods that a mesh must implement to allow surface parameterization. Among other things, this concept defines accessors to fields specific to parameterizations methods: index, u, v, *is_parameterized*.

ParameterizationMesh_3 meshes can have any genus, arity or number of components. On the other hand, as parameterization methods deal only with topological disks, *ParameterizationMesh_3* defines an interface oriented towards topological disks.

Design Pattern

ParameterizationMesh_3 is an Adaptor [GHJV95]: it changes the interface of a 3D mesh to match the interface expected by the parameterization methods.

Types

The following mutable handles, iterators, and circulators have appropriate non-mutable counterparts, i.e. *const_handle*, *const_iterator*, and *const_circulator*. The mutable types are assignable to their non-mutable counterparts. Both circulators are assignable to the *Vertex_iterator*. The iterators are assignable to the respective handle types. Wherever the handles appear in function parameter lists, the corresponding iterators can be used as well.

ParameterizationMesh_3:: NT	Number type to represent coordinates.
ParameterizationMesh_3:: Point_2	2D point that represents (u, v) coordinates computed by parameterization methods. Must provide X() and Y() methods.
ParameterizationMesh_3:: Point_3	3D point that represents vertices coordinates. Must provide X() and Y() methods.
ParameterizationMesh_3:: Vector_2	2D vector. Must provide X() and Y() methods.
ParameterizationMesh_3:: Vector_3	3D vector. Must provide X() and Y() methods.
ParameterizationMesh_3:: Facet	Opaque type representing a facet of the 3D mesh. No methods are expected.
ParameterizationMesh_3:: Facet_handle	Handle to a facet. Model of the Handle concept.
ParameterizationMesh_3:: Facet_const_handle	
ParameterizationMesh_3:: Facet_iterator	Iterator over all mesh facets. Model of the *ForwardIterator* concept.

ParameterizationMesh_3:: Facet_const_iterator	
ParameterizationMesh_3:: Vertex	Opaque type representing a vertex of the 3D mesh. No methods are expected.
ParameterizationMesh_3:: Vertex_handle	Handle to a vertex. Model of the Handle concept.
ParameterizationMesh_3:: Vertex_const_handle	
ParameterizationMesh_3:: Vertex_iterator	Iterator over all vertices of a mesh. Model of the *ForwardIterator* concept.
ParameterizationMesh_3:: Vertex_const_iterator	
ParameterizationMesh_3:: Border_vertex_iterator	Iterator over vertices of the mesh *main border*. Model of the *ForwardIterator* concept.
ParameterizationMesh_3:: Border_vertex_const_iterator	
ParameterizationMesh_3:: Vertex_around_facet_circulator	Counter-clockwise circulator over a facet's vertices. Model of the *BidirectionalCirculator* concept.
ParameterizationMesh_3:: Vertex_around_facet_const_circulator	
ParameterizationMesh_3:: Vertex_around_vertex_circulator	Clockwise circulator over the vertices incident to a vertex. Model of the *BidirectionalCirculator* concept.
ParameterizationMesh_3:: Vertex_around_vertex_const_circulator	

Creation

Construction and destruction are undefined.

Operations

The following mutable methods returning a handle, iterator, or circulator have appropriate non-mutable counterpart methods, i.e. *const*, returning a *const_handle*, *const_iterator*, or *const_circulator*.

bool	*mesh.is_valid() const*	Indicate if the mesh matches the *ParameterizationMesh_3* concept.
Vertex_iterator	*mesh.mesh_vertices_begin()*	Get iterator over first vertex of mesh.
Vertex_const_iterator	*mesh.mesh_vertices_begin() const*	
Vertex_iterator	*mesh.mesh_vertices_end()*	Get iterator over past-the-end vertex of mesh.
Vertex_const_iterator	*mesh.mesh_vertices_end() const*	
int	*mesh.count_mesh_vertices() const*	Count the number of vertices of the mesh.

void *mesh.index_mesh_vertices()*

Index vertices of the mesh from 0 to *count_mesh_vertices*()-1.

Border_vertex_iterator

mesh.mesh_main_border_vertices_begin()

Get iterator over first vertex of mesh's *main border*.

Border_vertex_const_iterator

mesh.mesh_main_border_vertices_begin() const

Border_vertex_iterator

mesh.mesh_main_border_vertices_end()

Get iterator over past-the-end vertex of mesh's *main border*.

Border_vertex_const_iterator

mesh.mesh_main_border_vertices_end() const

std::list<Vertex_handle>

mesh.get_border(Vertex_handle seed_vertex)

Return the border containing *seed_vertex*. Return an empty list if not found.

Facet_iterator *mesh.mesh_facets_begin()*

Get iterator over first facet of mesh.

Facet_const_iterator *mesh.mesh_facets_begin() const*

Facet_iterator *mesh.mesh_facets_end()*

Get iterator over past-the-end facet of mesh.

Facet_const_iterator *mesh.mesh_facets_end() const*

int *mesh.count_mesh_facets() const*

Count the number of facets of the mesh.

bool *mesh.is_mesh_triangular() const*

Return true of all mesh's facets are triangles.

int *mesh.count_mesh_halfedges() const*

Count the number of halfedges of the mesh.

Vertex_around_facet_circulator

mesh.facet_vertices_begin(Facet_handle facet)

Get circulator over facet's vertices.

Vertex_around_facet_const_circulator

mesh.facet_vertices_begin(Facet_const_handle facet) const *int* *mesh.count_facet_vertices(Facet_const_handle facet) const*

Count the number of vertices of a facet.

Point_3 *mesh.get_vertex_position(Vertex_const_handle vertex) const*

Get the 3D position of a vertex.

Point_2 *mesh.get_vertex_uv(Vertex_const_handle vertex) const*

Get/set the 2D position (u/v pair) of a vertex. Default value is undefined.

void *mesh.set_vertex_uv(Vertex_handle vertex, Point_2 uv)*

bool *mesh.is_vertex_parameterized(Vertex_const_handle vertex) const*

Get/set *is parameterized* field of vertex. Default value is undefined.

void *mesh.set_vertex_parameterized(Vertex_handle vertex, bool parameterized)*

int *mesh.get_vertex_index(Vertex_const_handle vertex) const*

Get/set vertex index. Default value is undefined.

void *mesh.set_vertex_index(Vertex_handle vertex, int index)*

int *mesh.get_vertex_tag(Vertex_const_handle vertex) const*

Get/set vertex' all purpose tag. Default value is undefined.

void *mesh.set_vertex_tag(Vertex_handle vertex, int tag)*

bool *mesh.is_vertex_on_border(Vertex_const_handle vertex) const*

Return true if a vertex belongs to ANY mesh's border.

bool *mesh.is_vertex_on_main_border(Vertex_const_handle vertex) const*

Return true if a vertex belongs to the UNIQUE mesh's main border.

Vertex_around_vertex_circulator

mesh.vertices_around_vertex_begin(Vertex_handle vertex, Vertex_handle start_position = Vertex_handle())

Get circulator over the vertices incident to *vertex*. *start_position* defines the optional initial position of the circulator.

Vertex_around_vertex_const_circulator

mesh.vertices_around_vertex_begin(Vertex_const_handle vertex, Vertex_const_handle start_position = Vertex_const_handle())

Has Models

We provide 2 models of this concept:

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>
Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>

CGAL::Parameterization_mesh_feature_extractor< ParameterizationMesh_3>

Class

Definition

The class *Parameterization_mesh_feature_extractor* computes features (genus, borders, ...) of a 3D surface, model of the *ParameterizationMesh_3* concept.

#include <CGAL/Parameterization_mesh_feature_extractor.h>

Parameters

The full template declaration is:

template<class *ParameterizationMesh_3*>
class *Parameterization_mesh_feature_extractor*;

Types

Parameterization_mesh_feature_extractor<ParameterizationMesh_3>:: Adaptor

Export *ParameterizationMesh_3* template parameter.

Parameterization_mesh_feature_extractor<ParameterizationMesh_3>:: Border

Type representing a border = STL container of vertex handles.

Parameterization_mesh_feature_extractor<ParameterizationMesh_3>:: Skeleton

Type representing the list of all borders of the mesh = STL container of Border elements.

Creation

Parameterization_mesh_feature_extractor<ParameterizationMesh_3> extractor(Adaptor& mesh);

Constructor.
CAUTION: This class caches the result of feature extractions => The caller must **not** modify *mesh* during the *Parameterization_mesh_feature_extractor* life cycle.

Operations

int *extractor.get_nb_borders()*

Get number of borders.

Skeleton *extractor.get_borders()*

Get extracted borders. The longest border is the first one.

Border	*extractor.get_longest_border()*	
		Get longest border.
int	*extractor.get_nb_connex_components()*	
		Get # of connected components.
int	*extractor.get_genus()*	Get the genus.

CGAL::Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>

Class

Definition

Parameterization_mesh_patch_3 is a Decorator class to *virtually* cut a patch in a *ParameterizationPatchableMesh_3* 3D surface. Only the patch is exported, making the 3D surface look like a topological disk.

The input mesh can be of any genus, but it has to come with a *seam* that describes the border of a topological disc. This border may be an actual border of the mesh or a virtual border.

#include <CGAL/Parameterization_mesh_patch_3.h>

Is Model for the Concepts

Model of *ParameterizationMesh_3* concept, whose purpose is to allow the *Surface_mesh_parameterization* package to access meshes in a uniform manner.

Design Pattern

Parameterization_mesh_patch_3 is a Decorator [GHJV95]: it changes the behavior of a *ParameterizationPatchableMesh_3* 3D surface while keeping its *ParameterizationMesh_3* interface.

Parameters

The full template declaration is:

template<class *ParameterizationPatchableMesh_3*>
class *Parameterization_mesh_patch_3*;

Parameters:
ParameterizationPatchableMesh_3: 3D surface mesh.

Types

The following mutable handles, iterators, and circulators have appropriate non-mutable counterparts, i.e. *const_handle*, *const_iterator*, and *const_circulator*. The mutable types are assignable to their non-mutable counterparts. Both circulators are assignable to the *Vertex_iterator*. The iterators are assignable to the respective handle types. Wherever the handles appear in function parameter lists, the corresponding iterators can be used as well.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Adaptor

Export template parameter.

Types implementing the ParameterizationMesh_3 interface

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: NT

Number type to represent coordinates.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Point_2

2D point that represents (u, v) coordinates computed by parameterization methods. Must provide X() and Y() methods.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Point_3

3D point that represents vertices coordinates. Must provide X() and Y() methods.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vector_2

2D vector. Must provide X() and Y() methods.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vector_3

3D vector. Must provide X() and Y() methods.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Facet

Opaque type representing a facet of the 3D mesh. No methods are expected.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Facet_handle

Handle to a facet. Model of the Handle concept.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Facet_const_handle
Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Facet_iterator

Iterator over all mesh facets. Model of the *ForwardIterator* concept.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Facet_const_iterator
Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex

Opaque type representing a vertex of the 3D mesh. No methods are expected.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_handle

Handle to a vertex. Model of the Handle concept.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_const_handle
Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_iterator

Iterator over all vertices of a mesh. Model of the *ForwardIterator* concept.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_const_iterator
Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Border_vertex_iterator

Iterator over vertices of the mesh *main border*. Model of the *ForwardIterator* concept.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Border_vertex_const_iterator

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_around_facet_circulator

Counter-clockwise circulator over a facet's vertices. Model of the *BidirectionalCirculator* concept.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_around_facet_const_circulator
Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_around_vertex_circulator

Clockwise circulator over the vertices incident to a vertex. Model of the *BidirectionalCirculator* concept.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_around_vertex_const_circulator

Variables

Adaptor&	*m_mesh_adaptor;*	The decorated mesh.

Creation

template<class InputIterator>
Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3> mesh(Adaptor& mesh, InputIterator first_seam_vertex, InputIterator end_seam_vertex)

Create a Decorator for an existing *ParameterizationPatchableMesh_3* mesh. The input mesh can be of any genus, but it has to come with a *seam* that describes the border of a topological disc. This border may be an actual border of the mesh or a virtual border.
Preconditions:
first_seam_vertex -> *end_seam_vertex* defines the outer seam, i.e. *Parameterization_mesh_patch_3* will export the *right* of the seam. The *seam* is given as a container of *Adaptor::Vertex_handle* elements. The *seam* is implicitely a loop. The first vertex should **not** be duplicated at the end.

Operations

The following methods returning a mutable handle, iterator, or circulator have appropriate non-mutable counterpart methods, i.e. *const*, returning a *const_handle*, *const_iterator*, or *const_circulator*.

Adaptor& *mesh.get_decorated_mesh()*

Returns: the decorated mesh.

Adaptor *mesh.get_decorated_mesh() const*

Methods implementing the ParameterizationMesh_3 interface

bool *mesh.is_valid() const* Indicate if the mesh matches the *ParameterizationMesh_3* concept.

Vertex_iterator *mesh.mesh_vertices_begin()*

Get iterator over first vertex of mesh.

Vertex_const_iterator

mesh.mesh_vertices_begin() const

Vertex_iterator *mesh.mesh_vertices_end()*

Get iterator over past-the-end vertex of mesh.

Vertex_const_iterator

mesh.mesh_vertices_end() const

int *mesh.count_mesh_vertices() const*

Count the number of vertices of the mesh.

void *mesh.index_mesh_vertices()*

Index vertices of the mesh from 0 to *count_mesh_vertices*()-1.

Border_vertex_iterator

mesh.mesh_main_border_vertices_begin()

Get iterator over first vertex of mesh's main border (aka *seam*).

Border_vertex_const_iterator

mesh.mesh_main_border_vertices_begin() const

Border_vertex_iterator

mesh.mesh_main_border_vertices_end()

Get iterator over past-the-end vertex of mesh's main border (aka *seam*).

Border_vertex_const_iterator

mesh.mesh_main_border_vertices_end() const

std::list<Vertex_handle>

mesh.get_border(Vertex_handle seed_vertex)

Returns: the border containing *seed_vertex* (or an empty list if not found).
Parameters:
seed_vertex: a border vertex.

Facet_iterator *mesh.mesh_facets_begin()*

Get iterator over first facet of mesh.

Facet_const_iterator *mesh.mesh_facets_begin() const*

Facet_iterator *mesh.mesh_facets_end()*

Get iterator over past-the-end facet of mesh.

Facet_const_iterator *mesh.mesh_facets_end() const*

int *mesh.count_mesh_facets() const*

Count the number of facets of the mesh.

bool *mesh.is_mesh_triangular() const*

Return true of all mesh's facets are triangles.

int *mesh.count_mesh_halfedges() const*

Count the number of halfedges of the mesh.

Vertex_around_facet_circulator

mesh.facet_vertices_begin(Facet_handle facet)

Get circulator over facet's vertices.

Vertex_around_facet_const_circulator

mesh.facet_vertices_begin(Facet_const_handle facet) const

int *mesh.count_facet_vertices(Facet_const_handle facet) const*

Count the number of vertices of a facet.

Point_3 *mesh.get_vertex_position(Vertex_const_handle vertex) const*

Get the 3D position of a vertex.

Point_2 *mesh.get_vertex_uv(Vertex_const_handle vertex) const*

Get/set the 2D position (u/v pair) of a vertex. Default value is undefined.

void *mesh.set_vertex_uv(Vertex_handle vertex, Point_2 uv)*

bool *mesh.is_vertex_parameterized(Vertex_const_handle vertex) const*

Get/set *is parameterized* field of vertex. Default value is undefined.

void *mesh.set_vertex_parameterized(Vertex_handle vertex, bool parameterized)*

int *mesh.get_vertex_index(Vertex_const_handle vertex) const*

Get/set vertex index. Default value is undefined.

void *mesh.set_vertex_index(Vertex_handle vertex, int index)*

int *mesh.get_vertex_tag(Vertex_const_handle vertex) const*

Get/set vertex' all purpose tag. Default value is undefined.

void *mesh.set_vertex_tag(Vertex_handle vertex, int tag)*

bool *mesh.is_vertex_on_border(Vertex_const_handle vertex) const*

Return true if a vertex belongs to ANY mesh's border.

bool *mesh.is_vertex_on_main_border(Vertex_const_handle vertex) const*

Return true if a vertex belongs to the UNIQUE mesh's main border set by the constructor.

Vertex_around_vertex_circulator

mesh.vertices_around_vertex_begin(Vertex_handle vertex, Vertex_handle start_position = Vertex_handle())

Get circulator over the vertices incident to *vertex*. *start_position* defines the optional initial position of the circulator.

Vertex_around_vertex_const_circulator

mesh.vertices_around_vertex_begin(Vertex_const_handle vertex, Vertex_const_handle start_position = Vertex_const_handle())

Example

See *Mesh_cutting_parameterization.cpp* example.

Concept

ParameterizationPatchableMesh_3

Definition

ParameterizationPatchableMesh_3 inherits from concept *ParameterizationMesh_3*, thus is a concept of a 3D surface mesh.

ParameterizationPatchableMesh_3 adds the ability to support patches and virtual seams. *Patches* are a subset of a 3D mesh. *Virtual seams* are the ability to behave exactly as if the surface was cut following a certain path.

This mainly means that: vertices can be tagged as inside or outside the patch to parameterize. the fields specific to parameterizations (index, u, v, *is_parameterized*) can be set per *corner* (aka half-edge).

The main purpose of this feature is to allow the *Surface_mesh_parameterization* package to parameterize any 3D surface by decomposing it as a list of topological disks.

Design Pattern

ParameterizationPatchableMesh_3 is an Adaptor [GHJV95]: it changes the interface of a 3D mesh to match the interface expected by class *Parameterization_mesh_patch_3*.

Refines

ParameterizationMesh_3

In addition to the requirements described in the concept *ParameterizationMesh_3*, *ParameterizationPatchableMesh_3* provides the following:

Creation

Construction and destruction are undefined.

Operations

int	*mesh.get_vertex_seaming(Vertex_const_handle vertex) const*	
		Get/set vertex seaming flag. Default value is undefined.
void	*mesh.set_vertex_seaming(Vertex_handle vertex, int seaming)*	
int	*mesh.get_halfedge_seaming(Vertex_const_handle source, Vertex_const_handle target) const*	
		Get/set oriented edge's seaming flag, i.e. position of the oriented edge w.r.t. to the UNIQUE main border.
void	*mesh.set_halfedge_seaming(Vertex_handle source, Vertex_handle target, int seaming)*	

Point_2	*mesh.get_corners_uv(Vertex_const_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex) const*	
		Get/set the 2D position (= (u, v) pair) of corners at the *right* of the *prev_vertex* -> vertex -> *next_vertex* line. Default value is undefined.
void	*mesh.set_corners_uv(Vertex_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex, Point_2 uv)*	
bool	*mesh.are_corners_parameterized(Vertex_const_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex) const*	
		Get/set *is parameterized* field of corners at the *right* of the *prev_vertex* -> vertex -> *next_vertex* line. Default value is undefined.
void	*mesh.set_corners_parameterized(Vertex_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex, bool parameterized)*	
int	*mesh.get_corners_index(Vertex_const_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex) const*	
		Get/set index of corners at the *right* of the *prev_vertex* -> vertex -> *next_vertex* line. Default value is undefined.
void	*mesh.set_corners_index(Vertex_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex, int index)*	
int	*mesh.get_corners_tag(Vertex_const_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex) const*	
		Get/set all purpose tag of corners at the *right* of the *prev_vertex* -> vertex -> *next_vertex* line. Default value is undefined.
void	*mesh.set_corners_tag(Vertex_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex, int tag)*	

Has Models

Adaptator for *Polyhedron_3* is provided.

Class

CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron_3_>

Definition

Parameterization_polyhedron_adaptor_3 is an adaptor class to access to a Polyhedron 3D mesh using the *ParameterizationPatchableMesh_3* interface. Among other things, this concept defines the accessor to the (u, v) values computed by parameterizations methods.

Note that these interfaces are decorators that add *on the fly* the necessary fields to unmodified CGAL data structures (using STL maps). For performance reasons, it is recommended to use CGAL data structures enriched with the proper fields.

A *ParameterizationMesh_3* surface consists of vertices, facets and an incidence relation on them. No notion of edge is requested.

ParameterizationMesh_3 meshes can have any genus, arity or number of components.

It can have have any number of borders. Its *main border* will be the mesh's longest border (if there is at least one border).

It has also the ability to support patches and virtual seams. *Patches* are a subset of a 3D mesh. *Virtual seams* are the ability to behave exactly as if the surface was cut following a certain path.

#include <CGAL/Parameterization_polyhedron_adaptor_3.h>

Is Model for the Concepts

Model of *ParameterizationPatchableMesh_3* concept, whose purpose is to allow the *Surface_mesh_parameterization* package to access meshes in a uniform manner.

Design Pattern

Parameterization_polyhedron_adaptor_3 is an Adaptor [GHJV95]: it changes the Polyhedron interface to match the *ParameterizationPatchableMesh_3* concept.

Parameters

The full template declaration is:

template<class *Polyhedron_3_*>
class *Parameterization_polyhedron_adaptor_3*;

*Polyhedron_3_* must be of type *CGAL::Polyhedron<Traits>* and *Traits* must be a model of the concept *PolyhedronTraitsWithKernel_3*.

Types

The following mutable handles, iterators, and circulators have appropriate non-mutable counterparts, i.e. *const_handle*, *const_iterator*, and *const_circulator*. The mutable types are assignable to their non-mutable counterparts. Both circulators are assignable to the *Vertex_iterator*. The iterators are assignable to the respective handle types. Wherever the handles appear in function parameter lists, the corresponding iterators can be used as well.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Polyhedron

Export template parameter.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: NT

Number type to represent coordinates.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Point_2

2D point that represents (u, v) coordinates computed by parameterization methods. Must provide X() and Y() methods.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Point_3

3D point that represents vertices coordinates. Must provide X() and Y() methods.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vector_2

2D vector. Must provide X() and Y() methods.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vector_3

3D vector. Must provide X() and Y() methods.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Facet

Opaque type representing a facet of the 3D mesh. No methods are expected.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Facet_handle

Handle to a facet. Model of the Handle concept.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Facet_const_handle
Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Facet_iterator

Iterator over all mesh facets. Model of the *ForwardIterator* concept.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Facet_const_iterator
Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vertex

Opaque type representing a vertex of the 3D mesh. No methods are expected.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vertex_handle

Handle to a vertex. Model of the Handle concept.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vertex_const_handle
Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vertex_iterator

Iterator over all vertices of a mesh. Model of the *ForwardIterator* concept.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vertex_const_iterator
Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Border_vertex_iterator

Iterator over vertices of the mesh *main border*. Model of the *ForwardIterator* concept.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Border_vertex_const_iterator

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vertex_around_facet_circulator

Counter-clockwise circulator over a facet's vertices. Model of the *BidirectionalCirculator* concept.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vertex_around_facet_const_circulator
Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vertex_around_vertex_circulator

Clockwise circulator over the vertices incident to a vertex. Model of the *BidirectionalCirculator* concept.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vertex_around_vertex_const_circulator

Creation

Parameterization_polyhedron_adaptor_3<Polyhedron_3_> mesh(Polyhedron& mesh);

Create an adaptator for an existing *Polyhedron_3* mesh. The input mesh can be of any genus. It can have have any number of borders. Its *main border* will be the mesh's longest border (if there is at least one border).

Operations

The following methods returning a mutable handle, iterator, or circulator have appropriate non-mutable counterpart methods, i.e. *const*, returning a *const_handle*, *const_iterator*, or *const_circulator*.

Polyhedron& *mesh.get_adapted_mesh()*

Get the adapted mesh.

Polyhedron *mesh.get_adapted_mesh() const*
Polyhedron::Halfedge_const_handle

mesh.get_halfedge(Vertex_const_handle source, Vertex_const_handle target) const

Get halfedge from source and target vertices. Will assert if such a halfedge doesn't exist.

Polyhedron::Halfedge_handle

mesh.get_halfedge(Vertex_handle source, Vertex_handle target)
*const Halfedge_info** *mesh.info(Halfedge_const_handle halfedge) const*

Access to additional info attached to halfedges.

*Halfedge_info** *mesh.info(Halfedge_const_handle halfedge)*
*const Vertex_info** *mesh.info(Vertex_const_handle vertex) const*

Access to additional info attached to vertices.

*Vertex_info** *mesh.info(Vertex_const_handle vertex)*
bool *mesh.is_valid() const* Indicate if the mesh matches the *ParameterizationMesh_3* concept.

Vertex_iterator *mesh.mesh_vertices_begin()*

Get iterator over first vertex of mesh.

Vertex_const_iterator

mesh.mesh_vertices_begin() const

Vertex_iterator *mesh.mesh_vertices_end()*

Get iterator over past-the-end vertex of mesh.

Vertex_const_iterator

mesh.mesh_vertices_end() const

int *mesh.count_mesh_vertices() const*

Count the number of vertices of the mesh.

void *mesh.index_mesh_vertices()*

Border_vertex_iterator

mesh.mesh_main_border_vertices_begin()

Get iterator over first vertex of mesh's *main border*.

Border_vertex_const_iterator

mesh.mesh_main_border_vertices_begin() const

Border_vertex_iterator

mesh.mesh_main_border_vertices_end()

Get iterator over past-the-end vertex of mesh's *main border*.

Border_vertex_const_iterator

mesh.mesh_main_border_vertices_end() const

std::list<Vertex_handle>

mesh.get_border(Vertex_handle seed_vertex)

Return the border containing *seed_vertex*. Return an empty list if not found.

Facet_iterator *mesh.mesh_facets_begin()*

Get iterator over first facet of mesh.

Facet_const_iterator *mesh.mesh_facets_begin() const*

Facet_iterator *mesh.mesh_facets_end()*

Get iterator over past-the-end facet of mesh.

Facet_const_iterator *mesh.mesh_facets_end() const*

int *mesh.count_mesh_facets() const*

Count the number of facets of the mesh.

bool *mesh.is_mesh_triangular() const*

Return true of all mesh's facets are triangles.

int *mesh.count_mesh_halfedges() const*

Count the number of halfedges of the mesh.

Vertex_around_facet_circulator

mesh.facet_vertices_begin(Facet_handle facet)

Get circulator over facet's vertices.

Vertex_around_facet_const_circulator

	mesh.facet_vertices_begin(Facet_const_handle facet) const	
int	*mesh.count_facet_vertices(Facet_const_handle facet) const*	
		Count the number of vertices of a facet.
Point_3	*mesh.get_vertex_position(Vertex_const_handle vertex) const*	
		Get the 3D position of a vertex.
Point_2	*mesh.get_vertex_uv(Vertex_const_handle vertex) const*	
		Get/set the 2D position (u/v pair) of a vertex. Default value is undefined. (stored in halfedges sharing the same vertex).
void	*mesh.set_vertex_uv(Vertex_handle vertex, Point_2 uv)*	
bool	*mesh.is_vertex_parameterized(Vertex_const_handle vertex) const*	
		Get/set *is parameterized* field of vertex. Default value is undefined. (stored in halfedges sharing the same vertex).
void	*mesh.set_vertex_parameterized(Vertex_handle vertex, bool parameterized)*	
int	*mesh.get_vertex_index(Vertex_const_handle vertex) const*	
		Get/set vertex index. Default value is undefined. (stored in Polyhedron vertex for debugging purpose).
void	*mesh.set_vertex_index(Vertex_handle vertex, int index)*	
int	*mesh.get_vertex_tag(Vertex_const_handle vertex) const*	
		Get/set vertex' all purpose tag. Default value is undefined. (stored in halfedges sharing the same vertex).
void	*mesh.set_vertex_tag(Vertex_handle vertex, int tag)*	
bool	*mesh.is_vertex_on_border(Vertex_const_handle vertex) const*	
		Return true if a vertex belongs to ANY mesh's border.
bool	*mesh.is_vertex_on_main_border(Vertex_const_handle vertex) const*	
		Return true if a vertex belongs to the UNIQUE mesh's main border, i.e. the mesh's LONGEST border.

Vertex_around_vertex_circulator

	mesh.vertices_around_vertex_begin(Vertex_handle vertex, Vertex_handle start_position = Vertex_handle())	
		Get circulator over the vertices incident to *vertex*. *start_position* defines the optional initial position of the circulator.

Vertex_around_vertex_const_circulator

	mesh.vertices_around_vertex_begin(Vertex_const_handle vertex, Vertex_const_handle start_position = Vertex_const_handle())	
int	*mesh.get_vertex_seaming(Vertex_const_handle vertex) const*	
		Get/set vertex seaming flag. Default value is undefined.
void	*mesh.set_vertex_seaming(Vertex_handle vertex, int seaming)*	

int	*mesh.get_halfedge_seaming(Vertex_const_handle source, Vertex_const_handle target) const*	
		Get/set oriented edge's seaming flag, i.e. position of the oriented edge w.r.t. to the UNIQUE main border.
void	*mesh.set_halfedge_seaming(Vertex_handle source, Vertex_handle target, int seaming)*	
Point_2	*mesh.get_corners_uv(Vertex_const_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex) const*	
		Get/set the 2D position (= (u, v) pair) of corners at the *right* of the *prev_vertex* -> vertex -> *next_vertex* line. Default value is undefined. (stored in incident halfedges).
void	*mesh.set_corners_uv(Vertex_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex, Point_2 uv)*	
bool	*mesh.are_corners_parameterized(Vertex_const_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex) const*	
		Get/set *is parameterized* field of corners at the *right* of the *prev_vertex* -> vertex -> *next_vertex* line. Default value is undefined. (stored in incident halfedges).
void	*mesh.set_corners_parameterized(Vertex_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex, bool parameterized)*	
int	*mesh.get_corners_index(Vertex_const_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex) const*	
		Get/set index of corners at the *right* of the *prev_vertex* -> vertex -> *next_vertex* line. Default value is undefined. (stored in incident halfedges).
void	*mesh.set_corners_index(Vertex_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex, int index)*	
int	*mesh.get_corners_tag(Vertex_const_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex) const*	
		Get/set all purpose tag of corners at the *right* of the *prev_vertex* -> vertex -> *next_vertex* line. Default value is undefined. (stored in incident halfedges).
void	*mesh.set_corners_tag(Vertex_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex, int tag)*

CGAL::Parameterizer_traits_3<ParameterizationMesh_3>

Class

Definition

The class *Parameterizer_traits_3* is the base class of all parameterization methods. This class is a pure virtual class, thus cannot be instantiated.

This class doesn't do much. Its main goal is to ensure that subclasses will be proper models of the *ParameterizerTraits_3* concept: *Parameterizer_traits_3* defines the *Error_code* list of errors detected by this package. *Parameterizer_traits_3* declares a pure virtual method parameterize().

#include <CGAL/Parameterizer_traits_3.h>

Is Model for the Concepts

Model of the *ParameterizerTraits_3* concept (although you cannot instantiate this class).

Design Pattern

ParameterizerTraits_3 models are Strategies [GHJV95]: they implement a strategy of surface parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

template<class *ParameterizationMesh_3*>
class *Parameterizer_traits_3*;

Types

Parameterizer_traits_3<ParameterizationMesh_3>:: Adaptor

Export *ParameterizationMesh_3* template parameter.

Parameterizer_traits_3<ParameterizationMesh_3>:: NT
Parameterizer_traits_3<ParameterizationMesh_3>:: Point_2
Parameterizer_traits_3<ParameterizationMesh_3>:: Point_3
Parameterizer_traits_3<ParameterizationMesh_3>:: Vector_2
Parameterizer_traits_3<ParameterizationMesh_3>:: Vector_3
Parameterizer_traits_3<ParameterizationMesh_3>:: Facet
Parameterizer_traits_3<ParameterizationMesh_3>:: Facet_handle
Parameterizer_traits_3<ParameterizationMesh_3>:: Facet_const_handle
Parameterizer_traits_3<ParameterizationMesh_3>:: Facet_iterator
Parameterizer_traits_3<ParameterizationMesh_3>:: Facet_const_iterator
Parameterizer_traits_3<ParameterizationMesh_3>:: Vertex

ERROR_NON_CONVEX_BORDER,
ERROR_CANNOT_SOLVE_LINEAR_SYSTEM,
ERROR_NO_1_TO_1_MAPPING,
ERROR_OUT_OF_MEMORY,
ERROR_WRONG_PARAMETER}

List of errors detected by this package.
Values:
OK: Success. *ERROR_EMPTY_MESH*: Input mesh is empty. *ERROR_NON_TRIANGULAR_MESH*: Input mesh is not triangular. *ERROR_NO_TOPOLOGICAL_DISC*: Input mesh is not a topological disc. *ERROR_BORDER_TOO_SHORT*: This border parameterization requires a longer border. *ERROR_NON_CONVEX_BORDER*: This parameterization method requires a convex border. *ERROR_CANNOT_SOLVE_LINEAR_SYSTEM*: Cannot solve linear system. *ERROR_NO_1_TO_1_MAPPING*: Parameterization failed: no one-to-one mapping. *ERROR_OUT_OF_MEMORY*: Not enough memory. *ERROR_WRONG_PARAMETER*: A method received an unexpected parameter.

Creation

Operations

virtual Error_code *param.parameterize(Adaptor& mesh)*

Compute a one-to-one mapping from a 3D surface *mesh* to a piece of the 2D space. The mapping is linear by pieces (linear in each triangle). The result is the (u, v) pair image of each vertex of the 3D surface.
Preconditions:
mesh must be a surface with one connected component. *mesh* must be a triangular mesh.

*static const char** *param.get_error_message(int error_code)*

Get message (in English) corresponding to an error code
Parameters:
error_code: The code returned by parameterize().
Returns: The string describing the error code

ERROR_OUT_OF_MEMORY,
ERROR_WRONG_PARAMETER}

List of errors detected by this package.
Values:
OK: Success. *ERROR_EMPTY_MESH*: Input mesh is empty. *ERROR_NON_TRIANGULAR_MESH*: Input mesh is not triangular. *ERROR_NO_TOPOLOGICAL_DISC*: Input mesh is not a topological disc. *ERROR_BORDER_TOO_SHORT*: This border parameterization requires a longer border. *ERROR_NON_CONVEX_BORDER*: This parameterization method requires a convex border. *ERROR_CANNOT_SOLVE_LINEAR_SYSTEM*: Cannot solve linear system. *ERROR_NO_1_TO_1_MAPPING*: Parameterization failed: no one-to-one mapping. *ERROR_OUT_OF_MEMORY*: Not enough memory. *ERROR_WRONG_PARAMETER*: A method received an unexpected parameter.

Creation

Construction and destruction are undefined.

Operations

Error_code *param.parameterize(Adaptor& mesh)*

Compute a one-to-one mapping from a triangular 3D surface *mesh* to a piece of the 2D space. The mapping is linear by pieces (linear in each triangle). The result is the (u, v) pair image of each vertex of the 3D surface.
Preconditions:
mesh must be a surface with one connected component and no hole. *mesh* must be a triangular mesh.

Function

CGAL::parameterize

Definition

CGAL::parameterize() is the main entry-point of the *Surface_mesh_parameterization* package.

It computes a one-to-one mapping from a 3D triangle surface 'mesh' to a simple 2D domain. The mapping is piecewise linear on the triangle mesh. The result is a pair (u,v) of parameter coordinates for each vertex of the input mesh. One-to-one mapping may be guaranteed or not, depending on the chosen *ParametizerTraits* algorithm.

The *CGAL::parameterize()* function exists in two flavors, to provide a default parameterization algorithm of Floater Mean Value Coordinates.

#include <CGAL/parameterize.h>

template<class ParameterizationMesh_3>
Parameterizer_traits_3<ParameterizationMesh_3>::Error_code

parameterize(ParameterizationMesh_3& mesh)

Compute a one-to-one mapping from a 3D triangle surface *mesh* to a 2D circle, using Floater Mean Value Coordinates algorithm. A one-to-one mapping is guaranteed.
The mapping is piecewise linear on the input mesh triangles. The result is a (u, v) pair of parameter coordinates for each vertex of the input mesh.
Preconditions:
mesh must be a surface with one connected component. *mesh* must be a triangular mesh.
Parameters:
mesh: 3D mesh, model of *ParameterizationMesh_3* concept.

template<class ParameterizationMesh_3, class ParameterizerTraits_3>
Parameterizer_traits_3<ParameterizationMesh_3>::Error_code

parameterize(ParameterizationMesh_3& mesh, ParameterizerTraits_3 parameterizer)

Compute a one-to-one mapping from a 3D triangle surface *mesh* to a simple 2D domain. The mapping is piecewise linear on the triangle mesh. The result is a pair (u, v) of parameter coordinates for each vertex of the input mesh.
One-to-one mapping may be guaranteed or not, depending on the chosen *ParametizerTraits_3* algorithm.
Preconditions:
mesh must be a surface with one connected component. *mesh* must be a triangular mesh. The mesh border must be mapped onto a convex polygon (for fixed border parameterizations).
Parameters:
mesh: 3D mesh, model of *ParameterizationMesh_3*. *parameterizer*: Parameterization method for *mesh*.

Example

See *Simple_parameterization.cpp* example.

Implementation

This function simply calls the parameterize() method of the parameterization algorithm chosen.

Concept

SparseLinearAlgebraTraits_d

Definition

The concept *SparseLinearAlgebraTraits_d* is used to solve sparse linear systems $A*X = B$.

Refines

LinearAlgebraTraits_d

Types

SparseLinearAlgebraTraits_d:: Matrix
SparseLinearAlgebraTraits_d:: Vector
SparseLinearAlgebraTraits_d:: NT

Creation

SparseLinearAlgebraTraits_d sparse_LA; Default constructor.

Operations

bool *sparse_LA.linear_solver(Matrix A, Vector B, Vector& X, NT& D)*

Solve the sparse linear system $A*X = B$. Return true on success. The solution is then (1/D) $*$ X.
Preconditions:
A.*row_dimension*() == B.dimension(). A.*column_dimension*() == X.dimension().

CGAL::Square_border_arc_length_parameterizer_3< ParameterizationMesh_3>

Class

Definition

This class parameterizes the border of a 3D surface onto a square, with an arc-length parameterization: (u, v) values are proportional to the length of border edges.

Square_border_parameterizer_3 implements most of the border parameterization algorithm. This class implements only *compute_edge_length*() to compute a segment's length.

#include <CGAL/Square_border_parameterizer_3.h>

Inherits From

Square_border_parameterizer_3<ParameterizationMesh_3>

Is Model for the Concepts

Model of the *BorderParameterizer_3* concept.

Design Pattern

BorderParameterizer_3 models are Strategies [GHJV95]: they implement a strategy of border parameterization for models of *ParameterizationMesh_3*

Parameters

The full template declaration is:

template<class *ParameterizationMesh_3*>
class *Square_border_arc_length_parameterizer_3*;

Creation

Operations

virtual double *bp.compute_edge_length(Adaptor mesh, Vertex_const_handle source, Vertex_const_handle target) [protected, virtual]*

Compute the length of an edge.
Arc-length border parameterization: (u, v) values are proportional to the length of border edges.

CGAL::Eigen_sparse_symmetric_matrix<T> .... page 3408
CGAL::Eigen_vector<T> .... page 3409

CGAL::Eigen_vector<T>

Class

Definition

The class *Eigen_vector* is a C++ wrapper around EIGEN's vector, which is a simple array of numbers. The version 3.1 (or greater) of EIGEN must be available on the system.

#include <CGAL/Eigen_vector.h>

Is Model for the Concepts

SparseLinearAlgebraTraits_d::Vector.

Parameters

T: Number type.

Types

Eigen_vector<T>:: EigenType	The internal vector type from EIGEN.

See Also

CGAL::Eigen_solver_traits<T> . . . . page 3410
CGAL::Eigen_sparse_matrix<T> . . . . page 3407
CGAL::Eigen_sparse_symmetric_matrix<T> . . . . page 3408

CGAL::Eigen_solver_traits<T>

Definition

The class *Eigen_solver_traits* provides an interface to the sparse solvers of EIGEN. The version 3.1 (or greater) of EIGEN must be available on the system.

#include <CGAL/Eigen_solver_traits.h>

Is Model for the Concepts

SparseLinearAlgebraTraits_d.

Parameters

T: a sparse solver of EIGEN. The default solver is the iterative bi-congugate gradient stabilized solver *Eigen::BiCGSTAB* for *double*.

Types

typedef typename T::Scalar

NT;

typedef CGAL::Eigen_vector<NT>

Vector;

Eigen_solver_traits<T>:: Matrix — If *T* is *Eigen::ConjugateGradient<M>* or *Eigen::SimplicialCholesky<M>*, *Matrix* is *CGAL::Eigen_sparse_symmetric_matrix<T>* and *CGAL::Eigen_sparse_matrix<T>* otherwise.

Operations

T& *st.solver()* — Returns a reference to the internal EIGEN solver. This function can be used for example to set specific parameters of the solver.

CGAL::Eigen_vector<T> . . . . page 3409
`http://eigen.tuxfamily.org`

Example

The instantiation of this class assumes an EIGEN sparse solver is provided. Here are few examples:

```
typedef CGAL::Eigen_sparse_matrix<double>::EigenType EigenMatrix;

//iterative general solver
typedef CGAL::Eigen_solver_traits< Eigen::BiCGSTAB<EigenMatrix> >
    Iterative_general_solver;

//iterative symmetric solver
typedef CGAL::Eigen_solver_traits< Eigen::ConjugateGradient<EigenMatrix>
    > Iterative_symmetric_solver;

//direct symmetric solver
typedef CGAL::Eigen_solver_traits< Eigen::SimplicialCholesky<EigenMatrix>
     > Direct_symmetric_solver;
```

Class

CGAL::Two_vertices_parameterizer_3<ParameterizationMesh_3>

Definition

Two_vertices_parameterizer_3 is the default border parameterizer for Least Squares Conformal Maps parameterization.

The class *Two_vertices_parameterizer_3* parameterizes two extreme vertices of a 3D surface. This kind of border parameterization is used by free border parameterizations.

Implementation note: To simplify the implementation, *BorderParameterizer_3* models know only the *ParameterizationMesh_3* class. They do not know the parameterization algorithm requirements or the kind of sparse linear system used.

#include <CGAL/Two_vertices_parameterizer_3.h>

Is Model for the Concepts

Model of the *BorderParameterizer_3* concept.

Design Pattern

BorderParameterizer_3 models are Strategies [GHJV95]: they implement a strategy of border parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

template<class *ParameterizationMesh_3*>
class *Two_vertices_parameterizer_3*;

Types

Two_vertices_parameterizer_3<ParameterizationMesh_3>:: Adaptor

Export *ParameterizationMesh_3* template parameter.

Creation

Operations

Parameterizer_traits_3<Adaptor>::Error_code

bp.parameterize_border(Adaptor& mesh)

Map two extreme vertices of the 3D mesh and mark them as *parameterized*.

bool *bp.is_border_convex()*

Indicate if border's shape is convex. Meaningless for free border parameterization algorithms.

Concept

SparseLinearAlgebraTraits_d::Vector

Definition

SparseLinearAlgebraTraits_d::Vector is a concept of a vector that can be multiplied by a sparse matrix.

Refines

LinearAlgebraTraits_d::Vector

Types

Vector:: NT

Creation

Vector v(int rows);	Create a vector initialized with zeros.
Vector v(Vector toCopy);	Copy constructor.

Operations

int	*v.dimension() const*	Return the vector's number of coefficients.
NT	*v*[*int row*]	Read/write access to a vector coefficient. *Precondition*: 0 <= row < dimension().
NT&	*v*[*int row*]	

Has Models

Eigen_vector<T>
OpenNL::FullVector<T> in *OpenNL* package

Chapter 55

2D Placement of Streamlines

Abdelkrim Mebarki

Contents

This chapter describes the CGAL 2D streamline placement package. Basic definitions and notions are given in Section 55.1. Section 55.2 gives a description of the integration process. Section 55.3 provides a brief description of the algorithm. Section 55.4 presents the implementation of the package, and Section 55.5 details two example placements.

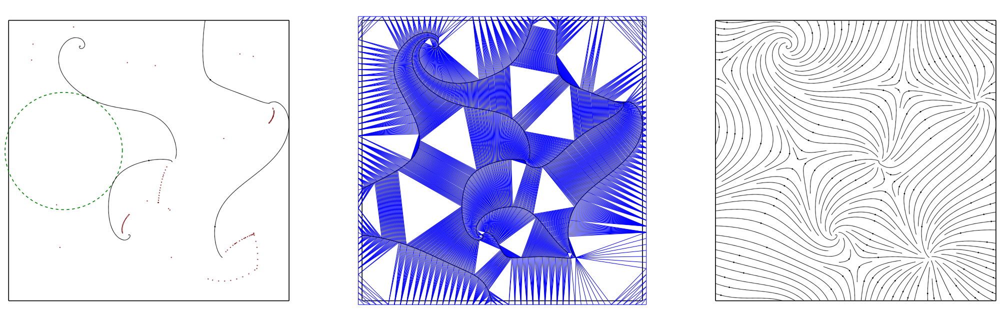

Figure 55.1: The core idea of the algorithm is to integrate the streamlines from the center of the biggest empty cavities in the domain (left). A Delaunay triangulation of all the sample points is used to model the streamlines and the spaces within the domain (middle). A final result is shown (right).

55.1 Definitions

In physics, a *field* is an assignment of a quantity to every point in space. For example, a gravitational field assigns a gravitational potential to each point in space.

Vector and direction fields are commonly used for modeling physical phenomena, where a direction and magnitude, namely a vector is assigned to each point inside a domain (such as the magnitude and direction of the force at each point in a magnetic field).

Streamlines are important tools for visualizing flow fields. A *streamline* is a curve everywhere tangent to the field. In practice, a streamline is often represented as a polyline (series of points) iteratively elongated by bidirectional numerical integration started from a *seed point*, until it comes close to another streamline (according to a specified distance called *the separating distance*), hits the domain boundary, reaches a critical point or generates a closed path.

A *valid* placement of streamlines consists of saturating the domain with a set of tangential streamlines in accordance with a specified *density*, determined by the *separating distance* between the streamlines.

55.2 Fundamental Notions

A streamline can be considered as the path traced by an imaginary massless particle dropped into a steady fluid flow described by the field. The construction of this path consists in the solving an ordinary differential equation for successive time intervals. In this way, we obtain a series of points $p_k, 0 < k < n$ which allow visualizing the streamline. The differential equation is defined as follows :

$$\frac{dp}{dt} = v(p(t)), \qquad p(0) = p_0$$

where *p(t)* is the position of the particle at time t, v is a function which assigns a vector value at each point in the domain (possibly by interpolation), and p_0 is the initial position. The position after a given interval Δt is given by :

$$p(t+\Delta t) = p(t) + \int_t^{t+\Delta t} v(p(t))dt$$

. Several numeric methods have been proposed to solve this equation. In this package, the Euler, and the Second Order Runge-Kutta algorithm are implemented.

55.2.1 Euler Integrator

This algorithm approximates the point computation by this formula

$$p_{k+1} = p_k + hv(p_k)$$

where h specifies the *integration step* (see Figure 55.2). The integration can be done forward (resp. backward) by specifying a positive (resp. negative) integration step h. The streamline is then constructed by successive integration from a seed point both forward and backward.

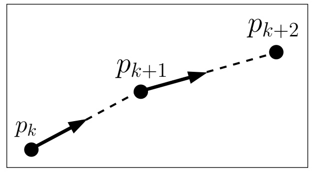

Figure 55.2: Euler integrator.

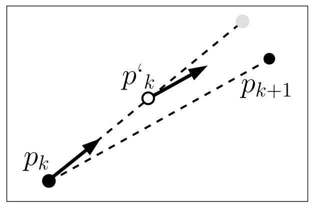

Figure 55.3: Runge-Kutta second order integrator (The empty circle represents the intermediate point, and the gray disk represents the Euler integrated point).

55.2.2 Second Order Runge-Kutta Integrator

This method introduces an intermediate point p'_k between p_k and p_{k+1} to increase the precision of the computation (see Figure 55.3), where:

$$\begin{array}{rcccl} p'_k & = & p_k & + & \frac{1}{2}hv(p_k) \\ p_{k+1} & = & p_k & + & hv(p'_k) \end{array}$$

See [PTVF02] for further details about numerical integration.

55.3 Farthest Point Seeding Strategy

The algorithm implemented in this package [MAD05] consists of placing one streamline at a time by numerical integration starting farthest away from all previously placed streamlines.

The input of our algorithm is given by (i) a flow field, (ii) a *density* specified either globally, by the inverse of the ideal spacing distance, or locally by a density field, and (iii) a *saturation* ratio over the desired spacing required to trigger the seeding of a new streamline.

The input flow field is given by a discrete set of vectors or directions sampled within a domain, associated with an interpolation scheme (*e.g.* bilinear interpolation over a regular grid, or natural neighbor interpolation over an irregular point set to allow for an evaluation at each point coordinate within the domain).

The *output* is a streamline placement, represented as a list of streamlines. The core idea of our algorithm consists of placing one streamline at a time by numerical integration seeded at the farthest point from all previously placed streamlines.

The streamlines are approximated by polylines, whose points are inserted to a 2D Delaunay triangulation (see figure 55). The empty circumscribed circles of the Delaunay triangles provide us with a good approximation of the cavities in the domain.

After each streamline integration, all incident triangles whose circumcircle diameter is larger (within the saturation ratio) than the desired spacing distance are pushed to a priority queue sorted by the triangle circumcircle diameter. To start each new streamline integration, the triangle with largest circumcircle diameter (and hence the biggest cavity) is popped out of the queue. We first test if it is still a valid triangle of the triangulation, since it could have been destroyed by a streamline previously added to the triangulation. If it is not, we pop another triangle out of the queue. If it is, we use the center of its circumcircle as seed point to integrate a new streamline.

Our algorithm terminates when the priority queue is empty. The size of the biggest cavity being monotonically decreasing, our algorithm guarantees the domain saturation.

55.4 Implementation

Streamlines are represented as polylines, and are obtained by iterative integration from the seed point. A polyline is represented as a range of points. The computation is processed via a list of Delaunay triangulation vertices.

To implement the triangular grid, the CGAL *Delaunay_triangulation_2* class is used. The priority queue used to store candidate seed points is taken from the Standard Template Library [Sil97].

55.5 Examples

The first example illustrates the generation of a 2D streamline placement from a vector field defined on a regular grid.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Stream_lines_2.h>
#include <CGAL/Runge_kutta_integrator_2.h>
#include <CGAL/Regular_grid_2.h>
#include <CGAL/Triangular_field_2.h>

#include <iostream>
#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel         K;
typedef CGAL::Regular_grid_2<K> Field;
typedef CGAL::Runge_kutta_integrator_2<Field> Runge_kutta_integrator;
typedef CGAL::Stream_lines_2<Field, Runge_kutta_integrator> Strl;
typedef Strl::Point_iterator_2 Point_iterator;
```

```
typedef Strl::Stream_line_iterator_2 Strl_iterator;
typedef Strl::Point_2 Point_2;
typedef Strl::Vector_2 Vector_2;

int main()
{
  Runge_kutta_integrator runge_kutta_integrator;

  /*data.vec.cin is an ASCII file containing the vector field values*/
  std::ifstream infile("data/vnoise.vec.cin", std::ios::in);
  double iXSize, iYSize;
  unsigned int x_samples, y_samples;
  iXSize = iYSize = 512;
  infile >> x_samples;
  infile >> y_samples;
  Field regular_grid_2(x_samples, y_samples, iXSize, iYSize);
  /*fill the grid with the appropreate values*/
  for (unsigned int i=0;i<x_samples;i++)
    for (unsigned int j=0;j<y_samples;j++)
      {
        double xval, yval;
        infile >> xval;
        infile >> yval;
        regular_grid_2.set_field(i, j, Vector_2(xval, yval));
      }
  infile.close();

  /* the placement of streamlines */
  std::cout << "processing...\n";
  double dSep = 3.5;
  double dRat = 1.6;
  Strl Stream_lines(regular_grid_2, runge_kutta_integrator,dSep,dRat);
  std::cout << "placement generated\n";

  /*writing streamlines to streamlines_on_regular_grid_1.stl */
  std::ofstream fw("streamlines_on_regular_grid_1.stl",std::ios::out);
  fw << Stream_lines.number_of_lines() << "\n";
  for(Strl_iterator sit = Stream_lines.begin(); sit !=
   Stream_lines.end(); sit++)
    {
      fw << "\n";
      for(Point_iterator pit = sit->first; pit != sit->second; pit++){
        Point_2 p = *pit;
        fw << p.x() << " " << p.y() << "\n";
      }
    }

  fw.close();

}
```

File: examples/Stream_lines_2/stl_regular_field.cpp

The second example depicts the generation of a streamline placement from a vector field defined on a triangular grid.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Stream_lines_2.h>
#include <CGAL/Runge_kutta_integrator_2.h>
#include <CGAL/Triangular_field_2.h>

#include <iostream>
#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel         K;
typedef K::Point_2
    Point;
typedef K::Vector_2
    Vector;
typedef CGAL::Triangular_field_2<K>
    Field;
typedef CGAL::Runge_kutta_integrator_2<Field>
    Runge_kutta_integrator;
typedef CGAL::Stream_lines_2<Field, Runge_kutta_integrator>         Strl;
typedef Strl::Stream_line_iterator_2
    stl_iterator;

int main()
{
  Runge_kutta_integrator runge_kutta_integrator(1);

  /*datap.tri.cin and datav.tri.cin are ascii files where are stored the
    vector velues*/
  std::ifstream inp("data/datap.tri.cin");
  std::ifstream inv("data/datav.tri.cin");
  std::istream_iterator<Point> beginp(inp);
  std::istream_iterator<Vector> beginv(inv);
  std::istream_iterator<Point> endp;

  Field triangular_field(beginp, endp, beginv);

  /* the placement of streamlines */
  std::cout << "processing...\n";
  double dSep = 30.0;
  double dRat = 1.6;
  Strl Stream_lines(triangular_field, runge_kutta_integrator,dSep,dRat);
  std::cout << "placement generated\n";

  /*writing streamlines to streamlines.stl */
  std::cout << "streamlines.stl\n";
  std::ofstream fw("streamlines.stl",std::ios::out);
  Stream_lines.print_stream_lines(fw);
}
```

File: examples/Stream_lines_2/stl_triangular_field.cpp

2D Placement of Streamlines Reference Manual

Abdelkrim Mebarki

Vector and direction fields are commonly used for modeling physical phenomena, where a direction and magnitude, namely a vector is assigned to each point inside a domain.

A streamline is a curve everywhere tangent to the field. It can be considered as the path traced by an imaginary massless particle dropped into a steady fluid flow described by the field.

A streamline is represented as a polyline iteratively elongated by bidirectional numerical integration started from a seed point, until it comes close to another streamline, hits the domain boundary, or reaches a critical point.

The *Stream_lines_2* class consists of saturating the domain with a set of tangential streamlines in accordance with a specified density.

Streamlines are represented as containers of points, manipulated by an iterator range of points, and the whole placement is accessible via an iterator range of streamlines.

The main class in this package, the *Stream_lines_2* class of CGAL depends on two template parameters. The first template parameter stands for a class which represents both the vector field and the visualization domain with operations on them, and should be instantiated by a model of the concept *VectorField_2*. The second template parameter stands for a function object that ensures the numerical integration used to construct the streamlines, and should be instantiated by a model of the concept *Integrator_2*.

CGAL::Euler_integrator_2<VectorField_2>

Definition

This class implements the first order Euler integrator. The template parameter *VectorField_2* has to be instantiated by a model of the concept *VectorField_2*.

Creation

Euler_integrator_2<VectorField_2> einteg(FT integration_step);

Creates an Euler integrator class *einteg* with *integration_step* as integration step.

Is Model for the Concepts

Integrator_2

See Also

Runge_kutta_integrator_2<VectorField_2>

Functor Concept

Integrator_2

Definition

The concept Integrator_2 describes the set of requirements to be fulfilled by any function object used to instantiate the second template parameter of the class *Stream_lines_2<VectorField_2,Integrator_2>*. This concept provides the operation that integrates a new point from a given point with a predefined step, and according to a specified vector.

Types

Integrator_2:: FT	The scalar type.
Integrator_2:: Point_2	The point type.
Integrator_2:: Vector_2	The vector type.
Integrator_2:: Vector_field_2	The vector field type.

Creation

Integrator_2 integ;	only a default constructor is needed.

Operations

The following operations return the newly integrated point.

Point_2 *integ(Point_2 p, Vector_field_2 vector_field_2)*

returns the new position from the actual position defined by *p*, according to the vector given by *vector_field_2* at *p*.
Precondition: *vector_field_2.is_in_domain(p)* must be true.

Point_2 *integ(Point_2 p, Vector_field_2 vector_field_2, FT integration_step)*

As above. The integration step is defined by *integration_step*.
Precondition: *vector_field_2.is_in_domain(p)* must be true.

Point_2 *integ(Point_2 p, Vector_field_2 vector_field_2, FT integration_step, bool direction)*

As above. In addition, this function integrates forward if *direction* is true, and backward if it is false.
Precondition: *vector_field_2.is_in_domain(p)* must be true.

Has Models

CGAL::Euler_integrator_2<VectorField_2>
CGAL::Runge_kutta_integrator_2<VectorField_2>

CGAL::Regular_grid_2<StreamLinesTraits_2>

Class

Definition

The template parameter *StreamLinesTraits_2* has to be instantiated by a model of the concept *StreamLinesTraits_2*.

This class provides a 2D vector field specified by a set of sample points defined on a regular grid, with a bilinear interpolation scheme over its cells (i.e. for each point p in a cell c, the vector value is interpolated from the vertices of c).

Types

typedef StreamLinesTraits_2::FT	*FT;*	the scalar type.
typedef StreamLinesTraits_2::Point_2	*Point_2;*	the point type.
typedef StreamLinesTraits_2::Vector_2	*Vector_2;*	the vector type.

Creation

Regular_grid_2<StreamLinesTraits_2> rgrid(int x_samples, int y_samples, FT x_size, FT y_size);

Generate a regular grid *rgrid* whose size is *x_size* by *y_size*, while *x_samples* and *y_samples* specify the number of samples on x and y.

Modifiers

In addition to the minimum interface required by the concept definition, the class *Regular_grid_2< StreamLinesTraits_2>* provides the following function to fill the vector field with the user data.

void *rgrid.set_xy(int i, int j, Vector_2 v)*

Attribute the vector v to the position (i,j) on the regular grid.

Access Functions

std::pair<int, int>	*rgrid.get_dimension()*	returns the dimension of the grid.
std::pair<FT, FT>	*rgrid.get_size()*	returns the size of the grid.

Euler_integrator_2<VectorField_2>

StreamLinesTraits_2

Definition

The concept StreamLinesTraits_2 describes the set of requirements to be fulfilled by any class used to instantiate the template parameter of the class *Regular_grid_2<StreamLinesTraits_2>*. This concept provides the types handled by the *Stream_lines_2<VectorField_2, Integrator_2>* class.

Types

StreamLinesTraits_2:: FT	The scalar type.
StreamLinesTraits_2:: Point_2	The point type.
StreamLinesTraits_2:: Vector_2	The vector type.

Has Models

The kernels of CGAL are models for this traits class.

CGAL::Stream_lines_2<VectorField_2,Integrator_2>

Class

Definition

The class *Stream_lines_2<VectorField_2,Integrator_2>* is designed to handle a placement of streamlines in a 2D domain according to a bidimensional vector field.

The class *Stream_lines_2<VectorField_2,Integrator_2>* creates a placement of streamlines according to a specified density and gives access to those streamlines via two iterators over a container of iterators that provide access to the streamline points.

Parameters

The class *Stream_lines_2<VectorField_2,Integrator_2>* has two template parameters. The first parameter *VectorField_2* has to be instantiated by a model of the concept *VectorField_2*. The second parameter is the function object *Integrator_2*, and has to be instantiated by a model of the concept *Integrator_2*.

Types

typedef VectorField_2::Geom_traits	*Geom_traits;*	the traits class.
typedef VectorField_2::FT	*FT;*	the scalar type.
typedef VectorField_2::Point_2	*Point_2;*	the point type.
typedef VectorField_2::Vector_2	*Vector_2;*	the vector type.

The class *Stream_lines_2<VectorField_2,Integrator_2>* provides also two types for handling streamlines:

Stream_lines_2<VectorField_2,Integrator_2>:: Point_iterator_2

iterator of points with value type *Point_2*.

Stream_lines_2<VectorField_2,Integrator_2>:: Stream_line_iterator_2

an iterator to visit the streamlines with value type *std::pair< Point_iterator_2, Point_iterator_2>*.

Creation

Stream_lines_2<VectorField_2,Integrator_2> stl(VectorField_2 vector_field_2,
Integrator_2 integrator_2,
FT separating_distance,
FT saturation_ratio)

Generates a streamline placement *stl*.

Modifiers

void *stl.set_separating_distance(FT new_value)*

Modify the separating distance.

void	*stl.set_saturation_ratio(FT new_value)*	
		Modify the saturation ratio.
void	*stl.update()*	Update the placement after changing the separating distance or the saturation ratio.

Access Functions

void	*stl.get_separating_distance()*	returns the separating distance.
void	*stl.get_saturation_ratio()*	returns the saturation ratio.
void	*stl.print_stream_lines(std::ofstream & fw)*	
		prints the streamlines to an ASCII file : line by line, and point by point.

Streamline iterators

The following iterators allow to visit all the streamlines generated by the constructor or the update function.

Stream_line_iterator	*stl.begin() const*	Starts at the first streamline
Stream_line_iterator	*stl.end() const*	Past-the-end iterator

CGAL::Triangular_field_2<StreamLinesTraits_2>

Definition

The template parameter *StreamLinesTraits_2* has to be instantiated by a model of the concept *StreamLinesTraits_2*.

This class provides a vector field specified by a set of sample points defined on a triangulated domain. All sample points are inserted to a *Delaunay triangulation*, and for each point p in the domain located in a face f, its vector value is interpolated from the vertices of the face f.

Types

typedef StreamLinesTraits_2::FT	*FT;*	the scalar type.
typedef StreamLinesTraits_2::Point_2	*Point_2;*	the point type.
typedef StreamLinesTraits_2::Vector_2	*Vector_2;*	the vector type.

Creation

Triangular_field_2<StreamLinesTraits_2> tfield_2(InputIterator1 first_point, InputIterator1 last_point, InputIterator2 first_vector)

Defines the points in the range [*first_point*, *last_point*) as the sample points of the grid, with the corresponding number of vectors started at *first_vector*.
Precondition: The *value_type* of *InputIterator1* is *Point*.
Precondition: The *value_type* of *InputIterator2* is *Vector*.

Concept

VectorField_2

Definition

The concept VectorField_2 describes the set of requirements to be fulfilled by any class used to instantiate the first template parameter of the class *Stream_lines_2<VectorField_2,Integrator_2>*. This concept provides the types of the geometric primitives used in the placement of streamlines and some functions for answering different queries.

Types

VectorField_2:: Geom_traits	The traits class.
VectorField_2:: FT	The scalar type.
VectorField_2:: Point_2	The point type.
VectorField_2:: Vector_2	The vector type.

Creation

VectorField_2 vfield;

Any constructor has to allow the user to fill the vector values (i.e. assign a vector to each position within the domain).

Query Functions

Geom_traits::Iso_rectangle_2 *vfield.bbox()*

returns the bounding box of the whole domain.

std::pair<Vector_2,FT> *vfield.get_field(Point_2 p)*

returns the vector field value and the local density.
Precondition: *is_in_domain(p)* must be true.

bool *vfield.is_in_domain(Point_2 p)*

returns true if the point p is inside the domain boundaries, false otherwise.

FT *vfield.get_integration_step(Point_2 p)*

returns the integration step at the point p (i.e. the distance between *p* and the next point in the polyline.).
Precondition: *is_in_domain(p)* must be true.

Chapter 56

Approximation of Ridges and Umbilics on Triangulated Surface Meshes

Marc Pouget and Frédéric Cazals

Contents

This chapter describes the CGAL package for the approximating the ridges and umbilics of a smooth surface discretized by a triangle mesh. Given a smooth surface, a ridge is a curve along which one of the principal curvatures has an extremum along its curvature line. An umbilic is a point at which both principal curvatures are equal. Ridges define a singular curve, i.e., a self-intersecting curve, and umbilics are special points on this curve. Ridges are curves of *extremal* curvature and therefore encode important informations used in segmentation, registration, matching and surface analysis. Based on the results of the article [CP05c], we propose algorithms to identify and extract different parts of this singular ridge curve as well as umbilics on a surface given as a triangulated surface mesh. Differential quantities associated to the mesh vertices are assumed to be given for these algorithms; such quantities may be computed by the package *Estimation of Local Differential Properties of Sampled Surfaces via Polynomial Fitting*.

Note that this package needs the third party library Eigen (Page 28)for linear algebra operations.

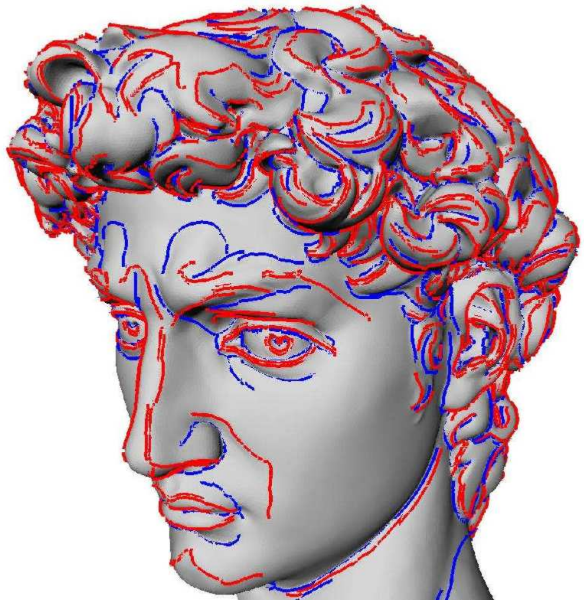

Figure 56.1: Crest ridges on the David, model provided by the Digital Michelangelo Project.

56.0.1 Overview

Section 56.1 presents the basics of the theory of ridges and umbilics on smooth surfaces. Sections 56.2 and 56.3 present algorithms for approximating the ridges and umbilics (of a smooth surface) from a triangle mesh. Section 56.4 gives the package specifications, while example calls to functions of the package are provided in Section 56.5.

56.1 Ridges and Umbilics of a Smooth Surface

For a detailed introduction to ridges and related topics, the reader may consult [HGY+99, Por01], as well as the following survey article [CP05b]. In the sequel, we just introduce the basic notions so as to explain our algorithms. Consider a smooth embedded surface, and denote k_1 and k_2 the principal curvatures, with $k_1 \geq k_2$. Umbilics are the points where $k_1 = k_2$. For any non umbilical point, the corresponding principal directions of curvature are well defined, and we denote them d_1 and d_2. In local coordinates, we denote $\langle , \rangle$ the inner product induced by the ambient Euclidean space, and dk_1, dk_2 the gradients of the principal curvatures. Ridges, illustrated in Figure 56.2 for the standard ellipsoid, are defined by:

Definition. 1 *A non umbilical point is called*

- *a max ridge point, if the* extremality coefficient $b_0 = \langle dk_1, d_1 \rangle$ *vanishes, i.e.* $b_0 = 0$.
- *a min ridge point, if the* extremality coefficient $b_3 = \langle dk_2, d_2 \rangle$ *vanishes, i.e.* $b_3 = 0$ [1].

The previous characterization of ridges involves third-order differential properties. Using fourth-order differential quantities, a ridge point can further be qualified as *elliptic* if it corresponds to a maximum of k_1 or a minimum of k_2, or *hyperbolic* otherwise. Hence we end up with four types of ridges, namely: *MAX_ELLIPTIC_RIDGE*,

[1] Notations b_0, b_3 comes from Equation 57.2

MAX_HYPERBOLIC_RIDGE, *MIN_ELLIPTIC_RIDGE*, *MIN_HYPERBOLIC_RIDGE*, which are illustrated in Figure 56.2. Also of interest are the *crest lines*, a crest line being an elliptic ridge which is a maximum of $\max(|k_1|, |k_2|)$. Crest lines form a subset of elliptic ridges, and can be seen as the visually most salient curves on a surface. Hence we provide the two additional ridge types *MAX_CREST_RIDGE* and *MIN_CREST_RIDGE*, which are illustrated in Figure 56.

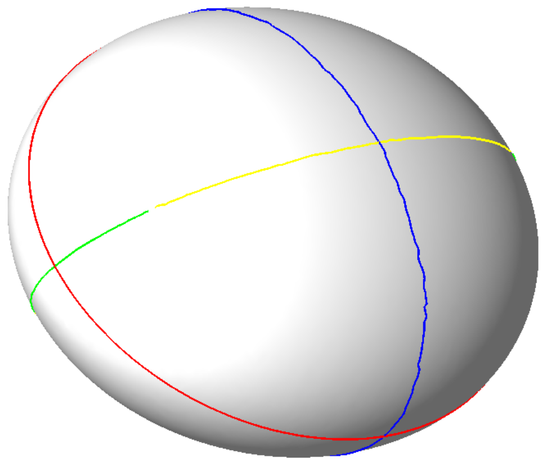

Figure 56.2: Ridges on the ellipsoid, normals pointing outward. Color coding: *MAX_ELLIPTIC_RIDGE* are blue, *MAX_HYPERBOLIC_RIDGE* are green, *MIN_ELLIPTIC_RIDGE* are red and *MIN_HYPERBOLIC_RIDGE* are yellow. The red line is also the *MIN_CREST_RIDGE* and this is the only crest ridge of the ellipsoid.

At any point of the surface which is not an umbilic, principal directions d_1, d_2 are well defined, and these (non oriented) directions together with the normal vector n define two direct orthonormal frames. If v_1 is a unit vector of direction d_1 then there exists a unique unit vector v_2 so that (v_1, v_2, n) is direct, that is has the same orientation as the canonical basis of the ambient $3d$ space (and the other possible frame is $(-v_1, -v_2, n)$). In the coordinate systems (v_1, v_2, n), the surface has the following canonical form, known as the Monge form :

$$z(x,y) = \frac{1}{2}(k_1x^2 + k_2y^2) + \frac{1}{6}(b_0x^3 + 3b_1x^2y + 3b_2xy^2 + b_3y^3) \tag{56.1}$$

$$+\frac{1}{24}(c_0x^4 + 4c_1x^3y + 6c_2x^2y^2 + 4c_3xy^3 + c_4y^4) + h.o.t \tag{56.2}$$

The Taylor expansion of k_1 (resp. k_2) along the max (resp. min) curvature line going through the origin and parameterized by x (resp. y) are:

$$k_1(x) = k_1 + b_0x + \frac{P_1}{2(k_1 - k_2)}x^2 + h.o.t, \qquad P_1 = 3b_1^2 + (k_1 - k_2)(c_0 - 3k_1^3). \tag{56.3}$$

$$k_2(y) = k_2 + b_3y + \frac{P_2}{2(k_2 - k_1)}y^2 + h.o.t, \qquad P_2 = 3b_2^2 + (k_2 - k_1)(c_4 - 3k_2^3). \tag{56.4}$$

Notice also that switching from one to the other of the two afore-mentioned coordinate systems reverts the sign of all the odd coefficients on the Monge form of the surface.

Hence ridge types are characterized by

- max ridge if $b_0 = 0$
- *MAX_ELLIPTIC_RIDGE* if $b_0 = 0$ and $P_1 < 0$
- *MAX_HYPERBOLIC_RIDGE* if $b_0 = 0$ and $P_1 > 0$

- min ridge if $b_3 = 0$
- *MIN_ELLIPTIC_RIDGE* if $b_3 = 0$ and $P_2 < 0$
- *MIN_HYPERBOLIC_RIDGE* if $b_3 = 0$ and $P_2 > 0$
- *MAX_CREST_RIDGE* if $b_0 = 0$ and $P_1 < 0$ and $|k_1| > |k_2|$
- *MIN_CREST_RIDGE* if $b_3 = 0$ and $P_2 < 0$ and $|k_2| > |k_1|$

As illustrated in Figures 56.3 and 56.4, the patterns made by curvature lines around an umbilic can be characterized using the notion of an *index* associated to the principal directions — see also [CP05b]. As depicted in Figure 56.3, consider a small circuit C around the umbilic, and a point $p \in C$. Starting from an initial orientation u of a tangent vector to the curvature line through point p, propagate *by continuity* this orientation around the circuit. The index is defined by the angle swept by u around this revolution, normalized by 2π. In our example, the index is thus 1/2.

If the index of the principal direction field is $1/2$ then it is called a *ELLIPTIC_UMBILIC*, if it is $-1/2$ it is called a *HYPERBOLIC_UMBILIC*. Otherwise the umbilic is qualified *NON_GENERIC_UMBILIC*.

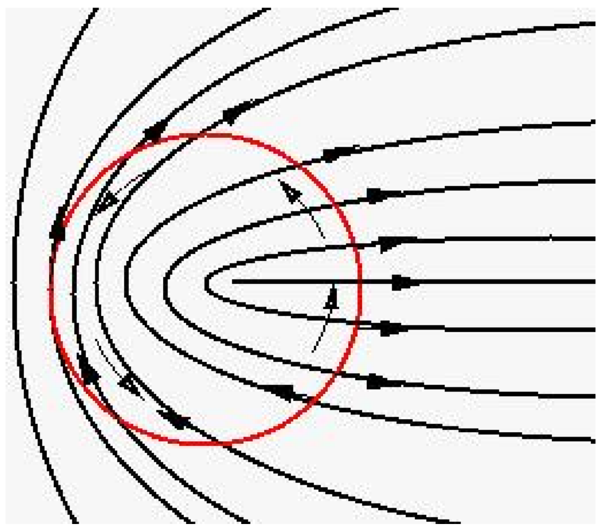

Figure 56.3: Index $1/2$ umbilic or elliptic umbilic.

56.2 Approximating Ridges on Triangulated Surface Meshes

Our method aims at reporting ridges as polygonal lines living on the mesh. It assumes differential quantities are available for each vertex of the mesh (principal curvatures and directions together with third order quantities b_0, b_3 and optionally fourth order quantities P_1, P_2). These differential quantities may be computed for the smooth surface the mesh is inscribed in (analytically or using approximation methods), or may be estimated for a mesh given without reference to an underlying smooth surface. Although the ridge approximation algorithm is the same in both cases, one cannot ambition to ask for the same certificates. This distinction calls for the notion of *compliant* mesh.

Compliant meshes. Ridges of a smooth surface are points with prescribed differential properties, and reporting them from a mesh inscribed in the surface requires delicate hypothesis on the geometry of that mesh so as

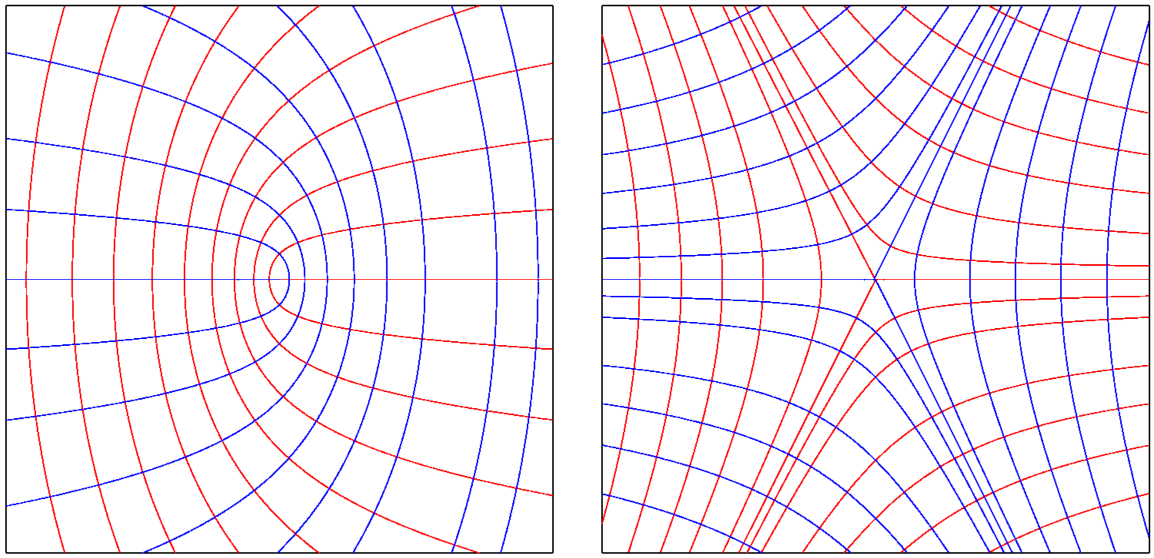

Figure 56.4: Elliptic and hyperbolic umbilics.

to get a certified result. In this paragraph, we assume the mesh provided complies with a number of hypothesis, which guarantee the topology of the ridges reported matches that of the ridges on the smooth surface. To summarize things, a compliant mesh is a mesh dense enough so that (i) umbilics are properly isolated (ii) ridges running next to one another are also properly separated. See [CP05c] for a detailed discussion of *compliant* meshes.

As 0-level set of the extremality coefficients b_0 and b_3, ridges are extracted by a marching triangles algorithm.[2]

As the signs of these extremality coefficients depend on the orientation of the principal directions, we expect both extremalities and vectors orienting the principal direction to be given at each point vertex of the mesh. Except in the neighborhood of umbilics, if the mesh is dense enough, a coherent orientation of principal directions at both endpoints of an edge is chosen such that the angle between the two vectors is acute. This rule, the *acute rule*, is precisely analyzed in [CP05c]. Moreover, we only seek ridges in triangles for which one can find an orientation of its three vertices such that the three edges are coherently oriented by the acute rule. Such triangles are called *regular*. This said, two remarks are in order.

—*Regular triangles and ridge segments.* A regular triangle has 0 or 2 edges crossed by a max (resp. min) ridge, which is tantamount to a sign change of b_0 (resp. b_3) along the corresponding edges. In the latter case, we say that the triangle contains a ridge segment. Two methods are provided to compute its type, be it elliptic or hyperbolic. First, if fourth order differential quantities are provided, one can use the P_1 (P_2) values of Equations 56.3 (56.4) for a max (min) ridge. The value of P_i for a ridge segment is defined as the mean value of the P_i values of the two crossing points on edges (while the value at a crossing point on an edge is the b_i-weighted mean value of the values at endpoints). Alternatively, if third order differential quantities only are available, one may use the geometric method developed in [CP05c].

Using the notion of ridge segment, a *Ridge_line* is defined as a maximal connected sequence of ridge segments of the same type and connected together. Notice that the topology of a *Ridge_line* is either that of an interval or a circle.

—*Non-regular triangles.* In the neighborhood of umbilics, triangle are less likely to be regular and the detec-

[2]A marching triangles algorithm is similar to a 2d marching cubes algorithm (or marching rectangles algorithm), except that a one-manifold is reported on a two-manifold tessellated by triangles.

tion of ridges cannot be relevant by this method. This is why we propose another method to detect umbilics independently.

Non compliant meshes: filtering ridges on *strength* and *sharpness*. For real world applications dealing with coarse meshes, or meshes featuring degenerate regions or sharp features, or meshes conveying some amount of noise, the *compliance* hypothesis [CP05c] cannot be met. In that case, it still makes sense to seek loci of points featuring extremality of estimated principal curvatures, but the ridges reported may require filtering. For example, if the principal curvatures are constant —which is the case on a plane or a cylinder, then all points are ridge points. In this context, an appealing notion is that of *sharp* ridge or *prominent* ridge. Since ridges are witnessed by zero crossings of b_0 and b_3, one can expect erroneous detections as long as these coefficients remain small. In order to select the most prominent ridge points, we focus on points where the variation of the curvature is fast along the curvature line. One can observe that, at a ridge point, according to Equation 56.3, the second derivative of k_1 along its curvature line satisfies $k_1^{''}(0) = P_1/(k_1 - k_2)$. Using this observation, one can define the *sharpness of a ridge* as the integral of the absolute value of $P_1/(k_1 - k_2)$ along the ridge. As the second derivative of the curvature is homogeneous to the inverse of the cube of a length, the sharpness is homogeneous to the inverse of the square of a length. Multiplying the sharpness by the square of the model size gives a threshold and an associated sharpness-filter which are scale independent. Another filtering is also available with the *strength* which is the integral of the curvature along the ridge line [OBS04].

56.3 Approximating Umbilics on Triangulated Surface Meshes

The method aims at identifying some vertices of a mesh as umbilics. It assumes principal curvatures and directions are given at each vertex on the mesh.

Algorithm. Assume each vertex v of the mesh comes with a patch (a topological disk) around it. Checking whether vertex v is an umbilic is a two stages process, which are respectively concerned with the variation of the function $k_1 - k_2$ over the patch, and the index of the vertex computed from the boundary of the patch. More precisely, vertex v is declared to be an umbilic if the following two conditions are met:

- the function $k_1 - k_2$ has its minimum at v amongst all the vertices of the patch;
- the deviation δ of any principal direction along the patch boundary, traversed counter-clock-wise (CCW), has prescribed properties:
  - $\delta \in]\pi/2, 3\pi/2[$, then the umbilic is called elliptic,
  - $\delta \in]-3\pi/2, -\pi/2[$, then the umbilic is called a hyperbolic,
  - otherwise the umbilic is called non-generic.

Finding patches around vertices. Given a vertex v and a parameter t, we aim at defining a collection of triangles around v so that (i) this collection defines a topological disk on the triangulation T and (ii) its size depends on t. First we collect the 1-ring triangles. We define the size s of this 1-ring patch as the (Euclidean) distance from v to its farthest 1-ring vertex neighbor. We then collect recursively adjacent triangles so that the patch remains a topological disk and such that these triangles are at distance less than $s \times t$. Parameter t is the only parameter of the algorithm.

Umbilical patches versus ridges. On a generic surface, generic umbilics are traversed by one or three ridges. For compliant meshes, an umbilic can thus be connected to the ridge points located on the boundary of its patch. This functionality is not provided, and the interested reader is referred to [CP05c] for more details.

56.4 Software Design

All classes of this package are templated by the parameter *TriangulatedSurfaceMesh*, which defines the type of the mesh to which the approximation algorithms operate.

The differential quantities are provided at vertices of this mesh via property maps, a concept commonly used in the Boost library. Scalar data (curvatures and their derivatives) are provided via *Vertex2FTPropertyMap* concepts, while 3*d* vector data (principal directions of curvatures) are provided via *Vertex2VectorPropertyMap* concepts. The rationale for introducing these concepts is that properties are used independently from the way they are stored. This enables the user to store them *internally* in extended vertices or *externally* with maps. We provide a class *Vertex2Data_Property_Map_with_std_map* to adapt *std::map* with a *boost::associative_property_map* to model these concepts.

Output of ridges or umbilics are provided via output iterator.

Approximation of ridges and umbilics are performed by two independent classes, which we now further describe.

56.4.1 Ridge Approximation

The main class is *Ridge_approximation<TriangulatedSurfaceMesh,Vertex2FTPropertyMap,Vertex2VectorPropertyMap>* . Its construction requires the mesh and the property maps defining the differential quantities for principal curvatures k_1 and k_2, the third order extremalities b_0 and b_3, the principal directions of curvature d_1 and d_2, and the fourth order quantities P_1 and P_2 if the tagging of ridges as elliptic or hyperbolic is to be done using the polynomials P_1 and P_2.

Three functions (provided as members and also as global functions) enable the computation of different types of ridges :

- *compute_max_ridges* (resp. *compute_min_ridges*) outputs ridges of types *MAX_ELLIPTIC_RIDGE* and *MAX_HYPERBOLIC_RIDGE* (resp. *MIN_ELLIPTIC_RIDGE* and *MIN_HYPERBOLIC_RIDGE*).
- *compute_crest_ridges* outputs ridges of types *MAX_CREST_RIDGE* and *MIN_CREST_RIDGE*.

These functions allows the user to specify how the elliptic/hyperbolic tagging is carried out. Notice the rationale for the choice of these three functions is simple: each computation needs a single pass over the triangles of the mesh. This should be clear for the min and max ridges. For crests, just notice max and min crests cannot intersect over a triangle.

The ridge lines are stored in *Ridge_line* objects and output through an iterator. Each ridge line is represented as a list of halfedges of the mesh it crosses with a scalar defining the barycentric coordinate of the crossing point with respect to the half-egde endpoints. Each ridge line comes with its type *Ridge_type*, its strength and sharpness.

If one chooses to use only third order quantities, the quantities P_i do not have to be defined. Then the sharpness will not be defined.

56.4.2 Umbilic Approximation

The main class is *Umbilic_approximation<TriangulatedSurfaceMesh,Vertex2FTPropertyMap,Vertex2VectorPropertyMap>* . Its construction requires the mesh and the property maps defining the differential quantities for principal curvatures k_1 and k_2, and the principal directions of curvature d_1 and d_2. The member function *compute* (or the global function *compute_umbilics*) has a parameter to define the size of the neighborhood of the umbilic.

Umbilics are stored in *Umbilic* objects, they come with their type : *ELLIPTIC_UMBILIC*, *HYPERBOLIC_UMBILIC* or *NON_GENERIC_UMBILIC*; the vertex of the mesh they are associated to and the list of half-edges representing the contour of the neighborhood.

56.4.3 Models for the Property Map Concepts

The class *Vertex2Data_Property_Map_with_std_map<TriangulatedSurfaceMesh>* enables the definition of models for the concepts *Vertex2FTPropertyMap* and *Vertex2VectorPropertyMap* using *std::maps* and *boost::associative_property_map*.

56.5 Examples

56.5.1 Example program

The following program computes ridges and umbilics from an off file.[3] It uses the Jet fitting package to estimate the differential quantities. The default output file gives rough data for visualization purpose, a verbose output file may also be asked for. Parameters are

- d, the degree of the jet for the *Monge_via_jet_fitting* class, d must be greater or equal to 3 which is the default value;
- m, the degree of the Monge representation for the *Monge_via_jet_fitting* class, m must be 3 (the default value) or 4 and smaller than d;
- a, the number of rings of neighbors collected for the *Monge_via_jet_fitting* class, in addition the number of vertices collected must be greater than $Nd := (d+1)(d+2)/2$ to make the approximation possible. a may be an integer greater than 1, the value 0 (which is the default) means that the minimum number of rings is collected to make the approximation possible. (Alternatively option p allows the specification of a constant number of neighbors);
- t, the *CGAL::Ridge_order* for the distinction between elliptic and hyperbolic ridges, t is 3 (default) or 4;
- u, the parameter for umbilic patch size, $u \geq 1$ (default is 1).

```
#include <CGAL/Ridges.h>
#include <CGAL/Umbilics.h>

//this is an enriched Polyhedron with facets' normal
#include "PolyhedralSurf.h"

typedef PolyhedralSurf::Traits          Kernel;
typedef Kernel::FT                      FT;
typedef Kernel::Point_3                 Point_3;
typedef Kernel::Vector_3                Vector_3;
```

[3]Model data may be downloaded via ftp://ftp.mpi-sb.mpg.de/pub/outgoing/CGAL/Ridges_3_datafiles.tgz . The mechanical part model has been provided courtesy of Dassault System to produce Figure 56.6, due to copyright issues the available model is not the same, it is provided by the AIM@SHAPE Shape Repository.

56.5.2 Example: Ridges and Umbilics on an Ellipsoid

For Figure56.5, the data have been computed as follows:

```
./Compute_Ridges_Umbilics -f data/ellipsoid_u_0.02.off -d 4 -m 4 -a 3 -t
   3
```

In addition, the four elliptic umbilics are detected, the standard output being

```
nb of umbilics 4
Umbilic at location (-0.80899 0.00426003 0.293896) of type elliptic
Umbilic at location (-0.811197 0.0122098 -0.292259) of type elliptic
Umbilic at location (0.808372 -0.00551307 -0.29431) of type elliptic
Umbilic at location (0.81413 0.0018689 0.290339) of type elliptic
```

56.5.3 Example: Filtering of Crest Ridges on a Mechanical Par

Figure 56.6 illustrates the filtering of crest ridges on a mechanical model, and has been computed as follows:

```
./Compute_Ridges_Umbilics -f data/mecanic.off -d 4 -m 4 -a 4 -t 4
```

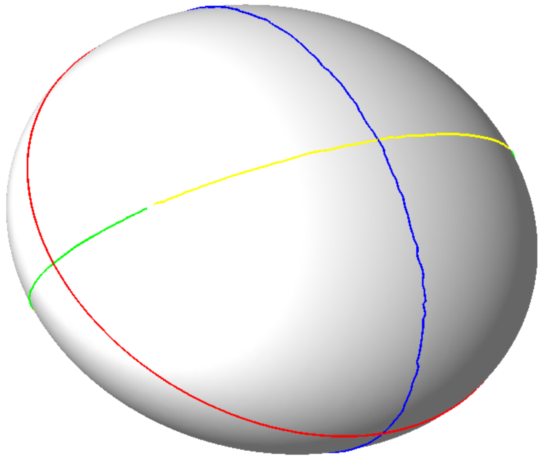

Figure 56.5: Ridges on the ellipsoid, normals pointing outward. Color coding : *MAX_ELLIPTIC_RIDGE* are blue, *MAX_HYPERBOLIC_RIDGE* are green, *MIN_ELLIPTIC_RIDGE* are red and *MIN_HYPERBOLIC_RIDGE* are yellow.

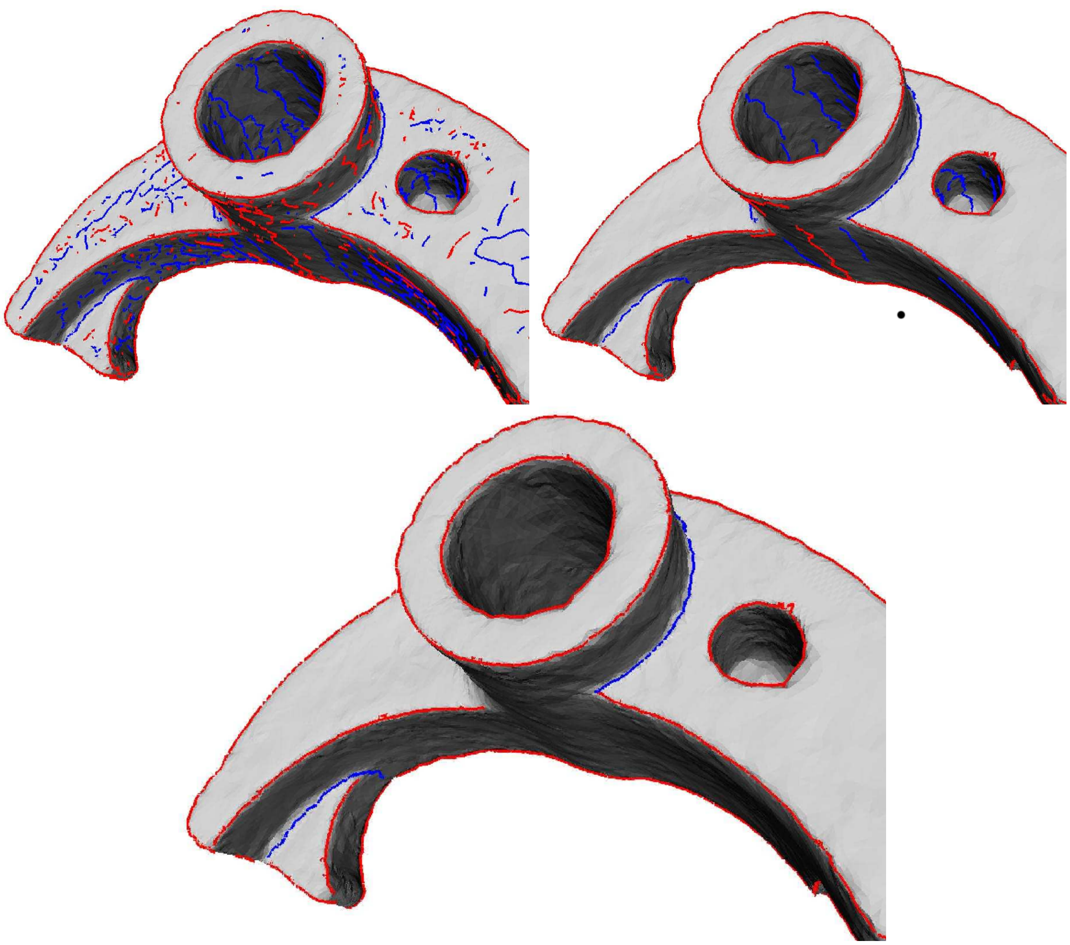

Figure 56.6: Mechanical part (37k pts): (a) All crest lines, (b) crests filtered with the strength threshold 1 and (c) crests filtered with the sharpness threshold 100 000. Notice that any point on a flat or cylindrical part lies on two ridges, so that the noise observed on the top two Figs. is unavoidable. It is however easily filtered out with the sharpness on the bottom figure.

CGAL::Ridge_approximation<TriangulatedSurfaceMesh,Vertex2FTPropertyMap,Ver

Class

Definition

The class *Ridge_approximation<TriangulatedSurfaceMesh,Vertex2FTPropertyMap,Vertex2VectorPropertyMap>* computes the approximation of ridges of a triangular polyhedral surface.

#include <CGAL/Ridges.h>

Parameters

The class *Ridge_approximation<TriangulatedSurfaceMesh,Vertex2FTPropertyMap,Vertex2VectorPropertyMap>* has three template parameters. *TriangulatedSurfaceMesh* provides the surface. Parameters *Vertex2FTPropertyMap* and *Vertex2VectorPropertyMap* provide the differential properties of the surface associated to its vertices.

Requirements (checked at compile time) : the types *TriangulatedSurfaceMesh::Traits::FT* and *Vertex2FTPropertyMap::value_type* must coincide; the types *TriangulatedSurfaceMesh::Traits::Vector_3* and *Vertex2VectorPropertyMap::value_type* must coincide; the types *TriangulatedSurfaceMesh::Vertex_handle*, *Vertex2FTPropertyMap::key_type* and *Vertex2VectorPropertyMap::key_type* must coincide;

Types

enum Tag_order { *Tag_3, Tag_4*};	Order of differential quantities used to distinguish elliptic and hyperbolic ridges. Third (*Tag_3*) or fourth (*Tag_4*) order quantities may be used as explained in section 56.2 of the user manual.

Creation

Ridge_approximation<TriangulatedSurfaceMesh,Vertex2FTPropertyMap,Vertex2VectorPropertyMap> ridge_approximation(TriangulatedSurfaceMesh P,

Vertex2FTPropertyMap vertex2k1_pm,

Vertex2FTPropertyMap vertex2k2_pm,

Vertex2FTPropertyMap vertex2b0_pm,

Vertex2FTPropertyMap vertex2b3_pm,

Vertex2VectorPropertyMap vertex2d1_pm,

Vertex2VectorPropertyMap vertex2d2_pm,

Ver-

tex2FTPropertyMap vertex2P1_pm,

Ver-

tex2FTPropertyMap vertex2P2_pm)

The two last property maps may not be used if computations are performed with the parameter *Tag_3*, in which case these property maps shall be initialized with their default constructors.

template <class OutputIterator>
OutputIterator ridge_approximation.compute_max_ridges(OutputIterator it, Tag_order ord = Tag_3)

Outputs ridges of types *MAX_ELLIPTIC_RIDGE* and *MAX_HYPERBOLIC_RIDGE*. Parameter *it* is a STL output iterator whose *value_type* is *Ridge_line**.

template <class OutputIterator>
OutputIterator ridge_approximation.compute_min_ridges(OutputIterator it, Tag_order ord = Tag_3)

Outputs ridges of types *MIN_ELLIPTIC_RIDGE* and *MIN_HYPERBOLIC_RIDGE*. Parameter *it* is a STL output iterator whose *value_type* is *Ridge_line**.

template <class OutputIterator>
OutputIterator ridge_approximation.compute_crest_ridges(OutputIterator it, Tag_order ord = Tag_3)

Outputs ridges of types *MAX_CREST_RIDGE* and *MIN_CREST_RIDGE*. Parameter *it* is a STL output iterator whose *value_type* is *Ridge_line**.

Ridge_line

CGAL::Ridge_line<TriangulatedSurfaceMesh>

Definition

The class *Ridge_line<TriangulatedSurfaceMesh>* stores the description of a ridge line. The list of halfedges defines a connected sequence of edges (but not as oriented halfedges). The scalar b paired with a halfedge pq is the barycentric coordinate of the crossing point r with the ridge : $r = b \times p + (1 - b) \times q$.

#include <CGAL/Ridges.h>

Types

typedef typename TriangulatedSurfaceMesh::Traits::FT

FT;

typedef typename TriangulatedSurfaceMesh::Halfedge_handle

Halfedge_handle;

typedef std::pair< Halfedge_handle, FT>

Ridge_halfhedge; A halfedge crossed by a ridge is paired with the barycentric coordinate of the crossing point.

Creation

Ridge_line<TriangulatedSurfaceMesh> ridge_line;

default constructor.

Access Functions

const Ridge_type	*ridge_line.line_type()*
const FT	*ridge_line.strength()*
const FT	*ridge_line.sharpness()*
*const std::list<Ridge_halfhedge>**	*ridge_line.line()*

The opertor $<<$ is overloaded for this class and returns the line type, strength, sharpness and coordinates of the points of the polyline.

Concept

TriangulatedSurfaceMesh

Definition

The concept TriangulatedSurfaceMesh describes an oriented surface (possibly with boundary) embedded in the 3 space. It is combinatorially based on a halfedge data structure with triangular faces, geometrically 3d points associated to the vertices define the embedding.

Types

TriangulatedSurfaceMesh:: Traits	geometric Traits, this is a CGAL::Kernel concept.
TriangulatedSurfaceMesh:: Facet	Opaque type representing a facet of the TriangulatedSurfaceMesh .
TriangulatedSurfaceMesh:: Facet_handle	Handle to a facet. Model of the Handle concept.
TriangulatedSurfaceMesh:: Facet_const_handle	
TriangulatedSurfaceMesh:: Facet_iterator	Iterator over all mesh facets. Model of the ForwardIterator concept.
TriangulatedSurfaceMesh:: Facet_const_iterator	
TriangulatedSurfaceMesh:: Vertex	Opaque type representing a vertex of the TriangulatedSurfaceMesh .
TriangulatedSurfaceMesh:: Vertex_handle	Handle to a vertex. Model of the Handle concept.
TriangulatedSurfaceMesh:: Vertex_const_handle	
TriangulatedSurfaceMesh:: Vertex_iterator	Iterator over all vertices of a mesh. Model of the ForwardIterator concept.
TriangulatedSurfaceMesh:: Vertex_const_iterator	
TriangulatedSurfaceMesh:: Halfedge	Opaque type representing a halfedge of the TriangulatedSurfaceMesh .
TriangulatedSurfaceMesh:: Halfedge_handle	Handle to a halfedge. Model of the Handle concept.
TriangulatedSurfaceMesh:: Halfedge_const_handle	
TriangulatedSurfaceMesh:: Halfedge_iterator	Iterator over all halfedges of a TriangulatedSurfaceMesh . Model of the ForwardIterator concept.
TriangulatedSurfaceMesh:: Halfedge_const_iterator	
TriangulatedSurfaceMesh:: Point_iterator	Iterator over all points of a TriangulatedSurfaceMesh , its value type is *Traits::Point_3*. Model of the ForwardIterator concept.
TriangulatedSurfaceMesh:: Point_const_iterator	

Creation

Construction and destruction are undefined.

Operations

Facet_const_iterator	*mesh.facets_begin()*	iterator over all facets (excluding holes).
Facet_const_iterator	*mesh.facets_end()*	past-the-end iterator.
Point_iterator	*mesh.points_begin()*	iterator over all points.

Point_iterator	*mesh.points_end()*	past-the-end iterator.

Methods for the Vertex :

Traits::Point_3&	*vertex.point()*	The point associated to the vertex

Methods for the Halfedge :

Halfedge_const_handle	*halfedge.opposite() const*	the opposite halfedge.
Halfedge_const_handle	*halfedge.next() const*	the next halfedge around the facet.
Halfedge_const_handle	*halfedge.prev() const*	the previous halfedge around the facet.
bool	*halfedge.is_border_edge() const*	is true if *halfedge* or *halfedge.opposite()* is a border halfedge.
Vertex_const_handle	*halfedge.vertex() const*	the incident vertex of *halfedge*.
Facet_const_handle	*halfedge.facet() const*	the incident facet of *halfedge*. If *halfedge* is a border halfedge the result is default construction of the handle.

Methods for the Facet :

Halfedge_const_handle	*facet.halfedge() const*	an incident halfedge that points to *facet*.

Has Models

CGAL::Polyhedron_3 with the restriction that faces are triangular.

Class

CGAL::Umbilic<TriangulatedSurfaceMesh>

Definition

The class *Umbilic<TriangulatedSurfaceMesh>* stores the description of an umbilic.

#include <CGAL/Umbilics.h>

Types

typedef typename TriangulatedSurfaceMesh::Vertex_handle

Vertex_handle;

typedef typename TriangulatedSurfaceMesh::Halfedge_handle

Halfedge_handle;

Creation

Access Functions

const Vertex_handle *umbilic.vertex()*

const Umbilic_type *umbilic.umbilic_type()*

std::list<Halfedge_handle>

umbilic.contour_list()

Operations

The usual insert operator (<<) is overloaded for *Umbilic*, it gives the location (3d coordinates of the vertex) and the type.

Estimation of Local Differential Properties of Point-Sampled Surfaces

Marc Pouget and Frédéric Cazals

Contents

This package allows the estimation of local differential quantities of a surface from a point sample, given either as a mesh or as point cloud.

Note that this package needs the third party library Eigen (Page 28) to be installed to compile the example code.

Figure 57.1: Principal directions associated with k_{max} scaled by k_{min}.

57.1 Introduction

57.1.1 Overview

Consider a sampled smooth surface, and assume we are given a collection of points P about a given sample p. We aim at estimating the differential properties up to any fixed order of the surface at point p from the point set $P^+ = P \cup \{p\}$ — we denote $N = | P^+ |$. More precisely, first order properties correspond to the normal or the tangent plane; second order properties provide the principal curvatures and directions, third order properties provide the directional derivatives of the principal curvatures along the curvature lines, etc. Most of the time, estimating first and second order differential quantities is sufficient. However, some applications involving shape analysis require estimating third and fourth order differential quantities. Many different estimators have been proposed in the vast literature of applied geometry [Pet01] (section 3, page 7), and all of them need to define a neighborhood around the point at which the estimation is computed. Our method relies on smooth differential geometry calculations, carried out on smooth objects *fitted* from the sample points. Datasets amenable to such a processing are naturally unstructured point clouds, as well as meshes —whose topological information may be discarded.

Estimating differential properties from discrete date always raises a philosophical issue. On one hand, estimating differential quantities subsumes a smooth surface does exist. In this spirit one wishes to recover its differential properties, so that any estimation method must come with an asymptotic convergence analysis of the results returned. For the method developed in this CGAL package, the interested will find such an analysis in [CP05a], (Theorem 3)— it should be stressed the error bounds proved therein are optimal.

On the other hand, any estimation method may be applied to arbitrarily data —surface unknown, surface piecewise smooth etc. In such a case, no analysis can be carried out, and it is up to the users to check the results match their needs.

Unlike most of the CGAL packages, this package uses approximation methods and is not intended to provide an exact canonical result in any sense. This is why internal computations are performed with a number type possibly different from that of the input data, even if for convenience the results are returned with this original number type. A reasonable choice for this internal number type is for example the *double* type.

57.1.2 Smooth Surfaces, d-Jets and the Monge Form

To present the method, we shall need the following notions. Consider a smooth surface. About one of its points, consider a coordinate system whose z-axis does not belong to the tangent space. In such a frame, the surface can locally be written as the graph of a bivariate function. Letting $h.o.t.$ stand for *higher order terms*, one has :

$$z(x,y) = J_{B,d}(x,y) + h.o.t. \ ; \quad J_{B,d}(x,y) = \sum_{k=0}^{d} \Big(\sum_{i=0}^{i} \frac{B_{k-i,i}x^{k-i}y^{i}}{i!(k-i)!}\Big). \tag{57.1}$$

The degree d polynomial $J_{B,d}$ is the Taylor expansion of the function z, and is called its *d-jet*. Notice that a d-jet contains $N_d = (d+1)(d+2)/2$ coefficients.

Recall that an umbilical point of a surface — or umbilic for short, is a point where both principal curvatures are identical. At any point of the surface which is not an umbilic, principal directions d_1, d_2 are well defined, and these (non oriented) directions together with the normal vector n define two direct orthonormal frames. If v_1 is a unit vector of direction d_1, there exists a unique unit vector v_2 so that (v_1, v_2, n) is direct; and the other possible frame is $(-v_1, -v_2, n)$. Both these coordinate systems are known as the *Monge coordinate systems*. In both these systems, the surface is said to be given in the Monge form and its jet has the following canonical form :

$$z(x,y) = \quad \tfrac{1}{2}(k_1x^2 + k_2y^2) + \tfrac{1}{6}(b_0x^3 + 3b_1x^2y + 3b_2xy^2 + b_3y^3) \tag{57.2}$$

$$+ \tfrac{1}{24}(c_0x^4 + 4c_1x^3y + 6c_2x^2y^2 + 4c_3xy^3 + c_4y^4) + h.o.t. \tag{57.3}$$

The coefficients k_1, k_2 are the principal curvatures, b_0, b_3 are the directional derivatives of k_1, k_2 along their respective curvature line, while b_1, b_2 are the directional derivatives of k_1, k_2 along the other curvature lines.

The Monge coordinate system can be computed from any d-jet ($d \geq 2$), and so are the Monge coefficients. These informations characterize the local geometry of the surface in a canonical way, and are the quantities returned by our algorithm.

57.1.3 Algorithm

Based on the above concepts, the algorithm consists of 4 steps.

1. We perform a Principal Component Analysis (PCA) on P^+. This analysis outputs three orthonormal eigenvectors and the associated eigenvalues. The fitting basis consists of these three vectors so that the vector associated to the smallest eigenvalue is the last vector of the basis. (Indeed, if the surface is well sampled, one expects the PCA to provide one small and two large eigenvalues, the eigenvector associated to the small one approximating the normal vector.)

2. We perform a change of coordinates to move the samples into the coordinate system of the fitting basis and with origin the point p at which the estimation is sought. We then resort to polynomial fitting, so as to either interpolate or approximate the d-jet of the surface in this coordinate system. This bivariate polynomial approximation reduces to linear algebra operations.

3. From the fitted d-jet, we compute the Monge basis (d_1, d_2, n).

4. Finally, we compute the Monge coefficients : k_i, b_i, c_i.

Further details can be found in section 57.4 and in [CP05a] (section 6).

57.1.4 Degenerate Cases

As usual, the fitting procedure may run into (almost) degenerate cases:

- Due to poor sampling, the PCA used to determine a rough normal vector may not be good. The nearer this direction to the tangent plane the worse the estimation.
- As observed in [CP05a] (section 3.1), the interpolating problem is not *poised* if the points project, into the fitting frame, onto an algebraic curve of degree d. More generally, the problem is ill poised if the condition number is too large.

In these cases, even if a result is provided, the estimation may not be relevant. To inform the user of these issues, we provide the PCA results and the condition number of the fitting. In any case, it is up to the user to judge if the result meets its need.

57.2 Software Design

57.2.1 Options and Interface Specifications

The fitting strategy performed by the class *Monge_via_jet_fitting* requires the following parameters:

- the degree d of the fitted polynomial ($d \geq 1$),
- the degree d' of the Monge coefficients sought, with $1 \leq d' \leq \min(d, 4)$,
- a range of N input points on the surface, with the precondition that $N \geq N_d = (d+1)(d+2)/2$. Note that if $N = N_d$, interpolation is performed; and if $N > N_d$, approximation is used.

57.2.2 Output

As explained in Section 57.1, the output consists of a coordinate system, the Monge basis, together with the Monge coefficients which are stored in the *Monge_form* class. In addition, more information on the computational issues are stored in the *Monge_via_jet_fitting* class.

The *Monge_form* class provides the following information.

- Origin. This is the point on the fitted polynomial surface where the differential quantities have been computed. In the approximation case, it differs from the input point p : it is the projection of p onto the fitted surface following the z-direction of the fitting basis.

- Monge Basis. The Monge basis (d_1, d_2, n) is orthonormal direct, and the maximal, minimal curvatures are defined wrt this basis. If the user has a predefined normal n_0 (e.g. the sample points come from an oriented mesh) then if $n_0.n > 0$ then max-min is correct; if not, i.e. $n_0.n < 0$, the user should switch to the orthonormal direct basis $(d'_1, d'_2, n') = (d_2, d_1, -n)$ with the maximal curvature $k'_1 = -k_2$ and the minimal curvature $k'_2 = -k_1$. If $n_0.n = 0$ or is small, the orientation of the surface is clearly ill-defined, and the user may proof-check the samples used to comply with its predefined normal.

- Monge Coefficients. The coefficient of the Monge form is $(k_1, k_2(\leq k_1), b_0, b_1, b_2, b_3, c_0, c_1, c_2, c_3, c_4)$ for $d' = 4$.

In addition, the class *Monge_via_jet_fitting* stores

- the condition number of the fitting system,
- the coordinate system of the PCA (in which the fitting is performed).

57.2.3 Template Parameters

Template parameter `DataKernel`

This concept provides the types for the input sample points, together with $3d$ vectors and a number type. It is used as template for the class *Monge_via_jet_fitting<DataKernel, LocalKernel, SvdTraits>* . Typically, one can use *CGAL::Cartesian<double>*.

Template parameter `LocalKernel`

This is a parameter of the class *Monge_via_jet_fitting<DataKernel, LocalKernel, SvdTraits>*. This concept defines the vector and number types used for local computations and to store the PCA basis data.

Input points of type *DataKernel::Point_3* are converted to *LocalKernel::Point_3*. For output of the *Monge_form* class, these types are converted back to *Data_Kernel* ones. Typically, one can use *CGAL::Cartesian<double>* which is the default.

Template parameter `SvdTraits`

This concept provides the number, vector and matrix types for algebra operations required by the fitting method in *Monge_via_jet_fitting<DataKernel, LocalKernel, SvdTraits>* . The main method is a linear solver using a singular value decomposition.

Compatibility requirements

To solve the fitting problem, the sample points are first converted from the *DataKernel* to the *LocalKernel* (this is done using the *CGAL::Cartesian_converter*). Then change of coordinate systems and linear algebra operations are performed with this kernel. This implies that the number types *LocalKernel::FT* and *SvdTraits::FT* must be identical. Second the Monge basis and coefficients, computed with the *LocalKernel*, are converted back to the *DataKernel* (this is done using the *CGAL::Cartesian_converter* and the *CGAL::NT_converter*).

57.3 Examples

57.3.1 Single Estimation about a Point of a Point Cloud

The first example illustrates the computation of the local differential quantities from a set of points given in a text file as input. The first point of the list is the one at which the computation is performed. The user has to specify a file for the input points and the degrees d and d'.

```
#include <CGAL/Cartesian.h>

#include <fstream>
#include <vector>

#include <CGAL/Monge_via_jet_fitting.h>
typedef double                     DFT;
typedef CGAL::Cartesian<DFT>       Data_Kernel;
typedef Data_Kernel::Point_3       DPoint;
typedef CGAL::Monge_via_jet_fitting<Data_Kernel>
   My_Monge_via_jet_fitting;
typedef My_Monge_via_jet_fitting::Monge_form     My_Monge_form;

int main(int argc, char *argv[])
{
  size_t d_fitting = 4;
  size_t d_monge = 4;
  const char* name_file_in = "data/in_points_d4.txt";
  //check command line
  if (argc<4)
    {
      std::cout << " Usage : " << argv[0]
                << " <inputPoints.txt> <d_fitting> <d_monge>" <<
   std::endl
                << "test with default arguments" << std::endl;
    }
  else {
    name_file_in = argv[1];
    d_fitting = std::atoi(argv[2]);
    d_monge = std::atoi(argv[3]);
  }

  //open the input file
  std::ifstream inFile(name_file_in);
  if ( !inFile )
    {
      std::cerr << "cannot open file for input\n";
      exit(-1);
    }

  //initalize the in_points container
  double x, y, z;
  std::vector<DPoint> in_points;
  while (inFile >> x) {
```

```
    inFile >> y >> z;
    DPoint p(x,y,z);
    in_points.push_back(p);
  }
  inFile.close();
  // fct parameters

  My_Monge_form monge_form;
  My_Monge_via_jet_fitting monge_fit;
  monge_form = monge_fit(in_points.begin(), in_points.end(), d_fitting,
    d_monge);

  //OUTPUT on std::cout
  CGAL::set_pretty_mode(std::cout);
  std::cout << "vertex : " << in_points[0] << std::endl
            << "number of points used : " << in_points.size() <<
    std::endl
            << monge_form;
  std::cout  << "condition_number : " << monge_fit.condition_number() <<
    std::endl
             << "pca_eigen_vals and associated pca_eigen_vecs :"  <<
    std::endl;
  for (int i=0; i<3; i++)
    std::cout << monge_fit.pca_basis(i).first << std::endl
              << monge_fit.pca_basis(i).second  << std::endl;
  return 0;
}
```

File: examples/Jet_fitting_3/Single_estimation.cpp

57.3.2 On a Mesh

The second example (cf Mesh_estimation.cpp in the example directory) illustrates the computation of local differential quantities for all vertices of a given mesh. The neighborhood of a given vertex is computed using rings on the triangulation. Results are twofold:

- a human readable text file featuring the *Monge_form* and numerical informations on the computation : condition number and the PCA basis;
- another text file that records raw data (better for a vizualization post-processing).

Figs. 57.1 and 57.2 provide illustrations of principal directions of curvature.

advanced

57.4 Mathematical and Algorithmic Details

In this Section, we detail the mathematics involved, in order to justify the design choices made. To begin with, observe the fitting problem involves three relevant direct orthonormal basis: the world-basis (w_x, w_y, w_z), the fitting-basis (f_x, f_y, f_z), the Monge basis (d_1, d_2, n).

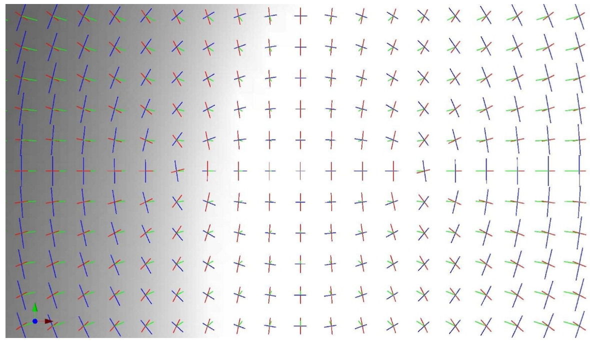

Figure 57.2: Principal directions of curvature and normals at vertices of a mesh of the graph of the function $f(x,y) = 2x^2 + y^2$.

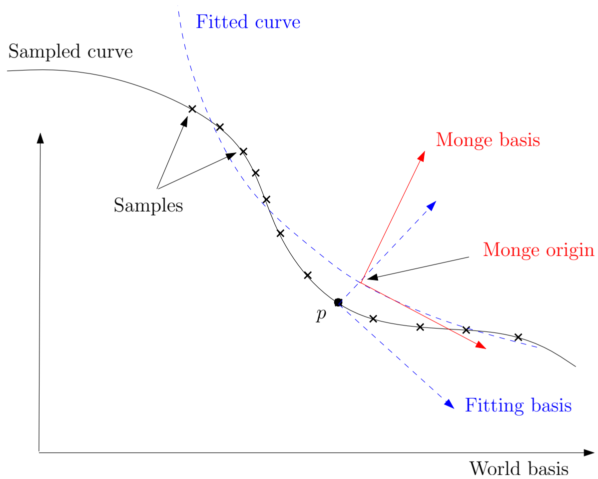

Figure 57.3: The three bases involved in the estimation.

57.4.1 Computing a Basis for the Fitting

Input : samples
Output : fitting-basis

Performing a PCA requires diagonalizing a symmetric matrix. This analysis gives an orthonormal basis whose z-axis is provided by the eigenvector associated to the smallest eigenvalue.[1] Note one may have to swap the orientation of a vector to get a direct basis.

Let us denote $P_{W \to F}$ the matrix that changes coordinates from the world-basis (w_x, w_y, w_z) to the fitting-basis (f_x, f_y, f_z). The rows of $P_{W \to F}$ are the coordinates of the vectors (f_x, f_y, f_z) in the world-basis. This matrix represents a orthogonal transformation hence its inverse is its transpose. To obtain the coordinates of a point in the fitting-basis from the coordinates in the world-basis, one has to multiply by $P_{W \to F}$.

As mentioned above, the eigenvalues are returned, from which the sampling quality can be assessed. For a good sampling, the eigenvector associated to the smallest eigenvalue should roughly give the normal direction.

[1] Another possibility is to choose as z-axis the axis of the world-basis with the least angle with the axis determined with the PCA. Then the change of basis reduces to a permutation of axis.

57.4.2 Solving the Interpolation / Approximation Problem

Input : samples, fitting-basis
Output : coefficients $A_{i,j}$ of the bivariate fitted polynomial in the fitting-basis

Computations are done in the fitting-basis and the origin is the point p. First, one has to transform coordinates of sample points with a translation $(-p)$ and multiplication by $P_{W\to F}$.

The fitting process consists of finding the coefficients $A_{i,j}$ of the degree d polynomial

$$J_{A,d} = \sum_{k=0}^{d} (\sum_{i=0}^{k} \frac{A_{k-i,i}x^{k-i}y^i}{i!(k-i)!}). \tag{57.4}$$

Denote $p_i = (x_i, y_i, z_i),\ i = 1,\ldots,N$ the coordinates of the sample points of P^+. For interpolation the linear equations to solve are $A(x_i, y_i) = z_i\ i = 1,\ldots,N$, and for approximation one has to minimize $\sum_{i=1}^{N}(A(x_i, y_i) - z_i)^2$. The linear algebra formulation of the problem is given by

$$A = \quad (A_{0,0}, A_{1,0}, A_{0,1}, \ldots, A_{0,d})^T \tag{57.5}$$

$$Z = \quad (z_1, z_2, \ldots, z_N)^T \tag{57.6}$$

$$M = \quad (1, x_i,\ y_i,\ \tfrac{x_i^2}{2}, \ldots,\ \tfrac{x_i y_i^{d-1}}{(d-1)!},\ \tfrac{y_i^d}{d!})_{i=1,\ldots,N} \tag{57.7}$$

$$\tag{57.8}$$

The equations for interpolation become $MA = Z$. For approximation, the system $MA = Z$ is solved in the least square sense, i.e. one seeks the vector A such that $A = \arg\min_A ||MA - Z||_2$.

In any case, there is a preconditioning of the matrix M so as to improve the condition number. Assuming the $\{x_i\}$, $\{y_i\}$ are of order h, the pre-conditioning consists of performing a column scaling by dividing each monomial $x_i^k y_i^l$ by h^{k+l} — refer to Eq. (57.5). Practically, the parameter h is chosen as the mean value of the $\{x_i\}$ and $\{y_i\}$. In other words, the new system is $M'Y = (MD^{-1})(DA) = Z$ with D the diagonal matrix $D = (1, h, h, h^2, \ldots, h^d, h^d)$, so that the solution A of the original system is $A = D^{-1}Y$.

There is always a single solution since for under constrained systems we also minimize $||A||_2$. The method uses a singular value decomposition of the $N \times N_d$ matrix $M = USV^T$, where U is a $N \times N$ orthogonal matrix, V is a $N_d \times N_d$ orthogonal matrix and S is a $N \times N_d$ matrix with the singular values on its diagonal. Denote r the rank of M, we can decompose $S = \begin{pmatrix} D_r & 0_{r,\ N_d-r} \\ 0_{N-r,\ r} & 0_{N-r,\ N_d-r} \end{pmatrix}$. The number r, which is the number of non zero singular values, is strictly lower than N_d if the system is under constrained. In any case, the unique solution which minimize $||A||_2$ is given by :

$$A = V \begin{pmatrix} D_r^{-1} & 0_{N_d-r,\ r} \\ 0_{r,\ N-r} & 0_{N_d-r,\ N-r} \end{pmatrix} U^T Z. \tag{57.9}$$

One can provide the condition number of the matrix M (after preconditioning) which is the ratio of the maximal and the minimal singular values. It is infinite if the system is under constrained, that is the smallest singular value is zero.

Implementation details. We assume a *solve* function is provided by the traits *SvdTraits*. This function solves the system MX=B (in the least square sense if M is not square) using a Singular Value Decomposition and gives the condition number of M.

Remark: as an alternative, other methods may be used to solve the system. A *QR* decomposition can be substituted to the *SVD*. One can also use the normal equation $M^T MX = MTB$ and apply methods for square systems such as LU, QR or Cholesky since $M^T M$ is symmetric definite positive when M has full rank. The advantages of the SVD is that it works directly on the rectangular system and gives the condition number of the system. For more on these alternatives, see [GvL83] (Chap. 5).

57.4.3 Principal Curvature / Directions

Input : coefficients of the fit $A_{i,j}$, fitting-basis
Output : Monge basis wrt fitting-basis and world-basis

In the fitting basis, we have determined a height function expressed by Eq. (57.4). Computations are done in the fitting-basis. The partial derivatives, evaluated at $(x,y) = (0,0)$, of the fitted polynomial $J_{A,d}(x,y)$ are $A_{i,j} = \frac{\partial^{i+j} J_{A,d}}{\partial^i x \partial^j y}$ Expanding Eq. (57.4) yields:

$$J_{A,d}(x,y) = A_{0,0} + A_{1,0}x + A_{0,1}y + \frac{1}{2}(A_{2,0}x^2 + 2A_{1,1}xy + A_{0,2}y^2) + \frac{1}{6}(A_{3,0}x^3 + 3A_{2,1}x^2y + \dots) + \dots \quad (57.10)$$

- The origin, that is the point of the fitted surface where the estimation is performed, is $(0,0,A_{0,0})$.
- The normal is $n = (-A_{1,0}, -A_{0,1}, 1)/\sqrt{A_{1,0}^2 + A_{0,1}^2 + 1}$.
- Curvature related properties are retrieved resorting to standard differential calculus [dC76] (Chap. 3). More precisely, the Weingarten operator $W = -I^{-1}II$ is first computed in the basis of the tangent plane $\{(1,0,A_{1,0}),(0,1,A_{0,1})\}$. We compute an orthonormal basis of the tangent plane using the Gram-Schmidt algorithm, and then we compute Weingarten in this basis (applying a change of basis with the matrix $W' = P^{-1}WP$). In this orthonormal basis, the matrix of the Weingarten map is symmetric and we diagonalize it. One finally gets the principal curvatures which are the eigenvalues of W, and the associated principal directions. This gives an orthonormal direct basis (d_1,d_2,n). Let us denote $P_{F\to M}$ the matrix to change coordinates from the fitting-basis to the Monge basis. Its rows are the coordinates of the vectors (d_1,d_2,n) in the fitting-basis. It is an orthogonal matrix $P_{F\to M}^{-1} = P_{F\to M}^T$. The Monge basis expressed in the world-basis is obtained by multiplying the coordinates of (d_1,d_2,n) in the fitting-basis by $P_{W\to F}^{-1}$, (the same holds for the origin point which has in addition to be translated by p, i.e. the coordinates of the origin point are $P_{W\to F}^{-1}(0,0,A_{0,0}) + p$.

57.4.4 Computing Higher Order Monge Coefficients

Input : coefficients of the fit, Monge basis wrt fitting-basis ($P_{F\to M}$)
Output : third and fourth order coefficients of Monge

We use explicit formula. The implicit equation of the fitted polynomial surface in the fitting-basis with origin the point $(0,0,A_{0,0})$ is $Q = 0$ with

$$Q = -w - A_{0,0} + \sum_{i,j} \frac{A_{i,j} u^i v^j}{i!j!}. \quad (57.11)$$

The equation in the Monge basis is obtained by substituting (u,v,w) by $P_{F\to M}^T(x,y,z)$. Denote $f(x,y,z) = 0$ this implicit equation. By definition of the Monge basis, we have locally (at $(0,0,0)$)

$$f(x,y,z) = 0 \Leftrightarrow z = g(x,y) \quad (57.12)$$

and the Taylor expansion of g at $(0,0)$ are the Monge coefficients sought. Let us denote the partial derivatives evaluated at the origin of f and g by $f_{i,j,k} = \frac{\partial^{i+j+k} f}{\partial^i x \partial^j y \partial^k z}$ and $g_{i,j} = \frac{\partial^{i+j} g}{\partial^i x \partial^j y}$. One has $f_{1,0,0} = f_{0,1,0} = f_{1,1,0} = 0$, $g_{0,0} = g_{1,0} = g_{0,1} = g_{1,1} = 0$ and $g_{2,0} = k_1$, $g_{0,2} = k_2$. The partial derivative of order n of f depends on the matrix $P_{F\to M}$ and the partial derivatives of order at most n of $J_{A,d}$. The third and fourth order coefficients of are computed with the implicit function theorem. For instance :

$$
\begin{array}{c}
b_0 = g_{3,0} = -\frac{f_{3,0,0}f_{0,0,1}-3f_{1,0,1}f_{2,0,0}}{f_{0,0,1}^2} \\
b_1 = g_{2,1} = -\frac{-f_{0,1,1}f_{2,0,0}+f_{2,1,0}f_{0,0,1}}{f_{0,0,1}^2} \\
\ldots.
\end{array}
$$

DataKernel

Definition

The concept DataKernel describes the set of requirements to be fulfilled by any class used to instantiate first template parameter of the class *Monge_via_jet_fitting<DataKernel,LocalKernel,SvdTraits>*.

Types

DataKernel:: FT	The scalar type.
DataKernel:: Point_3	The point type.
DataKernel:: Vector_3	The vector type.

Operations

Only constructors (from 3 scalars and copy constructors) and access methods to coordinates *x()*, *y()*, *z()* are needed.

Has Models

CGAL::Cartesian<FieldNumberType>

See Also

The *LocalKernel* concept.

Class

CGAL::Eigen_svd

Definition

The class *Eigen_svd* provides an algorithm to solve in the least square sense a linear system with a singular value decomposition using Eigen (Page 28). The field type is *double*.

#include <CGAL/Eigen_svd.h>

Is Model for the Concepts

SvdTraits

LocalKernel

Concept

Definition

The concept LocalKernel describes the set of requirements to be fulfilled by any class used to instantiate the second template parameter of the class *Monge_via_jet_fitting<DataKernel,LocalKernel,SvdTraits>*.

This concept provides the geometric primitives used for the computations in the class *Monge_via_jet_fitting*.

Requirements

In the class *Monge_via_jet_fitting* the scalar type, *LocalKernel::FT*, must be the same as that of the *SvdTraits* concept : *SvdTraits::FT*.

The type *LocalKernel::FT* is a model of the FieldWithSqrt concept.

Types

LocalKernel:: FT	The scalar type.
LocalKernel:: Point_3	The point type.
LocalKernel:: Vector_3	The vector type.

Operations

The scalar type *LocalKernel::FT* must be a field type with a square root.

Only constructors (from 3 scalars and copy constructors) and access methods to coordinates *x()*, *y()*, *z()* are needed for the point and vector types.

Has Models

CGAL::Cartesian<FieldNumberType>

See Also

The *DataKernel* and *SvdTraits* concepts.

CGAL::Monge_via_jet_fitting< DataKernel, LocalKernel, SvdTraits> ::Monge_form

Definition

The class *Monge_form* stores the Monge representation, i.e., the Monge coordinate system and the coefficients of the Monge form in this system.

#include <CGAL/Monge_via_jet_fitting.h>

Types

typedef typename DataKernel::FT

FT;

typedef typename DataKernel::Point_3

Point_3;

typedef typename DataKernel::Vector_3

Vector_3;

Creation

Monge_form monge_form; default constructor.

Access Functions

Point_3	*monge_form.origin()*	Point on the fitted surface where differential quantities are computed.

The Monge basis is given by:

Vector_3	*monge_form.maximal_principal_direction()*
Vector_3	*monge_form.minimal_principal_direction()*
Vector_3	*monge_form.normal_direction()*

The Monge coefficients are given by:

FT *monge_form.principal_curvatures(size_t i)*

$i = 0$ for the maximum and $i = 1$ for the minimum.

FT *monge_form.third_order_coefficients(size_t i)*

$0 \leq i \leq 3$

FT *monge_form.fourth_order_coefficients(size_t i)*

$0 \leq i \leq 4$

Operations

void *monge_form.comply_wrt_given_normal(const Vector_3 given_normal)*

change principal basis and Monge coefficients so that the given_normal and the Monge normal make an acute angle. If given_normal.monge_normal < 0 then change the orientation: if $z = g(x,y)$ in the basis (d1,d2,n) then in the basis (d2,d1,-n) $z = h(x,y) = -g(y,x)$.

The usual insert operator (*operator*<<) is overloaded for *Monge_form*, it gives the Monge coordinate system (the origin and an orthonormal basis) and the coefficients of the Monge form in this system.

Monge_via_jet_fitting

CGAL::Monge_via_jet_fitting<DataKernel, LocalKernel, SvdTraits>

Definition

The class *Monge_via_jet_fitting<DataKernel, LocalKernel, SvdTraits>* is designed to perform the estimation of the local differential quantities at a given point. The point range is given by a pair of input iterators, and it is assumed that the point where the calculation is carried out is the point that the begin iterator refers to. The results are stored in an instance of the nested class *Monge_form*, the particular information returned depending on the degrees specified for the polynomial fitting and for the Monge form.

The default for the template *LocalKernel* is *Cartesian<double>* and the default for *SvdTraits* is *Eigen_svd* if *CGAL_EIGEN3_ENABLED* is defined.

#include <CGAL/Monge_via_jet_fitting.h>

Parameters

The class *Monge_via_jet_fitting<DataKernel, LocalKernel, SvdTraits>* has three template parameters. Parameter *DataKernel* provides the geometric classes and tools corresponding to the input points, and also members of the *Monge_form* class. Parameter *LocalKernel* provides the geometric classes and tools required by local computations. Parameter *SvdTraits* features the linear algebra algorithm required by the fitting method.

Types

typedef DataKernel *Data_kernel;*
typedef LocalKernel *Local_kernel;*
typedef typename Local_kernel::FT

FT;
typedef typename Local_kernel::Vector_3

Vector_3;

Monge_via_jet_fitting<DataKernel, LocalKernel, SvdTraits>:: Monge_form

see the section below.

Creation

Monge_via_jet_fitting<DataKernel, LocalKernel, SvdTraits> *monge_fitting*;

default constructor

Operations

template <class InputIterator>

Monge_form *monge_fitting(InputIterator begin, InputIterator end, size_t d, size_t d')*

This operator performs all the computations. The N input points are given by the *InputIterator* parameters which value-type are *Data_kernel::Point_3*, d is the degree of the fitted polynomial, *d'* is the degree of the expected Monge coefficients.
Precondition: $N \geq N_d := (d+1)(d+2)/2$, $1 \leq d' \leq \min(d,4)$.

FT *monge_fitting.condition_number()*

condition number of the linear fitting system.

std::pair<FT, Vector_3>

monge_fitting.pca_basis(size_t i)

pca eigenvalues and eigenvectors, the pca_basis has always 3 such pairs. Precondition : i ranges from 0 to 2.

SvdTraits

Definition

The concept SvdTraits describes the set of requirements to be fulfilled by any class used to instantiate the third template parameter of the class *Monge_via_jet_fitting<DataKernel,LocalKernel,SvdTraits>*.

It describes the linear algebra types and algorithms needed by the class *Monge_via_jet_fitting*.

Requirements

The scalar type, *SvdTraits::FT*, must be the same as that of the *LocalKernel* concept : *LocalKernel::FT*.

Types

SvdTraits:: FT	The scalar type.
SvdTraits:: Vector	The vector type.
SvdTraits:: Matrix	The matrix type.

Operations

SvdTraits vector(size_t n);	initialize all the elements of the vector to zero.

The type *Vector* has the access methods

size_t	*vector.size()*	
FT	*vector(size_t i)*	return the i^{th} entry, i from 0 to $size() - 1$.
void	*vector.set(size_t i, const FT value)*	set the i^{th} entry to *value*.
*FT**	*vector.vector()*	return the vector as an array.

The type *Matrix* has the access methods

SvdTraits matrix(size_t n1, size_t n2);	initialize all the entries of the matrix to zero.

size_t	*matrix.number_of_rows()*	
size_t	*matrix.number_of_columns()*	
FT	*matrix(size_t i, size_t j)*	return the entry at row i and column j, i from 0 to *number_of_rows - 1*, j from 0 to *number_of_columns - 1*.
void	*matrix.set(size_t i, size_t j, const FT value)*	set the entry at row i and column j to *value*.

The concept *SvdTraits* has a linear solver using a singular value decomposition algorithm.

FT *traits.solve(Matrix& M, Vector& B)*

Solves the system $MX = B$ (in the least square sense if M is not square) using a singular value decomposition and returns the condition number of M. The solution is stored in B.

Chapter 58

Point Set Processing

Pierre Alliez, Laurent Saboret, Nader Salman

Contents

58.1 Introduction

This CGAL component implements methods to analyze and process unorganized 3D point sets. The input is an unorganized 3D point set, possibly with normal attributes (unoriented or oriented). This point set can be analyzed to measure geometric properties such as average spacing between the points and their K nearest neighbors. It can be processed with functions devoted to the simplification, outlier removal, smoothing, normal estimation and normal orientation. The processing of point sets is often needed in applications dealing with measurement data, such as surface reconstruction from laser scanned data (see Figure 58.1).

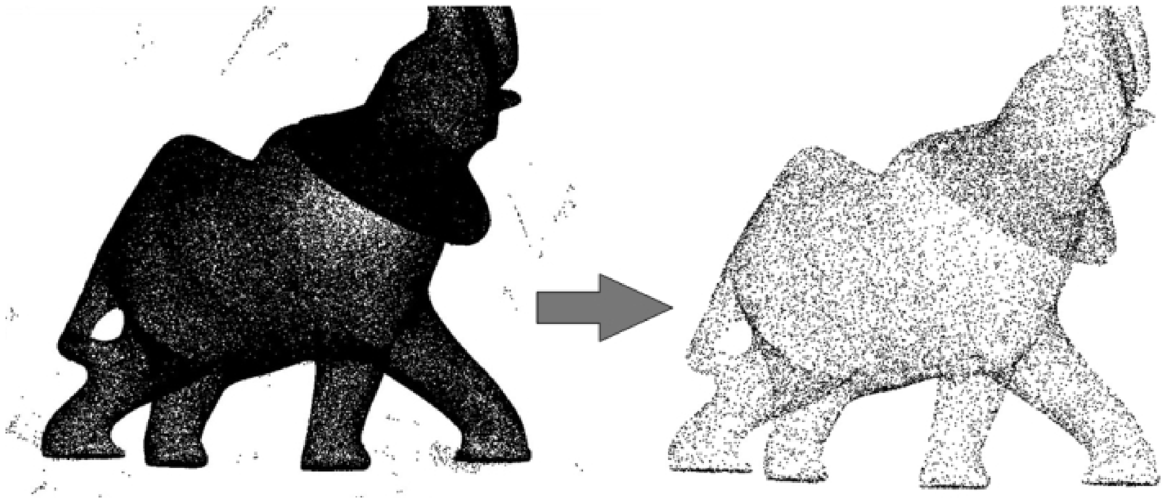

Figure 58.1: Point set processing. Left: 275K points sampled on the statue of an elephant with a Minolta laser scanner. Right: point set after clean-up and simplification to 17K points.

In the context of surface reconstruction we can position the elements of this component along the common surface reconstruction pipeline (Figure 58.2) which involves the following steps: 1) Scanning and scan alignment to produce a set of points or points with normals (alignment is not yet covered in CGAL); 2) Outlier removal; 3) Simplification to reduce the number of input points; 4) Smoothing to reduce noise in the input data; 5) Normal estimation and orientation when the normals are not already provided by the acquisition device; and 6) Surface reconstruction. Chapter *Surface_reconstruction_points_3* 49 deals with surface reconstruction from point sets with normal attributes.

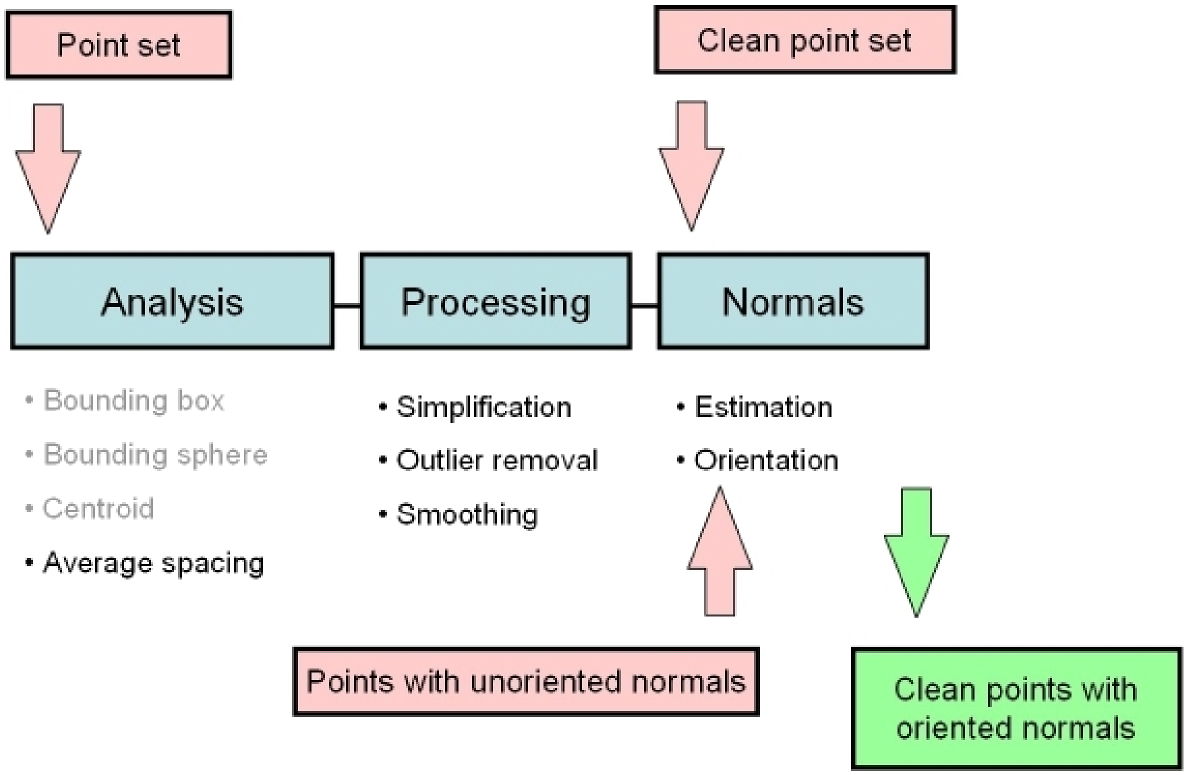

Figure 58.2: Point set processing pipeline for surface reconstruction. The algorithms listed in gray are available from other CGAL components (bounding volumes and principal component analysis).

58.2 Input/Output

58.2.1 Property Maps

The algorithms of this component take as input parameters iterator ranges of 3D points, or of 3D points with normals. The property maps are used to access the point or normal information from the input data, so as to let the user decide upon the implementation of a point with normal. The latter can be represented as, e.g., a class derived from the CGAL 3D point, or as a *std::pair<Point_3<K>, Vector_3<K> >*, or as a *boost::tuple<..,Point_3<K>, ..., Vector_3<K> >*.

The following classes described in Chapter 75 provide property maps for the implementations of points with normals listed above:
CGAL::Dereference_property_map<T>
CGAL::First_of_pair_property_map<Pair> and *CGAL::Second_of_pair_property_map<Pair>*
CGAL::Nth_of_tuple_property_map<N, Tuple>

Dereference_property_map<Point_3> is the default value of the position property map expected by all functions in this component.
See below examples using pair and tuple property maps.
Users of this package may use other types to represent positions and normals if they implement the corresponding property maps.

58.2.2 Streams

We provide functions to read and write sets of points or sets of points with normals from the following ASCII file formats: XYZ (three point coordinates *x y z* per line or three point coordinates and three normal vector coordinates *x y z nx ny nz* per line), and OFF (Object File Format) [Phi96].

CGAL::read_xyz_points
CGAL::read_off_points
CGAL::write_off_points
CGAL::write_xyz_points

58.2.3 Example

The following example reads a point set from an input file and writes it to a file, both in the XYZ format. Positions and normals are stored in pairs and accessed through property maps.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/property_map.h>
#include <CGAL/IO/read_xyz_points.h>
#include <CGAL/IO/write_xyz_points.h>

#include <utility> // defines std::pair
#include <vector>
#include <fstream>

// types
typedef CGAL::Exact_predicates_inexact_constructions_kernel Kernel;
typedef Kernel::Point_3 Point;
typedef Kernel::Vector_3 Vector;

// Point with normal vector stored as a std::pair.
typedef std::pair<Point, Vector> Pwn;

int main(void)
{
    // Reads a .xyz point set file in points[].
    // Note: read_xyz_points_and_normals() requires an output iterator
    // over points and as well as property maps to access each
    // point position and normal.
    std::vector<Pwn> points;
    std::ifstream in("data/oni.xyz");
    if (!in ||
        !CGAL::read_xyz_points_and_normals(
            in,std::back_inserter(points),
            CGAL::First_of_pair_property_map<Pwn>(),
            CGAL::Second_of_pair_property_map<Pwn>()))
    {
      std::cerr << "Error: cannot read file data/oni.xyz" << std::endl;
      return EXIT_FAILURE;
    }

    // Saves point set.
```

```
    // Note: write_xyz_points_and_normals() requires an output iterator
    // over points as well as property maps to access each
    // point position and normal.
    std::ofstream out("oni_copy.xyz");
    if (!out ||
        !CGAL::write_xyz_points_and_normals(
            out, points.begin(), points.end(),
            CGAL::First_of_pair_property_map<Pwn>(),
            CGAL::Second_of_pair_property_map<Pwn>()))
    {
      return EXIT_FAILURE;
    }

    return EXIT_SUCCESS;
}
```

File: examples/Point_set_processing_3/read_write_xyz_point_set_example.cpp

58.3 Analysis

Function *CGAL::compute_average_spacing()* computes the average spacing of all input points to their k nearest neighbor points, k being specified by the user. As it provides an order of a point set density, this function is used downstream the surface reconstruction pipeline to automatically determine some parameters such as output mesh sizing for surface reconstruction.

Example

The following example reads a point set in the *xyz* format and computes the average spacing. Index, position and color are stored in a tuple and accessed through property maps.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/compute_average_spacing.h>
#include <CGAL/IO/read_xyz_points.h>

#include <vector>
#include <fstream>
#include <boost/tuple/tuple.hpp>

// Types
typedef CGAL::Exact_predicates_inexact_constructions_kernel Kernel;
typedef Kernel::FT FT;
typedef Kernel::Point_3 Point;

// Data type := index, followed by the point, followed by three integers
    that
// define the Red Green Blue color of the point.
typedef boost::tuple<int, Point, int, int, int>
    IndexedPointWithColorTuple;
```

```
int main(void)
{
    // Reads a .xyz point set file in points.
    // As the point is the second element of the tuple (that is with
   index 1)
    // we use a property map that accesses the 1st element of the tuple.
    std::vector<IndexedPointWithColorTuple> points;
    std::ifstream stream("data/sphere_20k.xyz");
    if (!stream ||
        !CGAL::read_xyz_points(
            stream, std::back_inserter(points),

   CGAL::Nth_of_tuple_property_map<1,IndexedPointWithColorTuple>()))
    {
      std::cerr << "Error: cannot read file data/sphere_20k.xyz" <<
   std::endl;
      return EXIT_FAILURE;
    }

    // Initialize index and RGB color fields in tuple.
    // As the index and RGB color are respectively the first and
   third-fifth elements
    // of the tuple we use a get function from the property map that
   accesses the 0
    // and 2-4th elements of the tuple.
    for(unsigned int i = 0; i < points.size(); i++)
    {
      points[i].get<0>() = i;   // set index value of tuple to i

      points[i].get<2>() = 0;   // set RGB color to black
      points[i].get<3>() = 0;
      points[i].get<4>() = 0;
    }

    // Computes average spacing.
    const unsigned int nb_neighbors = 6; // 1 ring
    FT average_spacing = CGAL::compute_average_spacing(
                          points.begin(), points.end(),

   CGAL::Nth_of_tuple_property_map<1,IndexedPointWithColorTuple>(),
                          nb_neighbors);
    std::cout << "Average spacing: " << average_spacing << std::endl;

    return EXIT_SUCCESS;
}
```

File: examples/Point_set_processing_3/average_spacing_example.cpp

Note that other functions such as centroid or bounding volumes are found in other CGAL components:
CGAL::centroid
CGAL::bounding_box
Min_sphere_of_spheres_d<Traits>

58.4 Outlier Removal

Function *CGAL::remove_outliers()* deletes a user-specified fraction of outliers from an input point set. More specifically, it sorts the input points in increasing order of average squared distances to their k nearest neighbors and deletes the points with largest value.

Example

The following example reads a point set and removes 5% of the points. It uses the *CGAL::Dereference_property_map<Point_3>* property map (optional as it is the default position property map of all functions in this component.)

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/property_map.h>
#include <CGAL/remove_outliers.h>
#include <CGAL/IO/read_xyz_points.h>

#include <vector>
#include <fstream>

// types
typedef CGAL::Exact_predicates_inexact_constructions_kernel Kernel;
typedef Kernel::Point_3 Point;

int main(void)
{
  // Reads a .xyz point set file in points[].
  // The Dereference_property_map property map can be omitted here as it
   is the default value.
  std::vector<Point> points;
  std::ifstream stream("data/oni.xyz");
  if (!stream ||
      !CGAL::read_xyz_points(stream, std::back_inserter(points),
                             CGAL::Dereference_property_map<Point>()))
  {
    std::cerr << "Error: cannot read file data/oni.xyz" << std::endl;
    return EXIT_FAILURE;
  }

  // Removes outliers using erase-remove idiom.
  // The Dereference_property_map property map can be omitted here as it
   is the default value.
  const double removed_percentage = 5.0; // percentage of points to
   remove
  const int nb_neighbors = 24; // considers 24 nearest neighbor points
  points.erase(CGAL::remove_outliers(points.begin(), points.end(),

   CGAL::Dereference_property_map<Point>(),
                                     nb_neighbors, removed_percentage),
              points.end());

  // Optional: after erase(), use Scott Meyer's "swap trick" to trim
   excess capacity
```

```
  std::vector<Point>(points).swap(points);

  return EXIT_SUCCESS;
}
```

File: examples/Point_set_processing_3/remove_outliers_example.cpp

58.5 Simplification

Two simplification functions are devised to reduce an input point set, either randomly or using a grid-based clustering approach.

Function *CGAL::random_simplify_point_set()* randomly deletes a user-specified fraction of points from the input point set. This algorithm is fast.

Function *CGAL::grid_simplify_point_set()* considers a regular grid covering the bounding box of the input point set, and clusters all points sharing the same cell of the grid by picking as representant one arbitrarily chosen point. This algorithm is slower than *CGAL::random_simplify_point_set()*.

Example

The following example reads a point set and simplifies it by clustering.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/grid_simplify_point_set.h>
#include <CGAL/IO/read_xyz_points.h>

#include <vector>
#include <fstream>

// types
typedef CGAL::Exact_predicates_inexact_constructions_kernel Kernel;
typedef Kernel::Point_3 Point;

int main(void)
{
  // Reads a .xyz point set file in points[].
  std::vector<Point> points;
  std::ifstream stream("data/oni.xyz");
  if (!stream ||
      !CGAL::read_xyz_points(stream, std::back_inserter(points)))
  {
    std::cerr << "Error: cannot read file data/oni.xyz" << std::endl;
    return EXIT_FAILURE;
  }

  // simplification by clustering using erase-remove idiom
  double cell_size = 0.001;
  points.erase(CGAL::grid_simplify_point_set(points.begin(),
   points.end(), cell_size),
```

```
              points.end());

  // Optional: after erase(), use Scott Meyer's "swap trick" to trim
    excess capacity
  std::vector<Point>(points).swap(points);

  return EXIT_SUCCESS;
}
```

File: examples/Point_set_processing_3/grid_simplification_example.cpp

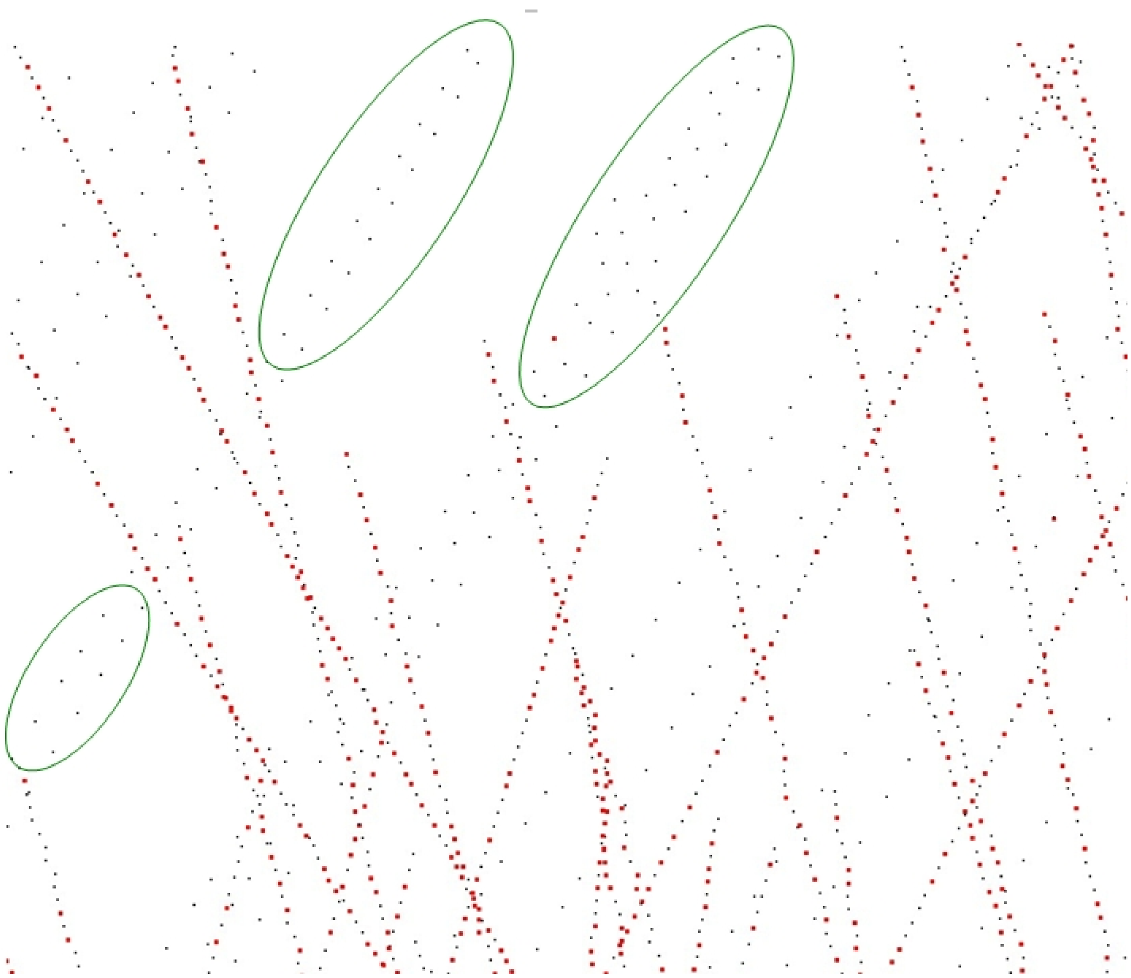

Figure 58.3: Point set simplification through grid-based clustering. Removed points are depicted in red. Notice how low-density areas (in green) are not simplified.

58.6 Smoothing

Function *CGAL::jet_smooth_point_set* smooths the input point set by projecting each point onto a smooth parametric surface patch (so-called jet surface) fitted over its k nearest neighbors.

Example

The following example generates a set of 9 points close to the xy plane and smooths them using 8 nearest neighbors:

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/jet_smooth_point_set.h>
#include <vector>

// types
typedef CGAL::Exact_predicates_inexact_constructions_kernel Kernel;
typedef Kernel::Point_3 Point;

int main(void)
{
  // generate point set
  std::vector<Point> points;
  points.push_back(Point( 0.0, 0.0, 0.001));
  points.push_back(Point(-0.1,-0.1, 0.002));
  points.push_back(Point(-0.1,-0.2, 0.001));
  points.push_back(Point(-0.1, 0.1, 0.002));
  points.push_back(Point( 0.1,-0.1, 0.000));
  points.push_back(Point( 0.1, 0.2, 0.001));
  points.push_back(Point( 0.2, 0.0, 0.002));
  points.push_back(Point( 0.2, 0.1, 0.000));
  points.push_back(Point( 0.0,-0.1, 0.001));

  // Smoothing.
  const unsigned int nb_neighbors = 8; // default is 24 for real-life
    point sets
  CGAL::jet_smooth_point_set(points.begin(), points.end(), nb_neighbors);

  return EXIT_SUCCESS;
}
```

File: examples/Point_set_processing_3/jet_smoothing_example.cpp

58.7 Normal Estimation

Assuming a point set sampled over an inferred surface S, two functions provide an estimate of the normal to S at each point. The result is an unoriented normal vector for each input point.

Function *CGAL::jet_estimate_normals()* estimates the normal direction at each point from the input set by fitting a jet surface over its k nearest neighbors. The default jet is a quadric surface. This algorithm is well suited to point sets scattered over curved surfaces.

Function *CGAL::pca_estimate_normals()* estimates the normal direction at each point from the set by linear least squares fitting of a plane over its k nearest neighbors. This algorithm is simpler and faster than *CGAL::jet_estimate_normals()*.

58.8 Normal Orientation

Function *CGAL::mst_orient_normals()* orients the normals of a set of points with unoriented normals using the method described by Hoppe et al. in *Surface reconstruction from unorganized points* [HDD+92]. More specifically, this method constructs a Riemannian graph over the input points (the graph of the K nearest neighbor points) and propagates a seed normal orientation within a minimum spanning tree computed over this graph. The result is an oriented normal vector for each input unoriented normal, except for the normals which could not be successfully oriented.

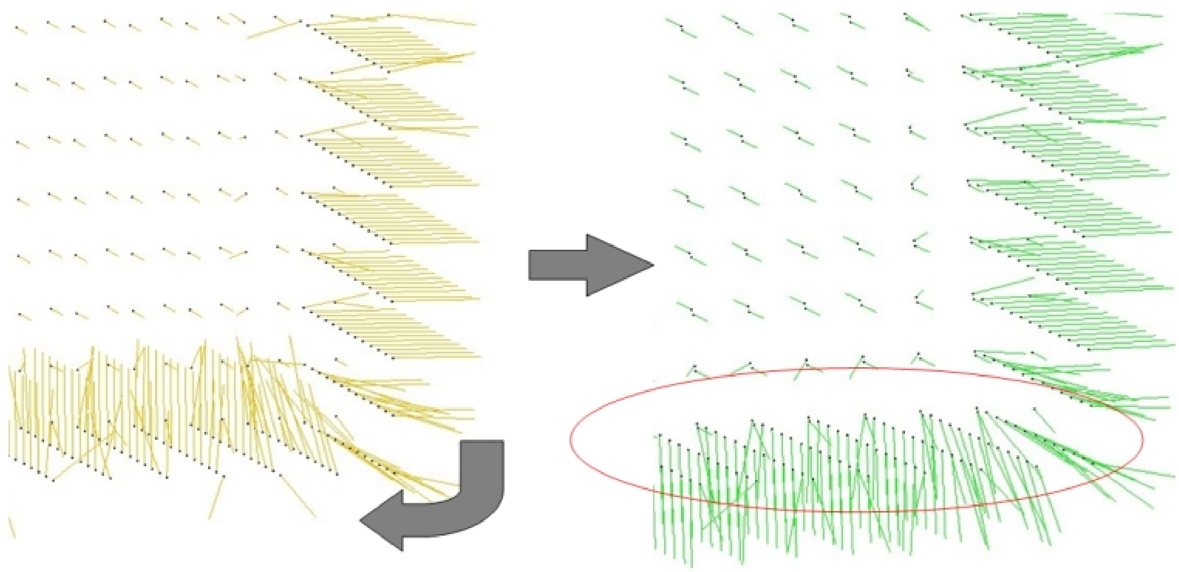

Figure 58.4: Normal orientation of a sampled cube surface. Left: unoriented normals. Right: orientation of right face normals is propagated to bottom face.

Example

The following example reads a point set from a file, estimates the normals through PCA over the 6 nearest neighbors and orients the normals:

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/pca_estimate_normals.h>
#include <CGAL/mst_orient_normals.h>
#include <CGAL/property_map.h>
#include <CGAL/IO/read_xyz_points.h>

#include <utility> // defines std::pair
```

```
#include <list>
#include <fstream>

// Types
typedef CGAL::Exact_predicates_inexact_constructions_kernel Kernel;
typedef Kernel::Point_3 Point;
typedef Kernel::Vector_3 Vector;

Point Set Processing Reference Manual

Pierre Alliez, Laurent Saboret, Nader Salman

This CGAL component implements methods to analyze and process unorganized point sets. The input is an unorganized point set, possibly with attributes. This point set can be analyzed to measure average spacing, a global estimation of the point set density. Furthermore we can process it with functions devoted to simplification, outlier removal, smoothing, normal estimation and normal orientation.

CGAL::compute_average_spacing

Function

Definition

CGAL::compute_average_spacing() computes the average spacing of all points from the input set to their k nearest neighbors. This value depends on the k parameter which can be set to 6 for isotropically sampled surfaces.

#include <CGAL/compute_average_spacing.h>

```
template<typename InputIterator, typename PointPMap, typename Kernel>
Kernel::FT      compute_average_spacing( InputIterator first,
                                         InputIterator beyond,
                                         PointPMap point_pmap,
                                         unsigned int k,
                                         Kernel kernel)
```

Computes average spacing from k nearest neighbors.
Precondition: k >= 2.
Template Parameters:
InputIterator: iterator over input points. *PointPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type = Point_3<Kernel>*. It can be omitted if *InputIterator value_type* is convertible to *Point_3<Kernel>*. *Kernel*: Geometric traits class. It can be omitted and deduced automatically from *PointPMap value_type*.
Returns: average spacing (scalar).
Parameters:
first: iterator over the first input point. *beyond*: past-the-end iterator over the input points. *point_pmap*: property map *InputIterator* -> *Point_3*. *k*: number of neighbors. *kernel*: geometric traits.

Example

See *average_spacing_example.cpp*.

Function

CGAL::grid_simplify_point_set

Definition

Function *CGAL::grid_simplify_point_set()* considers a regular grid covering the bounding box of the input point set, and clusters all points sharing the same cell of the grid by picking as representant one arbitrarily chosen point.

This method modifies the order of input points so as to pack all remaining points first, and returns an iterator over the first point to remove (see erase-remove idiom). For this reason it should not be called on sorted containers.

#include <CGAL/grid_simplify_point_set.h>

```
template<typename ForwardIterator, typename PointPMap, typename Kernel>
ForwardIterator        grid_simplify_point_set( ForwardIterator first,
                                                ForwardIterator beyond,
                                                PointPMap point_pmap,
                                                double epsilon,
                                                Kernel kernel)
```

Merges points which belong to the same cell of a grid of cell size = epsilon. This method modifies the order of input points so as to pack all remaining points first, and returns an iterator over the first point to remove (see erase-remove idiom). For this reason it should not be called on sorted containers.
Precondition: epsilon > 0.
Template Parameters:
ForwardIterator: iterator over input points. *PointPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type* = *Point_3<Kernel>*. It can be omitted if *ForwardIterator value_type* is convertible to *Point_3<Kernel>*. *Kernel*: Geometric traits class. It can be omitted and deduced automatically from *PointPMap value_type*.
Returns: iterator over the first point to remove.
Parameters:
first: iterator over the first input point. *beyond*: past-the-end iterator over the input points. *point_pmap*: property map *ForwardIterator* -> *Point_3*. *epsilon*: tolerance value when merging 3D points. *kernel*: geometric traits.

CGAL::jet_estimate_normals

Definition

CGAL::jet_estimate_normals() estimates normal directions of all points from the input set by fitting jet surfaces over the k nearest neighbors. The default jet surface is a quadric, and the result is an unoriented normal vector for each input point.

The output of the normal estimation algorithm highly depends on the k parameter. The number of neighbors controls the size of the point subset considered for jet fitting at each input point. As this parameter is application-specific we do not provide any default value. Larger values lead to smoother normal fields and are more time consuming. For point sets with limited noise this value can be set to small number such as 18. For noisy point sets this value must be increased.

#include <CGAL/jet_estimate_normals.h>

```
template<typename InputIterator, typename PointPMap, typename NormalPMap, typename Kernel>
void    jet_estimate_normals( InputIterator first,
                              InputIterator beyond,
                              PointPMap point_pmap,
                              NormalPMap normal_pmap,
                              unsigned int k,
                              Kernel kernel,
                              unsigned int degree_fitting = 2)
```

Estimates normal directions of the [first, beyond) range of points using jet fitting on the k nearest neighbors. The output normals are randomly oriented.
Precondition: k >= 2.
Template Parameters:
InputIterator: iterator over input points. *PointPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type = Point_3<Kernel>*. It can be omitted if *InputIterator value_type* is convertible to *Point_3<Kernel>*. *NormalPMap*: is a model of *boost::WritablePropertyMap* with a *value_type = Vector_3<Kernel>*. *Kernel*: Geometric traits class. It can be omitted and deduced automatically from *PointPMap value_type*.
Parameters:
first: iterator over the first input point. *beyond*: past-the-end iterator over the input points. *point_pmap*: property map *InputIterator -> Point_3*. *normal_pmap*: property map *InputIterator -> Vector_3*. *k*: number of neighbors. *kernel*: geometric traits.

Function

CGAL::jet_smooth_point_set

Definition

CGAL::jet_smooth_point_set() smooths a point set by fitting for each point a jet surface and projecting it onto the jet. The default jet surface is a quadric.

The output of the smoothing algorithm highly depends on the *k* parameter. The number of neighbors controls the size of the point subset considered for jet fitting at each input point. As this parameter is application-specific we do not provide any default value. Larger values lead to smoother point sets and are more time consuming. For point sets with limited noise this value can be set to small number such as 24. For noisy point sets this value must be increased.

#include <CGAL/jet_smooth_point_set.h>

```
template<typename InputIterator, typename PointPMap, typename Kernel>
void    jet_smooth_point_set( InputIterator first,
                              InputIterator beyond,
                              PointPMap point_pmap,
                              unsigned int k,
                              Kernel kernel,
                              unsigned int degree_fitting = 2,
                              unsigned int degree_monge = 2)
```

Smoothes the [first, beyond) range of points using jet fitting on the k nearest neighbors and reprojection onto the jet. As this method relocates the points, it should not be called on containers sorted w.r.t. point locations.
Precondition: k >= 2.
Template Parameters:
InputIterator: iterator over input points. *PointPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type = Point_3<Kernel>*. It can be omitted if *InputIterator value_type* is convertible to *Point_3<Kernel>*. *Kernel*: Geometric traits class. It can be omitted and deduced automatically from *PointPMap value_type*.
Parameters:
first: iterator over the first input point. *beyond*: past-the-end iterator over the input points. *point_pmap*: property map *InputIterator -> Point_3*. *k*: number of neighbors. *kernel*: geometric traits.

Example

See *jet_smoothing_example.cpp*.

CGAL::mst_orient_normals

Function

Definition

CGAL::mst_orient_normals() orients the normals of a point set using the propagation of a seed orientation through a minimum spanning tree computed over the Riemannian graph [HDD+92].

The seed is chosen as the top point of the point set. Its normal is oriented towards +Z axis. The success of the orientation algorithm depends on the *k* parameter. The number of neighbors controls the number of candidates to propagate the orientation to around each input point. In general the value 18 works well. With smaller values the propagation may be blocked by large gaps in sparse point sets as the graph may be disconnected. Large values cause problems with points scattered over thin objects as the algorithm may incorrectly propagate the orientation from one side of the object to the other. In presence of disconnected clusters of points the algorithm may fail propagating the orientation from one cluster to the others and may only orient the top cluster.

This method modifies the order of the input points so as to pack all successfully oriented normals first, and returns an iterator over the first point with an unoriented normal (see erase-remove idiom). For this reason it should not be called on sorted containers.

#include <CGAL/mst_orient_normals.h>

```
template<typename ForwardIterator, typename PointPMap, typename NormalPMap, typename Kernel>
ForwardIterator    mst_orient_normals( ForwardIterator first,
                                       ForwardIterator beyond,
                                       PointPMap point_pmap,
                                       NormalPMap normal_pmap,
                                       unsigned int k,
                                       Kernel kernel)
```

Orients the normals of the [first, beyond) range of points using the propagation of a seed orientation through a minimum spanning tree of the Riemannian graph [HDD+92].
This method modifies the order of input points so as to pack all sucessfully oriented points first, and returns an iterator over the first point with an unoriented normal (see erase-remove idiom). For this reason it should not be called on sorted containers.
Preconditions:
Normals must be unit vectors. k >= 2.
Template Parameters:
ForwardIterator: iterator over input points. *PointPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type* = *Point_3<Kernel>*. It can be omitted if *ForwardIterator value_type* is convertible to *Point_3<Kernel>*. *NormalPMap*: is a model of *boost::ReadWritePropertyMap* with a *value_type* = *Vector_3<Kernel>*. *Kernel*: Geometric traits class. It can be omitted and deduced automatically from *PointPMap value_type*.
Returns: iterator over the first point with an unoriented normal.
Parameters:
first: iterator over the first input point. *beyond*: past-the-end iterator over the input points. *point_pmap*: property map *ForwardIterator -> Point_3*. *normal_pmap*: property map *ForwardIterator -> Vector_3*. *k*: number of neighbors. *kernel*: geometric traits.

CGAL::pca_estimate_normals

Function

Definition

CGAL::pca_estimate_normals() estimates normal directions at all points of an input point set by linear least squares fitting of a plane over their *k* nearest neighbors. The result is an unoriented normal for each input point.

The output of the normal estimation algorithm highly depends on the *k* parameter. The number of neighbors controls the size of the point subset considered for plane fitting at each input point. As this parameter is application-specific we do not provide any default value. For noise-free point sets this value can be set to a small number, e.g., 18. Larger values (e.g., 30 or more) lead to smoother normal fields and are more time consuming. We thus recommend using them only for noisy data sets.

#include <CGAL/pca_estimate_normals.h>

```
template<typename InputIterator, typename PointPMap, typename NormalPMap, typename Kernel>
void    pca_estimate_normals( InputIterator first,
                              InputIterator beyond,
                              PointPMap point_pmap,
                              NormalPMap normal_pmap,
                              unsigned int k,
                              Kernel kernel)
```

Estimates normal directions of the [first, beyond) range of points by linear least squares fitting of a plane over the k nearest neighbors. The output normals are randomly oriented.
Precondition: k >= 2.
Template Parameters:
InputIterator: iterator over input points. *PointPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type = Point_3<Kernel>*. It can be omitted if *InputIterator value_type* is convertible to *Point_3<Kernel>*. *NormalPMap*: is a model of *boost::WritablePropertyMap* with a *value_type = Vector_3<Kernel>*. *Kernel*: Geometric traits class. It can be omitted and deduced automatically from *PointPMap value_type*.
Parameters:
first: iterator over the first input point. *beyond*: past-the-end iterator over the input points. *point_pmap*: property map *InputIterator -> Point_3*. *normal_pmap*: property map *InputIterator -> Vector_3*. *k*: number of neighbors. *kernel*: geometric traits.

Function

CGAL::random_simplify_point_set

Definition

CGAL::random_simplify_point_set() randomly deletes a user-specified fraction of the input points. This method modifies the order of input points so as to pack all remaining points first, and returns an iterator over the first point to remove (see erase-remove idiom). For this reason it should not be called on sorted containers.

#include <CGAL/random_simplify_point_set.h>

```
template<typename ForwardIterator, typename PointPMap, typename Kernel>
ForwardIterator    random_simplify_point_set( ForwardIterator first,
                                              ForwardIterator beyond,
                                              PointPMap point_pmap,
                                              double removed_percentage,
                                              Kernel kernel)
```

Randomly deletes a user-specified fraction of the input points.
This method modifies the order of input points so as to pack all remaining points first, and returns an iterator over the first point to remove (see erase-remove idiom). For this reason it should not be called on sorted containers.
Template Parameters:
ForwardIterator: iterator over input points. *PointPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type = Point_3<Kernel>*. It can be omitted if *ForwardIterator value_type* is convertible to *Point_3<Kernel>*. *Kernel*: Geometric traits class. It can be omitted and deduced automatically from *PointPMap value_type*.
Returns: iterator over the first point to remove.
Parameters:
first: iterator over the first input point. *beyond*: past-the-end iterator over the input points. *point_pmap*: property map *ForwardIterator -> Point_3*. *removed_percentage*: percentage of points to remove. *kernel*: geometric traits.

CGAL::read_off_points

Definition

CGAL::read_off_points() reads the point from a .off ASCII stream. More specifically, it reads only the point locations and ignores all point attributes available from the stream. *CGAL::read_off_points_and_normals()* reads the points as well as the normals (if available) from a .off ASCII stream. In both cases the other primitives (segments, faces) are ignored.

#include <CGAL/IO/read_off_points.h>

template<typename OutputIterator, typename PointPMap, typename Kernel>
bool read_off_points(std::istream& stream, OutputIterator output, PointPMap point_pmap, Kernel kernel)

Reads points (position only) from a .off ASCII stream. The function expects for each point a line with the x y z position. If the position is followed by the nx ny nz normal, then the normal will be ignored. Faces are ignored.
Template Parameters:
OutputIterator: iterator over output points. *PointPMap*: is a model of *boost::WritablePropertyMap* with a *value_type = Point_3<Kernel>*. It can be omitted if *OutputIterator value_type* is convertible to *Point_3<Kernel>*. *Kernel*: Geometric traits class. It can be omitted and deduced automatically from *PointPMap value_type*.
Returns: true on success.
Parameters:
stream: input stream. *output*: output iterator over points. *point_pmap*: property map *OutputIterator -> Point_3*. *kernel*: geometric traits.

template<typename OutputIterator, typename PointPMap, typename NormalPMap, typename Kernel>
bool read_off_points_and_normals(std::istream& stream, OutputIterator output, PointPMap point_pmap, NormalPMap normal_pmap, Kernel kernel)

Reads points (positions + normals, if available) from a .off ASCII stream. The function expects for each point a line with the x y z position, optionally followed by the nx ny nz normal. Faces are ignored.
Template Parameters:
OutputIterator: iterator over output points. *PointPMap*: is a model of *boost::WritablePropertyMap* with a *value_type = Point_3<Kernel>*. It can be omitted if *OutputIterator value_type* is convertible to *Point_3<Kernel>*. *NormalPMap*: is a model of *boost::WritablePropertyMap* with a *value_type = Vector_3<Kernel>*. *Kernel*: Geometric traits class. It can be omitted and deduced automatically from *PointPMap value_type*.
Returns: true on success.
Parameters:
stream: input stream. *output*: output iterator over points. *point_pmap*: property map *OutputIterator -> Point_3*. *normal_pmap*: property map *OutputIterator -> Vector_3*. *kernel*: geometric traits.

CGAL::read_xyz_points

Function

Definition

CGAL::read_xyz_points() reads the point locations from a .xyz ASCII stream. *CGAL::read_xyz_points_and_normals()* reads the points as well as the normals (if available) from a .xyz ASCII stream.

#include <CGAL/IO/read_xyz_points.h>

template<typename OutputIterator, typename PointPMap, typename Kernel>
bool read_xyz_points(std::istream& stream, OutputIterator output, PointPMap point_pmap, Kernel kernel)

Reads points (positions only) from a .xyz ASCII stream. The function expects for each point a line with the x y z position. If the position is followed by the nx ny nz normal, then the normal will be ignored. The first line may contain the number of points in the file. Empty lines and comments starting by # character are allowed.
Template Parameters:
OutputIterator: iterator over output points. *PointPMap*: is a model of *boost::WritablePropertyMap* with a *value_type = Point_3<Kernel>*. It can be omitted if *OutputIterator value_type* is convertible to *Point_3<Kernel>*. *Kernel*: Geometric traits class. It can be omitted and deduced automatically from *PointPMap value_type*.
Returns: true on success.
Parameters:
stream: input stream. *output*: output iterator over points. *point_pmap*: property map *OutputIterator -> Point_3*. *kernel*: geometric traits.

template<typename OutputIterator, typename PointPMap, typename NormalPMap, typename Kernel>
bool read_xyz_points_and_normals(std::istream& stream, OutputIterator output, PointPMap point_pmap, NormalPMap normal_pmap,

Kernel kernel)

Reads points (positions + normals, if available) from a .xyz ASCII stream. The function expects for each point a line with the x y z position, optionally followed by the nx ny nz normal. The first line may contain the number of points in the file. Empty lines and comments starting by # character are allowed.

Template Parameters:

OutputIterator: iterator over output points. *PointPMap*: is a model of *boost::WritablePropertyMap* with a *value_type* = *Point_3<Kernel>*. It can be omitted if *OutputIterator value_type* is convertible to *Point_3<Kernel>*. *NormalPMap*: is a model of *boost::WritablePropertyMap* with a *value_type* = *Vector_3<Kernel>*. *Kernel*: Geometric traits class. It can be omitted and deduced automatically from *PointPMap value_type*.

Returns: true on success.

Parameters:

stream: input stream. *output*: output iterator over points. *point_pmap*: property map *OutputIterator* -> *Point_3*. *normal_pmap*: property map *OutputIterator* -> *Vector_3*. *kernel*: geometric traits.

CGAL::remove_outliers

Definition

CGAL::remove_outliers() deletes a user-specified fraction of outliers from the input point set. More specifically, it sorts the input points in increasing order of average squared distances to the k nearest neighbors and computes the points with largest value.

The outliers detection depends on the k parameter, specifically the detection of clusters of outliers. The number of neighbors should be higher than the size of clusters of outliers in the point set. For datasets with no cluster of outliers, this value can be set to a few rings, e.g. 24. Larger value leads to longer computation times. For these reasons, we do not provide any default value for this parameter.

This method modifies the order of input points so as to pack all remaining points first, and returns and returns an iterator over the first point to remove (see erase-remove idiom). For this reason it should not be called on sorted containers.

#include <CGAL/remove_outliers.h>

template<typename InputIterator, typename PointPMap, typename Kernel>
InputIterator remove_outliers(InputIterator first,
InputIterator beyond,
PointPMap point_pmap,
unsigned int k,
double threshold_percent,
Kernel kernel)

Removes outliers: computes average squared distance to the K nearest neighbors, and sorts the points in increasing order of average distance.
This method modifies the order of input points so as to pack all remaining points first, and returns an iterator over the first point to remove (see erase-remove idiom). For this reason it should not be called on sorted containers.
Precondition: k >= 2.
Template Parameters:
InputIterator: iterator over input points. *PointPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type = Point_3<Kernel>*. It can be omitted if *InputIterator value_type* is convertible to *Point_3<Kernel>*. *Kernel*: Geometric traits class. It can be omitted and deduced automatically from *PointPMap value_type*.
Returns: iterator over the first point to remove.
Parameters:
first: iterator over the first input point. *beyond*: past-the-end iterator over the input points. *point_pmap*: property map *InputIterator -> Point_3*. *k*: number of neighbors. *threshold_percent*: percentage of points to remove. *kernel*: geometric traits.

Example

See *remove_outliers_example.cpp*.

Function

CGAL::write_off_points

Definition

CGAL::write_off_points() saves the points of an iterator range to a .off ASCII stream. More specifically, it saves only the point locations and ignores all other attributes. *CGAL::write_off_points_and_normals()* saves the points as well the normals of an iterator range to a .off ASCII stream.

#include <CGAL/IO/write_off_points.h>

```
template<typename ForwardIterator, typename PointPMap, typename Kernel>
bool          write_off_points( std::ostream& stream,
                                ForwardIterator first,
                                ForwardIterator beyond,
                                PointPMap point_pmap,
                                Kernel kernel)
```

Saves the [first, beyond) range of points (positions only) to a .off ASCII stream. The function writes for each point a line with the x y z position.
Template Parameters:
ForwardIterator: iterator over input points. *PointPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type* = *Point_3<Kernel>*. It can be omitted if *ForwardIterator value_type* is convertible to *Point_3<Kernel>*. *Kernel*: Geometric traits class. It can be omitted and deduced automatically from *PointPMap value_type*.
Returns: true on success.
Parameters:
stream: output stream. *first*: iterator over the first input point. *beyond*: past-the-end iterator over the input points. *point_pmap*: property map *ForwardIterator* -> *Point_3*. *kernel*: geometric traits.

```
template<typename ForwardIterator, typename PointPMap, typename NormalPMap, typename Kernel>
bool          write_off_points_and_normals( std::ostream& stream,
                                            ForwardIterator first,
                                            ForwardIterator beyond,
                                            PointPMap point_pmap,
                                            NormalPMap normal_pmap,
```

Kernel kernel)

Saves the [first, beyond) range of points (positions + normals) to a .off ASCII stream. The function writes for each point a line with the x y z position followed by the nx ny nz normal.
Precondition: normals must be unit vectors.
Template Parameters:
ForwardIterator: iterator over input points. *PointPMap*: is a model of *boost::ReadablePropertyMap* with a *value_type* = *Point_3*<*Kernel*>. It can be omitted if *ForwardIterator value_type* is convertible to *Point_3*<*Kernel*>. *NormalPMap*: is a model of *boost::WritablePropertyMap* with a *value_type* = *Vector_3*<*Kernel*>. *Kernel*: Geometric traits class. It can be omitted and deduced automatically from *PointPMap value_type*.
Returns: true on success.
Parameters:
stream: output stream. *first*: iterator over the first input point. *beyond*: past-the-end iterator over the input points. *point_pmap*: property map *ForwardIterator* -> *Point_3*. *normal_pmap*: property map *ForwardIterator* -> *Vector_3*. *kernel*: geometric traits.

Spatial Searching and Sorting

Chapter 59

2D Range and Neighbor Search

Matthias Bäsken

Contents

59.1 Introduction

Geometric queries are fundamental to many applications in computational geometry. The task is to maintain a dynamic set of geometric objects in such a way that certain queries can be performed efficiently. Typical examples of queries are: find out whether a given object is contained in the set, find all objects of the set lying in a given area (e.g. rectangle), find the object closest to a given point or find the pair of objects in the set lying closest to each other. Furthermore, the set should be dynamic in the sense that deletions and insertions of objects can be performed efficiently.

In computational geometry literature one can find many different data structures for maintaining sets of geometric objects. Most of them are data structures that have been developed to support a single very special kind of query operation. Examples are Voronoi diagrams for answering nearest neighbor searches, range trees for orthogonal range queries, partition trees for more general range queries, hierarchical triangulations for point location and segment trees for intersection queries ....

In many applications, different types of queries have to be performed on the same set of objects. A naive approach to this problem would use a collection of the above mentioned data structures to represent the set of objects and delegate every query operation to the corresponding structure. However, this is completely impractical since it uses too much memory and requires the maintenance of all these data structures in the presence of update operations.

Data structures that are non-optimal in theory seem to perform quite well in practice for many of these queries. For example, the Delaunay diagram turns out to be a very powerful data structure for storing dynamic sets of points under range and nearest neighbor queries. A first implementation and computational study of using Delaunay diagrams for geometric queries is described by Mehlhorn and Näher in [MN00].

In this section we present a generic variant of a two dimensional point set data type supporting various geometric queries.

The *CGAL::Point_set_2* class in this section is inherited from the two-dimensional CGAL *Delaunay Triangulation* data type.

The *CGAL::Point_set_2* class depends on two template parameters *T1* and *T2*. They are used as template parameters for the *CGAL::Delaunay_triangulation_2* class *CGAL::Point_set_2* is inherited from. *T1* is a model for the geometric traits and *T2* is a model for the triangulation data structure that the Delaunay triangulation expects.

The *CGAL::Point_set_2* class supports the following kinds of queries:

- circular range search
- triangular range search
- isorectangular range search
- (k) nearest neighbor(s)

For details about the running times see [MN00].

59.2 Example: Range Search

The following example program demonstrates the various range search operations of the two dimensional point set. First we construct a two dimensional point set *PSet* and initialize it with a few points. Then we perform circular, triangular and isorectangular range search operations on the point set.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Point_set_2.h>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel  K;

typedef CGAL::Point_set_2<K>::Vertex_handle  Vertex_handle;
typedef K::Point_2                           Point_2;

int main()
{
  CGAL::Point_set_2<K> PSet;
  std::list<Point_2> Lr;

  Point_2 p1(12,14);
  Point_2 p2(-12,14);
  Point_2 p3(2,11);
  Point_2 p4(5,6);
  Point_2 p5(6.7,3.8);
  Point_2 p6(11,20);
  Point_2 p7(-5,6);
  Point_2 p8(12,0);
  Point_2 p9(4,31);
  Point_2 p10(-10,-10);
```

```
  Lr.push_back(p1); Lr.push_back(p2); Lr.push_back(p3);
  Lr.push_back(p4); Lr.push_back(p5); Lr.push_back(p6);
  Lr.push_back(p7); Lr.push_back(p8); Lr.push_back(p9);
  Lr.push_back(p10);

  PSet.insert(Lr.begin(),Lr.end());

  std::cout << "circular range search !\n";
  CGAL::Circle_2<K> rc(p5,p6);

  std::list<Vertex_handle> LV;
  PSet.range_search(rc, std::back_inserter(LV));

  std::list<Vertex_handle>::const_iterator it;
  for (it=LV.begin();it != LV.end(); it++)
     std::cout << (*it)->point() << "\n";

  std::cout << "triangular range search !\n";

  LV.clear();
  PSet.range_search(p1,p2,p3, std::back_inserter(LV));
  for (it=LV.begin();it != LV.end(); it++)
     std::cout << (*it)->point() << "\n";
  LV.clear();

  std::cout << "isorectangular range search !\n";
  Point_2 pt1=p10;
  Point_2 pt3=p3;
  Point_2 pt2 = Point_2(pt3.x(),pt1.y());
  Point_2 pt4 = Point_2(pt1.x(),pt3.y());

  PSet.range_search(pt1,pt2,pt3,pt4, std::back_inserter(LV));
  for (it=LV.begin();it != LV.end(); it++)
    std::cout << (*it)->point() << "\n";
  return 0;
}
```

2D Range and Neighbor Search Reference Manual

Matthias Bäsken

The two dimensional point set is a class for geometric queries. It supports circular, triangular and iso rectangular range searches and nearest neighbor searches. The point set is inherited from the CGAL Delaunay triangulation data type. That means that it is a dynamic data structure supporting the insertion and deletion of points.

This package also provides function template versions of the range search and nearest neighbor query operations. They all have to be templated by the type of a CGAL Delaunay triangulation and provide functionality similar to the corresponding member functions of the point set class.

CGAL::Point_set_2<Gt,Tds>

Definition

#include <CGAL/Point_set_2.h>

An instance *PS* of the data type *Point_set_2<Gt,Tds>* is a *Delaunay Triangulation* of its vertex set. The class *Point_set_2<Gt,Tds>* is inherited from the CGAL Delaunay triangulation, and provides additional nearest neighbor query operations and range searching operations.

The *Point_set_2<Gt,Tds>* class of CGAL depends on template parameters standing for the geometric traits classes used by the point set and by the Delaunay triangulation (Gt) and for the triangulation data structure (Tds).

Types

typedef Gt::Point_2	*Point;*	the point type
typedef Gt::Segment_2	*Segment;*	the segment type
typedef Gt::Circle_2	*Circle;*	the circle type
typedef Gt::FT	*Numb_type;*	the representation field number type.
Point_set_2<Gt,Tds>:: Triangulation		the underlying triangulation type.

Point_set_2<Gt,Tds>:: Triangulation::size_type

the size type of the underlying triangulation.

Point_set_2<Gt,Tds>:: Triangulation::Vertex

the vertex type of the underlying triangulation.

Point_set_2<Gt,Tds>:: Triangulation::Edge

the edge type of the underlying triangulation.

Point_set_2<Gt,Tds>:: Triangulation::Vertex_handle

handles to vertices.

Creation

Point_set_2<Gt,Tds> PS; creates an empty *Point_set_2<Gt,Tds>* .

template<class InputIterator>
Point_set_2<Gt,Tds> PS(InputIterator first, InputIterator last);

creates a *Point_set_2<Gt,Tds> PS* of the points in the range $[first, last)$.

Operations

Vertex_handle *PS.lookup(Point p)*

if *PS* contains a Vertex v with $|pos(v)| = p$ the result is a handle to v otherwise the result is $NULL$.

Vertex_handle *PS.nearest_neighbor(Point p)*

computes a handle to a vertex v of *PS* that is closest to p. If *PS* is empty, $NULL$ is returned.

Vertex_handle *PS.nearest_neighbor(Vertex_handle v)*

computes a handle to a vertex w of *PS* that is closest to v. If v is the only vertex in *PS* , $NULL$ is returned.

template<class OutputIterator>
OutputIterator *PS.nearest_neighbors(Point p, size_type k, OutputIterator res)*

computes the k nearest neighbors of p in *PS*, and places the handles to the corresponding vertices as a sequence of objects of type Vertex_handle in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence.

template<class OutputIterator>
OutputIterator *PS.nearest_neighbors(Vertex_handle v, size_type k, OutputIterator res)*

computes the k nearest neighbors of v, and places them as a sequence of objects of type Vertex_handle in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence.

template<class OutputIterator>

OutputIterator *PS.range_search(Circle C, OutputIterator res)*

computes handles to all vertices contained in the closure of disk *C*. The computed vertex handles will be placed as a sequence of objects in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence.

template<class OutputIterator>
OutputIterator *PS.range_search(Point a, Point b, Point c, OutputIterator res)*

computes handles to all vertices contained in the closure of the triangle (a,b,c).

Precondition: a, b, and c must not be collinear. The computed vertex handles will be placed as a sequence of objects in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence.

template<class OutputIterator>
OutputIterator *PS.range_search(Point a1, Point b1, Point c1, Point d1, OutputIterator res)*

computes handles to all vertices contained in the closure of the iso-rectangle $(a1,b1,c1,d1)$.

Precondition: $a1$ is the upper left point, $b1$ the lower left, $c1$ the lower right and $d1$ the upper right point of the iso rectangle. The computed vertex handles will be placed as a sequence of objects in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence.

Concept

PointSetTraits

A point set traits class has to provide some primitives that are used by the point set class. The following catalog lists the involved primitives. For details about these types see the Kernel traits documentation.

Types

PointSetTraits:: Point_2

PointSetTraits:: Circle_2

PointSetTraits:: Segment_2

PointSetTraits:: FT

PointSetTraits:: Orientation_2

PointSetTraits:: Side_of_oriented_circle_2

PointSetTraits:: Construct_circle_2

PointSetTraits:: Compute_squared_distance_2

PointSetTraits:: Bounded_side_2

PointSetTraits:: Compare_distance_2

PointSetTraits:: Construct_center_2

CGAL::nearest_neighbor

Function

Definition

The function *nearest_neighbor* is the function template version of the nearest neighbor search on Delaunay triangulations.

#include <CGAL/nearest_neighbor_delaunay_2.h>

template<class Dt>
Dt::Vertex_handle *nearest_neighbor(Dt delau, Dt::Vertex_handle v)*

computes a handle to a vertex w of $delau$ that is closest to v. If v is the only vertex in $delau$, $NULL$ is returned.

Requirements

Dt is a CGAL Delaunay triangulation and contains the following subset of types from the concept *PointSetTraits* and from the Delaunay triangulation data type:

- *Dt::Geom_traits*
- *Dt::Point*
- *Dt::Vertex_circulator*
- *Dt::Vertex_handle*
- *Dt::Geom_traits::Compare_distance_2*

Function

CGAL::nearest_neighbors

Definition

The function *nearest_neighbors* is the function template version of the k nearest neighbors search on Delaunay triangulations. There are two versions of this function, one taking a point of the Delaunay triangulation and the other taking a vertex handle.

#include <CGAL/nearest_neighbor_delaunay_2.h>

template<class Dt, class OutputIterator>
OutputIterator *nearest_neighbors(Dt& delau, Dt::Point p, Dt::size_type k, OutputIterator res)*

computes the k nearest neighbors of p in *delau*, and places the handles to the corresponding vertices as a sequence of objects of type Vertex_handle in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence.

Requirements

Dt is a CGAL Delaunay triangulation and contains the following subset of types from the concept *PointSetTraits* and from the Delaunay triangulation data type:

- *Dt::Geom_traits*
- *Dt::Vertex_handle*
- *Dt::Vertex_iterator*
- *Dt::Vertex_circulator*
- *Dt::Vertex*
- *Dt::Face*
- *Dt::Face_handle*
- *Dt::Locate_type*
- *Dt::Point*
- *Dt::Geom_traits::FT*
- *Dt::Geom_traits::Compute_squared_distance_2*

template<class Dt, class OutputIterator>

OutputIterator	*nearest_neighbors(Dt& delau, Dt::Vertex_handle v, Dt::size_type k, OutputIterator res)*

computes the k nearest neighbors of v (including v) in $delau$, and places them as a sequence of objects of type Vertex_handle in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence.

Requirements

Dt is a CGAL Delaunay triangulation and contains the following subset of types from the concept *PointSetTraits* and from the Delaunay triangulation data type:

- *Dt::Geom_traits*
- *Dt::Vertex_handle*
- *Dt::Vertex_iterator*
- *Dt::Vertex_circulator*
- *Dt::Vertex*
- *Dt::Point*
- *Dt::Geom_traits::FT*
- *Dt::Geom_traits::Compute_squared_distance_2*

Function

CGAL::range_search

Definition

There are six versions of the function template *range_search* that perform range searches on Delaunay triangulations. The first performs circular range searches, the second triangular range searches and the third performs iso-rectangular range searches. The other three range search function templates perform enhanced variants of the three aforementioned operations.
They get a user-defined object that has to control the range search operation. This way one can for instance stop the search, when n points were found.

#include <CGAL/range_search_delaunay_2.h>

template<class Dt, class Circle, class OutputIterator>
OutputIterator *range_search(Dt& delau, Circle C, OutputIterator res)*

computes handles to all vertices contained in the closure of disk C. The computed vertex handles will be placed as a sequence of objects in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence. *delau* is the CGAL Delaunay triangulation on which we perform the range search operation.

Requirements

- *Dt* is a CGAL Delaunay triangulation and contains the following subset of types from the concept *PointSetTraits* and from the Delaunay triangulation data type:
  - *Dt::Geom_traits*
  - *Dt::Vertex_handle*
  - *Dt::Vertex*
  - *Dt::Vertex_circulator*
  - *Dt::Vertex_iterator*
  - *Dt::Point*
  - *Dt::Geom_traits::Bounded_side_2*
  - *Dt::Geom_traits::Construct_center_2*
- the template parameter *Circle* corresponds to *Dt::Geom_traits::Cricle_2*

template<class Dt, class OutputIterator>

OutputIterator *range_search(Dt& delau, Dt::Point a, Dt::Point b, Dt::Point c, OutputIterator res)*

computes handles to all vertices contained in the closure of the triangle (a,b,c).

Precondition: *a*, *b*, and *c* must not be collinear. The computed vertex handles will be placed as a sequence of objects in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence. *delau* is the CGAL Delaunay triangulation on which we perform the range search operation.

Requirements

Dt is a CGAL Delaunay triangulation and contains the following subset of types from the concept *PointSetTraits* and from the Delaunay triangulation data type:

- *Dt::Geom_traits*
- *Dt::Vertex_handle*
- *Dt::Vertex*
- *Dt::Vertex_circulator*
- *Dt::Vertex_iterator*
- *Dt::Point*
- *Dt::Geom_traits::Circle_2*
- *Dt::Geom_traits::Bounded_side_2*
- *Dt::Geom_traits::Construct_center_2*
- *Dt::Geom_traits::Orientation_2*
- *Dt::Geom_traits::Construct_circle_2*

template<class Dt, class OutputIterator>
OutputIterator *range_search(Dt& delau,*
Dt::Point a,
Dt::Point b,
Dt::Point c,
Dt::Point d,

OutputIterator res)

computes handles to all vertices contained in the closure of the iso-rectangle (a,b,c,d).

Precondition: a is the upper left point, b the lower left, c the lower right and d the upper right point of the iso rectangle. The computed vertex handles will be placed as a sequence of objects in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence. $delau$ is the CGAL Delaunay triangulation on which we perform the range search operation.

Requirements

Dt is a CGAL Delaunay triangulation and contains the following subset of types from the concept *PointSetTraits* and from the Delaunay triangulation data type:

- *Dt::Geom_traits*
- *Dt::Vertex_handle*
- *Dt::Vertex*
- *Dt::Vertex_circulator*
- *Dt::Vertex_iterator*
- *Dt::Point*
- *Dt::Geom_traits::Circle_2*
- *Dt::Geom_traits::Bounded_side_2*
- *Dt::Geom_traits::Construct_center_2*
- *Dt::Geom_traits::Orientation_2*
- *Dt::Geom_traits::Construct_circle_2*

template<class Dt, class Circle, class OutputIterator, class Pred>
OutputIterator *range_search(Dt& delau,*
Circle C,
OutputIterator res,
Pred& pred,
bool return_if_succeded)

computes handles to all vertices contained in the closure of disk C. The computed vertex handles will be placed as a sequence of objects in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence. $delau$ is the CGAL Delaunay triangulation on that we perform the range search operation. *pred* controls the search operation. If $return\_if\_succeded$ is $true$, we will end the search after the first success of the predicate, otherwise we will continue till the search is finished.

Requirements

For the requirements of *Dt* see the description for the non-predicate version.
Requirements of *Pred*:

- *void set_result(bool);*
- *bool operator()(const Point&);*

The *operator()* is used for testing the current point in the search operation. If this operator returns *true* and *return_if_succeded* is *true*, the range search will stop. Otherwise the range search operation will continue. Member function *set_result* can be used to store the result of the range search in the function object. The result will be *true* if the last call to the *operator()* of the predicate returned *true*, *false* otherwise.

template<class Dt, class OutputIterator, class Pred>
OutputIterator range_search(Dt& delau, Dt::Point a, Dt::Point b, Dt::Point c, OutputIterator res, Pred& pred, bool return_if_succeded)

computes handles to all vertices contained in the closure of the triangle (a,b,c).

Precondition: *a*, *b*, and *c* must not be collinear. The computed vertex handles will be placed as a sequence of objects in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence. *delau* is the CGAL Delaunay triangulation on which we perform the range search operation. *pred* controls the search operation. If *return_if_succeded* is *true*, we will end the search after the first success of the predicate, otherwise we will continue till the search is finished.

Requirements

For the requirements of *Dt* see the description for the non-predicate version.
For the requirements of *Pred* see the description above.

template<class Dt, class OutputIterator, class Pred>
OutputIterator range_search(Dt& delau, Dt::Point a, Dt::Point b, Dt::Point c, Dt::Point d, OutputIterator res, Pred& pred,

bool return_if_succeded)

computes handles to all vertices contained in the closure of the iso-rectangle (a,b,c,d).

Precondition: *a* is the upper left point, *b* the lower left, *c* the lower right and *d* the upper right point of the iso rectangle. The computed vertex handles will be placed as a sequence of objects in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence. $delau$ is the CGAL Delaunay triangulation on which we perform the range search operation. *pred* controls the search operation. If $return\_if\_succeded$ is $true$, we will end the search after the first success of the predicate, otherwise we will continue till the search is finished.

Requirements

For the requirements of *Dt* see the description for the non-predicate version.
For the requirements of *Pred* see the description above.

Chapter 60

Interval Skip List

Andreas Fabri

Contents

60.1 Definition

An interval skip list is a data structure for finding all intervals that contain a point, and for stabbing queries, that is for answering the question whether a given point is contained in an interval or not. The implementation we provide is dynamic, that is the user can freely mix calls to the methods *insert(..)*, *remove(..)*, *find_intervals(..)*, and *is_contained(..)*

The interval skip list class is parameterized with an interval class.

The data structure was introduced by Hanson [Han91], and it is called interval skip list, because it is an extension of the randomized list structure known as skip list [Pug90].

60.2 Example Programs

We give two examples. The first one uses a basic interval class. In the second example we create an interval skip list for the z-ranges of the faces of a terrain, allowing to answer level queries.

60.2.1 First Example with Simple Interval

The first example reads two numbers n and d from *std::cin*. It creates n intervals of length d with the left endpoint at n. It then reads out the intervals for the 1-dimensional points with coordinates $0 \ldots n+d$.

The interval skip list class has as template argument an interval class. In this example we use the class *Interval_skip_list_interval*.

```
#include <CGAL/Interval_skip_list.h>
#include <CGAL/Interval_skip_list_interval.h>
#include <vector>
#include <list>
#include <iostream>

typedef CGAL::Interval_skip_list_interval<double> Interval;
typedef CGAL::Interval_skip_list<Interval> Interval_skip_list;

int main()
{

60.2.2 Example with Faces of a Triangulated Terrain

The second example creates an interval skip list that allows to find all the faces of a terrain intersected by an horizontal plane at a given height. The data points for the terrain are read from a file.

As model for the interval concept, we use a class that is a wrapper around a face handle of a triangulated terrain. Lower and upper bound of the interval are smallest and largest z-coordinate of the face.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Projection_traits_xy_3.h>
#include <CGAL/Interval_skip_list.h>
#include <CGAL/Level_interval.h>
#include <iostream>
#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel EIK;
typedef EIK::Point_3                                    Point_3;
typedef CGAL::Projection_traits_xy_3<EIK> K;
typedef CGAL::Delaunay_triangulation_2<K>               Delaunay;
typedef Delaunay::Face_handle                           Face_handle;
typedef Delaunay::Finite_faces_iterator
   Finite_faces_iterator;
typedef CGAL::Level_interval<Face_handle>               Interval;
typedef CGAL::Interval_skip_list<Interval>
   Interval_skip_list;

int main()
{
  std::ifstream fin("terrain.pts"); // elevation ranges from 0 to 100
  Delaunay dt;

  dt.insert(std::istream_iterator<Point_3>(fin),
            std::istream_iterator<Point_3>());

  Interval_skip_list isl;
  for(Finite_faces_iterator fh = dt.finite_faces_begin();
      fh != dt.finite_faces_end();
      ++fh){
    isl.insert(Interval(fh));
  }
  std::list<Interval> level;
  isl.find_intervals(50, std::back_inserter(level));
  for(std::list<Interval>::iterator it = level.begin();
      it != level.end();
      ++it){
    std::cout << dt.triangle(it->face_handle()) << std::endl;
  }
  return 0;
}
```

Interval Skip List Reference Manual

Andreas Fabri

This chapter presents the interval skip list introduced by Hanson [Han91], and derived from the skip list data structure [Pug90].

The data structure stores intervals and allows to perform stabbing queries, that is to test whether a point is covered by any of the intervals. It further allows to find all intervals that contain a point.

The interval skip list is, as far as its functionality is concerned, related to the *Segment_tree*. Both allow to do stabbing queries and both allow to find all intervals that contain a given point. The implementation of segment trees in CGAL works in higher dimensions, whereas the interval skip list is limited to the 1D case. However, this interval skip list implementation is fully dynamic, whereas the segment tree implementation in CGAL is static, that is all intervals must be known in advance.

This package has one concept, namely for the interval with which the interval skip list class is parameterized.

Concepts

Classes

60.4 Alphabetical List of Reference Pages

CGAL::Interval_skip_list<Interval>

Definition

The class *Interval_skip_list<Interval>* is a dynamic data structure that allows to find all members of a set of intervals that overlap a point.

#include <CGAL/Interval_skip_list.h>

Types

typedef Interval::Value	*Value;*	the type of inf and sup of the interval.

Interval_skip_list<Interval>:: const_iterator

An iterator over all intervals.

Creation

Interval_skip_list<Interval> isl;

Default constructor.

template < class InputIterator >
Interval_skip_list<Interval> isl(InputIterator first, InputIterator last);

Constructor that inserts the iterator range *[first, last)* in the interval skip list.
Precondition: The *value_type* of *first* and *last* is *Interval*.

Operations

template < class InputIterator >
int *isl.insert(InputIterator first, InputIterator last)*

Inserts the iterator range *[first, last)* in the interval skip list, and returns the number of inserted intervals.
Precondition: The *value_type* of *first* and *last* is *Interval*.

void *isl.insert(Interval i)*

inserts interval *i* in the interval skip list.

bool *isl.remove(Interval i)*

removes interval *i* from the interval skip list. Returns *true* iff removal was successful.

bool *isl.is_contained(Value v)*

Returns *true* iff there is an interval that contains *v*.

template < class OutputIterator >
OutputIterator *isl.find_intervals(Value v, OutputIterator out)*

Writes the intervals *i* with *i.inf()* $\leq v \leq$ *i.sup* to the output iterator *out*.
Precondition: The *value_type* of *out* is *Interval*.

void *isl.clear()*

Removes all intervals from the interval skip list.

const_iterator *isl.begin() const*

Returns an iterator over all intervals.

const_iterator *isl.end() const*

Returns the past the end iterator.

I/O

ostream& *ostream& os << isl*

Inserts the interval skip list *isl* into the stream *os*.
Precondition: The output operator must be defined for *Interval*.

Implementation

The insertion and deletion of a segment in the interval skip list takes expected time $O(\log^2 n)$, if the segment endpoints are chosen from a continuous distribution. A stabbing query takes expected time $O(\log n)$, and finding all intervals that contain a point takes expected time $O(\log n + k)$, where k is the number of intervals.

The implementation is based on the code developed by Eric N. Hansen, which can be found at `http://www-pub.cise.ufl.edu/~hanson/IS-lists/`. Attention, this code has memory leaks.

Interval

Definition

The concept Interval describes the requirements for the template argument *Interval* of a *Interval_skip_list< Interval>*.

The concept does not specify, whether the interval is open or closed. It is up to the implementer of a model for this concept to define that.

Creation

Interval in;	default constructor.

Types

Interval:: Value	The type of the lower and upper bound of the interval.

Access Functions

Value	*in.inf() const*	returns the lower bound.
Value	*in.sup() const*	returns the upper bound.
bool	*in.contains(Value v) const*	
		returns *true*, iff *in* contains *v*.
bool	*in.contains_interval(Value i, Value s) const*	
		returns *true*, iff *in* contains *(i,s)*.
bool	$in == I$	Equality test.
bool	$in \,!= I$	Unequality test.

Has Models

CGAL::Interval_skip_list_interval<Value>
CGAL::Face_interval

See Also

Interval_skip_list

Class

CGAL::Interval_skip_list_interval<Value>

Definition

The class *Interval_skip_list_interval<Value>* represents intervals with lower and upper bound of type *Value*. These intervals can be opened or closed at each endpoint.

#include <CGAL/Interval_skip_list_interval.h>

Creation

Interval_skip_list_interval<Value> i;

Default constructor.

Interval_skip_list_interval<Value> i(Value i, Value s, bool ic = true, bool uc = true);

Constructs the interval with infimum *i* and supremum *s*. The arguments *ic* and *uc* have value *true*, iff the interval is closed at the lower and upper bound, respectively.

Operations

bool *i.inf_closed() const*

returns *true*, iff the interval is closed at the lower bound.

bool *i.sup_closed() const*

returns *true*, iff the interval is closed at the upper bound.

I/O

The output operator is defined for *std::ostream*.

ostream& *ostream& os << Interval_skip_list_interval<V> i*

Inserts the interval *i* into the stream *os*.

Precondition: The output operator for *Value* is defined.

Is Model for the Concepts

Interval

CGAL::Level_interval<FaceHandle>

Class

Definition

The class *Level_interval<FaceHandle>* represents intervals for the minimum and maximum value of the z-coordinate of a face of a triangulation.

#include <CGAL/Level_interval.h>

Requirements

The *value_type* of *FaceHandle* must be *Face*, which must have a nested type *Vertex*, which must have a nested type *Point*, whose *Kernel_traits<Point>Kernel* must have a nested type *FT*. These requirements are fulfilled, if one uses a CGAL triangulation and a CGAL kernel.

Types

typedef FT	*Value;*	The type of the z-coordinate of points stored in vertices of faces.

Creation

Level_interval<FaceHandle> i; — Default constructor.

Level_interval<FaceHandle> i(FaceHandle fh);

Constructs the interval with smallest and largest z coordinate of the points stored in the vertices of the face *fh* points to.

Operations

FaceHandle	*i.face_handle()*	returns the face handle.

I/O

ostream&	*ostream& os << i*	Inserts the interval *i* into the stream *os*. *Precondition*: The output operator for **Face_handle* is defined.

Chapter 61

dD Spatial Searching

Hans Tangelder and Andreas Fabri

Contents

61.1 Introduction

The spatial searching package implements exact and approximate distance browsing by providing implementations of algorithms supporting

- both nearest and furthest neighbor searching
- both exact and approximate searching
- (approximate) range searching
- (approximate) k-nearest and k-furthest neighbor searching

- (approximate) incremental nearest and incremental furthest neighbor searching
- query items representing points and spatial objects.

In these searching problems a set P of data points in d-dimensional space is given. The points can be represented by Cartesian coordinates or homogeneous coordinates. These points are preprocessed into a tree data structure, so that given any query item q the points of P can be browsed efficiently. The approximate spatial searching package is designed for data sets that are small enough to store the search structure in main memory (in contrast to approaches from databases that assume that the data reside in secondary storage).

61.1.1 Neighbor Searching

Spatial searching supports browsing through a collection of d-dimensional spatial objects stored in a spatial data structure on the basis of their distances to a query object. The query object may be a point or an arbitrary spatial object, e.g, a d-dimensional sphere. The objects in the spatial data structure are d-dimensional points.

Often the number of the neighbors to be computed is not know beforehand, e.g., because the number may depend on some properties of the neighbors (for example when querying for the nearest city to Paris with population greater than a million) or the distance to the query point. The conventional approach is *k-nearest neighbor searching* that makes use of a k-nearest neighbor algorithm, where k is known prior to the invocation of the algorithm. Hence, the number of nearest neighbors has to be guessed. If the guess is too large redundant computations are performed. If the number is too small the computation has to be re-invoked for a larger number of neighbors, thereby performing redundant computations. Therefore, Hjaltason and Samet [HS95] introduced *incremental nearest neighbor searching* in the sense that having obtained the k nearest neighbors, the $k + 1^{st}$ neighbor can be obtained without having to calculate the $k + 1$ nearest neighbor from scratch.

Spatial searching typically consists of a preprocessing phase and a searching phase. In the preprocessing phase one builds a search structure and in the searching phase one makes the queries. In the preprocessing phase the user builds a tree data structure storing the spatial data. In the searching phase the user invokes a searching method to browse the spatial data.

With relatively minor modifications, nearest neighbor searching algorithms can be used to find the furthest object from the query object. Therefore, *furthest neighbor searching* is also supported by the spatial searching package.

The execution time for exact neighbor searching can be reduced by relaxing the requirement that the neighbors should be computed exactly. If the distances of two objects to the query object are approximately the same, instead of computing the nearest/furthest neighbor exactly, one of these objects may be returned as the approximate nearest/furthest neighbor. I.e., given some non-negative constant ε the distance of an object returned as an approximate k-nearest neighbor must not be larger than $(1+\varepsilon)r$, where r denotes the distance to the real k^{th} nearest neighbor. Similar the distance of an approximate k-furthest neighbor must not be smaller than $r/(1+\varepsilon)$. Obviously, for $\varepsilon = 0$ we get the exact result, and the larger ε is, the less exact the result.

Neighbor searching is implemented by the following four classes.

The class *CGAL::Orthogonal_k_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree>* implements the standard search strategy for orthogonal distances like the weighted Minkowski distance. It requires the use of extended nodes in the spatial tree and supports only k neighbor searching for point queries.

The class *CGAL::K_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>* implements the standard search strategy for general distances like the Manhattan distance for iso-rectangles. It does not require the use of extended nodes in the spatial tree and supports only k neighbor searching for queries defined by points or spatial objects.

The class *Orthogonal_incremental_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>* implements the incremental search strategy for general distances like the weighted Minkowski distance. It requires the use of extended nodes in the spatial tree and supports incremental neighbor searching and distance browsing for point queries.

The class *CGAL::Incremental_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>* implements the incremental search strategy for general distances like the Manhattan distance for iso-rectangles. It does not require the use of extended nodes in the spatial tree and supports incremental neighbor searching and distance browsing for queries defined by points or spatial objects.

61.1.2 Range Searching

Exact range searching and *approximate range searching* is supported using exact or fuzzy d-dimensional objects enclosing a region. The fuzziness of the query object is specified by a parameter ε denoting a maximal allowed distance to the boundary of a query object. If the distance to the boundary is at least ε, points inside the object are always reported and points outside the object are never reported. Points within distance ε to the boundary may be or may be not reported. For exact range searching the fuzziness parameter ε is set to zero.

The class *Kd_tree* implements range searching in the method *search*, which is a template method with an output iterator and a model of the concept *FuzzyQueryItem* as *CGAL::Fuzzy_iso_box_d* or *CGAL::Fuzzy_sphere_d*. For range searching of large data sets the user may set the parameter *bucket_size* used in building the *k-d* tree to a large value (e.g. 100), because in general the query time will be less then using the default value.

61.2 Splitting Rules

Instead of using the default splitting rule *Sliding_midpoint* described below, a user may, depending upon the data, select one from the following splitting rules, which determine how a separating hyperplane is computed:

Midpoint_of_rectangle This splitting rule cuts a rectangle through its midpoint orthogonal to the longest side.

Midpoint_of_max_spread This splitting rule cuts a rectangle through $(Mind + Maxd)/2$ orthogonal to the dimension with the maximum point spread $[Mind, Maxd]$.

Sliding_midpoint This is a modification of the midpoint of rectangle splitting rule. It first attempts to perform a midpoint of rectangle split as described above. If data points lie on both sides of the separating plane the sliding midpoint rule computes the same separator as the midpoint of rectangle rule. If the data points lie only on one side it avoids this by sliding the separator, computed by the midpoint of rectangle rule, to the nearest data point.

Median_of_rectangle The splitting dimension is the dimension of the longest side of the rectangle. The splitting value is defined by the median of the coordinates of the data points along this dimension.

Median_of_max_spread The splitting dimension is the dimension of the longest side of the rectangle. The splitting value is defined by the median of the coordinates of the data points along this dimension.

Fair This splitting rule is a compromise between the median of rectangle splitting rule and the midpoint of rectangle splitting rule. This splitting rule maintains an upper bound on the maximal allowed ratio of the longest and shortest side of a rectangle (the value of this upper bound is set in the constructor of the fair splitting rule). Among the splits that satisfy this bound, it selects the one in which the points have the largest spread. It then splits the points in the most even manner possible, subject to maintaining the bound on the ratio of the resulting rectangles.

Sliding_fair This splitting rule is a compromise between the fair splitting rule and the sliding midpoint rule. Sliding fair-split is based on the theory that there are two types of splits that are good: balanced splits that produce fat rectangles, and unbalanced splits provided the rectangle with fewer points is fat.

Also, this splitting rule maintains an upper bound on the maximal allowed ratio of the longest and shortest side of a rectangle (the value of this upper bound is set in the constructor of the fair splitting rule). Among the splits that satisfy this bound, it selects the one one in which the points have the largest spread. It then considers the most extreme cuts that would be allowed by the aspect ratio bound. This is done by dividing the longest side of the rectangle by the aspect ratio bound. If the median cut lies between these extreme cuts, then we use the median cut. If not, then consider the extreme cut that is closer to the median. If all the points lie to one side of this cut, then we slide the cut until it hits the first point. This may violate the aspect ratio bound, but will never generate empty cells.

61.3 Example Programs

We give six examples. The first example illustrates k nearest neighbor searching, and the second example incremental neighbor searching. The third is an example of approximate furthest neighbor searching using a *d*-dimensional iso-rectangle as an query object. Approximate range searching is illustrated by the fourth example. The fifth example illustrates k neighbor searching for a user defined point class. The last example shows how to choose another splitting rule in the *k*-*d* tree that is used as search tree.

61.3.1 Example for K Neighbor Searching

The first example illustrates k neighbor searching with an Euclidean distance and 2-dimensional points. The generated random data points are inserted in a search tree. We then initialize the k neighbor search object with the origin as query. Finally, we obtain the result of the computation in the form of an iterator range. The value of the iterator is a pair of a point and its square distance to the query point. We use square distances, or *transformed distances* for other distance classes, as they are computationally cheaper.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/Orthogonal_k_neighbor_search.h>
#include <CGAL/Search_traits_2.h>
#include <list>
#include <cmath>

typedef CGAL::Simple_cartesian<double> K;
typedef K::Point_2 Point_d;
typedef CGAL::Search_traits_2<K> TreeTraits;
typedef CGAL::Orthogonal_k_neighbor_search<TreeTraits> Neighbor_search;
typedef Neighbor_search::Tree Tree;

int main() {
  const unsigned int N = 1;

  std::list<Point_d> points;
  points.push_back(Point_d(0,0));

  Tree tree(points.begin(), points.end());

  Point_d query(0,0);

  // Initialize the search structure, and search all N points

  Neighbor_search search(tree, query, N);

   // report the N nearest neighbors and their distance
  // This should sort all N points by increasing distance from origin
  for(Neighbor_search::iterator it = search.begin(); it != search.end();
   ++it){
    std::cout << it->first << " "<< std::sqrt(it->second) << std::endl;
  }

  return 0;
}
```

File: examples/Spatial_searching/nearest_neighbor_searching.cpp

61.3.2 Example for Incremental Searching

This example program illustrates incremental searching for the closest point with a positive first coordinate. We can use the orthogonal incremental neighbor search class, as the query is also a point and as the distance is the Euclidean distance.

As for the *k* neighbor search, we first initialize the search tree with the data. We then create the search object, and finally obtain the iterator with the *begin()* method. Note that the iterator is of the input iterator category, that is one can make only one pass over the data.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Orthogonal_incremental_neighbor_search.h>
#include <CGAL/Search_traits_2.h>

typedef CGAL::Simple_cartesian<double> K;
typedef K::Point_2 Point_d;
typedef CGAL::Search_traits_2<K> TreeTraits;
typedef CGAL::Orthogonal_incremental_neighbor_search<TreeTraits>
    NN_incremental_search;
typedef NN_incremental_search::iterator NN_iterator;
typedef NN_incremental_search::Tree Tree;

// A functor that returns true, iff the x-coordinate of a dD point is not
     positive
struct X_not_positive {
  bool operator()(const NN_iterator& it) { return ((*it).first)[0]<0;  }
};

// An iterator that only enumerates dD points with positive x-coordinate
typedef CGAL::Filter_iterator<NN_iterator, X_not_positive>
    NN_positive_x_iterator;

int main() {

  Tree tree;
  tree.insert(Point_d(0,0));
  tree.insert(Point_d(1,1));
  tree.insert(Point_d(0,1));
  tree.insert(Point_d(10,110));
  tree.insert(Point_d(45,0));
  tree.insert(Point_d(0,2340));
  tree.insert(Point_d(0,30));

  Point_d query(0,0);

  NN_incremental_search NN(tree, query);
  NN_positive_x_iterator it(NN.end(), X_not_positive(), NN.begin()),
    end(NN.end(), X_not_positive());

  std::cout <<  "The first 5 nearest neighbours with positive x-coord
    are: " << std::endl;
  for (int j=0; (j < 5)&&(it!=end); ++j,++it)
    std::cout <<   (*it).first << "  at squared distance = " <<
   (*it).second << std::endl;
```

```
  return 0;
}
```

File: examples/Spatial_searching/distance_browsing.cpp

61.3.3 Example for General Neighbor Searching

This example program illustrates approximate nearest and furthest neighbor searching using 4-dimensional Cartesian coordinates. Five approximate nearest neighbors of the query rectangle $[0.1, 0.2]^4$ are computed. Because the query object is a rectangle we cannot use the Orthogonal neighbor search. As in the previous examples we first initialize a search tree, create the search object with the query, and obtain the result of the search as iterator range.

```
#include <CGAL/Cartesian_d.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/Manhattan_distance_iso_box_point.h>
#include <CGAL/K_neighbor_search.h>
#include <CGAL/Search_traits_2.h>

typedef CGAL::Cartesian_d<double> K;
typedef K::Point_d Point_d;
typedef CGAL::Random_points_in_square_2<Point_d> Random_points_iterator;
typedef K::Iso_box_d Iso_box_d;
typedef K TreeTraits;
typedef CGAL::Manhattan_distance_iso_box_point<TreeTraits> Distance;
typedef CGAL::K_neighbor_search<TreeTraits, Distance> Neighbor_search;
typedef Neighbor_search::Tree Tree;

int  main() {
  const int N = 1000;
  const unsigned int K = 10;

  Tree tree;
  Random_points_iterator rpg;
  for(int i = 0; i < N; i++){
    tree.insert(*rpg++);
  }
  Point_d pp(0.1,0.1);
  Point_d qq(0.2,0.2);
  Iso_box_d query(pp,qq);

  Distance tr_dist;
  Neighbor_search N1(tree, query, K, 0.0, false); // eps=10.0,
   nearest=false

  std::cout << "For query rectange = [0.1,0.2]^2 " << std::endl
            <<  "The " << K << " approximate furthest neighbors are: " <<
     std::endl;
  for (Neighbor_search::iterator it = N1.begin();it != N1.end();it++) {
    std::cout << " Point " << it->first << " at distance = " <<
   tr_dist.inverse_of_transformed_distance(it->second) << std::endl;
  }
  return 0;
}
```

File: examples/Spatial_searching/general_neighbor_searching.cpp

61.3.4 Example for a Range Query

This example program illustrates approximate range querying for 4-dimensional fuzzy iso-rectangles and spheres using homogeneous coordinates. The range queries are member functions of the *k-d* tree class.

```
#include <CGAL/Cartesian_d.h>
#include <CGAL/point_generators_d.h>
#include <CGAL/Kd_tree.h>
#include <CGAL/Fuzzy_sphere.h>
#include <CGAL/Fuzzy_iso_box.h>
#include <CGAL/Search_traits_d.h>

typedef CGAL::Cartesian_d<double> K;
typedef K::Point_d Point_d;
typedef CGAL::Search_traits_d<K> Traits;
typedef CGAL::Random_points_in_cube_d<Point_d>
    Random_points_iterator;
typedef CGAL::Counting_iterator<Random_points_iterator>
    N_Random_points_iterator;
typedef CGAL::Kd_tree<Traits> Tree;
typedef CGAL::Fuzzy_sphere<Traits> Fuzzy_sphere;
typedef CGAL::Fuzzy_iso_box<Traits> Fuzzy_iso_box;

int main() {
  const int D = 4;
  const int N = 1000;
  // generator for random data points in the square ( (-1000,-1000),
    (1000,1000) )
  Random_points_iterator rpit(4, 1000.0);

  // Insert N points in the tree
  Tree tree(N_Random_points_iterator(rpit,0),
            N_Random_points_iterator(rpit,N));

  // define range query objects
  double  pcoord[D] = { 300, 300, 300, 300 };
  double  qcoord[D] = { 900.0, 900.0, 900.0, 900.0 };
  Point_d p(D, pcoord, pcoord+D);
  Point_d q(D, qcoord, qcoord+D);
  Fuzzy_sphere fs(p, 700.0, 100.0);
  Fuzzy_iso_box fib(p, q, 100.0);

  std::cout << "points approximately in fuzzy range query" << std::endl;
  std::cout << "with center (300.0, 300.0, 300.0, 300.0)" << std::endl;
  std::cout << "and fuzzy radius <200.0,400.0> are:" << std::endl;
  tree.search(std::ostream_iterator<Point_d>(std::cout, "\n"), fs);

  std::cout << "points approximately in fuzzy range query ";
  std::cout << "[<200,4000>,<800,1000>]]^4 are:" << std::endl;

  tree.search(std::ostream_iterator<Point_d>(std::cout, "\n"), fib);
  return 0;
}
```

File: examples/Spatial_searching/fuzzy_range_query.cpp

61.3.5 Example for User Defined Point and Distance Class

The neighbor searching works with all CGAL kernels, as well as with user defined points and distance classes. In this example we assume that the user provides the following 3-dimensional points class.

```
struct Point {
  double vec[3];

  Point() { vec[0]= vec[1] = vec[2] = 0; }
  Point (double x, double y, double z) { vec[0]=x; vec[1]=y; vec[2]=z;  }

  double x() const { return vec[ 0 ]; }
  double y() const { return vec[ 1 ]; }
  double z() const { return vec[ 2 ]; }

  double& x() { return vec[ 0 ]; }
  double& y() { return vec[ 1 ]; }
  double& z() { return vec[ 2 ]; }

  bool operator==(const Point& p) const
  {
    return (x() == p.x()) && (y() == p.y()) && (z() == p.z())  ;
  }

  bool  operator!=(const Point& p) const { return ! (*this == p); }
}; //end of class

namespace CGAL {

  template <>
  struct Kernel_traits<Point> {
    struct Kernel {
      typedef double FT;
      typedef double RT;
    };
  };
}

struct Construct_coord_iterator {
  typedef  const double* result_type;
  const double* operator()(const Point& p) const
  { return static_cast<const double*>(p.vec); }

  const double* operator()(const Point& p, int)  const
  { return static_cast<const double*>(p.vec+3); }
};
```

File: examples/Spatial_searching/Point.h

We have put the glue layer in this file as well, that is a class that allows to iterate over the Cartesian coordinates of the point, and a class to construct such an iterator for a point. We next need a distance class

```
struct Distance {
  typedef Point Query_item;
  typedef double FT;

  double transformed_distance(const Point& p1, const Point& p2) const {
    double distx= p1.x()-p2.x();
    double disty= p1.y()-p2.y();
    double distz= p1.z()-p2.z();
    return distx*distx+disty*disty+distz*distz;
  }

  template <class TreeTraits>
  double min_distance_to_rectangle(const Point& p,
                                   const
   CGAL::Kd_tree_rectangle<TreeTraits>& b) const {
    double distance(0.0), h = p.x();
    if (h < b.min_coord(0)) distance +=
   (b.min_coord(0)-h)*(b.min_coord(0)-h);
    if (h > b.max_coord(0)) distance +=
   (h-b.max_coord(0))*(h-b.max_coord(0));
    h=p.y();
    if (h < b.min_coord(1)) distance +=
   (b.min_coord(1)-h)*(b.min_coord(1)-h);
    if (h > b.max_coord(1)) distance +=
   (h-b.max_coord(1))*(h-b.min_coord(1));
    h=p.z();
    if (h < b.min_coord(2)) distance +=
   (b.min_coord(2)-h)*(b.min_coord(2)-h);
    if (h > b.max_coord(2)) distance +=
   (h-b.max_coord(2))*(h-b.max_coord(2));
    return distance;
  }

  template <class TreeTraits>
  double max_distance_to_rectangle(const Point& p,
                                   const
   CGAL::Kd_tree_rectangle<TreeTraits>& b) const {
    double h = p.x();

    double d0 = (h >= (b.min_coord(0)+b.max_coord(0))/2.0) ?
                (h-b.min_coord(0))*(h-b.min_coord(0)) :
   (b.max_coord(0)-h)*(b.max_coord(0)-h);

    h=p.y();
    double d1 = (h >= (b.min_coord(1)+b.max_coord(1))/2.0) ?
                (h-b.min_coord(1))*(h-b.min_coord(1)) :
   (b.max_coord(1)-h)*(b.max_coord(1)-h);
    h=p.z();
    double d2 = (h >= (b.min_coord(2)+b.max_coord(2))/2.0) ?
                (h-b.min_coord(2))*(h-b.min_coord(2)) :
   (b.max_coord(2)-h)*(b.max_coord(2)-h);
    return d0 + d1 + d2;
  }
```

```
  double new_distance(double& dist, double old_off, double new_off,
                      int /* cutting_dimension */)  const {
    return dist + new_off*new_off - old_off*old_off;
  }

  double transformed_distance(double d) const { return d*d; }

  double inverse_of_transformed_distance(double d) { return std::sqrt(d);
    }

}; // end of struct Distance
```

File: examples/Spatial_searching/Distance.h

We are ready to put the pieces together. The class *Search_traits*<..> which you see in the next file is then a mere wrapper for all these types. The searching itself works exactly as for CGAL kernels.

```
#include <CGAL/basic.h>
#include <CGAL/Search_traits.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Orthogonal_k_neighbor_search.h>
#include "Point.h"  // defines types Point, Construct_coord_iterator
#include "Distance.h"

typedef CGAL::Random_points_in_cube_3<Point> Random_points_iterator;
typedef CGAL::Counting_iterator<Random_points_iterator>
    N_Random_points_iterator;
typedef CGAL::Search_traits<double, Point, const double*,
    Construct_coord_iterator> Traits;
typedef CGAL::Orthogonal_k_neighbor_search<Traits, Distance>
    K_neighbor_search;
typedef K_neighbor_search::Tree Tree;

int main() {
  const int N = 1000;
  const unsigned int K = 5;
  // generator for random data points in the cube ( (-1,-1,-1), (1,1,1) )
  Random_points_iterator rpit( 1.0);

  // Insert number_of_data_points in the tree
  Tree tree(N_Random_points_iterator(rpit,0),
            N_Random_points_iterator(N));

  Point query(0.0, 0.0, 0.0);
  Distance tr_dist;

  // search K nearest neighbours
  K_neighbor_search search(tree, query, K);
  for(K_neighbor_search::iterator it = search.begin(); it !=
    search.end(); it++){
     std::cout << " d(q, nearest neighbor)=  "
               << tr_dist.inverse_of_transformed_distance(it->second) <<
    std::endl;
  }
  // search K furthest neighbour searching, with eps=0,
    search_nearest=false
  K_neighbor_search search2(tree, query, K, 0.0, false);

  for(K_neighbor_search::iterator it = search2.begin(); it !=
    search2.end(); it++){
     std::cout << " d(q, furthest neighbor)=  "
               << tr_dist.inverse_of_transformed_distance(it->second) <<
    std::endl;
  }
  return 0;
}
```

File: examples/Spatial_searching/user_defined_point_and_distance.cpp

61.3.6 Examples for Using an Arbitrary Point Type with Point Property Maps

The following three example programs illustrate how to use the classes *Search_traits_adapter<Key,PointPropertyMap,BaseTraits>* and *Distance_for_point_adapter<Key,PointPropertyMap,Base_distance>* to store in the kd-tree objects of an arbitrary key type. Points are accessed through a point property map. This is really convenient to associate information to a point or to reduce the size of the search structure.

Using a Point and an Integer as Key Type

In this example program, the search tree stores tuples of point and integer. The value type of the iterator of the neighbor searching algorithm is this tuple type.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/basic.h>
#include <CGAL/Search_traits_3.h>
#include <CGAL/Search_traits_adapter.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Orthogonal_k_neighbor_search.h>
#include <boost/iterator/zip_iterator.hpp>
#include <utility>

typedef CGAL::Exact_predicates_inexact_constructions_kernel Kernel;
typedef Kernel::Point_3 Point_3;
typedef boost::tuple<Point_3,int> Point_and_int;

//definition of the property map
struct My_point_property_map{
  typedef Point_3 value_type;
  typedef const value_type& reference;
  typedef const Point_and_int& key_type;
  typedef boost::readable_property_map_tag category;
};

//get function for the property map
My_point_property_map::reference
get(My_point_property_map,My_point_property_map::key_type p)
{return boost::get<0>(p);}

typedef CGAL::Random_points_in_cube_3<Point_3>
                   Random_points_iterator;
typedef CGAL::Search_traits_3<Kernel>
                   Traits_base;
typedef
    CGAL::Search_traits_adapter<Point_and_int,My_point_property_map,Traits_base>
        Traits;

typedef CGAL::Orthogonal_k_neighbor_search<Traits>
    K_neighbor_search;
typedef K_neighbor_search::Tree
    Tree;
```

```
typedef K_neighbor_search::Distance
    Distance;

int main() {
  const unsigned int K = 5;
  // generator for random data points in the cube ( (-1,-1,-1), (1,1,1) )
  Random_points_iterator rpit( 1.0);
  std::vector<Point_3> points;
  std::vector<int>     indices;

  points.push_back(Point_3(*rpit++));
  points.push_back(Point_3(*rpit++));
  points.push_back(Point_3(*rpit++));
  points.push_back(Point_3(*rpit++));
  points.push_back(Point_3(*rpit++));
  points.push_back(Point_3(*rpit++));
  points.push_back(Point_3(*rpit++));

  indices.push_back(0);
  indices.push_back(1);
  indices.push_back(2);
  indices.push_back(3);
  indices.push_back(4);
  indices.push_back(5);
  indices.push_back(6);

  // Insert number_of_data_points in the tree
  Tree tree(
    boost::make_zip_iterator(boost::make_tuple(
   points.begin(),indices.begin() )),
    boost::make_zip_iterator(boost::make_tuple(
   points.end(),indices.end() ) )
  );
  Point_3 query(0.0, 0.0, 0.0);
  Distance tr_dist;

  // search K nearest neighbours
  K_neighbor_search search(tree, query, K);
  for(K_neighbor_search::iterator it = search.begin(); it !=
   search.end(); it++){
    std::cout << " d(q, nearest neighbor)=  "
              << tr_dist.inverse_of_transformed_distance(it->second) <<
   " " << boost::get<0>(it->first)<< " " << boost::get<1>(it->first) <<
   std::endl;
  }
  return 0;
}
```

File: examples/Spatial_searching/searching_with_point_with_info.cpp

Using an Integer as Key Type

In this example program, the search tree stores only integers that refer to points stored within a user vector. The point type of the search traits is *std::size_t*.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/basic.h>
#include <CGAL/Search_traits_3.h>
#include <CGAL/Search_traits_adapter.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Orthogonal_k_neighbor_search.h>
#include <boost/iterator/counting_iterator.hpp>
#include <utility>

typedef CGAL::Exact_predicates_inexact_constructions_kernel Kernel;
typedef Kernel::Point_3 Point_3;

typedef std::size_t Point;

//definition of the property map and get
//function as friend function to have access to
//private member
class My_point_property_map{
  const std::vector<Point_3>& points;
public:
  typedef Point_3 value_type;
  typedef const value_type& reference;
  typedef Point key_type;
  typedef boost::readable_property_map_tag category;

  My_point_property_map(const std::vector<Point_3>& pts):points(pts){}

  friend reference get(const My_point_property_map& ppmap,key_type i)
  {return ppmap.points[i];}
};

typedef CGAL::Random_points_in_cube_3<Point_3>
                    Random_points_iterator;
typedef CGAL::Search_traits_3<Kernel>
                    Traits_base;
typedef
   CGAL::Search_traits_adapter<Point,My_point_property_map,Traits_base>
             Traits;

typedef CGAL::Orthogonal_k_neighbor_search<Traits>
   K_neighbor_search;
typedef K_neighbor_search::Tree
   Tree;
typedef Tree::Splitter
   Splitter;
typedef K_neighbor_search::Distance
   Distance;
```

```
int main() {
  const unsigned int K = 5;
  // generator for random data points in the cube ( (-1,-1,-1), (1,1,1) )
  Random_points_iterator rpit( 1.0);
  std::vector<Point_3> points;

  points.push_back(Point_3(*rpit++));
  points.push_back(Point_3(*rpit++));
  points.push_back(Point_3(*rpit++));
  points.push_back(Point_3(*rpit++));
  points.push_back(Point_3(*rpit++));
  points.push_back(Point_3(*rpit++));
  points.push_back(Point_3(*rpit++));

  My_point_property_map ppmap(points);

  // Insert number_of_data_points in the tree
  Tree tree(
    boost::counting_iterator<std::size_t>(0),
    boost::counting_iterator<std::size_t>(points.size()),
    Splitter(),
    Traits(ppmap)
  );
  Point_3 query(0.0, 0.0, 0.0);
  Distance tr_dist(ppmap);

  // search K nearest neighbours
  K_neighbor_search search(tree, query, K,0,true,tr_dist);
  for(K_neighbor_search::iterator it = search.begin(); it !=
   search.end(); it++){
    std::cout << " d(q, nearest neighbor)=  "
              << tr_dist.inverse_of_transformed_distance(it->second) <<
   " " << points[it->first] << " " << it->first << std::endl;
  }
  return 0;
}
```

Using a Model of L-value Property Map Concept

This example programs uses a BOOST LvaluePropertyMap. Points are read from a *std::map*. The search tree stores integers of type *std::size_t*. The value type of the iterator of the neighbor searching algorithm is *std::size_t*.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/basic.h>
#include <CGAL/Search_traits_3.h>
#include <CGAL/Search_traits_adapter.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Orthogonal_k_neighbor_search.h>
#include <boost/iterator/counting_iterator.hpp>
```

```
#include <utility>

typedef CGAL::Exact_predicates_inexact_constructions_kernel Kernel;
typedef Kernel::Point_3 Point_3;

typedef std::size_t Point;

typedef boost::const_associative_property_map<std::map<Point,Point_3> >
                  My_point_property_map;

typedef CGAL::Random_points_in_cube_3<Point_3>
                  Random_points_iterator;
typedef CGAL::Search_traits_3<Kernel>
                  Traits_base;
typedef
   CGAL::Search_traits_adapter<Point,My_point_property_map,Traits_base>
             Traits;

typedef CGAL::Orthogonal_k_neighbor_search<Traits>
   K_neighbor_search;
typedef K_neighbor_search::Tree
   Tree;
typedef Tree::Splitter
   Splitter;
typedef K_neighbor_search::Distance
   Distance;

int main() {
  const unsigned int K = 5;
  // generator for random data points in the cube ( (-1,-1,-1), (1,1,1) )
  Random_points_iterator rpit( 1.0);
  std::map<Point,Point_3> points;

  points[0]=Point_3(*rpit++);
  points[1]=Point_3(*rpit++);
  points[2]=Point_3(*rpit++);
  points[3]=Point_3(*rpit++);
  points[4]=Point_3(*rpit++);
  points[5]=Point_3(*rpit++);
  points[6]=Point_3(*rpit++);

  My_point_property_map ppmap(points);

  // Insert number_of_data_points in the tree
  Tree tree(
    boost::counting_iterator<std::size_t>(0),
    boost::counting_iterator<std::size_t>(points.size()),
    Splitter(),
    Traits(ppmap)
  );
  Point_3 query(0.0, 0.0, 0.0);
  Distance tr_dist(ppmap);
```

```
  // search K nearest neighbours
  K_neighbor_search search(tree, query, K,0,true,tr_dist);
  for(K_neighbor_search::iterator it = search.begin(); it !=
   search.end(); it++){
    std::cout << " d(q, nearest neighbor)=  "
              << tr_dist.inverse_of_transformed_distance(it->second) <<
   " " << points[it->first] << " " << it->first << std::endl;
  }
  return 0;
}
```

File: examples/Spatial_searching/searching_with_point_with_info_pmap.cpp

61.3.7 Example for Selecting a Splitting Rule and Setting the Bucket Size

This example program illustrates selecting a splitting rule and setting the maximal allowed bucket size. The only differences with the first example are the declaration of the *Fair* splitting rule, needed to set the maximal allowed bucket size.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/Search_traits_2.h>
#include <CGAL/Orthogonal_k_neighbor_search.h>
#include <cmath>

typedef CGAL::Simple_cartesian<double> R;
typedef R::Point_2 Point_d;
typedef CGAL::Random_points_in_square_2<Point_d> Random_points_iterator;
typedef CGAL::Counting_iterator<Random_points_iterator>
   N_Random_points_iterator;
typedef CGAL::Search_traits_2<R> Traits;
typedef CGAL::Euclidean_distance<Traits> Distance;
typedef CGAL::Fair<Traits> Fair;
typedef CGAL::Orthogonal_k_neighbor_search<Traits,Distance,Fair>
   Neighbor_search;
typedef Neighbor_search::Tree Tree;

int main() {
  const unsigned int N = 1000;
  // generator for random data points in the square ( (-1,-1), (1,1) )
  Random_points_iterator rpit( 1.0);

  Fair fair(5); // bucket size=5
  // Insert number_of_data_points in the tree
  Tree tree(N_Random_points_iterator(rpit,0),
            N_Random_points_iterator(N),
            fair);

  Point_d query(0,0);

  // Initialize the search structure, and search all N points
  Neighbor_search search(tree, query, N);

  // report the N nearest neighbors and their distance
  // This should sort all N points by increasing distance from origin
  for(Neighbor_search::iterator it = search.begin(); it != search.end();
   ++it){
    std::cout << it->first << " "<< std::sqrt(it->second) << std::endl;
  }
  return 0;
}
```

File: examples/Spatial_searching/using_fair_splitting_rule.cpp

61.4 Software Design

61.4.1 The *k*-*d* tree

Bentley [Ben75] introduced the *k*-*d* tree as a generalization of the binary search tree in higher dimensions. *k*-*d* trees hierarchically decompose space into a relatively small number of rectangles such that no rectangle contains too many input objects. For our purposes, a *rectangle* in real d dimensional space, $\mathbb{R}^d$, is the product of d closed intervals on the coordinate axes. *k*-*d* trees are obtained by partitioning point sets in $\mathbb{R}^d$ using (d-1)-dimensional hyperplanes. Each node in the tree is split into two children by one such separating hyperplane. Several splitting rules (see Section 61.2 can be used to compute a separating (d-1)-dimensional hyperplane.

Each internal node of the *k*-*d* tree is associated with a rectangle and a hyperplane orthogonal to one of the coordinate axis, which splits the rectangle into two parts. Therefore, such a hyperplane, defined by a splitting dimension and a splitting value, is called a separator. These two parts are then associated with the two child nodes in the tree. The process of partitioning space continues until the number of data points in the rectangle falls below some given threshold. The rectangles associated with the leaf nodes are called *buckets*, and they define a subdivision of the space into rectangles. Data points are only stored in the leaf nodes of the tree, not in the internal nodes.

Friedmann, Bentley and Finkel [FBF77] described the standard search algorithm to find the *k*th nearest neighbor by searching a *k*-*d* tree recursively.

When encountering a node of the tree, the algorithm first visits the child that is closest to the query point. On return, if the rectangle containing the other child lies within 1/ (1+ε) times the distance to the *k*th nearest neighbors so far, then the other child is visited recursively. Priority search [AM93b] visits the nodes in increasing order of distance from the queue with help of a priority queue. The search stops when the distance of the query point to the nearest nodes exceeds the distance to the nearest point found with a factor 1/ (1+ε). Priority search supports next neighbor search, standard search does not.

In order to speed-up the internal distance computations in nearest neighbor searching in high dimensional space, the approximate searching package supports orthogonal distance computation. Orthogonal distance computation implements the efficient incremental distance computation technique introduced by Arya and Mount [AM93a]. This technique works only for neighbor queries with query items represented as points and with a quadratic form distance, defined by $d_A(x,y) = (x-y)A(x-y)^T$, where the matrix A is positive definite, i.e. $d_A(x,y) \geq 0$. An important class of quadratic form distances are weighted Minkowski distances. Given a parameter $p > 0$ and parameters $w_i \geq 0, 0 < i \leq d$, the weighted Minkowski distance is defined by $l_p(w)(r,q) = (\Sigma_{i=1}^{i=d} w_i(r_i - q_i)^p)^{1/p}$ for $0 < p < \infty$ and defined by $l_\infty(w)(r,q) = max\{w_i|r_i - q_i| \mid 1 \leq i \leq d\}$. The Manhattan distance ($p = 1$, $w_i = 1$) and the Euclidean distance ($p = 2$, $w_i = 1$) are examples of a weighted Minkowski metric.

To speed up distance computations also transformed distances are used instead of the distance itself. For instance for the Euclidean distance, to avoid the expensive computation of square roots, squared distances are used instead of the Euclidean distance itself.

dD Spatial Searching Reference Manual

Hans Tangelder and Andreas Fabri

This package provides data structures and algorithms for exact and approximate distance browsing, supporting

- both nearest and furthest neighbor searching,
- both exact and approximate searching,
- (approximate) range searching,
- (approximate) *k*-nearest and *k*-furthest neighbor searching,
- (approximate) incremental nearest and incremental furthest neighbor searching,
- query items representing points and spatial objects.

The spatial searching package consists of the following concepts and classes that are described in the reference pages.

61.5 Classified Reference Pages

Search Classes

Range Query Item Classes

Search Traits Classes

Distance Classes

Splitter Classes

Advanced Classes

61.6 Alphabetical List of Reference Pages

Class

CGAL::Euclidean_distance<Traits>

Definition

The class *Euclidean_distance<Traits>* provides an implementation of the concept *OrthogonalDistance*, with the Euclidean distance (l_2 metric). To optimize distance computations squared distances are used.

#include <CGAL/Euclidean_distance.h>

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Search_traits_2<CGAL::Cartesian<double> >*.

Is Model for the Concepts

OrthogonalDistance

Types

Traits::FT	*FT;*	Number type.
Traits::Point_d	*Point_d;*	Point type.
Point_d	*Query_item;*	Query item type.

Creation

Euclidean_distance<Traits> ed(Traits t=Traits());

Default constructor.

Operations

FT *ed.transformed_distance(Query_item q, Point_d p) const*

Returns the squared Euclidean distance between q and p.

FT *ed.min_distance_to_rectangle(Query_item q, Kd_tree_rectangle<FT> r) const*

Returns the squared Euclidean distance between q and the point on the boundary of r closest to q.

FT	*ed.max_distance_to_rectangle(Query_item q, Kd_tree_rectangle<FT> r;) const*	
		Returns the squared Euclidean distance, where d denotes the distance between q and the point on the boundary of r farthest to q.
FT	*ed.new_distance(FT dist, FT old_off, FT new_off, int cutting_dimension) const*	
		Updates the squared *dist* incrementally and returns the updated squared distance.
FT	*ed.transformed_distance(FT d) const*	
		Returns d^2.
FT	*ed.inverse_of_transformed_distance(FT d) const*	
		Returns $d^{1/2}$.

See Also

OrthogonalDistance
CGAL::Weighted_Minkowski_distance<Traits>

Class

CGAL::Euclidean_distance_sphere_point<Traits>

Definition

The class *Euclidean_distance_sphere_point<Traits>* provides an implementation of the *GeneralDistance* concept for the Euclidean distance (l_2 metric) between a d-dimensional sphere and a point, and the Euclidean distance between a d-dimensional sphere and a d-dimensional iso-rectangle defined as a k-d tree rectangle.

#include <CGAL/Euclidean_distance_sphere_point.h>

Parameters

Expects for the template argument a model of the concept *SearchTraits*, for example *CGAL::Cartesian_d< double>*.

Is Model for the Concepts

GeneralDistance

Types

Traits::FT	*FT;*	Number type.
Traits::Point_d	*Point_d;*	Point type.
Traits::Sphere_d	*Sphere_d;*	Query item type.

Creation

Euclidean_distance_sphere_point<Traits> ed(Traits t=Traits());

Default constructor.

Operations

NT *ed.transformed_distance(Query_item s, Point_d p) const*

Returns the distance between s and p.

NT *ed.min_distance_to_rectangle(Query_item s, Kd_tree_rectangle<FT> r) const*

Returns the minimal distance between a point from the sphere s and a point from r.

NT *ed.max_distance_to_rectangle(Query_item s, Kd_tree_rectangle<FT> r) const*

Returns the maximal distance between the sphere *s* and a point from *r* furthest to *s*.

NT *ed.transformed_distance(NT d) const*

Returns d^2.

NT *ed.inverse_of_transformed_distance(NT d) const*

Returns $d^{1/2}$.

See Also

GeneralDistance

Functor
Class

CGAL::Fair<Traits, SpatialSeparator>

Definition

Implements the *fair* splitting rule. This splitting rule is a compromise between the median of rectangle splitting rule and the midpoint of rectangle splitting rule. This splitting rule maintains an upper bound on the maximal allowed ratio of the longest and shortest side of a rectangle (the value of this upper bound is set in the constructor of the fair splitting rule). Among the splits that satisfy this bound, it selects the one in which the points have the largest spread. It then splits the points in the most even manner possible, subject to maintaining the bound on the ratio of the resulting rectangles.

#include <CGAL/Splitters.h>

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *Cartesian_d<double>*.

Expects for the second template argument a model of the concept *Separator*. It has as default value the type, *CGAL::Plane_separator<Traits::FT>*.

Is Model for the Concepts

Splitter

Types

Traits::FT	*FT;*	Number type.

Creation

Fair<Traits, SpatialSeparator> s;	Default constructor.

Fair<Traits, SpatialSeparator> s(unsigned int bucket_size, FT aspect_ratio=FT(3));

Constructor.

FuzzyQueryItem

Concept

Definition

The concept FuzzyQueryItem describes the requirements for fuzzy d-dimensional spatial objects.

Has Models

CGAL::Fuzzy_sphere<Traits>,
CGAL::Fuzzy_iso_box<Traits>

Types

FuzzyQueryItem:: Point_d	represents a d-dimensional point.
FuzzyQueryItem:: FT	Number type.

Operations

bool *q.contains(Point_d p) const*

test whether q contains p.

bool *q.inner_range_intersects(Kd_tree_rectangle<FT> rectangle) const*

test whether the inner approximation of the spatial object intersects a rectangle associated with a node of a tree.

bool *q.outer_range_contains(Kd_tree_rectangle<FT> rectangle) const*

test whether the outer approximation of the spatial object encloses the rectangle associated with a node of a tree.

Class

CGAL::Fuzzy_iso_box<Traits>

Definition

The class *Fuzzy_iso_box<Traits>* implements fuzzy d-dimensional iso boxes. A fuzzy iso box with fuzziness value ε has as outer approximation a box dilated, and as inner approximation a box eroded by a d-dim square with side length ε.

#include <CGAL/Fuzzy_iso_box.h>

Parameters

Expects for the template argument a model of the concept *SearchTraits*, for example *CGAL::Search_traits_2< CGAL::Simple_cartesian<double> >*.

Is Model for the Concepts

FuzzyQueryItem

Types

Traits::Point_d	*Point_d;*	Point type.
Traits::FT	*FT;*	Number type.

Creation

Fuzzy_iso_box<Traits> b(Point_d p, Point_d q, FT epsilon=FT(0), Traits t=Traits());

Constructs a fuzzy iso box specified by the minimal iso box containing p and q and fuzziness value *epsilon*.
Precondition: p must be lexicographically smaller than q.

In case *Traits* is *Search_traits_adapter<Key,PointPropertyMap,BaseTraits>*, the following constructor is also available:

Fuzzy_iso_box<Traits> b(Traits::Base::Point_d p,
Traits::Base::Point_d q,
FT epsilon=FT(0),
Traits t=Traits())

Constructs a fuzzy iso box specified by the minimal iso box containing p and q and fuzziness value *epsilon*.
Precondition: p must be lexicographically smaller than q.

Operations

bool *b.contains(Point_d p) const*

test whether *b* contains *p*.

bool *b.inner_range_intersects(Kd_tree_rectangle<FT> rectangle) const*

test whether the inner box intersects the rectangle associated with a node of a tree.

bool *b.outer_range_contains(Kd_tree_rectangle<FT> rectangle) const*

test whether the outer box encloses the rectangle associated with a node of a tree.

FuzzyQueryItem

Class

CGAL::Fuzzy_sphere<Traits>

Definition

The class *Fuzzy_sphere<Traits>* implements fuzzy d-dimensional spheres. A fuzzy sphere with radius r and fuzziness value ε has as outer approximation a sphere with radius $r+\varepsilon$ and as inner approximation a sphere with radius $r-\varepsilon$.

#include <CGAL/Fuzzy_sphere.h>

Parameters

Expects for the template argument a model of the concept *SearchTraits*, for example *CGAL::Cartesian_d< double>*.

Is Model for the Concepts

FuzzyQueryItem

Types

Traits::Point_d	*Point_d;*	Point type.
Traits::FT	*FT;*	Number type.

Creation

Fuzzy_sphere<Traits> s(Point_d center, FT radius, FT epsilon=FT(0), Traits t=Traits());

Constructs a fuzzy sphere centered at *center* with radius *radius* and fuzziness value *epsilon*.

In case *Traits* is *Search_traits_adapter<Key,PointPropertyMap,BaseTraits>*, the following constructor is also available:

Fuzzy_sphere<Traits> s(Traits::Base::Point_d center, FT radius, FT epsilon=FT(0), Traits t=Traits());

Constructs a fuzzy sphere centered at *center* with radius *radius* and fuzziness value *epsilon*.

Operations

bool *s.contains(Point_d p) const*

test whether *s* contains *p*.

bool *s.inner_range_intersects(Kd_tree_rectangle<FT> rectangle) const*

test whether the inner sphere intersects the rectangle associated with a node of a tree.

bool *s.outer_range_contains(Kd_tree_rectangle<FT> rectangle) const*

test whether the outer sphere encloses the rectangle associated with a node of a tree.

Concept

GeneralDistance

Definition

Requirements of a distance class defining a distance between a query item denoting a spatial object and a point. To optimize distance computations transformed distances are used, e.g., for a Euclidean distance the transformed distance is the squared Euclidean distance.

Has Models

CGAL::Manhattan_distance_iso_box_point<Traits>
CGAL::Euclidean_distance_sphere_point<Traits>.

Types

GeneralDistance:: FT	Number type.
GeneralDistance:: Point_d	Point type.
GeneralDistance:: Query_item	Query item type.

Operations

FT *gd.transformed_distance(Query_item q, Point_d r)*

Returns the transformed distance between *q* and *r*.

FT *gd.min_distance_to_rectangle(Query_item q, Kd_tree_rectangle<FT> r) const*

Returns the transformed distance between *q* and the point on the boundary of *r* closest to *q*.

FT *gd.max_distance_to_rectangle(Query_item q, Kd_tree_rectangle<FT> r) const*

Returns the transformed distance between *q* and the point on the boundary of *r* furthest to *q*.

FT *gd.transformed_distance(FT d) const*

Returns the transformed distance.

FT *gd.inverse_of_transformed_distance(FT d) const*

Returns the inverse of the transformed distance.

CGAL::Incremental_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>

Class

Definition

The class *Incremental_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>* implements incremental nearest and furthest neighbor searching on a tree. The tree may have extended or unextended nodes.

#include <CGAL/Incremental_neighbor_search.h>

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Search_traits_2<CGAL::Cartesian<double> >*.

Expects for the second template argument a model of the concept *GeneralDistance*. If *Traits* is *CGAL::Search_traits_adapter<Key,PointPropertyMap,BaseTraits>* the default type is *CGAL::Distance_for_point_adapter<Key,PointPropertyMap,CGAL::Euclidean_distance<Traits> >*, and *CGAL::Euclidean_distance<Traits>* otherwise.

Expects for third template argument a model of the concept *Splitter*. The default type is *CGAL::Sliding_midpoint<Traits>*.

Expects for fourth template argument a model of the concept *SpatialTree*. The default type is *CGAL::Kd_tree<Traits,Splitter,CGAL::Tag_false>*. The template argument *CGAL::Tag_false* makes that the tree is built with unextended nodes.

Types

Traits::Point_d	*Point_d;*	Point type.
Traits::NT	*NT;*	Number type.
GeneralDistance	*Distance;*	Distance type.
std::pair<Point_d,NT>	*Point_with_transformed_distance;*	Pair of point and transformed distance.

Incremental_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>:: iterator

const input iterator with value type *Point_with_transformed_distance* for enumerating approximate neighbors.

GeneralDistance::Query_item

	Query_item;	Query item type.
SpatialTree	*Tree;*	The tree type.

Creation

Incremental_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree> s(
Tree& tree,
QueryItem q,
NT eps=NT(0.0),
bool search_nearest=true,
GeneralDistance d=GeneralDistance())

Constructor for incremental neighbor searching of the query item *q* in the points stored *tree* using a distance *d* and approximation factor *eps*.

Operations

iterator	*s.begin() const*	Returns a const iterator to the approximate nearest or furthest neighbor.
iterator	*s.end() const*	Returns the appropriate past-the-end const iterator.

advanced

std::ostream& *s.statistics(std::ostream& s)*

Inserts statistics of the search process into the output stream *s*.

advanced

CGAL::Orthogonal_incremental_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree>

CGAL::K_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>

Class

Definition

The class *K_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>* implements approximate k-nearest and k-furthest neighbor searching using standard search on a tree using a general distance class. The tree may be built with extended or unextended nodes.

#include <CGAL/K_neighbor_search.h>

Parameters

Expects for the first template argument an implementation of the concept *SearchTraits*, for example *CGAL::Cartesian_d<double>*.

Expects for the second template argument a model of the concept *GeneralDistance*. If *Traits* is *CGAL::Search_traits_adapter<Key,PointPropertyMap,BaseTraits>* the default type is *CGAL::Distance_for_point_adapter< Key,PointPropertyMap,CGAL::Euclidean_distance<Traits> >*, and *CGAL::Euclidean_distance<Traits>* otherwise.

Expects for fourth template argument an implementation of the concept *SpatialTree*. The default type is *CGAL::Kd_tree<Traits, Splitter, CGAL::Tag_false>*. The template argument *CGAL::Tag_false* makes that the tree is built with unextended nodes.

Types

Traits::Point_d	*Point_d;*	Point type.
Traits::FT	*FT;*	Number type.
GeneralDistance	*Distance;*	Distance type.
std::pair<Point_d,FT>	*Point_with_transformed_distance;*	Pair of point and transformed distance.

K_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>:: iterator

Bidirectional const iterator with value type *Point_with_distance* for enumerating approximate neighbors.

GeneralDistance::Query_item

Query_item; Query item type.

SpatialTree	*Tree;*	The tree type.

Creation

K_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree> s(
Tree tree,
Query_item q,
unsigned int k=1,
FT eps=FT(0.0),
bool search_nearest=true,
GeneralDistance d=GeneralDistance(),
bool sorted=true)

Constructor for searching approximately k neighbors of the query item q in the points stored in *tree* using distance class d and approximation factor *eps*. *sorted* indicates if the computed sequence of k-nearest neighbors needs to be sorted.

Operations

iterator	*s.begin() const*	Returns a const iterator to the approximate nearest or furthest neighbor.
iterator	*s.end() const*	Returns the appropriate past-the-end const iterator.

advanced

std::ostream& *s.statistics(std::ostream& s)*

Inserts statistics of the search process into the output stream s.

s

Class

CGAL::Kd_tree<Traits, Splitter, UseExtendedNode>

Definition

The class *Kd_tree<Traits, Splitter, UseExtendedNode>* defines a *k-d* tree.

#include <CGAL/Kd_tree.h>

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Search_traits_2<CGAL::Cartesian<double> >*.

Expects for the second template argument a model for the concept *Splitter*. It defaults to *Sliding_midpoint< Traits>*.

Expects for the third template argument *CGAL::Tag_true*, if the tree shall be built with extended nodes, and *CGAL::Tag_false* otherwise.

Types

Traits::Point_d	*Point_d;*	Point class.
Traits::FT	*FT;*	Number type.

Kd_tree<Traits, Splitter, UseExtendedNode>:: Splitter

Splitter type.

Kd_tree<Traits, Splitter, UseExtendedNode>:: iterator

Bidirectional const iterator with value type *Point_d* that allows to enumerate all points in the tree.

advanced

Kd_tree<Traits, Splitter, UseExtendedNode>:: Node_handle

A handle with value type *Kd_tree_node<Traits,Splitter>*.

Kd_tree<Traits, Splitter, UseExtendedNode>:: Node_const_handle

A const handle with value type *Kd_tree_node< Traits,Splitter>*.

Kd_tree<Traits, Splitter, UseExtendedNode>:: Point_d_iterator

Random access const iterator with value type *const Point_d**.

Kd_tree<Traits, Splitter, UseExtendedNode>:: size_type

A type that counts the number of elements in a *k-d* tree.

advanced

Creation

Kd_tree<Traits, Splitter, UseExtendedNode> tree(Splitter s=Splitter(), Traits t=Traits());

Constructs an empty *k-d* tree.

template <class InputIterator>
Kd_tree<Traits, Splitter, UseExtendedNode> tree(InputIterator first, InputIterator beyond, Splitter s=Splitter(), Traits t=Traits())

Constructs a *k-d* tree on the elements from the sequence *[first, beyond)* using the splitting rule implemented by *s*. The value type of the *InputIterator* must be *Point_d*.

Operations

void *tree.insert(Point_d p)*

Inserts the point *p* in the *k-d* tree.

template <class InputIterator>
void *tree.insert(InputIterator first, InputIterator beyond)*

Inserts the elements from the sequence *[first, beyond)* in the *k-d* tree. The value type of the *InputIterator* must be *Point_d*.

template <class OutputIterator, class FuzzyQueryItem>
OutputIterator *tree.search(OutputIterator it, FuzzyQueryItem q) const*

Reports the points that are approximately contained by *q*. The types *FuzzyQueryItem::Point_d* and *Point_d* must be equivalent. To use this function *Traits* must be a model of the concept *RangeSearchTraits*.

iterator *tree.begin() const* Returns a const iterator to the first point in the tree.

iterator *tree.end() const* Returns the appropriate past-the-end const iterator.

void *tree.clear()* Removes all points from the *k-d* tree.

size_type	*tree.size() const*	Returns the number of points that are stored in the tree.
Traits	*tree.traits() const*	return the instance of the traits used to construct the tree.

advanced

Node_handle	*tree.root()*	Returns a handle to the root node of the tree.
Node_const_handle	*tree.root() const*	Returns a const handle to the root node of the tree.
Kd_tree_rectangle<FT>	*tree.bounding_box() const*	returns a const reference to the bounding box of the root node of the tree.
std::ostream&	*tree.statistics(std::ostream& s) const*	Inserts statistics of the tree into the output stream *s*.

advanced

CGAL::Search_traits_3<Kernel>
CGAL::Search_traits<FT_,Point,CartesianIterator,ConstructCartesianIterator>

CGAL::Kd_tree_node<Traits, Splitter, UseExtendedNode>

advanced

Definition

The class *Kd_tree_node<Traits, Splitter, UseExtendedNode>* implements a node class for a *k-d* tree. A node is either a leaf node, an internal node or an extended internal node. A leaf node contains one or more points. An internal node contains a pointer to its lower child, a pointer to its upper child, and a pointer to its separator. An extended internal node is an internal node containing the lower and upper limit of an extended node's rectangle along the node's cutting dimension.

#include <CGAL/Kd_tree_node.h>

Parameters

Expects for the template argument a model of the concept *SearchTraits*, for example *CGAL::Search_traits_2< CGAL::Cartesian<double> >*, or *CGAL::Cartesian_d<double>*.

Types

enum Node_type { *LEAF, INTERNAL, EXTENDED_INTERNAL*}*;*

Denotes type of node.

Traits::FT	*FT;*	Number type.
Traits::Point_d	*Point_d;*	Point type.
Splitter::Separator	*Separator;*	Separator type.

Kd_tree<Traits,Splitter,UseExtendedNode>::Point_d_iterator

Point_d_iterator; const iterator over points.

Kd_tree<Traits,Splitter,UseExtendedNode>::Node_handle

Node_handle; Node handle.

Kd_tree<Traits,Splitter,UseExtendedNode>::Node_const_handle

Node_const_handle; const node handle.

Creation

Operations

template <class OutputIterator, class FuzzyQueryItem>
OutputIterator *n.search(OutputIterator it, FuzzyQueryItem q) const*

Reports the points from the subtree of the node, that are approximately contained by q.

template <class OutputIterator>
OutputIterator *n.tree_items(OutputIterator it) const*

Reports all the points contained by the subtree of the node.

bool	*n.is_leaf() const*	Indicates whether a node is a leaf node.
unsigned int	*n.size() const*	Returns the number of items stored in a leaf node.
Point_d_iterator	*n.begin() const*	Returns a const iterator to the first item in a leaf node.
Point_d_iterator	*n.end() const*	Returns the appropriate past-the-end const iterator.
Node_handle	*n.lower()*	Returns a handle to the lower child of an internal node.
Node_handle	*n.upper()*	Returns a handle to the upper child of an internal node.
Node_const_handle	*n.lower() const*	Returns a const handle to the lower child of an internal node.
Node_const_handle	*n.upper() const*	Returns a const handle to the upper child of an internal node.
Separator&	*n.separator()*	Returns a reference to the separator.
FT	*n.low_value() const*	Returns the lower limit of an extended node's rectangle along the node's cutting dimension.
FT	*n.high_value() const*	Returns the upper limit of an extended node's rectangle along the node's cutting dimension.

advanced

CGAL::Kd_tree_rectangle<FT>

advanced

Definition

The class *Kd_tree_rectangle<FT>* implements d-dimensional iso-rectangles and related operations, e.g., methods to compute bounding boxes of point sets.

#include <CGAL/Kd_tree_rectangle.h>

Types

FT	*FT;*	Number type.

Creation

Kd_tree_rectangle<FT>	*r(int d);*	Constructs a d-dimensional rectangle r with lower bound and upper bound set to zero in each dimension.

template <class Construct_cartesian_const_iterator_d,class PointIter>
Kd_tree_rectangle<FT> r(int d, PointIter begin, PointIter end, Construct_cartesian_const_iterator_d construct_it)

Constructs the bounding box of the points in the range [*begin,end*), where the value type of *PointIter* can be used by operators of functors *Construct_cartesian_const_iterator_d* to define iterators with value type *FT*.

Operations

FT	*r.min_coord(int i) const*	
		Returns the lower bound of the rectangle in dimension i.
FT	*r.max_coord(int i) const*	
		Returns the upper bound of the rectangle in dimension i.
void	*r.set_upper_bound(int i, FT x)*	
		Sets upper bound in dimension i to x.

Class

void	*r.set_lower_bound(int i, FT x)*	
		Sets lower bound in dimension *i* to *x*.
FT	*r.max_span() const*	Returns the maximal span of the rectangle.
FT	*r.max_span_coord() const*	
		Returns the smallest coordinate for which the rectangle has its maximal span.
int	*r.dimension() const*	Returns the dimension of the rectangle.
void	*r.split(& r, int d, FT value)*	
		Splits rectangle in dimension *d* at coordinate-value *value* by modifying itself to lower half and by modifying *r* to upper half.

Output Routines

template<class FT> *std::ostream&*	*std::ostream& s << & r*	
		Inserts rectangle *r* in the output stream *s* and returns *s*.

advanced

CGAL::Manhattan_distance_iso_box_point<Traits>

Definition

The class *Manhattan_distance_iso_box_point<Traits>* provides an implementation of the *GeneralDistance* concept for the Manhattan distance (l_1 metric) between a d-dimensional iso-box and a d-dimensional point and the Manhattan distance between a d-dimensional iso-box and a d-dimensional iso-box defined as a k-d tree rectangle.

#include <CGAL/Manhattan_distance_iso_box_point.h>

Parameters

Expects for the template argument a model for the concept *SearchTraits*, for example *CGAL::Search_traits_3< CGAL::Cartesian<double> >*.

Is Model for the Concepts

GeneralDistance

Types

Traits::FT	*FT;*	Number type.
Traits::Point_d	*Point_d;*	Point type.
Traits::Iso_box_d	*Query_item;*	Query item type.

Creation

Manhattan_distance_iso_box_point<Traits> md(Traits t=Traits());

Default constructor.

Operations

FT *md.transformed_distance(Query_item b, Point_d p) const*

Returns the transformed distance between b and p.

FT *md.transformed_distance(FT d) const*

Returns the transformed value of of d.

FT *md.inverse_of_transformed_distance(FT d) const*

Returns the value of the inverse of the transform function applied to d.

FT *md.min_distance_to_rectangle(Query_item b, Kd_tree_rectangle<FT> r) const*

Returns the minimal distance between a point from b and a point from r.

FT *md.max_distance_to_rectangle(Query_item b, Kd_tree_rectangle<FT> r) const*

Returns the maximal distance between the iso-box b and a point from r furthest to b.

OrthogonalDistance

Concept

Definition

Requirements of an orthogonal distance class supporting incremental distance updates. To optimize distance computations transformed distances are used. E.g., for an Euclidean distance the transformed distance is the squared Euclidean distance.

Refines

GeneralDistance

Has Models

CGAL::Euclidean_distance<Traits>,
CGAL::Weighted_Minkowski_distance<Traits>

Types

OrthogonalDistance:: FT	Number type.
OrthogonalDistance:: Point_d	Point type.
OrthogonalDistance:: Query_item	Query item type.

Creation

OrthogonalDistance od(int d);	Constructor implementing distance for d-dimensional points.

Operations

FT *od.transformed_distance(Query_item q, Point_d r) const*

Returns the transformed distance between q and r.

FT *od.min_distance_to_rectangle(Query_item q, Kd_tree_rectangle<FT> r) const*

Returns the transformed distance between q and the point on the boundary of r closest to q.

FT *od.max_distance_to_rectangle(Query_item q, Kd_tree_rectangle<FT> r) const*

Returns the transformed distance between q and the point on the boundary of r farthest to q.

FT *od.transformed_distance(FT d) const*

Returns the transformed distance.

FT *od.inverse_of_transformed_distance(FT d) const*

Returns the inverse of the transformed distance.

FT *od.new_distance(FT dist, FT old_off, FT new_off, int cutting_dimension) const*

Updates *dist* incrementally and returns the updated distance.

CGAL::Orthogonal_incremental_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree>

Class

Definition

The class *Orthogonal_incremental_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree>* implements incremental nearest and furthest neighbor searching on a tree.

#include <CGAL/Orthogonal_incremental_neighbor_search.h>

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Search_traits_2<CGAL::Cartesian<double> >*.

Expects for the second template argument a model of the concept *GeneralDistance*. If *Traits* is *CGAL::Search_traits_adapter<Key,PointPropertyMap,BaseTraits>* the default type is *CGAL::Distance_for_point_adapter<Key,PointPropertyMap,CGAL::Euclidean_distance<Traits> >*, and *CGAL::Euclidean_distance<Traits>* otherwise.

Expects for third template argument a model of the concept *Splitter*. The default type is *CGAL::Sliding_midpoint<Traits>*.

Expects for fourth template argument a model of the concept *SpatialTree*. The default type is *CGAL::Kd_tree<Traits, Splitter, CGAL::Tag_true>*. The template argument must be *CGAL::Tag_true* because orthogonal search needs extended kd tree nodes.

Types

Traits::Point_d	*Point_d;*	Point type.
Traits::FT	*FT;*	Number type.
OrthogonalDistance	*Distance;*	Distance type.
OrthogonalDistance::Query_item	*Query_item;*	Query item.
std::pair<Point_d,FT>	*Point_with_transformed_distance;*	Pair of point and transformed distance.

Orthogonal_incremental_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree>:: iterator

const input iterator with value type *Point_with_transformed_distance* for enumerating approximate neighbors.

SpatialTree	*Tree;*	The tree type.

Creation

Orthogonal_incremental_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree> s(
SpatialTree& tree,
Query_item query,
FT eps=FT(0.0),
bool search_nearest=true,
OrthogonalDistance d=OrthogonalDistance())

Constructor for incremental neighbor searching of the query item *query* in the points stored *tree* using a distance *d* and approximation factor *eps*.

Operations

iterator	*s.begin() const*	Returns a const iterator to the approximate nearest or furthest neighbor.
iterator	*s.end() const*	Returns the appropriate past-the-end const iterator.

advanced

std::ostream& *s.statistics(std::ostream& s) const*

Inserts statistics of the search process into the output stream *s*.

Class

Definition

The class *Orthogonal_k_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree>* implements approximate k-nearest and k-furthest neighbor searching on a tree using an orthogonal distance class.

#include <CGAL/Orthogonal_k_neighbor_search.h>

Parameters

Expects for the first template argument an implementation of the concept *SearchTraits*, for example *CGAL::Search_traits_2<CGAL::Cartesian<double> >*.

Expects for the second template argument a model of the concept *GeneralDistance*. If *Traits* is *CGAL::Search_traits_adapter<Key,PointPropertyMap,BaseTraits>* the default type is *CGAL::Distance_adapter<Key,PointPropertyMap,CGAL::Euclidean_distance<Traits> >*, and *CGAL::Euclidean_distance<Traits>* otherwise.

The default type is *CGAL::Euclidean_distance<Traits>*.

Expects for third template argument a model of the concept *Splitter*. The default type is *CGAL::Sliding_midpoint<Traits>*.

Expects for fourth template argument an implementation of the concept *SpatialTree*. The default type is *CGAL::Kd_tree<Traits, Splitter, CGAL::Tag_true>*. The template argument must be *CGAL::Tag_true* because orthogonal search needs extended kd tree nodes.

Types

Traits::Point_d	*Point_d;*	Point type.
Traits::FT	*FT;*	Number type.
OrthogonalDistance	*Distance;*	Distance type.
GeneralDistance::Query_item	*Query_item;*	Query item.
std::pair<Point_d,FT>	*Point_with_transformed_distance;*	Pair of point and transformed distance.

Orthogonal_k_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree>:: iterator

Bidirectional const iterator with value type *Point_with_transformed_distance* for enumerating approximate neighbors.

SpatialTree	*Tree;*	The tree type.

Operations

Orthogonal_k_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree> s(
SpatialTree tree,
Query_item query,
unsigned int k=1,
FT eps=FT(0.0),
bool search_nearest=true,
OrthogonalDistance d=OrthogonalDistance(),
bool sorted=true)

Constructor for searching approximately *k* neighbors of the query item *query* in the points stored in *tree* using distance *d* and approximation factor *eps*.*sorted* indicates if the computed sequence of *k*-nearest neighbors needs to be sorted.

iterator	*s.begin() const*	Returns a const iterator to the approximate nearest or furthest neighbor.
iterator	*s.end() const*	Returns the appropriate past-the-end const iterator.

advanced

std::ostream& *s.statistics(std::ostream& s)*

Inserts statistics of the search process into the output stream *s*.

CGAL::Plane_separator<FT>

advanced

Definition

The class *Plane_separator<FT>* implements a plane separator, i.e., a hyperplane that is used to separate two half spaces. This hyperplane is defined by a cutting dimension d and a cutting value v as $x_d = v$, where v denotes the d^{th} coordinate value.

#include <CGAL/Plane_separator.h>

Is Model for the Concepts

SpatialSeparator

Creation

Plane_separator<FT> s(int d, FT v);	Constructs a separator that separates two half spaces by a hyperplane defined by $x_d = v$, where v denotes the d^{th} coordinate value.
Plane_separator<FT> s(p);	Copy constructor.

Operations

void	*s.set_cutting_dimension(int d)*	
		Sets the cutting dimension to d.
void	*s.set_cutting_value(FT v)*	
		Sets the cutting value to v.
int	*s.cutting_dimension() const*	
		Returns the number of the cutting dimension.
FT	*s.cutting_value() const*	
		Returns the cutting value.
Plane_separator<FT>		
	$s = s2$	Assignment operator.

Class

Output Operators

template<class FT>
std::ostream& *std::ostream& os << s*

Inserts the plane separator *s* in the output stream *os* and returns *os*.

advanced

CGAL::Point_container<Traits>

advanced

Definition

A custom container for points used to build a tree. Each point container holds the points from a rectangle associated with a node of the tree. In the remainder of this reference page this rectangle is called the associated rectangle. Provides a method to split a container and a number of methods to support the implementation of splitting rules.

#include <CGAL/Point_container.h>

Parameters

Expects for the template argument an implementation for d-dimensional points of the concept *SearchTraits*, for example *CGAL::Cartesian_d<double>*.

Types

Traits::FT	*FT;*	Number type.
Traits::Point_d	*Point_d;*	Point type.
Point_container<Traits>:: iterator		An iterator with value type *Point_d**.
Point_container<Traits>:: const_iterator		A const iterator with value type *const Point_d**.

Creation

Point_container<Traits> c(int d);

Construct an empty container for storing d-dimensional points.

template <class InputIterator>
Point_container<Traits> c(int d, InputIterator begin, InputIterator end);

Construct the container of d-dimensional points of type *Point_d* given by the iterator sequence *[begin, end)*.

Operations

template <class SpatialSeparator>
void c.split(&c2, SpatialSeparator sep, bool sliding=false)

Given an empty container *c2* with the same dimension as *c*, splits *c* into *c*and *c2* using the separator *sep*. If sliding is *true* after splitting each container contains at least one point. Container *c* should contain at least two points.

void *c.swap(&c2)* Swap the contents of *c* and *c2*

void *c.recompute_tight_bounding_box()*

Recompute the bounding box of the points in the container.

iterator *c.begin()* Returns an iterator to a pointer to the first point.

iterator *c.end()* Returns the appropriate past-the-end iterator.

const_iterator *c.begin() const* Returns a const iterator to a pointer to the first point.

const_iterator *c.end() const* Returns the appropriate past-the-end const iterator.

int *c.dimension() const* Returns the dimension.

int *c.built_coordinate() const*

Returns coordinate for which the pointer list is built.

int *c.max_span_coord() const*

Returns coordinate where the associated rectangle has maximal span.

int *c.max_tight_span_coord() const*

Returns coordinate where the point coordinates have maximal span.

FT *c.max_span_lower() const*

Returns lower value of the interval corresponding to *max_span_coord()*.

FT *c.max_tight_span_lower() const*

Returns lower value of the interval corresponding to *max_tight_span_coord()*. That is, the smallest *max_tight_span_coord()*-th coordinate of the points in *c*.

FT *c.max_span_upper() const*

Returns upper value of the interval corresponding to *max_span_coord()*.

FT *c.max_span_upper_without_dim(int d) const*

Returns upper value of the interval over all dimensions without taking dimension *d* into account.

FT *c.max_tight_span_upper() const*

Returns upper value of the interval corresponding to *max_tight_span_coord()*.

FT *c.max_spread() const*

Returns the size of the interval corresponding to *max_span_coord()*.

FT *c.max_tight_spread() const*

Returns the size of the interval corresponding to *max_tight_span_coord()*.

FT *c.median(int split_coord) const*

Returns the median value of the points stored in the container for dimension *split_coord*.

Kd_tree_rectangle<Traits>

c.bounding_box() const

Returns the associated rectangle.

Kd_tree_rectangle<Traits>

c.tight_bounding_box()

Returns the bounding box of the items in associated rectangle.

int *c.max_tight_span_coord_balanced(FT aspect_ratio) const*

Returns the dimension with the maximal point spread, for which after fair splitting the ratio of the length of the longest side and the smallest side of the bounding box of the items in associated rectangle, does not exceed *aspect_ratio*.

FT *c.balanced_fair(int d, FT aspect_ratio)*

Returns the splitting value for fair splitting.

FT	*c.balanced_sliding_fair(int d, FT aspect_ratio)*	
		Returns the splitting value for sliding fair splitting.
std::size_t	*c.size() const*	Returns the number of points stored.
bool	*c.empty() const*	Returns true if no points are present, false otherwise.

Output Routines

template<class Traits> *std::ostream&*	*std::ostream& s << c*	Prints the point container *c* to the output stream *s* and returns *s*.

Concept

SearchTraits

Definition

The concept *SearchTraits* defines the requirements for the template parameter of the search classes.

Types

SearchTraits:: Point_d	Point type. *CGAL::Kernel_traits* has to be specialized for this type.
SearchTraits:: FT	The number type of the Cartesian coordinates of types *Point_d*
SearchTraits:: Cartesian_const_iterator_d	A random access iterator type to enumerate the Cartesian coordinates of a point.
SearchTraits:: Construct_cartesian_const_iterator_d	Functor with operators to construct iterators on the first and the past-the-end iterator for the Cartesian coordinates of a point. This functor must provides the type *result_type* that must be the same a *Cartesian_const_iterator_d*.

Creation

Operations

Construct_cartesian_const_iterator_d

t.construct_construct_cartesian_const_iterator_d_object(Point_d p) const

function used to construct an object of type *Construct_cartesian_const_iterator_d*.

Has Models

CGAL::Cartesian_d<FT>
CGAL::Homogeneous_d<RT>
CGAL::Search_traits_2<Kernel>
CGAL::Search_traits_3<Kernel>,
CGAL::Search_traits<NT,Point,CartesianCoordinateIterator,ConstructCartesianCoordinateIterator,ConstructMinVertex,ConstructM
.

Concept

RangeSearchTraits

Definition

The concept *RangeSearchTraits* defines the requirements for the template parameter of the search classes. This concept also defines requirements to range search queries in a model of *SpatialTree*.

Refines

SearchTraits

Types

RangeSearchTraits:: Iso_box_d	Iso box type. It is only needed for range search queries.
RangeSearchTraits:: Sphere_d	Sphere type. It is only needed for range search queries.
RangeSearchTraits:: Construct_iso_box_d	Functor with operator to construct the iso box from two points.
RangeSearchTraits:: Construct_center_d	Functor with operator to construct the center of an object of type *Sphere_d*.
RangeSearchTraits:: Construct_squared_radius_d	Functor with operator to compute the squared radius of a an object of type *Sphere_d*.
RangeSearchTraits:: Construct_min_vertex_d	Functor with operator to construct the vertex with lexicographically smallest coordinates of an object of type *Iso_box_d*.
RangeSearchTraits:: Construct_max_vertex_d	Functor with operator to construct the vertex with lexicographically largest coordinates of an object of type *Iso_box_d*.

Has Models

CGAL::Search_traits_2<Kernel>

Definition

The class *Search_traits_2<Kernel>* can be used as a template parameter of the kd tree and the search classes.

#include <CGAL/Search_traits_2.h>

Parameters

Expects for the template argument a model of the concept *Kernel*, for example *CGAL::Cartesian<double>* or *CGAL::Simple_cartesian<CGAL::Gmpq>*.

Is Model for the Concepts

SearchTraits and *RangeSearchTraits*.

Types

Kernel::FT	*FT;*	Number type.
Kernel::Point_2	*Point_d;*	Point type.
Kernel::Iso_rectangle_2	*Iso_box_d;*	Iso box type.
Kernel::Sphere_2	*Sphere_d;*	Sphere type.
Kernel::Cartesian_const_iterator_2	*Cartesian_const_iterator_d;*	An iterator over the Cartesian coordinates.
Kernel::Construct_cartesian_const_iterator_2	*Construct_cartesian_const_iterator_d;*	A functor with two function operators, which return the begin and past the end iterator for the Cartesian coordinates. The functor for begin has as argument a *Point_d*. The functor for the past the end iterator, has as argument a *Point_d* and an *int*.

Kernel::Construct_iso_rectangle_2

Construct_iso_box_d;	Functor with operator to construct the iso box from two points.

Kernel::Construct_center_2

Construct_center_d;	Functor with operator to construct the center of an object of type *Sphere_d*.

Kernel::Compute_squared_radius_2

Construct_squared_radius_d;

Functor with operator to compute the squared radius of a an object of type *Sphere_d*.

Kernel::Construct_min_vertex_2

Construct_min_vertex_d;

Functor with operator to construct the vertex with lexicographically smallest coordinates of an object of type *Iso_box_d*.

Kernel::Construct_max_vertex_2

Construct_max_vertex_d;

Functor with operator to construct the vertex with lexicographically largest coordinates of an object of type *Iso_box_d*.

CGAL::Search_traits_3<Kernel>

Class

Definition

The class *Search_traits_3<Kernel>* can be used as a template parameter of the kd tree and the search classes. *Kernel* must be a CGAL kernel.

#include <CGAL/Search_traits_3.h>

Parameters

Expects for the template argument a model of the concept *Kernel*, for example *CGAL::Cartesian<double>* or *CGAL::Simple_cartesian<CGAL::Gmpq>*.

Is Model for the Concepts

SearchTraits and *RangeSearchTraits*.

Types

Kernel::FT	*FT;*	Number type.
Kernel::Point_3	*Point_d;*	Point type.
Kernel::Iso_cuboid_3		
	Iso_box_d;	Iso box type.
Kernel::Sphere_3	*Sphere_d;*	Sphere type.
Kernel::Cartesian_const_iterator_3		
	Cartesian_const_iterator_d;	
		An iterator over the Cartesian coordinates.
Kernel::Construct_cartesian_const_iterator_3		
	Construct_cartesian_const_iterator_d;	
		A functor with two function operators, which return the begin and past the end iterator for the Cartesian coordinates. The functor for begin has as argument a *Point_d*. The functor for the past the end iterator, has as argument a *Point_d* and an *int*.

Kernel::Construct_center_3

Construct_center_d; Functor with operator to construct the center of an object of type *Sphere_d*.

Kernel::Compute_squared_radius_3

Construct_squared_radius_d;

Functor with operator to compute the squared radius of a an object of type *Sphere_d*.

Kernel::Construct_min_vertex_3

Construct_min_vertex_d;

Functor with operator to construct the vertex with lexicographically smallest coordinates of an object of type *Iso_box_d*.

Kernel::Construct_max_vertex_3

Construct_max_vertex_d;

Functor with operator to construct the vertex with lexicographically largest coordinates of an object of type *Iso_box_d*.

Base_distance::Query_item	*Query_item;*

Creation

Distance_for_point_adapter<Key,PointPropertyMap,Base_distance> d(PointPropertyMap ppmap=PointPropertyMap(), Base_distance base=Base_distance())

Constructor initializing the class to *base* and setting the point property map of the class to *ppmap*.

Operations

PointPropertyMap   *d.point_property_map() const*

Returns the point property map.

See Also

Search_traits_adapter<Key,PointPropertyMap,BaseTraits>

CGAL::Sliding_fair<Traits, SpatialSeparator>

Functor
Class

Definition

Implements the *sliding fair* splitting rule. This splitting rule is a compromise between the *Fair* splitting rule and the *Sliding_midpoint* rule. Sliding fair-split is based on the theory that there are two types of splits that are good: balanced splits that produce fat rectangles, and unbalanced splits provided the rectangle with fewer points is fat.

Also, this splitting rule maintains an upper bound on the maximal allowed ratio of the longest and shortest side of a rectangle (the value of this upper bound is set in the constructor of the fair splitting rule). Among the splits that satisfy this bound, it selects the one one in which the points have the largest spread. It then considers the most extreme cuts that would be allowed by the aspect ratio bound. This is done by dividing the longest side of the rectangle by the aspect ratio bound. If the median cut lies between these extreme cuts, then we use the median cut. If not, then consider the extreme cut that is closer to the median. If all the points lie to one side of this cut, then we slide the cut until it hits the first point. This may violate the aspect ratio bound, but will never generate empty cells.

#include <CGAL/Splitters.h>

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Cartesian_d< double>*.

Expects for the second template argument a model of the concept *Separator*. It has as default value the type, *CGAL::Plane_separator<Traits::FT>*

Is Model for the Concepts

Splitter

Types

Traits::FT	*FT;*	Number type.

Creation

Sliding_fair<Traits, SpatialSeparator> s(unsigned int bucket_size, FT aspect_ratio=FT(3));

Constructor.

Operations

FT	*s.aspect_ratio()*	Returns the maximal ratio between the largest and smallest side of a cell allowed for fair splitting.
unsigned int	*s.bucket_size()*	Returns the bucket size of the leaf nodes.

See Also

Splitter
SpatialSeparator

CGAL::Sliding_midpoint<Traits, SpatialSeparator>

Functor
Class

Definition

Implements the *sliding midpoint* splitting rule. This is a modification of the *Midpoint_of_rectangle* splitting rule. It first attempts to perform a midpoint of rectangle split as described above. If data points lie on both sides of the separating plane the sliding midpoint rule computes the same separator as the midpoint of rectangle rule. If the data points lie only on one side it avoids this by sliding the separator, computed by the midpoint of rectangle rule, to the nearest data point.

#include <CGAL/Splitters.h>

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Cartesian_d< double>*.

Expects for the second template argument a model of the concept *Separator*. It has as default value the type, *CGAL::Plane_separator<Traits::FT>*.

Is Model for the Concepts

Splitter

Creation

Sliding_midpoint<Traits, SpatialSeparator> s(unsigned int bucket_size);

Constructor.

Operations

unsigned int	*s.bucket_size()*	Returns the bucket size of the leaf nodes.

See Also

Splitter
SpatialSeparator

Concept

SpatialSeparator

advanced

Definition

The concept SpatialSeparator defines the requirements for a separator. A separator is a (d-1)-dimensional subspace that separates a d-dimensional space into two parts. One part of space is said to be on the negative side of the separator and the other part of space is said to be on the positive side of the separator.

Has Models

CGAL::Plane_separator<FT>.

Types

SpatialSeparator:: FT	Number type.

Creation

SpatialSeparator s;	Default constructor.

Operations

void	*s.set_cutting_dimension(int d)*	
		Sets the cutting dimension to d.
void	*s.set_cutting_value(FT v)*	
		Sets the cutting value to v.
int	*s.cutting_dimension()*	Returns the number of the cutting dimension.
FT	*s.cutting_value()*	Returns the cutting value.
template <class Point_d> *bool*	*s.has_on_negative_side(Point_d p)*	
		Returns true if and only if the point p is on the negative side of the separator.

advanced

SpatialTree

Definition

The concept SpatialTree defines the requirements for a tree supporting both neighbor searching and approximate range searching.

Types

SpatialTree:: SearchTraits	Search traits.
SpatialTree:: Point_d	Point type.
SpatialTree:: iterator	Bidirectional const iterator with value type *Point_d* that allows to enumerate all points in the tree.
SpatialTree:: Node_handle	Node handle.
SpatialTree:: Node_const_handle	const node handle.
SpatialTree:: Point_d_iterator	const iterator with value type *const Point_d**.
SpatialTree:: Splitter	Splitter.
SpatialTree:: Distance	Distance.

Creation

template <class InputIterator>
SpatialTree tree(InputIterator first, InputIterator beyond, SearchTraits t);

Constructs a tree on the elements from the sequence *[first,beyond)*.

Operations

template <class OutputIterator, class FuzzyQueryItem>
OutputIterator *tree.search(OutputIterator it, FuzzyQueryItem q)*

Reports the points that are approximately contained by q. The value type of *OutputIterator* must be *Point_d*.

iterator *tree.begin() const* Returns a const iterator to the first point in the tree.

iterator	*tree.end() const*	Returns the appropriate past-the-end const iterator.
Node_handle	*tree.root()*	Returns a handle to the root node of the tree.
Node_const_handle	*tree.root() const*	Returns a const handle to the root node of the tree.
Kd_tree_rectangle<SearchTraits::FT>	*tree.bounding_box() const*	returns a const reference to the bounding box of the root node of the tree.
unsigned int	*tree.size() const*	Returns the number of items that are stored in the tree.

Has Models

CGAL::Kd_tree<Traits,Splitter,UseExtendedNode>.

Splitter

advanced

Definition

The concept Splitter defines the requirements for a function object class implementing a splitting rule.

Has Models

CGAL::Fair<Traits, SpatialSeparator>,
CGAL::Median_of_rectangle<Traits, SpatialSeparator>,
CGAL::Median_of_max_spread<Traits, SpatialSeparator>,
CGAL::Midpoint_of_rectangle<Traits, SpatialSeparator>,
CGAL::Midpoint_of_max_spread<Traits, SpatialSeparator>,
CGAL::Sliding_fair<Traits, SpatialSeparator>,
CGAL::Sliding_midpoint<Traits, SpatialSeparator>.

Types

Splitter:: FT	Number type.
Splitter:: Separator	Separator.
Splitter:: Container	Typedef to an instantiation of *CGAL::Point_container< Traits>*.

The parameters *aspect_ratio* and *bucket_size* define the way in which *k-d* tree is constructed.

Operations

FT	*s.aspect_ratio() const*	Returns the maximal ratio between the largest and smallest side of a cell allowed for fair splitting.
unsigned int	*s.bucket_size() const*	Returns the bucket size of the leaf nodes.
void	*s(Separator& sep, Container& c0, Container& c1)*	

Sets up *sep* and splits points of *c0* into *c0* and *c1* using *sep*. Container *c0* should contain at least two points and *c1* must be empty.

advanced

Class

CGAL::Weighted_Minkowski_distance<Traits>

Definition

The class *Weighted_Minkowski_distance<Traits>* provides an implementation of the concept *OrthogonalDistance*, with a weighted Minkowski metric on d-dimensional points defined by $l_p(w)(r,q) = (\Sigma_{i=1}^{i=d} w_i(r_i - q_i)^p)^{1/p}$ for $0 < p < \infty$ and defined by $l_\infty(w)(r,q) = max\{w_i|r_i - q_i| \mid 1 \leq i \leq d\}$. For the purpose of the distance computations it is more efficient to compute the transformed distance $\sigma_{i=1}^{i=d} w_i(r_i - q_i)^p$ instead of the actual distance.

#include <CGAL/Weighted_Minkowski_distance.h>

Parameters

Expects for the template argument a model of the concept *SearchTraits*, for example *CGAL::Search_traits_2< Kernel>*.

Is Model for the Concepts

OrthogonalDistance

Types

Traits::FT	*FT;*	Number type.
Traits::Point_d	*Point_d;*	Point type.

Creation

Weighted_Minkowski_distance<Traits> wd(int d, Traits t=Traits());

Constructor implementing l_2 metric for d-dimensional points.

template <class InputIterator>
Weighted_Minkowski_distance<Traits> wd(FT power,
int dim,
InputIterator wb,
InputIterator we,
Traits t=Traits())

Constructor implementing the $l_{power}(weights)$ metric. $power \leq 0$ denotes the $l_\infty(weights)$ metric. The values in the iterator range *[wb,we)* are the weight.

Operations

FT *wd.transformed_distance(Point_d q, Point_d r) const*

Returns d^{power}, where d denotes the distance between q and r.

FT *wd.min_distance_to_rectangle(Point_d q, Kd_tree_rectangle<FT> r;) const*

Returns d^{power}, where d denotes the distance between the query item q and the point on the boundary of r closest to q.

FT *wd.max_distance_to_rectangle(Point_d q, Kd_tree_rectangle<FT> r;) const*

Returns d^{power}, where d denotes the distance between the query item q and the point on the boundary of r farthest to q.

FT *wd.new_distance(FT dist, FT old_off, FT new_off, int cutting_dimension) const*

Updates *dist* incrementally and returns the updated distance.

FT *wd.transformed_distance(FT d) const*

Returns d^p for $0 < p < \infty$. Returns d for $p = \infty$.

FT *wd.inverse_of_transformed_distance(FT d) const*

Returns $d^{1/p}$ for $0 < p < \infty$. Returns d for $p = \infty$.

Chapter 62

dD Range and Segment Trees

Gabriele Neyer

Contents

62.1 Introduction

This chapter presents the CGAL range tree and segment tree data structures.

62.2 Definitions

This section presents d-dimensional range and segment trees. A one-dimensional range tree is a binary search tree on *one-dimensional point data*. Here we call all one-dimensional data types having a strict ordering (like integer and double) *point data*. *d-dimensional point data* are d-tuples of one-dimensional point data.

A one-dimensional segment tree is a binary search tree as well, but with *one-dimensional interval data* as input data. One-dimensional interval data is a pair (i.e., 2-tuple) (a,b), where a and b are one-dimensional point data of the same type and $a < b$. The pair (a,b) represents a half open interval $[a,b)$. Analogously, a d-dimensional interval is represented by a d-tuple of one-dimensional intervals.

The *input data type* for a d-dimensional tree is a container class consisting of a d-dimensional point data type, interval data type or a mixture of both, and optionally a *value type*, which can be used to store arbitrary data. E.g., the d–dimensional bounding box of a d–dimensional polygon may define the interval data of a d–dimensional segment tree and the polygon itself can be stored as its value. An *input data item* is an instance of an input data type.

The range and segment tree classes are fully generic in the sense that they can be used to define *multilayer trees*. A multilayer tree of dimension (number of layers) d is a simple tree in the d-th layer, whereas the k-th layer, $1 \leq k \leq d-1$, of the tree defines a tree where each (inner) vertex contains a multilayer tree of dimension $d-k+1$. The $k-1$-dimensional tree which is nested in the k-dimensional tree (T) is called the *sublayer tree* (of T). For example, a d-dim tree can be a range tree on the first layer, constructed with respect to the first dimension of d-dimensional data items. On all the data items in each subtree, a $(d-1)$-dimensional tree is built, either a range or a segment tree, with respect to the second dimension of the data items. And so on. Figures 62.2, 62.3 and 62.5 illustrate the meaning of a sublayer tree graphically.

After creation of the tree, further insertions or deletions of data items are disallowed. The tree class does neither depend on the type of data nor on the concrete physical representation of the data items. E.g., let a multilayer tree be a segment tree for which each vertex defines a range tree. We can choose the data items to consist of intervals of type *double* and the point data of type *integer*. As value type we can choose *string*.

For this generality we have to define what the tree of each dimension looks like and how the input data is organized. For dimension k, $1 \leq k \leq 4$, CGAL provides ready-to-use range and segment trees that can store k-dimensional keys (intervals resp.). Examples illustrating the use of these classes are given in Sections 62.5.1 and 62.6.1. The description of the functionality of these classes as well as the definition of higher dimensional trees and mixed multilayer trees is given in the reference manual.

In the following two sections we give short definitions of the version of the range tree and segment tree implemented here together with some examples. The presentation closely follows [dBvKOS97].

62.3 Software Design

In order to be able to define a multilayer tree we first designed the range and segment tree to have a template argument defining the type of the sublayer tree. With this sublayer tree type information the sublayers could be created. This approach lead to nested template arguments, since the sublayer tree can again have a template argument defining the sublayer. Therefore, the internal class and function identifiers got longer than a compiler-dependent limit. This happend already for $d = 2$.

Therefore, we chose another, object oriented, design. We defined a pure virtual base class called *Tree_base* from which we derived the classes *Range_tree_d* and *Segment_tree_d*. The constructor of these classes expects an argument called *sublayer_prototype* of type *Tree_base*. Since class *Range_tree_d* and class *Segment_tree_d* are derived from class *Tree_base*, one can use an instantiation of class *Range_tree_d* or class *Segment_tree_d* as constructor argument. This argument defines the sublayer tree of the tree. E.g., you can construct a *Range_tree_d* with an instantiation of class *Segment_tree_d* as constructor argument. You then have defined a range tree with a segment tree as sublayer tree. Since both classes *Range_tree_d* and *Segment_tree_d* expect a sublayer tree in their constructor we had to derive a third class called *Tree_anchor* from class *Tree_base* which does not expect a constructor argument. An instantiation of this class is used as constructor argument of class *Range_tree_d* or *Segment_tree_d* in order to stop the recursion.

All classes provide a *clone()* function which returns an instance (a copy) of the same tree type. The *clone()* function of the *sublayer_prototype* is called in the construction of the tree. In case that the sublayer tree again has a sublayer, it also has a *sublayer_prototype* which is also cloned and so on. Thus, a call to the *clone()* function generates a sublayer tree which has the complete knowledge about its sublayer tree.

The trees allow to perform window queries, enclosing queries, and inverse range queries on the keys. Clearly, an inverse range query makes only sense in the segment tree. In order to perform an inverse range query, a range query of ε width has to be performed. We prefered not to offer an extra function for this sort of query, since the inverse range query is a special case of the range query. Furthermore, offering an inverse range query in the segment tree class implies offering this function also in the range tree class and having an extra item in the traits class that accesses the inverse range query point.

The trees are templatized with three arguments: *Data, Window* and *Traits*. Type *Data* defines the input data type and type *Window* defines the query window type. The tree uses a well defined set of functions in order to access data. These functions have to be provided by class *Traits*.

The design partly follows the *prototype design pattern* in [GHJV95]. In comparison to our first approach using templates we want to note the following: In this approach the sublayer type is defined in use of object oriented programming at run time, while in the approach using templates, the sublayer type is defined at compile time.

The runtime overhead caused in use of virtual member functions in this object oriented design is negligible since all virtual functions are non trivial. The design concept is illustrated in Figure 62.1.

E.g. in order to define a two dimensional multilayer tree, which consists of a range tree in the first dimension and a segment tree in the second dimension we proceed as follows: We construct an object of type *Tree_anchor* which stops the recursion. Then we construct an object of type *Segment_tree_d*, which gets as prototype argument our object of type *Tree_anchor*. After that, we define an object of type *Range_tree_d* which is constructed with the object of type *Segment_tree_d* as prototype argument. The following piece of code illustrates the construction of the two-dimensional multilayer tree.

```
int main(){
  Tree_Anchor *anchor=new Tree_Anchor;
  Segment_Tree_d *segment_tree = new Segment_Tree_d(*anchor);
  Range_Tree_d *range_segment_tree = new Range_Tree_d(*segment_tree);
  /* let data_items be a list of Data items */
  range_segment_tree->make_tree(data_items.begin(),data_items.end());
}
```

Here, class *Tree_Anchor, Segment_Tree_d*, and *Range_Tree_d* are defined by *typedef*s:

```
typedef Tree_anchor<Data,Window> Tree_Anchor;
typedef Segment_tree_d<Data,Window,Interval_traits> Segment_Tree_d;
typedef Range_tree_d<Data,Window,Point_traits> Range_Tree_d;
```

Class *Tree_base* and class *Tree_anchor* get two template arguments: a class *Data* which defines the type of data that is stored in the tree, and a class *Window* which defines the type of a query range. The derived classes *Range_tree_d* and *Segment_tree_d* additionally get an argument called *Tree_traits* which defines the interface between the *Data* and the tree. Let the *Data* type be a d-dimensional tuple, which is either a point data or an interval data in each dimension. Then, the class *Tree_traits* provides accessors to the point (resp. interval) data of that tree layer and a compare function. Remind our example of the two-dimensional tree which is a range tree in the first dimension and a segment tree in the second dimension. Then, the *Tree_traits* class template argument of class *Segment_tree_d* defines an accessor to the interval data of the *Data*, and the *Tree_traits* class template argument of class *Range_tree_d* defines an accessor to the point data of *Data*. An example implementation for these classes is listed below.

```
struct Data{
```

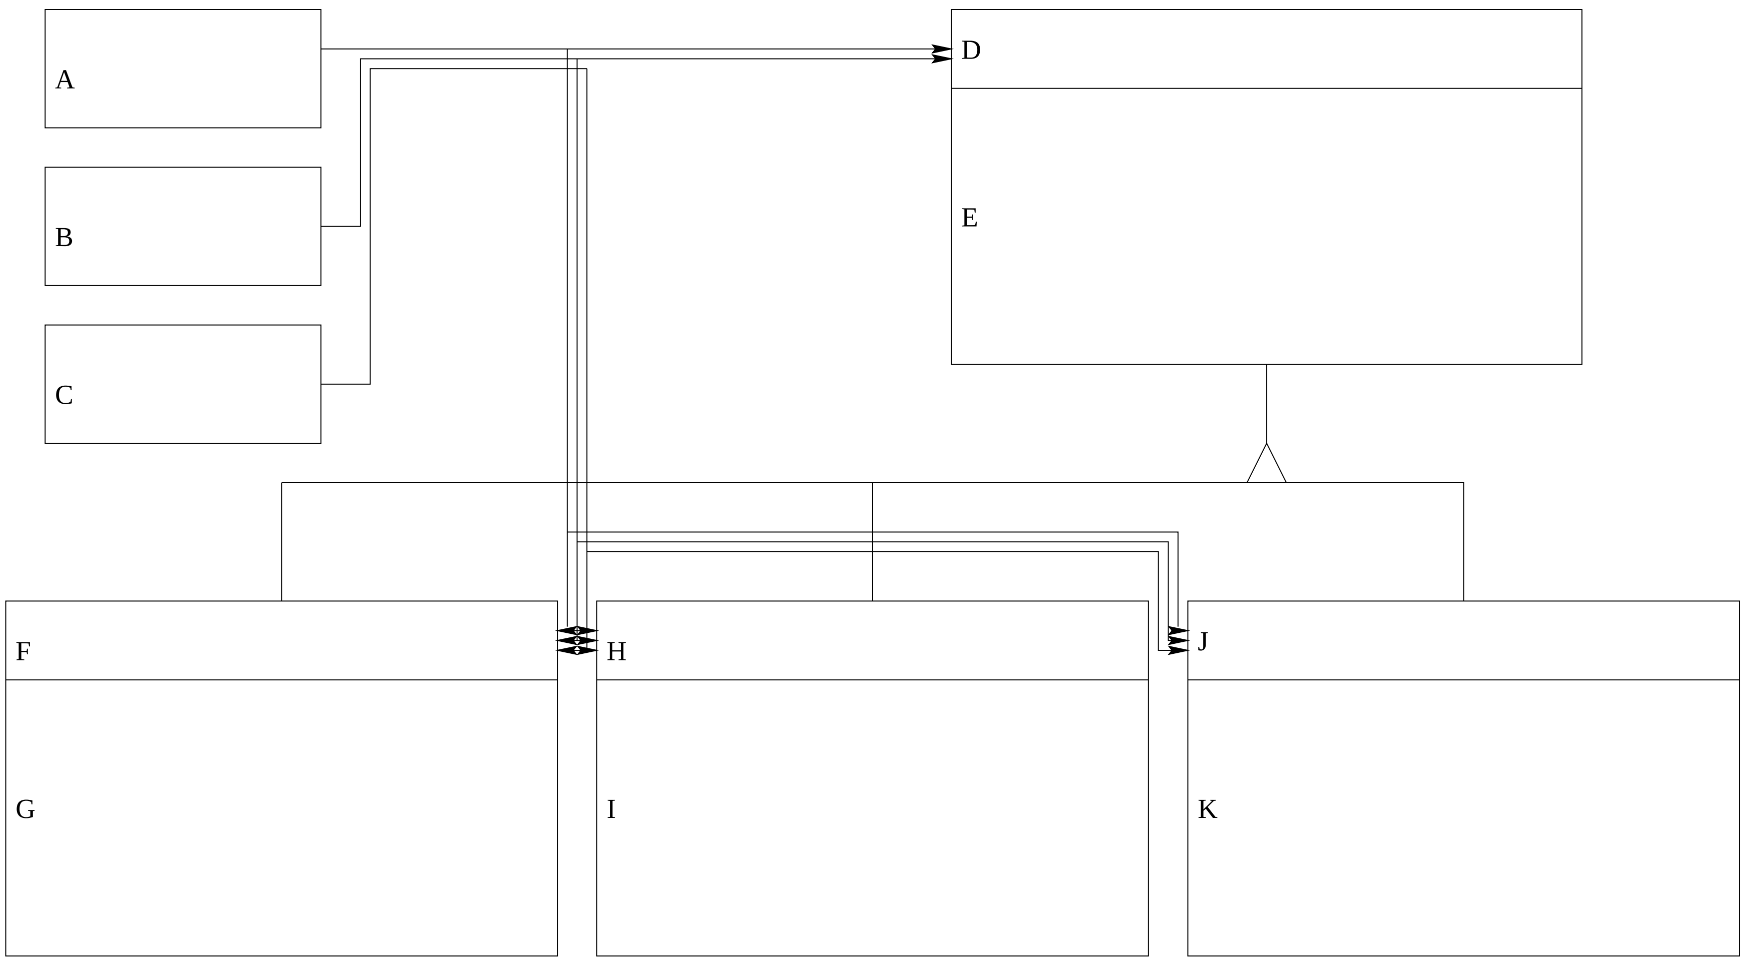

Figure 62.1: Design of the range and segment tree data structure. The symbol triangle means that the lower class is derived from the upper class.

```
  int min,max;  /* interval data */
  double point; /* point data    */
};

struct Window{
  int min,max;
  double min_point, max_point;
};

class Point_traits{
 public:
  typedef double Key;
  Key get_key(Data&  d){return d.point;} /*key accessor */
  Key get_left(Window& w){return w.min_point;}
  Key get_right(Window& w){return w.max_point;}
  bool comp(Key& key1, Key& key2){return (key1 < key2);}
}

class Interval_traits{
 public:
  typedef int Key;
  Key get_left(Data&  d){return d.min;}
  Key get_right(Data&  d){return d.max;}
  Key get_left_win(Window& w){return w.min;}
  Key get_right_win(Window& w){return w.max;}
  static bool comp(Key& key1, Key& key2){return (key1 < key2);}
}
```

62.4 Creating an Arbitrary Multilayer Tree

Now let us have a closer look on how a multilayer tree is built. In case of creating a d-dimensional tree, we handle a sequence of arbitrary data items, where each item defines a d-dimensional interval, point or other object. The tree is constructed with an iterator over this structure. In the i-th layer, the tree is built with respect to the data slot that defines the i-th dimension. Therefore, we need to define which data slot corresponds to which dimension. In addition we want our tree to work with arbitrary data items. This requires an adaptor between the algorithm and the data item. This is resolved by the use of traits classes, implemented in form of a traits class using function objects. These classes provide access functions to a specified data slot of a data item. A d-dimensional tree is then defined separately for each layer by defining a traits class for each layer.

62.5 Range Trees

A one-dimensional range tree is a binary search tree on one-dimensional point data. The point data of the tree is stored in the leaves. Each inner vertex stores the highest entry of its left subtree. The version of a range tree implemented here is static, which means that after construction of the tree, no elements be inserted or deleted. A d-dimensional range tree is a binary leaf search tree according to the first dimension of the d-dimensional point data, where each vertex contains a $(d-1)$-dimensional search tree of the points in the subtree (sublayer tree) with respect to the second dimension. See [dBvKOS97] and [Sam90] for more detailed information.

A d-dimensional range tree can be used to determine all d-dimensional points that lie inside a given d-dimensional interval (*window_query*). Figure 62.2 shows a two-dimensional range tree, Figure 62.3 a d-

dimensional one.

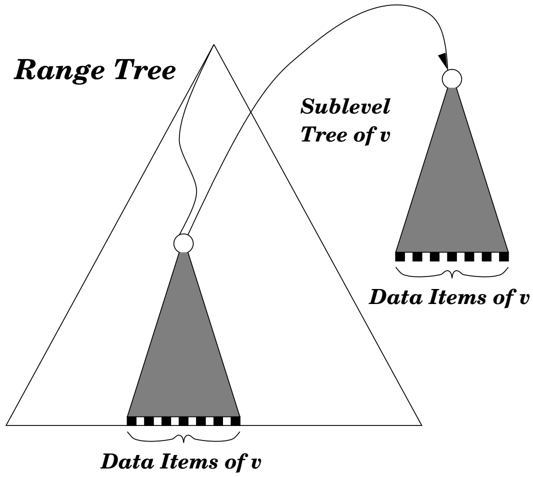

Figure 62.2: A two-dimensional range tree. The tree is a binary search tree on the first dimension. Each sublayer tree of a vertex *v* is a binary search tree on the second dimension. The data items in a sublayer tree of *v* are all data items of the subtree of *v*.

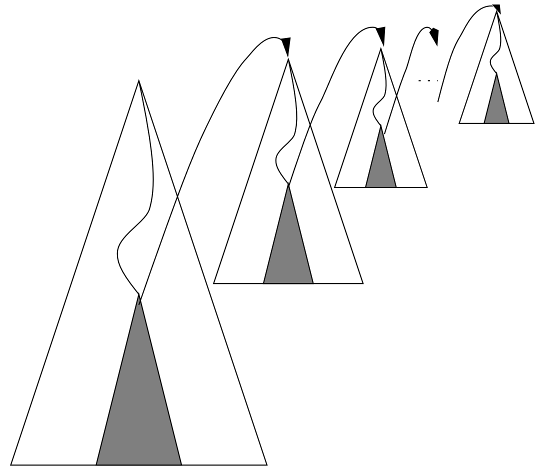

Figure 62.3: A d-dimensional range tree. For each layer of the tree, one sublayer tree is illustrated.

The tree can be built in $O(n \log^{d-1} n)$ time and needs $O(n \log^{d-1} n)$ space. The d-dimensional points that lie in the d-dimensional query interval can be reported in $O(\log^d n + k)$ time, where n is the total number of points and k is the number of reported points.

62.5.1 Example for Range Tree on Map-like Data

The following example program uses the predefined *Range_tree_2* data structure together with the predefined traits class *Range_tree_map_traits_2* which has two template arguments specifying the type of the point data in each dimension (*CGAL::Cartesian*<*double*>) and the value type of the 2-dimensional point data (*char*). Therefore the *Range_tree_2* is defined on 2-dimensional point data each of which is associated with a character. Then, a few data items are created and put into a list. After that the tree is constructed according to that list, a window query is performed, and the query elements are given out.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Range_segment_tree_traits.h>
#include <CGAL/Range_tree_k.h>

typedef CGAL::Cartesian<double> K;
typedef CGAL::Range_tree_map_traits_2<K, char> Traits;
typedef CGAL::Range_tree_2<Traits> Range_tree_2_type;

int main()
{
  typedef Traits::Key Key;
  typedef Traits::Interval Interval;
```

```
  std::vector<Key> InputList, OutputList;
  InputList.push_back(Key(K::Point_2(8,5.1), 'a'));
  InputList.push_back(Key(K::Point_2(1,1.1), 'b'));
  InputList.push_back(Key(K::Point_2(3,2.1), 'c'));

  Range_tree_2_type Range_tree_2(InputList.begin(),InputList.end());
  Interval win(Interval(K::Point_2(4,8.1),K::Point_2(5,8.2)));
  std::cout << "\n Window Query:\n ";
  Range_tree_2.window_query(win, std::back_inserter(OutputList));
  std::vector<Key>::iterator current=OutputList.begin();
  while(current!=OutputList.end()){
    std::cout << (*current).first.x() << "," << (*current).first.y()
         << ":" << (*current++).second << std::endl;
  }
}
```

62.5.2 Example for Range Tree on Set-like Data

This example illustrates the use of the range tree on 2-dimensional point data (no value is associated to a data item). After the definition of the tree, some input data items are created and the tree is constructed according to the input data items. After that, a window query is performed and the query elements are given to standard out.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Range_segment_tree_traits.h>
#include <CGAL/Range_tree_k.h>

typedef CGAL::Cartesian<double> K;
typedef CGAL::Range_segment_tree_set_traits_2<K> Traits;
typedef CGAL::Range_tree_2<Traits> Range_tree_2_type;

int main()
{
  typedef Traits::Key Key;
  typedef Traits::Interval Interval;
  std::vector<Key> InputList, OutputList;
  std::vector<Key>::iterator first, last, current;

  InputList.push_back(Key(8,5.1));
  InputList.push_back(Key(1,1.1));
  InputList.push_back(Key(3,2.1));

  Range_tree_2_type Range_tree_2(InputList.begin(),InputList.end());

  Interval win=Interval(Key(4,8.1),Key(5,8.2));
  std::cout << std::endl << "Window Query: lower left point: (4.0,5.0),";
  std::cout << "upper right point: (8.1,8.2)" << std::endl;
  Range_tree_2.window_query(win, std::back_inserter(OutputList));
  current=OutputList.begin();
  while(current!=OutputList.end()){
    std::cout << (*current).x()<< "-" << (*current).y() << std::endl;
    current++;
```

```
  }
}
```

62.6 Segment Trees

A segment tree is a static binary search tree for a given set of coordinates. The set of coordinates is defined by the endpoints of the input data intervals. Any two adjacent coordinates build an elementary interval. Every leaf corresponds to an elementary interval. Inner vertices correspond to the union of the subtree intervals of the vertex. Each vertex or leaf v contains a sublayer type (or a list, if it is one-dimensional) that will contain all intervals I, such that I contains the interval of vertex v but not the interval of the parent vertex of v.

A d-dimensional segment tree can be used to solve the following problems:

- Determine all d-dimensional intervals that contain a d-dimensional point. This query type is called "inverse range query".
- Determine all d-dimensional intervals that enclose a given d-dimensional interval (*enclosing_query*).
- Determine all d-dimensional intervals that partially overlap or are contained in a given d-dimensional interval (*window_query*).

In Figure 62.4 an example of a one-dimensional segment tree is given. Figure 62.5 shows a two-dimensional segment tree.

The tree can be built in $O(n \log^d n)$ time and needs $O(n \log^d n)$ space. The processing time for inverse range queries in an d-dimensional segment tree is $O(\log^d n + k)$ time, where n is the total number of intervals and k is the number of reported intervals.

One possible application of a two-dimensional segment tree is the following. Given a set of convex polygons in two-dimensional space (CGAL::Polygon_2), we want to determine all polygons that intersect a given rectangular query window. Therefore, we define a two-dimensional segment tree, where the two-dimensional interval of a data item corresponds to the bounding box of a polygon and the value type corresponds to the polygon itself. The segment tree is created with a sequence of all data items, and a window query is performed. The polygons of the resulting data items are finally tested independently for intersections.

62.6.1 Example for Segment Tree on Map-like Data

The following example program uses the predefined *Segment_tree_2* data structure together with the predefined traits class *Segment_tree_map_traits_2* which has two template arguments specifying the type of the point data in each dimension (*CGAL::Cartesian<double>*) and the value type of the 2-dimensional point data (*char*). Therefore the *Segment_tree_2* is defined on 2-dimensional point data (*CGAL::Point_2<Cartesian<double> >*) each of which is associated with a character. Then, a few data items are created and put into a list. After that the tree is constructed according to that list, a window query is performed, and the query elements are given out.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Segment_tree_k.h>
#include <CGAL/Range_segment_tree_traits.h>

typedef CGAL::Cartesian<double> K;
```

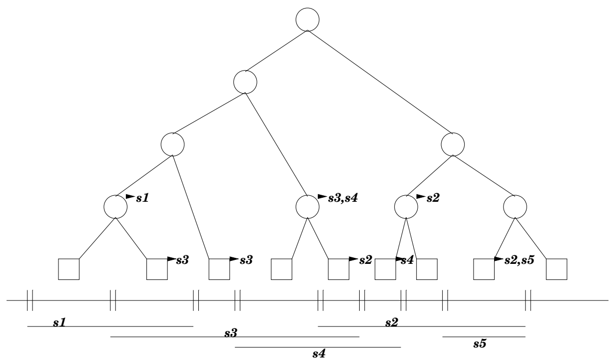

Figure 62.4: A one-dimensional segment tree. The segments and the corresponding elementary intervals are shown below the tree. The arcs from the nodes point to their subsets.

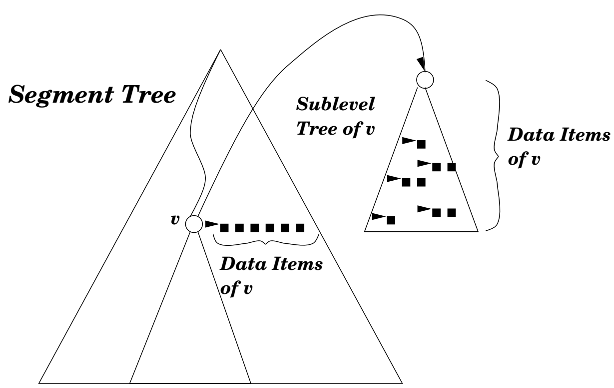

Figure 62.5: A two-dimensional segment tree. The first layer of the tree is built according to the elementary intervals of the first dimension. Each sublayer tree of a vertex v is a segment tree according to the second dimension of all data items of v.

```
typedef CGAL::Segment_tree_map_traits_2<K, char> Traits;
typedef CGAL::Segment_tree_2<Traits > Segment_tree_2_type;

int main()
{
  typedef Traits::Interval Interval;
  typedef Traits::Pure_interval Pure_interval;
  typedef Traits::Key Key;
  std::list<Interval> InputList, OutputList1, OutputList2;

  InputList.push_back(Interval(Pure_interval(Key(1,5), Key(2,7)),'a'));
  InputList.push_back(Interval(Pure_interval(Key(2,7), Key(3,8)),'b'));
  InputList.push_back(Interval(Pure_interval(Key(6,9), Key(9,13)),'c'));
  InputList.push_back(Interval(Pure_interval(Key(1,3), Key(3,9)),'d'));

  Segment_tree_2_type Segment_tree_2(InputList.begin(),InputList.end());

  Interval a=Interval(Pure_interval(Key(3,6), Key(7,12)),'e');
  Segment_tree_2.window_query(a,std::back_inserter(OutputList1));

  std::list<Interval>::iterator j = OutputList1.begin();
  std::cout << "\n window_query (3,6),(7,12)\n";
  while(j!=OutputList1.end()){
    std::cout << (*j).first.first.x() << "-" << (*j).first.second.x() << " "
         << (*j).first.first.y() << "-" << (*j).first.second.y() << std::endl;
    j++;
  }

  Interval b=Interval(Pure_interval(Key(6,10),Key(7,11)), 'f');
  Segment_tree_2.enclosing_query(b,std::back_inserter(OutputList2));
  j = OutputList2.begin();
  std::cout << "\n enclosing_query (6,10),(7,11)\n";
  while(j!=OutputList2.end()){
    std::cout << (*j).first.first.x() << "-" << (*j).first.second.x() << " "
         << (*j).first.first.y() << "-" << (*j).first.second.y() << std::endl;
    j++;
  }
  return 0;
}
```

62.6.2 Example for Segment Tree on Set-like Data

This example illustrates the use of the predefined segment tree on 3-dimensional interval data (with no value associated). After the definition of the traits type and tree type, some intervals are constructed and the tree is build according to the intervals. Then, a window query is performed and the query elements are given out.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Segment_tree_k.h>
#include <CGAL/Range_segment_tree_traits.h>

typedef CGAL::Cartesian<int> K;
```

```
typedef CGAL::Range_segment_tree_set_traits_3<K> Traits;
typedef CGAL::Segment_tree_3<Traits > Segment_tree_3_type;

int main()
{
  typedef Traits::Interval Interval;
  typedef Traits::Key Key;
  std::list<Interval> InputList, OutputList;

  InputList.push_back(Interval(Key(1,5,7), Key(2,7,9)));
  InputList.push_back(Interval(Key(2,7,6), Key(3,8,9)));
  InputList.push_back(Interval(Key(6,9,5), Key(9,13,8)));
  InputList.push_back(Interval(Key(1,3,4), Key(3,9,8)));

  Segment_tree_3_type Segment_tree_3(InputList.begin(),InputList.end());

  Interval a(Key(3,6,5), Key(7,12,8));
  Segment_tree_3.window_query(a,std::back_inserter(OutputList));
  std::list<Interval>::iterator j = OutputList1.begin();
  std::cout << "\n window_query (3,6,5),(7,12,8) \n";
  while(j!=OutputList.end()){
    std::cout << (*j).first.x() << "," << (*j).first.y() << ",";
    std::cout << (*j).first.z() <<", " << (*j).second.x() << ",";
    std::cout << (*j).second.y() << "," << (*j).second.z() << std::endl;
    j++;
  }
}
```

dD Range and Segment Trees Reference Manual

Gabriele Neyer

This chapter presents the CGAL range tree and segment tree data structures.

The range tree is theoretically superior to the Kd-tree, but the latter often seems to perform better. However, the range tree as implemented in CGAL is more flexible than the Kd-tree implementation, in that it enables to layer together range trees and segment trees in the same data structure.

RangeSegmentTreeTraits_k

Definition

A tree traits class gives the range tree and segment tree class the necessary type information of the keys and intervals. Further more, they define function objects that allow to access the keys and intervals, and provide comparison functions that are needed for window queries.

Types

RangeSegmentTreeTraits_k:: Key — The k-dimensional key type.

RangeSegmentTreeTraits_k:: Interval — The k-dimensional interval type.

RangeSegmentTreeTraits_k:: Key_i — The type in dimension i, with $1 \leq i \leq k$.

RangeSegmentTreeTraits_k:: key_i — function object providing an *operator()* that takes an argument of type *Key* and returns a component of type *Key_i*.

RangeSegmentTreeTraits_k:: low_i — function object providing an *operator()* that takes an argument of type *Interval* and returns a component of type *Key_i*.

RangeSegmentTreeTraits_k:: high_i — function object providing an *operator()* that takes an argument of type *Interval* and returns a component of type *Key_i*.

RangeSegmentTreeTraits_k:: compare_i — function object providing an *operator()* that takes two arguments argument a, b of type *Key_i* and returns true if $a < b$, false otherwise.

Example

The following piece of code gives an example of how a traits class might look like, if you have keys that are of the type *int* in the first and that are of the type *double* in the second dimension.

```
class Int_double_tree_traits_2{
 public:
  typedef std::pair<int, double> Key;
  typedef int Key_1;
  typedef double Key_2;
  typedef std::pair<Key,Key> Interval;

  class C_Key_1{
  public:
    Key_1 operator()(const Key& k)
    { return k.first;}
  };
  class C_Key_2{
```

```
  public:
    Key_2 operator()(const Key& k)
    { return k.second;}
  };
  class C_Low_1{
  public:
    Key_1 operator()(const Interval& i)
    { return i.first.first;}
  };
  class C_High_1{
  public:
    Key_1 operator()(const Interval& i)
    { return i.second.first;}
  };
  class C_Low_2{
  public:
    Key_2 operator()(const Interval& i)
    { return i.first.second;}
  };
  class C_High_2{
  public:
    Key_2 operator()(const Interval& i)
    { return i.second.second;}
  };
  class C_Compare_1{
  public:
    bool operator()(Key_1 k1, Key_1 k2)
    { return less<int>()(k1,k2);}
  };
  class C_Compare_2{
  public:
    bool operator()(Key_2 k1, Key_2 k2)
    { return less<double>()(k1,k2);}
  };
  typedef C_Compare_1 compare_1;
  typedef C_Compare_2 compare_2;
  typedef C_Low_1 low_1;
  typedef C_High_1 high_1;
  typedef C_Key_1 key_1;
  typedef C_Low_2 low_2;
  typedef C_High_2 high_2;
  typedef C_Key_2 key_2;
};
```

CGAL::Range_segment_tree_traits_set_2<R>

Definition

The class is a range and segment tree traits class for the 2-dimensional point class from the CGAL kernel. The class is parameterized with a representation class *R*.

#include <CGAL/Range_segment_tree_traits.h>

Types

Point_2<R>	*Key;*
std::pair<Key, Key>	*Interval;*

Class

CGAL::Range_segment_tree_traits_set_3<R>

Definition

The class is a range and segment tree traits class for the 3-dimensional point class from the CGAL kernel. The class is parameterized with a representation class *R*.

#include <CGAL/Range_segment_tree_traits.h>

Types

Point_3<R>	*Key;*
std::pair<Key, Key>	*Interval;*

CGAL::Range_tree_d<Data, Window, Traits>

Class

Types

Range_tree_d<Data, Window, Traits>:: Data	container *Data*.
Range_tree_d<Data, Window, Traits>:: Window	container *Window*.
Range_tree_d<Data, Window, Traits>:: Traits	container *Traits*.

Creation

#include <CGAL/Range_tree_d.h>
Range_tree_d<Data, Window, Traits> r(Tree_base<Data, Window> sublayer_tree);

A range tree is constructed, such that the subtree of each vertex is of the same type prototype *sublayer_tree* is.
We assume that the dimension of the tree is d. This means, that *sublayer_tree* is a prototype of a $d-1$-dimensional tree. All data items of the d-dimensional range tree have container type *Data*. The query window of the tree has container type *Window*. *Traits* provides access to the corresponding data slots of container *Data* and *Window* for the d-th dimension. The traits class *Traits* must at least provide all functions and type definitions as described in, for example, the reference page for *tree_point_traits*. The template class described there is fully generic and should fulfill the most requirements one can have. In order to generate a one-dimensional range tree instantiate *Tree_anchor<Data, Window> sublayer_tree* with the same template parameters (*Data* and *Window*) *Range_tree_d* is defined. In order to construct a two-dimensional range tree, create *Range_tree_d* with a one-dimensional *Range_tree_d* with the corresponding *Traits* class of the first dimension.
Precondition: Traits::Data==Data and Traits::Window==Window.

Operations

template<class ForwardIterator>
bool *r.make_tree(ForwardIterator first, ForwardIterator last)*

The tree is constructed according to the data items in the sequence between the element pointed by iterator *first* and iterator *last*. The data items of the iterator must have type *Data*.

Precondition: This function can only be called once. If it is the first call the tree is build and *true* is returned. Otherwise, nothing is done but a *CGAL warning* is given and *false* returned.

template<class OutputIterator>
OutputIterator *r.window_query(Window win, OutputIterator result)*

All elements that lay inside the d-dimensional interval defined through *win* are placed in the sequence container of *OutputIterator*; the output iterator that points to the last location the function wrote to is returned.

bool *r.is_valid()*

The tree structure is checked. For each vertex the subtree is checked on being valid and it is checked whether the value of the *Key_type* of a vertex corresponds to the highest *Key_type* value of the left subtree.

Protected Operations

bool	*r.is_inside(Window win, Data object)*	returns true, if the data of *object* lies between the start and endpoint of interval *win*. False otherwise.
bool	*r.is_anchor()*	returns false.

Implementation

The construction of a d-dimensional range tree takes $O(n \log n^{d-1})$ time. The points in the query window are reported in time $O(k + \log^d n)$, where k is the number of reported points. The tree uses $O(n \log n^{d-1})$ storage.

Class

CGAL::Range_tree_k<Traits>

Definition

An object of the class is a k-dimensional range tree that can store k-dimensional keys of type *Key*. The class allows to perform window queries on the keys. The class is parameterized with a range tree traits class *Traits* that defines, among other things, the type of the *Key*.

CGAL provides traits class implementations that allow to use the range tree with point classes from the CGAL kernel as keys. These classes are *CGAL::Range_segment_tree_traits_set_2<R>*, *CGAL::Range_segment_tree_traits_set_3<R>*, *CGAL::Range_tree_traits_map_2<R>* and *CGAL::Range_tree_traits_map_3<R>*. The concept RangeSegmentTreeTraits_d defines the requirements that range tree traits classes must fulfill. This allows the advanced user to develop further range tree traits classes.

#include <CGAL/Range_tree_k.h>

Types

Range_tree_k<Traits>:: Traits — the type of the range tree traits class.

typedef Traits::Key Key;

typedef Traits::Interval Interval;

Creation

Range_tree_k<Traits> R; — Introduces an empty range tree *R*.

template < class ForwardIterator >
Range_tree_k<Traits> R(ForwardIterator first, ForwardIterator last);

Introduces a range tree *R* and initializes it with the data in the range *[first, last)*.
Precondition: *value_type(first) == Traits::Key*.

Operations

template < class ForwardIterator >
void R.make_tree(ForwardIterator first, ForwardIterator last)

Introduces a range tree *R* and initializes it with the data in the range *[first, last)*. This function can only be applied once on an empty range tree.
Precondition: *value_type(first) == Traits::Key*.

template < class OutputIterator >
OutputIterator *R.window_query(Interval window, OutputIterator out)*

writes all data that are in the interval *window* to the container where *out* points to, and returns an output iterator that points to the last location the function wrote to.
Precondition: *value_type(out) == Traits::Key*.

Example

The following example program uses the predefined *Range_tree_2* data structure together with the predefined traits class *Range_tree_map_traits_2* which has two template arguments specifying the type of the point data in each dimension (*CGAL::Cartesian<double>*) and the value type of the 2-dimensional point data (*char*). Therefore the *Range_tree_2* is defined on 2-dimensional point data (*CGAL::Point_2<Cartesian<double> >*) each of which is associated with a character. Then, a few data items are created and put into a list. After that the tree is constructed according to that list, a window query is performed, and the query elements are given out.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Range_segment_tree_traits.h>
#include <CGAL/Range_tree_k.h>

typedef CGAL::Cartesian<double> K;
typedef CGAL::Range_tree_map_traits_2<K, char> Traits;
typedef CGAL::Range_tree_2<Traits> Range_tree_2_type;

int main()
{
  typedef Traits::Key Key;
  typedef Traits::Interval Interval;

  std::vector<Key> InputList, OutputList;
  InputList.push_back(Key(K::Point_2(8,5.1), 'a'));
  InputList.push_back(Key(K::Point_2(1,1.1), 'b'));
  InputList.push_back(Key(K::Point_2(3,2.1), 'c'));

  Range_tree_2_type Range_tree_2(InputList.begin(),InputList.end());
  Interval win(Interval(K::Point_2(4,8.1), K::Point_2(5,8.2)));
  std::cout << "\n Window Query:\n ";
  Range_tree_2.window_query(win, std::back_inserter(OutputList));
  std::vector<Key>::iterator current=OutputList.begin();
  while(current!=OutputList.end()){
    std::cout << (*current).first.x() << "," << (*current).first.y()
         << ":" << (*current++).second << std::endl;
  }
}
```

Class

CGAL::Range_tree_traits_map_2<R,T>

Definition

The class is a range tree traits class for the 2-dimensional point class from the CGAL kernel, where data of type T is associated to each key. The class is parameterized with a representation class R and the type of the associated data T.

#include <CGAL/Range_segment_tree_traits.h>

Types

std::pair<R::Point_2,T>

Key;

std::pair<R::Point_2, R::Point_2 >

Interval;

CGAL::Range_tree_traits_map_3<R,T>

Definition

The class is a range and segment tree traits class for the 3-dimensional point class from the CGAL kernel, where data of type T is associated to each key. The class is parameterized with a representation class R and the type of the associated data T.

#include <CGAL/Range_segment_tree_traits.h>

Types

std::pair<R::Point_3,T>

Key;

std::pair<R::Point_3, R::Point_3>

Interval;

Class

CGAL::Segment_tree_d<Data, Window, Traits>

Types

Segment_tree_d<Data, Window, Traits>:: Data

container *Data*.

Segment_tree_d<Data, Window, Traits>:: Window

container *Window*.

Segment_tree_d<Data, Window, Traits>:: Traits

class *Traits*.

Creation

#include <CGAL/Segment_tree_d.h>
Segment_tree_d<Data, Window, Traits> s(Tree_base<Data, Window> sublayer_tree);

A segment tree is defined, such that the subtree of each vertex is of the same type prototype *sublayer_tree* is.
We assume that the dimension of the tree is d. This means, that *sublayer_tree* is a prototype of a $d-1$-dimensional tree. All data items of the d-dimensional segment tree have container type *Data*. The query window of the tree has container type *Window*. *Traits* provides access to the corresponding data slots of container *Data* and *Window* for the d-th dimension. The traits class *Traits* must at least provide all functions and type definitions described, for example, in the reference page for *tree_point_traits*. The template class described there is fully generic and should fulfill the most requirements one can have. In order to generate a one-dimensional segment tree instantiate *Tree_anchor<Data, Window> sublayer_tree* with the same template parameters *Data* and *Window Segment_tree_d* is defined. In order to construct a two-dimensional segment tree, create *Segment_tree_d* with a one-dimensional *Segment_tree_d* with the corresponding *Traits* of the first dimension.
Precondition: Traits::Data==Data and Traits::Window==Window.

Operations

bool *s.make_tree(In_it first, In_it last)*

The tree is constructed according to the data items in the sequence between the element pointed by iterator *first* and iterator *last*.

Precondition: This function can only be called once. If it is the first call the tree is build and *true* is returned. Otherwise, nothing is done but a *CGAL warning* is given and *false* returned.

OutputIterator *s.window_query(Window win, OutputIterator result)*

win$= [a_1,b_1),\ldots,[a_d,b_d)$, $a_i,b_i \in T_i$, $1 \leq i \leq d$. All elements that intersect the associated d-dimensional interval of *win* are placed in the associated sequence container of *OutputIterator* and returns an output iterator that points to the last location the function wrote to. In order to perform an inverse range query, a range query of ε width has to be performed.

OutputIterator *s.enclosing_query(Window win, OutputIterator result)*

All elements that enclose the associated d-dimensional interval of *win* are placed in the associated sequence container of *OutputIterator* and returns an output iterator that points to the last location the function wrote to.

bool *s.is_valid()* The tree structure is checked. For each vertex either the sublayer tree is a tree anchor, or it stores a (possibly empty) list of data items. In the first case, the sublayer tree of the vertex is checked on being valid. In the second case, each data item is checked weather it contains the associated interval of the vertex and does not contain the associated interval of the parent vertex or not. True is returned if the tree structure is valid, false otherwise.

Protected Operations

bool *s.is_inside(Window win, Data object)*

returns true, if the interval of *object* is contained in the interval of *win*. False otherwise.

bool *s.is_anchor()* returns false.

Implementation

A d-dimensional segment tree is constructed in $O(n \log n^d)$ time. An inverse range query is performed in time $O(k + \log^d n)$, where k is the number of reported intervals. The tree uses $O(n \log n^d)$ storage.

CGAL::Segment_tree_k<Traits>

Definition

An object of the class is a *k*-dimensional segment tree that can store k-dimensional intervals of type *Interval*. The class allows to perform window queries, enclosing queries, and inverse range queries on the keys. The class is parameterized with a segment tree traits class *Traits* that defines, among other things, the type of the *Interval*. In order to perform an inverse range query, a range query of ε width has to be performed. We prefered not to offer an extra function for this sort of query, since the inverse range query is a special case of the range query. Furthermore, offering an inverse range query in the segment tree class implies offering this function also in the range tree class and having an extra item in the traits class that accesses the inverse range query point.

CGAL provides traits class implementations that allow to use the segment tree with point classes from the CGAL kernel as keys. These classes are *CGAL::Range_segment_tree_traits_set_2<R>*, *CGAL::Range_segment_tree_traits_set_3<R>*, *CGAL::Segment_tree_traits_map_2<R>* and *CGAL::Segment_tree_traits_map_3<R>*. The concept RangeSegmentTreeTraits_d defines the requirements that segment tree traits classes must fulfill. This allows the advanced user to develop further segment tree traits classes.

#include <CGAL/Segment_tree_k.h>

Types

Segment_tree_k<Traits>:: Traits — the type of the segment tree traits class.

typedef Traits::Key *Key;*

typedef Traits::Interval

Interval;

Creation

Segment_tree_k<Traits> S; — Introduces an empty segment tree *S*.

template < class ForwardIterator >
Segment_tree_k<Traits> S(ForwardIterator first, ForwardIterator last);

Introduces a segment tree *S* and initializes it with the data in the range *[first, last)*.
Precondition: *value_type(first) == Traits::Interval*.

Operations

template < class ForwardIterator >
void *S.make_tree(ForwardIterator first, ForwardIterator last)*

Introduces a segment tree *S* and initializes it with the data in the range *[first, last)*. This function can only be applied once on an empty segment tree.
Precondition: *value_type(first) == Traits::Interval*.

template < class OutputIterator >
OutputIterator *S.window_query(Interval window, OutputIterator out)*

writes all intervals that have non empty intersection with interval *window* to the container where *out* points to, and returns an output iterator that points to the last location the function wrote to.
Precondition: *value_type(out) == Traits::Interval*.

template < class OutputIterator >
OutputIterator *S.enclosing_query(Interval window, OutputIterator out)*

writes all intervals that enclose in the interval *window* to the container where *out* points to, and returns an output iterator that points to the last location the function wrote to.
Precondition: *value_type(out) == Traits::Interval*.

Example

This example illustrates the use of the predefined segment tree on 3-dimensional interval data (with no value associated). After the definition of the traits type and tree type, some intervals are constructed and the tree is build according to the intervals. Then, a window query is performed and the query elements are given out.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Segment_tree_k.h>
#include <CGAL/Range_segment_tree_traits.h>

typedef CGAL::Cartesian<int> K;
typedef CGAL::Range_segment_tree_set_traits_3<K> Traits;
typedef CGAL::Segment_tree_3<Traits> Segment_tree_3_type;

int main()
{
  typedef Traits::Interval Interval;
  typedef Traits::Key Key;
  std::list<Interval> InputList, OutputList;

  InputList.push_back(Interval(Key(1,5,7), Key(2,7,9)));
  InputList.push_back(Interval(Key(2,7,6), Key(3,8,9)));
  InputList.push_back(Interval(Key(6,9,5), Key(9,13,8)));
  InputList.push_back(Interval(Key(1,3,4), Key(3,9,8)));

  Segment_tree_3_type Segment_tree_3(InputList.begin(),InputList.end());

  Interval a(Key(3,6,5), Key(7,12,8));
  Segment_tree_3.window_query(a,std::back_inserter(OutputList));
  std::list<Interval>::iterator j = OutputList1.begin();
  std::cout << "\n window_query (3,6,5),(7,12,8) \n";
  while(j!=OutputList.end()){
    std::cout << (*j).first.x() << "," << (*j).first.y() << ",";
    std::cout << (*j).first.z() <<", " << (*j).second.x() << ",";
    std::cout << (*j).second.y() << "," << (*j).second.z() << std::endl;
```

```
      j++;
    }
  }
```

CGAL::Segment_tree_traits_map_2<R,T>

Definition

The class is a segment tree traits class for the 2-dimensional point class from the CGAL kernel, where data of type T is associated to each interval. The class is parameterized with a representation class R and the type of the associated data T.

#include <CGAL/Range_segment_tree_traits.h>

Types

R::Point_2	*Key;*
std::pair<std::pair<Key,Key>,T>	*Interval;*

Class

Class

CGAL::Segment_tree_traits_map_3<R,T>

Definition

The class is a segment tree traits class for the 3-dimensional point class from the CGAL kernel, where data of type T is associated to each interval. The class is parameterized with a representation class R and the type of the associated data T.

#include <CGAL/Range_segment_tree_traits.h>

Types

std::pair<R::Point_3 >

Key;

std::pair<std::pair<Key, Key>,T>

Interval;

Sublayer

Definition

Defines the requirements that a *Sublayer_type* of class *Range_tree_d* or *Segment_tree_d* has to fulfill.

First of all, the class has to be derived from the abstract base class *Tree_base* and therefore has to provide methods *make_tree*, *window_query*, *enclosing_query* and *is_inside* with the same parameter types as the instantiated class *Range_tree_d* or *Segment_tree_d*, respectively. Furthermore a method *bool is_anchor()* has to be provided. If the *Sublayer_type* class builds a recursion anchor for class *Segment_tree_d*, this function is expected to return *true*, *false* otherwise.

Such a recursion anchor class is provided by the class class. *Tree_anchor<Data, Window>*.

CGAL::tree_interval_traits

Definition

tree_interval_traits is a template class that provides an interface to data items. It is similar to *tree_point_traits*, except that it provides access to two data slots of the same type of each container class (*Data, Window*) instead of providing access to one data slot of container class *Data* and two data slots of class *Window*.

#include <CGAL/Tree_traits.h>

Types

typedef
tree_interval_traits<Data, Window, Key, Data_left_func, Data_right_func, Window_left_func, Window_right_func, Compare> Interval_traits;

tree_interval_traits:: Data	the container *Data* — the data type. It may consist of several data slots. Two of these data slots have to be of type *Key*.
tree_interval_traits:: Window	the container *Window* — the query window type. It may consist of several data slots. Two of these data slots have to be of type *Key*.
tree_interval_traits:: Key	the type *Key* of the data slot this traits class provides access to.
tree_interval_traits:: Data_left_func	*Data_left_func* is a function object providing an *operator()* that takes an argument of type *Data* and returns a (the left) component of type *Key*.
tree_interval_traits:: Data_right_func	*Data_right_func* is a function object providing an *operator()* that takes an argument of type *Data* and returns a (the right) component of type *Key*.
tree_interval_traits:: Window_left_func	*Window_left_func* is a function objects that allow to access the left data slot of container *Window* which has type *Key*
tree_interval_traits:: Window_right_func	*Window_right_func* is a function objects that allow to access the right data slot of container *Window* which has type *Key*
tree_interval_traits:: Compare	defines a comparison relation which must define a strict ordering of the objects of type *Key*. If defined, *less<Key>* is sufficient.

Creation

tree_interval_traits<Data, Window, Key, Data_left_func, Data_right_func, Window_left_func, Window_right_func, Compare> d();

Generation of a *tree_point_traits* instance. It is a template class that provides an interface to data items.

Operations

Key	*d.get_left(Data d)*	The data slot of the data item of *d* of type *Key* is accessed by function object *Data_left_func*.
Key	*d.get_right(Data d)*	The data slot of the data item of *d* of type *Key* is accessed by function object *Data_right_func*.
Key	*d.get_left_win(Window w)*	
		The data slot of the data item of *w* of type *Key* is accessed by function object *Window_left_func*.
Key	*d.get_right_win(Window w)*	
		The data slot of the data item of *w* of type *Key* is accessed by function object *Window_right_func*.
static bool	*d.comp(Key& key1, Key& key2)*	
		returns Compare(key1, key2).

Class

CGAL::tree_point_traits

Definition

tree_point_traits is a template class that provides an interface to data items.

#include <CGAL/Tree_traits.h>

Types

typedef
tree_point_traits<Data, Window, Key, Data_func, Window_left_func, Window_right_func, Compare> Point_traits;

tree_point_traits:: Data	the container *Data* — defines the Data type. It may consist of several data slots. One of these data slots has to be of type *Key*.
tree_point_traits:: Window	the container *Window* — defines the type of the query rectangle. It may consist of several data slots. Two of these data slots has to be of type *Key*
tree_point_traits:: Key	the type *Key* of the data slot this traits class provides access to.
tree_point_traits:: Data_func	*Data_func* is a function object providing an *operator()* that takes an argument of type *Data* and returns a component of type *Key*.
tree_point_traits:: Window_left_func	*Window_left_func* is a function objects that allow to access the left data slot of container *Window* which has type *Key*
tree_point_traits:: Window_right_func	*Window_right_func* is a function objects that allow to access the right data slot of container *Window* which has type *Key*
tree_point_traits:: Compare	defines a comparison relation which must define a strict ordering of the objects of type *Key*. If defined, *less<Key>* is sufficient.

Creation

tree_point_traits<Data, Window, Key, Data_func, Window_left_func, Window_right_func, Compare> d();

Generation of a *tree_point_traits* instance. It is a template class that provides an interface to data items.

Operations

Key	*d.get_key(Data d)*	The data slot of the data item of *d* of type *Key* is accessed by function object *Data_func*.
Key	*d.get_left(Window w)*	The data slot of the data item of *w* of type *Key* is accessed by function object *Window_left_func*.
Key	*d.get_right(Window w)*	The data slot of the data item of *w* of type *Key* is accessed by function object *Window_right_func*.
static bool	*d.comp(Key& key1, Key& key2)*	returns *Compare(key1, key2)*.
static bool	*d.key_comp(Data& data1, Data& data2)*	returns *Compare(get_key(data1), get_key(data2))*.

Class

CGAL::Tree_anchor<Data, Window>

Definition

Tree_anchor is also derived from *Tree_base*. Therefore, it provides the same methods as *Range_tree_d* and *Segment_tree_d*, but does nothing; it can be used as a recursion anchor for those classes. Therefore, instantiate *Sublayer_type* of *Range_tree_d* (*Segment_tree_d* respectively) with *Tree_anchor* and the container classes for the data items (*Data* and *Window*).

Definition

Tree_anchor<Data, Window>:: Data — container *Data*.

Tree_anchor<Data, Window>:: Window — container *Window*.

Creation

#include <CGAL/Tree_base.h>

Tree_anchor<Data, Window> a;

Operations

template<class OutputIterator>
OutputIterator *a.window_query(Window win, OutputIterator result)*

template<class OutputIterator>
OutputIterator *a.enclosing_query(Window win, OutputIterator result)*

bool *a.is_valid()* returns true;

Protected Operations

bool *a.is_inside(Window win, Data object)*

returns true.

bool *a.is_anchor()* returns true.

Example

The following figures show a number of rectangles and a 2-dimensional segment tree built on them.

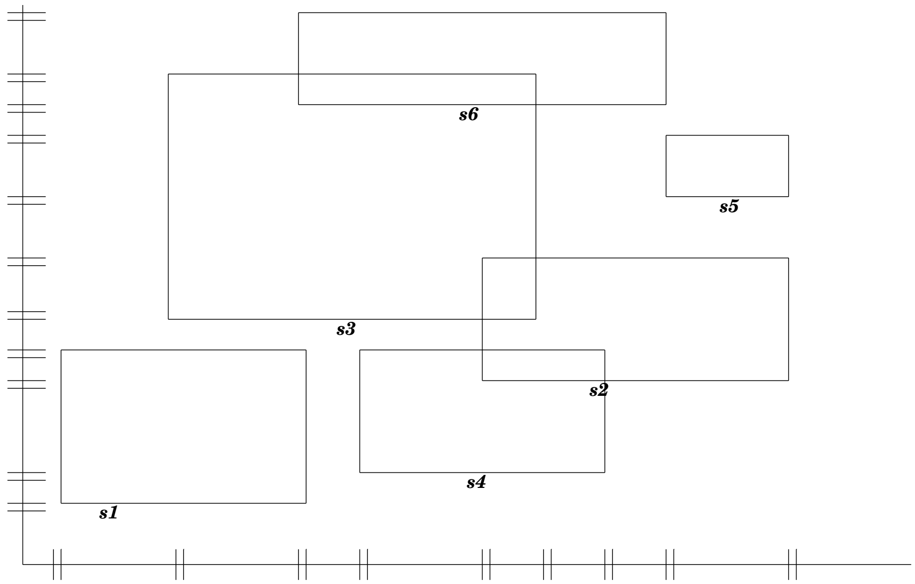

Figure 62.6: Two dimensional interval data.

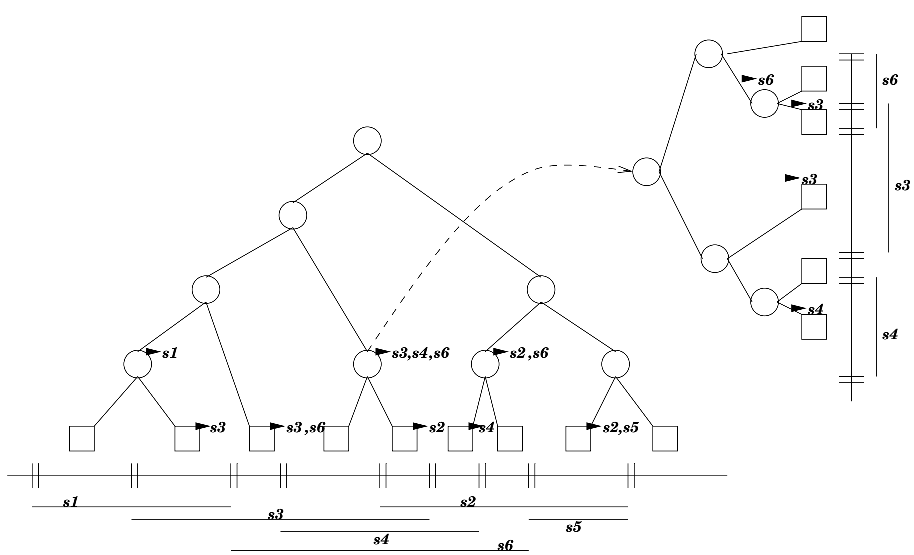

Figure 62.7: Two dimensional segment tree according to the interval data of Figure 62.6.

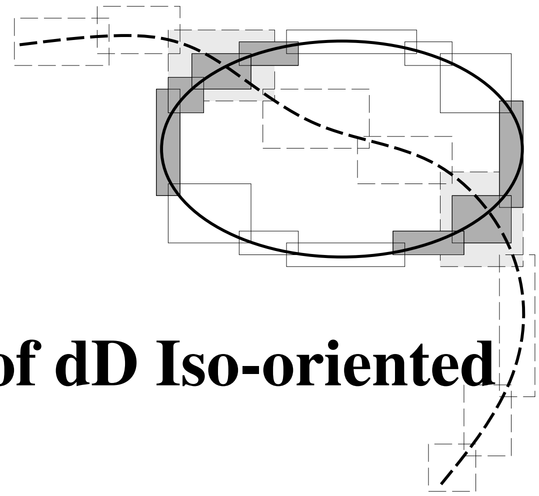

Chapter 63

Intersecting Sequences of dD Iso-oriented Boxes

Lutz Kettner, Andreas Meyer, and Afra Zomorodian

Contents

63.1 Introduction

Simple questions on geometric primitives, such as intersection and distance computations, can themselves become quite expensive if the primitives are not so simple anymore, for example, three-dimensional triangles and facets of polyhedral surfaces. Thus algorithms operating on these primitives tend to be slow in practice. A common (heuristic) optimization approximates the geometric primitives with their axis-aligned bounding boxes, runs a suitable modification of the algorithm on the boxes, and whenever a pair of boxes has an interesting interaction[1], only then the exact answer is computed on the complicated geometric primitives contained in the boxes.

[1] Boxes represent volumes or point-sets. So, *intersection* means intersection of the point-set enclosed by the box and not only intersection of the boundary, of course.

We provide an efficient algorithm [ZE02] for finding all intersecting pairs for large numbers of iso-oriented boxes, i.e., typically these will be such bounding boxes of more complicated geometries. One immediate application of this algorithm is the detection of all intersections (and self-intersections) for polyhedral surfaces, i.e., applying the algorithm on a large set of triangles in space, we give an example program later in this chapter. Not so obvious applications are proximity queries and distance computations among such surfaces, see Section 63.10 for an example and [ZE02] for more details.

63.2 Definition

A d-dimensional iso-oriented box is defined as the Cartesian product of d intervals. We call the box *half-open* if the d intervals $\{[lo_i, hi_i) \,|\, 0 \le i < d\}$ are half-open intervals, and we call the box *closed* if the d intervals $\{[lo_i, hi_i] \,|\, 0 \le i < d\}$ are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The distinction between closed and half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the two possible values for the *topology* parameter:

- *CGAL::Box_intersection_d::HALF_OPEN* and
- *CGAL::Box_intersection_d::CLOSED*.

The number type of the interval boundaries must be one of the built-in types `int`, `unsigned int`, `double` or `float`.

In addition, a box has an unique *id*-number. It is used to order boxes consistently in each dimension even if boxes have identical coordinates. In consequence, the algorithm guarantees that a pair of intersecting boxes is reported only once. Note that boxes with equal *id*-number are not reported since they obviously intersect trivially.

The box intersection algorithm comes in two flavors: One algorithm works on a single sequence of boxes and computes all pairwise intersections, which is called the *complete* case, and used, for example, in the self-intersection test. The other algorithm works on two sequences of boxes and computes the pairwise intersections between boxes from the first sequence with boxes from the second sequence, which is called the *bipartite* case. For each pairwise intersection found a callback function is called with two arguments; the first argument is a box from the first sequence and the second argument a box from the second sequence. In the complete case, the second argument is a box from an internal copy of the first sequence.

63.3 Software Design

The box intersection algorithm is implemented as a family of generic functions; the functions for the complete case accept one iterator range, and the functions for the bipartite case accept two iterator ranges. The callback function for reporting the intersecting pairs is provided as a template parameter of the *BinaryFunction* concept. The two principle function calls utilizing all default arguments look as follows:

#include <CGAL/box_intersection_d.h>

template< class RandomAccessIterator, class Callback >
void box_intersection_d(RandomAccessIterator begin, RandomAccessIterator end, Callback callback)

template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback >
void box_intersection_d(RandomAccessIterator1 begin1,
RandomAccessIterator1 end1,
RandomAccessIterator2 begin2,
RandomAccessIterator2 end2,
Callback callback)

Additional parameters to the functions calls are a *cutoff* value to adjust performance trade-offs, and a *topology* parameter selecting between topologically closed boxes (the default) and topologically half-open boxes.

The algorithm reorders the boxes in the course of the algorithm. Now, depending on the size of a box it can be faster to copy the boxes, or to work with pointers to boxes and copy only pointers. We offer automatic support for both options. To simplify the description, let us call the *value_type* of the iterator ranges *box handle*. The *box handle* can either be our box type itself or a pointer (or const pointer) to the box type; these choices represent both options from above.

In general, the algorithms treat the box type as opaque type and just assume that they are models of the *Assignable* concept, so that the algorithms can modify the input sequences and reorder the boxes. The access to the box dimension and box coordinates is mediated with a traits class of the *BoxIntersectionTraits_d* concept. A default traits class is provided that assumes that the box type is a model of the *BoxIntersectionBox_d* concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type (see the previous paragraph for the value versus pointer nature of the box handle).

Two implementations of iso-oriented boxes are provided; *CGAL::Box_intersection_d::Box_d* as a plain box, and *CGAL::Box_intersection_d::Box_with_handle_d* as a box plus a handle that can be used to point to the full geometry that is approximated by the box. Both implementations have template parameters for the number type used for the interval bounds, for the fixed dimension of the box, and for a policy class [Ale01] selecting among several solutions for providing the *id*-number.

The function signatures for the bipartite case look as follows. The signatures for the complete case with the *box_self_intersection_d* function look the same except for the single iterator range.

#include <CGAL/box_intersection_d.h>

template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback >
void box_intersection_d(RandomAccessIterator1 begin1,
RandomAccessIterator1 end1,
RandomAccessIterator2 begin2,
RandomAccessIterator2 end2,
Callback callback,
std::ptrdiff_t cutoff = 10,
Box_intersection_d::Topology topology = Box_intersection_d::CLOSED,
Box_intersection_d::Setting setting = Box_intersection_d::BIPARTITE)

template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback, class BoxTraits >
void box_intersection_d(RandomAccessIterator1 begin1,
RandomAccessIterator1 end1,
RandomAccessIterator2 begin2,
RandomAccessIterator2 end2,
Callback callback,
BoxTraits box_traits,
std::ptrdiff cutoff = 10,
Box_intersection_d::Topology topology = Box_intersection_d::CLOSED,
Box_intersection_d::Setting setting = Box_intersection_d::BIPARTITE)

63.4 Minimal Example for Intersecting Boxes

The box implementation provided with *CGAL::Box_intersection_d::Box_d<double,2>* has a dedicated constructor for the CGAL bounding box type *CGAL::Bbox_2* (similar for dimension 3). We use this in our minimal example to create easily nine two-dimensional *boxes* in a grid layout of 3×3 boxes. Additionally we pick the center box and the box in the upper-right corner as our second box sequence *query*.

The default policy of the box type implements the *id*-number with an explicit counter in the boxes, which is the default choice since it always works, but it costs space that could potentially be avoided, see the example in the next section. We use the *id*-number in our callback function to report the result of the intersection algorithm. The result will be that the first *query* box intersects all nine *boxes* and the second *query* box intersects the four boxes in the upper-right quadrant. See Section 63.7 for the change of the *topology* parameter and its effect.

```
#include <CGAL/box_intersection_d.h>
#include <CGAL/Bbox_2.h>
#include <iostream>

typedef CGAL::Box_intersection_d::Box_d<double,2> Box;
typedef CGAL::Bbox_2                              Bbox;
                                                     // 9 boxes of a grid
Box boxes[9] = { Bbox( 0,0,1,1), Bbox( 1,0,2,1), Bbox( 2,0,3,1), // low
                 Bbox( 0,1,1,2), Bbox( 1,1,2,2), Bbox( 2,1,3,2), //
   middle
                 Bbox( 0,2,1,3), Bbox( 1,2,2,3), Bbox( 2,2,3,3)};// upper
// 2 selected boxes as query; center and upper right
Box query[2] = { Bbox( 1,1,2,2), Bbox( 2,2,3,3)};

void callback( const Box& a, const Box& b ) {
    std::cout << "box " << a.id() << " intersects box " << b.id() <<
   std::endl;
}
int main() {
    CGAL::box_intersection_d( boxes, boxes+9, query, query+2, callback);
    return 0;
}
```

63.5 Example for Finding Intersecting 3D Triangles

The conventional application of the axis-aligned box intersection algorithm will start from complex geometry, here 3D triangles, approximate them with their bounding box, compute the intersecting pairs of boxes, and check only for those if the original triangles intersect as well.

We start in the *main* function and create ten triangles with endpoints chosen randomly in a cube $[-1,+1)^3$. We store the triangles in a vector called *triangles*.

Next we create a vector for the bounding boxes of the triangles called *boxes*. For the boxes we choose the type *Box_with_handle_d<double,3,Iterator>* that works nicely together with the CGAL bounding boxes of type *CGAL::Bbox_3*. In addition, each box stores the iterator to the corresponding triangle.

The default policy of this box type uses for the *id*-number the address of the value of the iterator, i.e., the address of the triangle. This is a good choice that works correctly iff the boxes have unique iterators, i.e., there is a one-to-one mapping between boxes and approximated geometry, which is the case here. It saves us the extra space that was needed for the explicit *id*-number in the previous example.

We run the self intersection algorithm with the *report_inters* function as callback. This callback reports the intersecting boxes. It uses the *handle* and the global *triangles* vector to calculate the triangle numbers. Then it checks the triangles themselves for intersection and reports if not only the boxes but also the triangles intersect. We take some precautions before the intersection test in order to avoid problems, although unlikely, with degenerate triangles that we might have created with the random process.

This example can be easily extended to test polyhedral surfaces of the *Polyhedron_3* class for (self-) intersections. The main difference are the numerous cases of incidences between triangles in the polyhedral surface that should not be reported as intersections, see the `examples/Polyhedron/polyhedron_self_intersection.cpp` example program in the CGAL distribution.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/intersections.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Bbox_3.h>
#include <CGAL/box_intersection_d.h>
#include <CGAL/function_objects.h>
#include <CGAL/Join_input_iterator.h>
#include <CGAL/algorithm.h>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel   Kernel;
typedef Kernel::Point_3                                        Point_3;
typedef Kernel::Triangle_3                                     Triangle_3;
typedef std::vector<Triangle_3>                                Triangles;
typedef Triangles::iterator                                    Iterator;
typedef CGAL::Box_intersection_d::Box_with_handle_d<double,3,Iterator>
    Box;

Triangles triangles; // global vector of all triangles

// callback function that reports all truly intersecting triangles
void report_inters( const Box& a, const Box& b) {
    std::cout << "Box " << (a.handle() - triangles.begin()) << " and "
              << (b.handle() - triangles.begin()) << " intersect";
    if ( ! a.handle()->is_degenerate() && ! b.handle()->is_degenerate()
         && CGAL::do_intersect( *(a.handle()), *(b.handle()))) {
        std::cout << ", and the triangles intersect also";
    }
    std::cout << '.' << std::endl;
}

int main() {
    // Create 10 random triangles
    typedef CGAL::Random_points_in_cube_3<Point_3>          Pts;
    typedef CGAL::Creator_uniform_3< Point_3, Triangle_3>    Creator;
    typedef CGAL::Join_input_iterator_3<Pts,Pts,Pts,Creator>
   Triangle_gen;
    Pts     points( 1); // in centered cube [-1,1)^3
```

```
    Triangle_gen triangle_gen( points, points, points);
    CGAL::cpp0x::copy_n( triangle_gen, 10,
   std::back_inserter(triangles));

    // Create the corresponding vector of bounding boxes
    std::vector<Box> boxes;
    for ( Iterator i = triangles.begin(); i != triangles.end(); ++i)
        boxes.push_back( Box( i->bbox(), i));

    // Run the self intersection algorithm with all defaults
    CGAL::box_self_intersection_d( boxes.begin(), boxes.end(),
   report_inters);
    return 0;
}
```

File: examples/Box_intersection_d/triangle_self_intersect.cpp

63.6 Example for Using Pointers to Boxes

We modify the previous example, finding intersecting 3D triangles, and add an additional vector *ptr* that stores pointers to the bounding boxes, so that the intersection algorithm will work on a sequence of pointers and not on a sequence of boxes. The change just affects the preparation of the additional vector and the call of the box intersection function. The box intersection function (actually its default traits class) detects automatically that the value type of the iterators is a pointer type and not a class type.

```
    // Create the corresponding vector of pointers to bounding boxes
    std::vector<Box *> ptr;
    for ( std::vector<Box>::iterator i = boxes.begin(); i != boxes.end();
    ++i)
        ptr.push_back( &*i);

    // Run the self intersection algorithm with all defaults on the
    // indirect pointers to bounding boxes. Avoids copying the boxes.
    CGAL::box_self_intersection_d( ptr.begin(), ptr.end(),
   report_inters);
```

In addition, the callback function *report_inters* needs to be changed to work with pointers to boxes. The full example program looks as follows:

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/intersections.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Bbox_3.h>
#include <CGAL/box_intersection_d.h>
#include <CGAL/function_objects.h>
#include <CGAL/Join_input_iterator.h>
#include <CGAL/algorithm.h>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel   Kernel;
typedef Kernel::Point_3                                       Point_3;
```

```
typedef Kernel::Triangle_3                                          Triangle_3;
typedef std::vector<Triangle_3>                                     Triangles;
typedef Triangles::iterator                                         Iterator;
typedef CGAL::Box_intersection_d::Box_with_handle_d<double,3,Iterator>
   Box;

Triangles triangles; // global vector of all triangles

// callback function that reports all truly intersecting triangles
void report_inters( const Box* a, const Box* b) {
    std::cout << "Box " << (a->handle() - triangles.begin()) << " and "
              << (b->handle() - triangles.begin()) << " intersect";
    if ( ! a->handle()->is_degenerate() && ! b->handle()->is_degenerate()
         && CGAL::do_intersect( *(a->handle()), *(b->handle()))) {
        std::cout << ", and the triangles intersect also";
    }
    std::cout << '.' << std::endl;
}

int main() {
    // Create 10 random triangles
    typedef CGAL::Random_points_in_cube_3<Point_3>          Pts;
    typedef CGAL::Creator_uniform_3< Point_3, Triangle_3>    Creator;
    typedef CGAL::Join_input_iterator_3<Pts,Pts,Pts,Creator>
   Triangle_gen;
    Pts    points( 1); // in centered cube [-1,1)^3
    Triangle_gen triangle_gen( points, points, points);
    CGAL::cpp0x::copy_n( triangle_gen, 10,
   std::back_inserter(triangles));

    // Create the corresponding vector of bounding boxes
    std::vector<Box> boxes;
    for ( Iterator i = triangles.begin(); i != triangles.end(); ++i)
        boxes.push_back( Box( i->bbox(), i));

    // Create the corresponding vector of pointers to bounding boxes
    std::vector<Box *> ptr;
    for ( std::vector<Box>::iterator i = boxes.begin(); i != boxes.end();
    ++i)
        ptr.push_back( &*i);

    // Run the self intersection algorithm with all defaults on the
    // indirect pointers to bounding boxes. Avoids copying the boxes.
    CGAL::box_self_intersection_d( ptr.begin(), ptr.end(),
   report_inters);
    return 0;
}
```

File: examples/Box_intersection_d/triangle_self_intersect_pointers.cpp

A note on performance: The algorithm sorts and partitions the input sequences. It is clearly costly to copy a large box compared to a simple pointer. However, the algorithm benefits from memory locality in the later stages when it copies the boxes, while the pointers would refer to boxes that become wildly scattered in memory. These two effects, copying costs and memory locality, counteract each other. For small box sizes, i.e., small dimension, memory locality wins and one should work with boxes, while for larger box sizes one should work with pointers. The exact threshold depends on the memory hierarchy (caching) of the hardware platform and the size of the boxes, most notably the type used to represent the box coordinates. A concrete example; on a laptop with an Intel Mobile Pentium4 running at 1.80GHz with 512KB cache and 254MB main memory under Linux this version with pointers was 20% faster than the version above that copies the boxes for 10000 boxes, but the picture reversed for 100000 boxes, where the version above that copies the boxes becomes 300% faster.

Note that switching to the built-in type *float* is supported by the box intersection algorithm, but the interfacing with the CGAL bounding box *CGAL::Bbox_3* would not be that easy. In particular, just converting from the *double* to the *float* representation incurs rounding that needs to be controlled properly, otherwise the box might shrink and one might miss intersections.

63.7 Example Using the *topology* and the *cutoff* Parameters

Boxes can be interpreted by the box intersection algorithm as closed or as half-open boxes, see also Section 63.2. Closed boxes support zero-width boxes and they can intersect at their boundaries, while half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The choice between closed or half-open boxes is selected with the *topology* parameter and its two values:

- *CGAL::Box_intersection_d::HALF_OPEN* and
- *CGAL::Box_intersection_d::CLOSED*.

The example program uses a two-dimensional box with *int* coordinates and *id*-numbers that are by default explicitly stored. We create the same boxes as in the minimal example in Section 63.4. We create a 3×3 grid of *boxes*, and two boxes for the *query* sequence, namely the box at the center and the box from the upper-right corner of the grid.

We write a more involved callback function object *Report* that stores an output iterator and writes the *id*-number of the box in the first argument to the output iterator. We also provide a small helper function *report* that simplifies the use of the function object.

We call the box intersection algorithm twice; once for the default *topology*, which is the closed box topology, and once for the half-open box topology. We sort the resulting output for better readability and verify its correctness with the *check1* and *check2* data. For the closed box topology, the center box in *query* intersects all *boxes*, and the upper-right box in *query* intersects the four boxes of the upper-right quadrant in *boxes*. Almost all intersections are with the box boundaries, thus, for the half-open topology only one intersection remains per *query* box, namely its corresponding box in *boxes*. So, the output of the algorithm will be:

```
0 1 2 3 4 4 5 5 6 7 7 8 8
4 8
```

For the second box intersection function call we have to specify the *cutoff* parameter explicitly. See the Section 63.8 below for a detailed discussion.

```
#include <CGAL/box_intersection_d.h>
#include <vector>
#include <algorithm>
```

```
#include <iterator>
#include <cassert>

typedef CGAL::Box_intersection_d::Box_d<int,2> Box;

// coordinates for 9 boxes of a grid
int p[9*4]   = { 0,0,1,1,  1,0,2,1,  2,0,3,1, // lower
                 0,1,1,2,  1,1,2,2,  2,1,3,2, // middle
                 0,2,1,3,  1,2,2,3,  2,2,3,3};// upper
// 9 boxes
Box boxes[9] = { Box( p,    p+ 2),  Box( p+ 4, p+ 6),  Box( p+ 8, p+10),
                 Box( p+12, p+14),  Box( p+16, p+18),  Box( p+20, p+22),
                 Box( p+24, p+26),  Box( p+28, p+30),  Box( p+32, p+34)};
// 2 selected boxes as query; center and upper right
Box query[2] = { Box( p+16, p+18),  Box( p+32, p+34)};

// callback function object writing results to an output iterator
template <class OutputIterator>
struct Report {
    OutputIterator it;
    Report( OutputIterator i) : it(i) {} // store iterator in object
    // We write the id-number of box a to the output iterator assuming
    // that box b (the query box) is not interesting in the result.
    void operator()( const Box& a, const Box&) { *it++ = a.id(); }
};
template <class Iter> // helper function to create the function object
Report<Iter> report( Iter it) { return Report<Iter>(it); }

int main() {
    // run the intersection algorithm and store results in a vector
    std::vector<std::size_t> result;
    CGAL::box_intersection_d( boxes, boxes+9, query, query+2,
                              report( std::back_inserter( result)));
    // sort, check, and show result
    std::sort( result.begin(), result.end());
    std::size_t check1[13] = {0,1,2,3,4,4,5,5,6,7,7,8,8};
    assert(result.size() == 13 &&
   std::equal(check1,check1+13,result.begin()));
    std::copy( result.begin(), result.end(),
               std::ostream_iterator<std::size_t>( std::cout, " "));
    std::cout << std::endl;

    // run it again but for different cutoff value and half-open boxes
    result.clear();
    CGAL::box_intersection_d( boxes, boxes+9, query, query+2,
                              report( std::back_inserter( result)),
                              std::ptrdiff_t(1),
                              CGAL::Box_intersection_d::HALF_OPEN);
    // sort, check, and show result
    std::sort( result.begin(), result.end());
    std::size_t check2[2]  = {4,8};
    assert(result.size() == 2 && std::equal(check2, check2+2,
   result.begin()));
    std::copy( result.begin(), result.end(),
```

```
                std::ostream_iterator<std::size_t>( std::cout, " "));
    std::cout << std::endl;
    return 0;
}
```

File: examples/Box_intersection_d/box_grid.cpp

63.8 Runtime Performance

The implemented algorithm is described in [ZE02] as version two. Its performance depends on a *cutoff* parameter. When the size of both iterator ranges drops below the *cutoff* parameter the function switches from the streamed segment-tree algorithm to the two-way-scan algorithm, see [ZE02] for the details.

The streamed segment-tree algorithm needs $O(n\log^d(n)+k)$ worst-case running time and $O(n)$ space, where n is the number of boxes in both input sequences, d the (constant) dimension of the boxes, and k the output complexity, i.e., the number of pairwise intersections of the boxes. The two-way-scan algorithm needs $O(n\log(n)+l)$ worst-case running time and $O(n)$ space, where l is the number of pairwise overlapping intervals in one dimensions (the dimension where the algorithm is used instead of the segment tree). Note that l is not necessarily related to k and using the two-way-scan algorithm is a heuristic.

Unfortunately, we have no general method to automatically determine an optimal cutoff parameter, since it depends on the used hardware, the runtime ratio between callback runtime and segment-tree runtime, and of course the number of boxes to be checked and their distribution. In cases where the callback runtime is dominant, it may be best to make the threshold parameter small. Otherwise a $cutoff = \sqrt{n}$ can lead to acceptable results. For well distributed boxes the original paper [ZE02] gives optimal cutoffs in the thousands. Anyway, for optimal runtime some experiments to compare different cutoff parameters are recommended.

To demonstrate that box intersection can be done quite fast, different box sequences are intersected in the range between 4 and 800000 boxes total. We use three-dimensional default boxes of closed topology with *float* coordinates and without additional data fields. The algorithm works directly on the boxes, not on pointer to boxes. Each box intersection is reported to an empty dummy callback.

For each box set, a near-optimal cutoff parameter is determined using an adaptive approximation. The runtime required for streaming is compared against usual scanning. Results on a Xeon 2.4GHz with 4GB main memory can be seen in Figure 63.1. For a small number of boxes, pure scanning is still faster than streaming with optimal cutoff, which would just delegate the box sets to the scanning algorithm. As there are more and more boxes, the overhead becomes less important.

63.9 Example Using a Custom Box Implementation

The example in the previous Section 63.7 uses an array to provide the coordinates and then creates another array for the boxes. In the following example we write our own box class *Box* that we can initialize directly with the four coordinates and create the array of boxes directly. We also omit the explicitly stored *id*-number and use the address of the box itself as *id*-number. This works only if the boxes do not change their position, i.e., we work with pointers to the boxes in the intersection algorithm.

We follow with our own box class *Box* the *BoxIntersectionBox_d* concept, which allows us to reuse the default traits implementation, i.e., we can use the same default function call to compute all intersections. See the

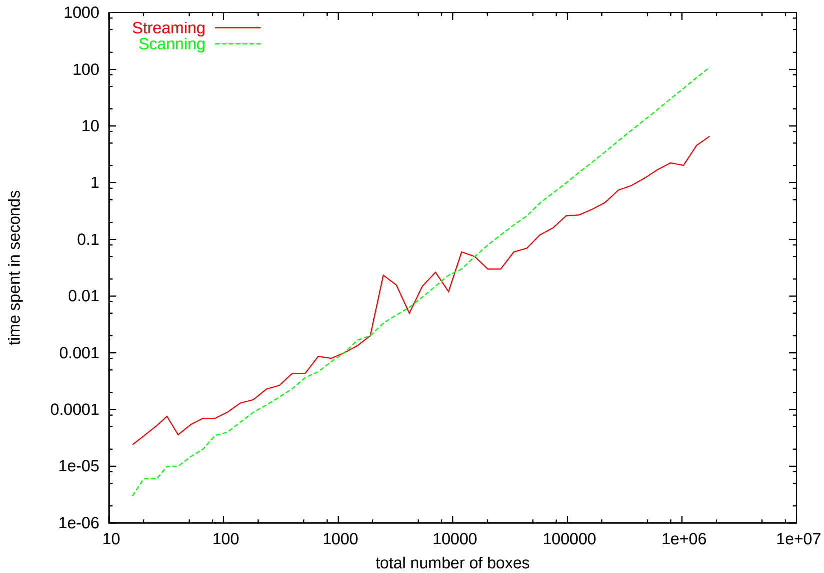

Figure 63.1: Runtime comparison between the scanning and the streaming algorithm.

example in the next section for a self-written traits class. So, in principle, the remainder of the example stays the same and we omit the part from the previous example for brevity that illustrates the half-open box topology.

The requirements for the box implementation are best studied on page 3714 in the Reference Manual. In a nutshell, we have to define the type *NT* for the box coordinates and the type *ID* for the *id*-number. Member functions give access to the coordinates and the *id*-number. A static member function returns the dimension.

```
#include <CGAL/box_intersection_d.h>
#include <vector>
#include <algorithm>
#include <iterator>
#include <cassert>

struct Box {
    typedef int             NT;
    typedef std::ptrdiff_t ID;
    int lo[2], hi[2];
    Box( int lo0, int lo1, int hi0, int hi1) { lo[0]=lo0; lo[1]=lo1;
   hi[0]=hi0; hi[1]=hi1;}
    static int dimension() { return 2; }
    int min_coord(int dim) const { return lo[dim]; }
    int max_coord(int dim) const { return hi[dim]; }
    // id-function using address of current box,
    // requires to work with pointers to boxes later
    std::ptrdiff_t id() const { return (std::ptrdiff_t)(this); }
};

// 9 boxes of a grid
Box boxes[9] = { Box( 0,0,1,1),  Box( 1,0,2,1),  Box( 2,0,3,1), // low
                 Box( 0,1,1,2),  Box( 1,1,2,2),  Box( 2,1,3,2), // middle
                 Box( 0,2,1,3),  Box( 1,2,2,3),  Box( 2,2,3,3)};// upper
// 2 selected boxes as query; center and upper right
```

```
Box query[2] = { Box( 1,1,2,2),  Box( 2,2,3,3)};

// With the special id-function we need to work on box pointers
Box* b_ptr[9] = { boxes,   boxes+1, boxes+2, boxes+3, boxes+4, boxes+5,
                  boxes+6, boxes+7, boxes+8};
Box* q_ptr[2] = { query,   query+1};

// callback function object writing results to an output iterator
template <class OutputIterator>
struct Report {
    OutputIterator it;
    Report( OutputIterator i) : it(i) {} // store iterator in object
    // We write the position with respect to 'boxes' to the output
   iterator
    // assuming that box b (the query box) is not interesting in the
   result.
    void operator()( const Box* a, const Box*) {
        *it++ = ( reinterpret_cast<Box*>(a->id()) - boxes);
    }
};
template <class Iter> // helper function to create the function object
Report<Iter> report( Iter it) { return Report<Iter>(it); }

int main() {
    // run the intersection algorithm and store results in a vector
    std::vector<std::size_t> result;
    CGAL::box_intersection_d( b_ptr, b_ptr+9, q_ptr, q_ptr+2,
                              report( std::back_inserter( result)),
                              std::ptrdiff_t(0));
    // sort and check result
    std::sort( result.begin(), result.end());
    std::size_t chk[13] = {0,1,2,3,4,4,5,5,6,7,7,8,8};
    assert( result.size()==13 && std::equal(chk,chk+13,result.begin()));
    return 0;
}
```

File: examples/Box_intersection_d/custom_box_grid.cpp

63.10 Example for Point Proximity Search with a Custom Traits Class

Given a set of 3D points, we want to find all pairs of points that are less than a certain distance apart. We use the box intersection algorithm to find good candidates, namely those that are less than this specified distance apart in the L_∞ norm, which is a good approximation of the Euclidean norm.

We use an unusual representation for the box, namely pointers to the 3D points themselves. We implement a special box traits class that interprets the point as a box of the dimensions $[-eps, +eps]^3$ centered at this point. The value for *eps* is half the specified distance from above, i.e., points are reported if their distance is smaller than *2*eps*.

The requirements for the box traits class are best studied on page 3715 in the Reference Manual. In a nutshell, we have to define the type *NT* for the box coordinates, the type *ID* for the *id*-number, and the type *Box_parameter* similar to the box handle, here *Point_3** since we work with the pointers. All member functions in the traits class are static. Two functions give access to the max and min coordinates that we compute from the point coordinates plus or minus the *eps* value, respectively. For the *id*-number function the address of the point itself is sufficient, since the points stay stable. Another function returns the dimension.

The *report* callback function computes than the Euclidean distance and prints a message for points that are close enough.

Note that we need to reserve sufficient space in the *points* vector to avoid reallocations while we create the *points* vector and the *boxes* vector in parallel, since otherwise the *points* vector might reallocate and invalidate all pointers stored in the *boxes* so far.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/box_intersection_d.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/algorithm.h>
#include <vector>
#include <algorithm>
#include <iterator>
#include <cmath>

typedef CGAL::Simple_cartesian<float>             Kernel;
typedef Kernel::Point_3                           Point_3;
typedef CGAL::Random_points_on_sphere_3<Point_3>  Points_on_sphere;

std::vector<Point_3>  points;
std::vector<Point_3*> boxes;     // boxes are just pointers to points
const float           eps = 0.1f; // finds point pairs of distance <
    2*eps

// Boxes are just pointers to 3d points. The traits class adds the
// +- eps size to each interval around the point, effectively building
// on the fly a box of size 2*eps centered at the point.
struct Traits {
    typedef float          NT;
    typedef Point_3*       Box_parameter;
    typedef std::ptrdiff_t ID;

    static int   dimension() { return 3; }
    static float coord( Box_parameter b, int d) {
        return (d == 0) ? b->x() : ((d == 1) ? b->y() : b->z());
    }
    static float min_coord( Box_parameter b, int d) { return
    coord(b,d)-eps;}
    static float max_coord( Box_parameter b, int d) { return
    coord(b,d)+eps;}
    // id-function using address of current box,
    // requires to work with pointers to boxes later
    static std::ptrdiff_t id(Box_parameter b) { return
    (std::ptrdiff_t)(b); }
};

// callback function reports pairs in close proximity
void report( const Point_3* a, const Point_3* b) {
    float dist = std::sqrt( CGAL::squared_distance( *a, *b));
```

```
    if ( dist < 2*eps) {
        std::cout << "Point " << (a - &(points.front())) << " and Point "
                  << (b - &(points.front())) << " have distance " << dist
                  << "." << std::endl;
    }
}

int main() {
    // create some random points on the sphere of radius 1.0
    Points_on_sphere generator( 1.0);
    points.reserve( 50);
    for ( int i = 0; i != 50; ++i) {
        points.push_back( *generator++);
        boxes.push_back( & points.back());
    }

    // run the intersection algorithm and report proximity pairs
    CGAL::box_self_intersection_d( boxes.begin(), boxes.end(),
                                   report, Traits());
    return 0;
}
```

63.11 Design and Implementation History

Lutz Kettner and Andreas Meyer implemented the algorithms starting from the publication [ZE02]. We had access to the original C implementation of Afra Zomorodian, which helped clarifying some questions, and we are grateful to the help of Afra Zomorodian in answering our questions during his visit. We thank Steve Robbins for an excellent review for this package. Steve Robbins provided an independent and earlier implementation of this algorithm, however, we learned too late about this implementation.

Intersecting Sequences of dD Iso-oriented Boxes Reference Manual

Lutz Kettner, Andreas Meyer, and Afra Zomorodian

We provide an efficient algorithm [ZE02] for finding all intersecting[2] pairs for large numbers of iso-oriented boxes, i.e., typically these will be bounding boxes of more complicated geometries. For comparison and as a base case for other methods, we also offer the simple all-pairs test as a generic function.

Concepts

Classes

Functions

[2]Boxes represent volumes or point-sets. So, *intersection* means intersection of the point-set enclosed by the box and not only intersection of the boundary, of course.

CGAL::box_intersection_d

Definition

The function *box_intersection_d* computes the pairwise intersecting boxes between two sequences of iso-oriented boxes in arbitrary dimension. The sequences of boxes are given with two random-access iterator ranges and will be reordered in the course of the algorithm. For each intersecting pair of boxes a *callback* function object is called with the two intersecting boxes as argument; the first argument is a box from the first sequence, the second argument a box from the second sequence. The performance of the algorithm can be tuned with a *cutoff* parameter, see the implementation section below for more details.

The algorithm reorders the boxes in the course of the algorithm. Now, depending on the size of a box it can be faster to copy the boxes, or to work with pointers to boxes and copy only pointers. We offer automatic support for both options. To simplify the description, let us call the *value_type* of the iterators *box handle*. The *box handle* can either be our box type itself or a pointer (or const pointer) to the box type.

A d-dimensional iso-oriented box is defined as the Cartesian product of d intervals. We call the box *half-open* if the d intervals $\{[lo_i,hi_i)\,|\,0 \leq i < d\}$ are half-open intervals, and we call the box *closed* if the d intervals $\{[lo_i,hi_i]\,|\,0 \leq i < d\}$ are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The distinction between closed or half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the *topology* parameter and its two values, *CGAL::Box_intersection_d::HALF_OPEN* and *CGAL::Box_intersection_d::CLOSED*.

In addition, a box has an unique *id*-number. It is used to order boxes consistently in each dimension even if boxes have identical coordinates. In consequence, the algorithm guarantees that a pair of intersecting boxes is reported only once. Boxes with equal *id*-number are not reported since they obviously intersect trivially.

The algorithm uses a traits class of the *BoxIntersectionTraits_d* concept to access the boxes. A default traits class is provided that assumes that the box type is a model of the *BoxIntersectionBox_d* concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type.

An important special application of this algorithm is the test for self-intersections where the second box sequence is an identical copy of the first sequence including the preserved *id*-number. Note that this implies that the address of the box is not sufficient for the *id*-number if boxes are copied by value. To ease the use of this special case we offer a simplified version of this function with one iterator range only, which then creates internally the second copy of the boxes, under the name *CGAL::box_self_intersection_d*.

In the general case, we distinguish between the bipartite case (the boxes are from different sequences) and the complete case (the boxes are from the same sequence, i.e., the self intersection case). The default is the bipartite case, since the complete case is typically handled with the simplified function call mentioned above. However, the general function call offers the *setting* parameter with the values *CGAL::Box_intersection_d::COMPLETE* and *CGAL::Box_intersection_d::BIPARTITE*.

#include <CGAL/box_intersection_d.h>

template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback >
void box_intersection_d(RandomAccessIterator1 begin1,

RandomAccessIterator1 end1,
RandomAccessIterator2 begin2,
RandomAccessIterator2 end2,
Callback callback,
std::ptrdiff_t cutoff = 10,
Box_intersection_d::Topology topology = Box_intersection_d::CLOSED,
Box_intersection_d::Setting setting = Box_intersection_d::BIPARTITE)

Invocation of box intersection with default box traits *CGAL::Box_intersection_d::Box_traits_d<Box_handle>*, where *Box_handle* corresponds to the iterator value type of *RandomAccessIterator1*.

template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback, class BoxTraits >
void *box_intersection_d(RandomAccessIterator1 begin1,*
RandomAccessIterator1 end1,
RandomAccessIterator2 begin2,
RandomAccessIterator2 end2,
Callback callback,
BoxTraits box_traits,
std::ptrdiff_t cutoff = 10,
Box_intersection_d::Topology topology = Box_intersection_d::CLOSED,
Box_intersection_d::Setting setting = Box_intersection_d::BIPARTITE)

Invocation with custom box traits.

Requirements

- *RandomAccessIterator1*, and *...2*, must be mutable random-access iterators and both value types must be the same. We call this value type *Box_handle* in the following.
- *Callback* must be of the *BinaryFunction* concept. The *Box_handle* must be convertible to both argument types. The return type is not used and can be *void*.
- The *Box_handle* must be a model of the *Assignable* concept.
- In addition, if the default box traits is used the *Box_handle* must be a class type *T* or a pointer to a class type *T*, where *T* must be a model of the *BoxIntersectionBox_d* concept. In both cases, the default box traits specializes to a suitable implementation.
- *BoxTraits* must be of the *BoxIntersectionTraits_d* concept.

BoxIntersectionBox_d .... page 3714
BoxIntersectionTraits_d .... page 3715

Implementation

The implemented algorithm is described in [ZE02] as version two. Its performance depends on a *cutoff* parameter. When the size of both iterator ranges drops below the *cutoff* parameter the function switches from the streamed segment-tree algorithm to the two-way-scan algorithm, see [ZE02] for the details.

The streamed segment-tree algorithm needs $O(n\log^d(n)+k)$ worst-case running time and $O(n)$ space, where n is the number of boxes in both input sequences, d the (constant) dimension of the boxes, and k the output complexity, i.e., the number of pairwise intersections of the boxes. The two-way-scan algorithm needs $O(n\log(n)+l)$ worst-case running time and $O(n)$ space, where l is the number of pairwise overlapping intervals in one dimensions (the dimension where the algorithm is used instead of the segment tree). Note that l is not necessarily related to k and using the two-way-scan algorithm is a heuristic.

Unfortunately, we have no general method to automatically determine an optimal cutoff parameter, since it depends on the used hardware, the runtime ratio between callback runtime and segment-tree runtime, and of course the number of boxes to be checked and their distribution. In cases where the callback runtime is dominant, it may be best to make the threshold parameter small. Otherwise a $cutoff = \sqrt{n}$ can lead to acceptable results. For well distributed boxes the original paper [ZE02] gives optimal cutoffs in the thousands. Anyway, for optimal runtime some experiments to compare different cutoff parameters are recommended. See also Section 63.8.

Example

The box implementation provided with *CGAL::Box_intersection_d::Box_d<double,2>* has a special constructor for the CGAL bounding box type *CGAL::Bbox_2* (and similar for dimension 3). We use this in the example to create 3×3 *boxes* in a grid layout. Additionally we pick the center box and the box in the upper-right corner as our second box sequence *query*.

The default policy of the box type implements the *id*-number with an explicit counter in the boxes, which is the default choice since it always works. We use the *id*-number in our callback function to report the result of the intersection algorithm call. The result will be that the first *query* box intersects all nine *boxes* and the second *query* box intersects the four boxes in the upper-right quadrant.

```
#include <CGAL/box_intersection_d.h>
#include <CGAL/Bbox_2.h>
#include <iostream>

typedef CGAL::Box_intersection_d::Box_d<double,2> Box;
typedef CGAL::Bbox_2                              Bbox;
                                                     // 9 boxes of a grid
Box boxes[9] = { Bbox( 0,0,1,1), Bbox( 1,0,2,1), Bbox( 2,0,3,1), // low
                 Bbox( 0,1,1,2), Bbox( 1,1,2,2), Bbox( 2,1,3,2), //
    middle
                 Bbox( 0,2,1,3), Bbox( 1,2,2,3), Bbox( 2,2,3,3)};// upper
// 2 selected boxes as query; center and upper right
Box query[2] = { Bbox( 1,1,2,2), Bbox( 2,2,3,3)};

void callback( const Box& a, const Box& b ) {
    std::cout << "box " << a.id() << " intersects box " << b.id() <<
   std::endl;
}
int main() {
    CGAL::box_intersection_d( boxes, boxes+9, query, query+2, callback);
    return 0;
}
```

CGAL::box_intersection_all_pairs_d

Definition

The function *box_intersection_all_pairs_d* computes the pairwise intersecting boxes between two sequences of iso-oriented boxes in arbitrary dimension. It does so by comparing all possible pairs of boxes and is thus inferior to the fast *CGAL::box_intersection_d* algorithm on page 3703.

The sequences of boxes are given with two forward iterator ranges. The sequences are not modified. For each intersecting pair of boxes a *callback* function object is called with the two intersecting boxes as argument; the first argument is a box from the first sequence, the second argument a box from the second sequence.

The algorithm is interface compatible with the *CGAL::box_intersection_d* function. Similarly, we call the *value_type* of the iterators the *box handle*, which is either our box type or a pointer type to our box type.

A d-dimensional iso-oriented box is defined as the Cartesian product of d intervals. We call the box *half-open* if the d intervals $\{[lo_i,hi_i)\,|\,0 \leq i < d\}$ are half-open intervals, and we call the box *closed* if the d intervals $\{[lo_i,hi_i]\,|\,0 \leq i < d\}$ are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The distinction between closed or half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the *topology* parameter and its two values, *CGAL::Box_intersection_d::HALF_OPEN* and *CGAL::Box_intersection_d::CLOSED*.

In addition, a box has an unique *id*-number. Boxes with equal *id*-number are not reported since they obviously intersect trivially.

The algorithm uses a traits class of the *BoxIntersectionTraits_d* concept to access the boxes. A default traits class is provided that assumes that the box type is a model of the *BoxIntersectionBox_d* concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type.

An important special application of this algorithm is the test for self-intersections where the second box sequence is an identical copy of the first sequence including the preserved *id*-number. We offer a specialized implementation *CGAL::box_self_intersection_all_pairs* for this application.

#include <CGAL/box_intersection_d.h>

```
template< class ForwardIterator1, class ForwardIterator2, class Callback >
void    box_intersection_all_pairs_d( ForwardIterator1 begin1,
                                      ForwardIterator1 end1,
                                      ForwardIterator2 begin2,
                                      ForwardIterator2 end2,
                                      Callback callback,
                                      Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)
```

Invocation of box intersection with default box traits *CGAL::Box_intersection_d::Box_traits_d<Box_handle>*, where *Box_handle* corresponds to the iterator value type of *ForwardIterator1*.

```
template< class ForwardIterator1, class ForwardIterator2, class Callback, class BoxTraits >
void    box_intersection_all_pairs_d( ForwardIterator1 begin1,
```

ForwardIterator1 end1,
ForwardIterator2 begin2,
ForwardIterator2 end2,
Callback callback,
BoxTraits box_traits,
Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)

Invocation with custom box traits.

Requirements

- *ForwardIterator1*, and ...*2*, must be forward iterators and both value types must be the same. We call this value type *Box_handle* in the following.
- *Callback* must be of the *BinaryFunction* concept. The *Box_handle* must be convertible to both argument types. The return type is not used and can be *void*.
- The *Box_handle* must be a model of the *Assignable* concept.
- In addition, if the default box traits is used the *Box_handle* must be a class type T or a pointer to a class type T, where T must be a model of the *BoxIntersectionBox_d* concept. In both cases, the default box traits specializes to a suitable implementation.
- *BoxTraits* must be of the *BoxIntersectionTraits_d* concept.

Implementation

The algorithm is trivially testing all pairs and runs therefore in time $O(nm)$ where n is the size of the first sequence and m is the size of the second sequence.

CGAL::box_self_intersection_d

Function

Definition

The function *box_self_intersection_d* computes the pairwise intersecting boxes in a sequence of iso-oriented boxes in arbitrary dimension. The sequence of boxes is given with as a random-access iterator range and will be reordered in the course of the algorithm. For each intersecting pair of boxes a *callback* function object is called with the two intersecting boxes as argument; the first argument is a box from the sequence, the second argument is a copy of a box from the sequence. The performance of the algorithm can be tuned with a *cutoff* parameter, see the implementation section of the *CGAL::box_intersection_d* function on page 3703.

The algorithm creates a second copy of the boxes and reorders the boxes in the course of the algorithm. Now, depending on the size of a box it can be faster to copy the boxes, or to work with pointers to boxes and copy only pointers. We offer automatic support for both options. To simplify the description, let us call the *value_type* of the iterators *box handle*. The *box handle* can either be our box type itself or a pointer (or const pointer) to the box type.

A d-dimensional iso-oriented box is defined as the Cartesian product of d intervals. We call the box *half-open* if the d intervals $\{[lo_i, hi_i) \,|\, 0 \leq i < d\}$ are half-open intervals, and we call the box *closed* if the d intervals $\{[lo_i, hi_i] \,|\, 0 \leq i < d\}$ are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The distinction between closed or half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the *topology* parameter and its two values, *CGAL::Box_intersection_d::HALF_OPEN* and *CGAL::Box_intersection_d::CLOSED*.

In addition, a box has an unique *id*-number. It is used to order boxes consistently in each dimension even if boxes have identical coordinates. In consequence, the algorithm guarantees that a pair of intersecting boxes is reported only once. This self-intersection function creates internally a second copy of the box sequence. The copying has to preserve the *id*-number of boxes. Note that this implies that the address of the box is not sufficient for the *id*-number if boxes are copied by value. Boxes of equal *id*-number are not reported as intersecting pairs since they are always intersecting trivially.

The algorithm uses a traits class of the *BoxIntersectionTraits_d* concept to access the boxes. A default traits class is provided that assumes that the box type is a model of the *BoxIntersectionBox_d* concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type.

#include <CGAL/box_intersection_d.h>

```
template< class RandomAccessIterator, class Callback >
void    box_self_intersection_d( RandomAccessIterator begin,
                                 RandomAccessIterator end,
                                 Callback callback,
                                 std::ptrdiff_t cutoff = 10,
                                 Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)
```

Invocation of box intersection with default box traits *CGAL::Box_intersection_d::Box_traits_d<Box_handle>*, where *Box_handle* corresponds to the iterator value type of *RandomAccessIterator*.

```
template< class RandomAccessIterator, class Callback, class BoxTraits >
void    box_self_intersection_d( RandomAccessIterator begin,
```

RandomAccessIterator end,
Callback callback,
BoxTraits box_traits,
std::ptrdiff_t cutoff = 10,
Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)

Invocation with custom box traits.

Requirements

- *RandomAccessIterator* must be a mutable random-access iterator. We call its value type *Box_handle* in the following.
- *Callback* must be of the *BinaryFunction* concept. The *Box_handle* must be convertible to both argument types. The return type is not used and can be *void*.
- The *Box_handle* must be a model of the *Assignable* concept.
- In addition, if the default box traits is used the *Box_handle* must be a class type *T* or a pointer to a class type *T*, where *T* must be a model of the *BoxIntersectionBox_d* concept. In both cases, the default box traits specializes to a suitable implementation.
- *BoxTraits* must be of the *BoxIntersectionTraits_d* concept.

Implementation

See the implementation section of the *CGAL::box_intersection_d* function on page 3703.

Example

The box implementation provided with *CGAL::Box_intersection_d::Box_d<double,2>* has a special constructor for the CGAL bounding box type *CGAL::Bbox_2* (and similar for dimension 3). We use this in the example to create 3×3 *boxes* in a grid layout.

The default policy of the box type implements the *id*-number with an explicit counter in the boxes, which is the default choice since it always works. We use the *id*-number in our callback function to report the result of the intersection algorithm call. The result will be 20 pairwise intersections, but the order in which they are reported is non-intuitive.

```
#include <CGAL/box_intersection_d.h>
#include <CGAL/Bbox_2.h>
#include <iostream>

typedef CGAL::Box_intersection_d::Box_d<double,2> Box;
typedef CGAL::Bbox_2                              Bbox;

// 9 boxes of a grid
Box boxes[9] = { Bbox( 0,0,1,1), Bbox( 1,0,2,1), Bbox( 2,0,3,1), // low
                 Bbox( 0,1,1,2), Bbox( 1,1,2,2), Bbox( 2,1,3,2), //
   middle
                 Bbox( 0,2,1,3), Bbox( 1,2,2,3), Bbox( 2,2,3,3)};// upper

void callback( const Box& a, const Box& b ) {
    std::cout << "box " << a.id() << " intersects box " << b.id() <<
   std::endl;
}

int main() {
    CGAL::box_self_intersection_d( boxes, boxes+9, callback);
    return 0;
}
```

Function

CGAL::box_self_intersection_all_pairs_d

Definition

The function *box_self_intersection_all_pairs_d* computes the pairwise intersecting boxes in a sequence of iso-oriented boxes in arbitrary dimension. It does so by comparing all possible pairs of boxes and is thus inferior to the fast *CGAL::box_self_intersection_d* algorithm on page 3709.

The sequence of boxes is given with a forward iterator range. The sequences are not modified. For each intersecting pair of boxes a *callback* function object is called with the two intersecting boxes as argument.

The algorithm is interface compatible with the *CGAL::box_self_intersection_d* function. Similarly, we call the *value_type* of the iterators the *box handle*, which is either our box type or a pointer type to our box type.

A d-dimensional iso-oriented box is defined as the Cartesian product of d intervals. We call the box *half-open* if the d intervals $\{[lo_i, hi_i) \,|\, 0 \leq i < d\}$ are half-open intervals, and we call the box *closed* if the d intervals $\{[lo_i, hi_i] \,|\, 0 \leq i < d\}$ are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The distinction between closed or half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the *topology* parameter and its two values, *CGAL::Box_intersection_d::HALF_OPEN* and *CGAL::Box_intersection_d::CLOSED*.

The algorithm uses a traits class of the *BoxIntersectionTraits_d* concept to access the boxes. A default traits class is provided that assumes that the box type is a model of the *BoxIntersectionBox_d* concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type.

#include <CGAL/box_intersection_d.h>

```
template< class ForwardIterator, class Callback >
void    box_self_intersection_all_pairs_d(
            ForwardIterator begin,
            ForwardIterator end,
            Callback callback,
            Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)
```

Invocation of box intersection with default box traits *CGAL::Box_intersection_d::Box_traits_d<Box_handle>*, where *Box_handle* corresponds to the iterator value type of *ForwardIterator*.

```
template< class ForwardIterator, class Callback, class BoxTraits >
void    box_self_intersection_all_pairs_d(
            ForwardIterator begin,
            ForwardIterator end,
            Callback callback,
            BoxTraits box_traits,
            Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)
```

Invocation with custom box traits.

Requirements

- *ForwardIterator* must be a forward iterator. We call its value type *Box_handle* in the following.
- *Callback* must be of the *BinaryFunction* concept. The *Box_handle* must be convertible to both argument types. The return type is not used and can be *void*.
- The *Box_handle* must be a model of the *Assignable* concept.
- In addition, if the default box traits is used the *Box_handle* must be a class type *T* or a pointer to a class type *T*, where *T* must be a model of the *BoxIntersectionBox_d* concept. In both cases, the default box traits specializes to a suitable implementation.
- *BoxTraits* must be of the *BoxIntersectionTraits_d* concept.

Implementation

The algorithm is trivially testing all pairs and runs therefore in time $O(n^2)$ where n is the size of the input sequence. This algorithm does not use the id-number of the boxes.

Concept

BoxIntersectionBox_d

Definition

The BoxIntersectionBox_d concept is used in the context of the intersection algorithms for sequences of iso-oriented boxes. These algorithms come with a default traits class that assumes that the boxes are a model of this BoxIntersectionBox_d concept. This concept defines the access functions to the dimension, the *id*-number, and the boundaries of the box.

Refines

Assignable.

Has Models

CGAL::Box_intersection_d::Box_d<NT,int D,IdPolicy> . . . . . page 3717
CGAL::Box_intersection_d::Box_with_handle_d<NT, int D, Handle, IdPolicy> . . . . . page 3721

Types

BoxIntersectionBox_d:: NT	number type to represent the box boundaries. Allowed are the built-in types *int*, *unsigned int*, *float*, and *double*.
BoxIntersectionBox_d:: ID	type for the box *id*-number, must be a model of the *LessThanComparable* concept.

Access Functions

int *BoxIntersectionBox_d::dimension()*

returns the dimension of the box.

ID	*box.id() const*	returns the unique *id*-number for the *box*.
NT	*box.min_coord(int d) const*	returns the lower boundary in dimension d, $0 \leq d < dimension()$.
NT	*box.max_coord(int d) const*	returns the upper boundary in dimension d, $0 \leq d < dimension()$.

BoxIntersectionTraits_d

Concept

Definition

The BoxIntersectionTraits_d concept is used for the intersection algorithms for sequences of iso-oriented boxes. This concept defines the access functions to the dimension, the *id*-number, and the boundaries of the boxes manipulated in these algorithms.

Refines

Assignable.

Has Models

CGAL::Box_intersection_d::Box_traits_d<BoxHandle> . . . . page 3720

Types

BoxIntersectionTraits_d:: Box_parameter

type used for passing box parameters in the functions below. Since we support in our algorithms passing the boxes by value as well as passing them as pointers, this type can be either *const B*`&`, *B**, or *const B** respectively, where *B* is the actual box type. The difference to the box handle type lies in the first case where the box handle would be *B* where this type is *const B*`&`.

BoxIntersectionTraits_d:: NT — number type to represent the box boundaries. Allowed are the built-in types *int*, *unsigned int*, *float*, and *double*.

BoxIntersectionTraits_d:: ID — type for the *id*-number, model of the *LessThanComparable* concept.

Access Functions

int *BoxIntersectionTraits_d::dimension()* — returns the dimension of the box.

ID *BoxIntersectionTraits_d::id(Box_parameter box)* — returns the unique *id*-number for the *box*.

NT *BoxIntersectionTraits_d::min_coord(Box_parameter box, int d)*

returns the lower boundary of the *box* in dimension *d*, $0 \leq d < dimension()$.

NT *BoxIntersectionTraits_d::max_coord(Box_parameter box, int d)*

returns the upper boundary of the *box* in dimension *d*, $0 \leq d < dimension()$.

CGAL::Box_intersection_d::Box_d<NT,int D,IdPolicy>

Class

Definition

Box_d<NT,int D,IdPolicy> is a generic iso-oriented bounding box in dimension *D*. It provides in each dimension an interval with lower and upper endpoints represented with the number type *NT*. This class is designed to work smoothly with the algorithms for intersecting sequences of iso-oriented boxes. For degeneracy handling, the boxes need to provide a unique *id*-number. The policy parameter *IdPolicy* offers several choices. The template parameters have to comply with the following requirements:

- *NT*: number type for the box boundaries, needs to be a model of the *Assignable* and the *LessThanComparable* concept.
- *int D*: the dimension of the box.
- *IdPolicy*: specifies how the *id*-number will be provided. Can be one of the following types, where *ID_EXPLICIT* is the default for this parameter:
  - *ID_NONE*: no *id*-number is provided. Can be useful if *Box_d* is used as a base class for a different implementation of *id*-numbers than the ones provided here.
  - *ID_EXPLICIT*: the *id*-number is stored explicitly in the box and automatically created and assigned at construction time of the box. Note that copying a box (copy-constructor and assignment) does not create a new *id*-number but keeps the old one, which is the behavior needed by the *CGAL::box_self_intersection* algorithm. This is therefore the safe default implementation.
  - *ID_FROM_BOX_ADDRESS*: casts the address of the box into a *std::ptrdiff_t* to create the *id*-number. Works fine if the intersection algorithms work effectively with pointers to boxes, but not in the case where the algorithms work with box values, because the algorithms modify the order of the boxes, and the *CGAL::box_self_intersection* algorithm creates copies of the boxes that would not have identical *id*-numbers.

#include <CGAL/Box_intersection_d/Box_d.h>
and also automatically with
#include <CGAL/box_intersection_d.h>

Is Model for the Concepts

BoxIntersectionBox_d . . . . page 3714

Types

Box_d<NT,int D,IdPolicy>:: NT	number type to represent the box boundaries. Allowed are the built-in types *int*, *unsigned int*, *float*, and *double*.
typedef std::size_t ID;	type for the box *id*-number.

Creation

Box_d<NT,int D,IdPolicy> box; — Default constructor. No particular initialization.

Box_d<NT,int D,IdPolicy> box(bool complete); — initializes to the complete or the empty space. If empty, all interval starting(end) points will be set to positive(negative) infinity.

Box_d<NT,int D,IdPolicy> box(NT lo[D], NT hi[D]);

initializes the box intervals to [*lo[i]*,*hi[i]*], $0 \leq i < D$.
Precondition: *lo[i]* $<$ *hi[i]* for $0 \leq i < D$.

Box_d<NT,int D,IdPolicy> box(Bbox_2 bbox); — constructs from bbox
Requirement: $D = 2$ and *NT*≡*double*.

Box_d<NT,int D,IdPolicy> box(Bbox_3 bbox); — constructs from bbox
Requirement: $D = 3$ and *NT*≡*double*.

Modifiers

void	*box.init(bool complete = false)*	initializes to the complete or the empty space. If empty, all interval starting(end) points will be set to positive(negative) infinity.
void	*box.extend(NT point[D])*	extend *box* to contain the old *box* and *point*.

Access Functions

int	*Box_d::dimension()*	returns *D*, the dimension of the box.
std::size_t	*box.id()*	returns a unique box id, see the *IdPolicy* template parameter above for the different choices. *Requirement*: *IdPolicy*≠*ID_NONE*
NT	*box.min_coord(int d) const*	returns the lower boundary in dimension *d* *Precondition*: $0 \leq d < D$
NT	*box.max_coord(int d) const*	returns the upper boundary in dimension *d* *Precondition*: $0 \leq d < D$
Bbox_2	*box.bbox() const*	returns the bounding box *Requirement*: $D = 2$ and *NT*≡*double*
Bbox_3	*box.bbox() const*	returns the bounding box *Requirement*: $D = 3$ and *NT*≡*double*
void	*box.extend(NT p[N])*	extends *box* to the smallest box that additionally contains the point represented by coordinates in *p*.

void *box.extend(std::pair<NT,NT> p[N])*

extends *box* to the smallest box that additionally contains the point represented by coordinate intervals in *p*.

Class

CGAL::Box_intersection_d::Box_traits_d<BoxHandle>

Definition

This is the default traits class for the intersection algorithms for iso-oriented boxes. There are actually three versions depending on the type of *BoxHandle*; there is one if *BoxHandle* is a class type and there are two if *BoxHandle* is a pointer type, one for a mutable and one for a const pointer, respectively.

This class implements the mapping from its *BoxHandle* argument to the *Box_parameter* type required in the *BoxIntersectionTraits_d* concept. In particular in the case where *BoxHandle* is a class type *B*, it defines *Box_parameter* to be of type *const B*&, while for the other cases it just uses the pointer type.

- *BoxHandle*: either a class type *B*, a pointer *B**, or a const-pointer *const B**, where *B* is a model of the *BoxIntersectionBox_d* concept.

#include <CGAL/Box_intersection_d/Box_traits_d.h> and also automatically with

CGAL::Box_intersection_d::Box_with_handle_d<NT, int D, Handle, IdPolicy>

Class

Definition

Box_with_handle_d<NT, int D, Handle, IdPolicy> is a generic iso-oriented bounding box in dimension *D* that stores additionally a handle to some underlying geometric object. It provides in each dimension an interval with lower and upper endpoints represented with the number type *NT*. This class is designed to work smoothly with the algorithms for intersecting sequences of iso-oriented boxes. For degeneracy handling, the boxes need to provide a unique *id*-number. The policy parameter *IdPolicy* offers several choices. The template parameters have to comply with the following requirements:

- *NT*: number type for the box boundaries, needs to be a model of the *Assignable* and the *LessThanComparable* concept.
- *int D*: the dimension of the box.
- *Handle* concept, e.g., a pointer, an iterator, or a circulator.
- *IdPolicy*: specifies how the *id*-number will be provided. Can be one of the following types, where *ID_EXPLICIT* is the default for this parameter:
  - *ID_NONE*: no *id*-number is provided. Can be useful to have this class as a base class for different implementations of *id*-numbers than the ones provided here.
  - *ID_EXPLICIT*: the *id*-number is stored explicitly in the box and automatically created and assigned at construction time of the box. Note that copying a box (copy-constructor and assignment) does not create a new *id*-number but keeps the old one, which is the behavior needed by the *CGAL::box_self_intersection* algorithm. This is therefore the safe default implementation.
  - *ID_FROM_BOX_ADDRESS*: casts the address of the box into a *std::ptrdiff_t* to create the *id*-number. Works fine if the intersection algorithms work effectively with pointers to boxes, but not in the case where the algorithms work with box values, because the algorithms modify the order of the boxes, and the *CGAL::box_self_intersection* algorithm creates copies of the boxes that would not have identical *id*-numbers.
  - *ID_FROM_HANDLE*: casts the address of the value of the handle into a *std::ptrdiff_t* to create the *id*-number. Works in many conceivable settings, e.g., it works with boxes copied by value or by pointer, and the self intersection test. It will not work if there is no one-to-one mapping between boxes and the geometry that is referred to with the handles, i.e., this *id*-number scheme fails if a geometric object creates several boxes with the same handle value. Note that this option is not available for the *CGAL::Box_intersection_d::Box_d* type that does not store a handle.

BoxIntersectionBox_d . . . . page 3714

Types

Box_with_handle_d<NT, int D, Handle, IdPolicy>:: NT

number type to represent the box boundaries. Allowed are the built-in types *int*, *unsigned int*, *float*, and *double*.

typedef std::size_t ID; type for the box *id*-number.

Creation

Box_with_handle_d<NT, int D, Handle, IdPolicy> box;

Default constructor. No particular initialization.

Box_with_handle_d<NT, int D, Handle, IdPolicy> box(bool complete, Handle h);

initializes to the complete or the empty space. If empty, all interval starting(end) points will be set to positive(negative) infinity, sets handle to *h*.

Box_with_handle_d<NT, int D, Handle, IdPolicy> box(NT lo[D], NT hi[D], Handle h);

initializes the box intervals to [*lo[i]*,*hi[i]*], $0 \leq i < D$ and sets the handle to *h*.
Precondition: *lo[i]* < *hi[i]* for $0 \leq i < D$.

Box_with_handle_d<NT, int D, Handle, IdPolicy> box(Bbox_2 bbox, Handle h);

constructs from bbox and sets the handle to *h*, exists iff $D = 2$ and *NT*≡*double*.

Box_with_handle_d<NT, int D, Handle, IdPolicy> box(Bbox_3 bbox, Handle h);

constructs from bbox and sets the handle to *h*, exists iff $D = 3$ and *NT*≡*double*.

Modifiers

void	*box.init(bool complete = false)*	initializes to the complete or the empty space. If empty, all interval starting(end) points will be set to positive(negative) infinity.
void	*box.extend(NT point[D])*	extend *box* to contain the old *box* and *point*.

Access Functions

Handle	*box.handle() const*	returns the handle stored in *box*.
int	*Box_with_handle_d::dimension()*	returns D, the dimension of the box.
std::size_t	*box.id()*	returns a unique box id, see the *IdPolicy* template parameter above for the different choices. Does not exist if *ID_NONE* has been chosen for the *IdPolicy*.
NT	*box.min_coord(int d) const*	returns the lower boundary in dimension d, $0 \leq d < D$.
NT	*box.max_coord(int d) const*	returns the upper boundary in dimension d, $0 \leq d < D$.
Bbox_2	*box.bbox() const*	returns the bounding box iff $D = 2$ and $NT \equiv double$.
Bbox_3	*box.bbox() const*	returns the bounding box iff $D = 3$ and $NT \equiv double$.

Chapter 64

3D Fast Intersection and Distance Computation (AABB Tree)

Pierre Alliez, Stéphane Tayeb, Camille Wormser

Contents

64.1 Introduction

The AABB tree component offers a static data structure and algorithms to perform efficient intersection and distance queries against sets of finite 3D geometric objects. The set of geometric objects stored in the data structure can be queried for intersection detection, intersection computation and distance. The intersection queries can be of any type, provided that the corresponding intersection predicates and constructors are implemented in the traits class. The distance queries are limited to point queries. Examples of intersection queries include line objects (rays, lines, segments) against sets of triangles, or plane objects (planes, triangles) against sets of segments. An example of a distance query consists of finding the closest point from a point query to a set of triangles.

Note that this component is not suited to the problem of finding all intersecting pairs of objects. We refer to the component *Box_intersection_d* (Intersecting Sequences of dD Iso-oriented Boxes) which can find all intersecting pairs of iso-oriented boxes.

The AABB tree data structure takes as input an iterator range of geometric data, which is then converted into primitives. From these primitives a hierarchy of axis-aligned bounding boxes (AABBs) is constructed and used to speed up intersection and distance queries (see Figure 64.1). Each primitive gives access to both one input geometric object (so-called datum) and one reference id to this object. A typical example primitive wraps a 3D triangle as datum and a face handle of a polyhedral surface as id. Each intersection query can return the intersection objects (e.g., 3D points or segments for ray queries) as well the as id (here the face handle) of the intersected primitives. Similarly, each distance query can return the closest point from the point query as well as the id of the closest primitive.

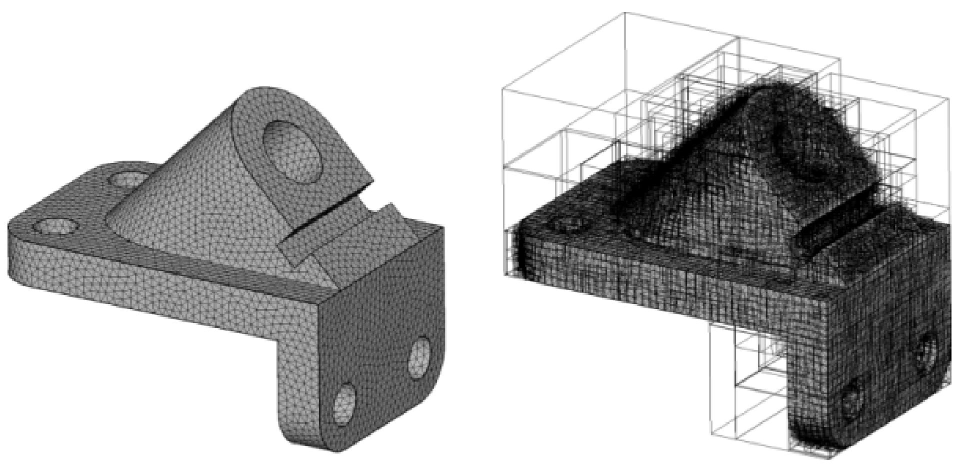

Figure 64.1: AABB tree. Left: surface triangle mesh of a mechanical part. Right: AABB tree constructed.

64.2 Interface

The main entry point to the component is the class *AABB_tree* which represents a static AABB tree constructed from an iterator range of geometric data. Once instantiated an AABB tree can be queried for intersection and distance queries.

Intersections. Assume for example that the tree contains triangle primitives. The tree can be queried for intersection against line objects (rays, segments or line) in various ways. We distinguish intersection *tests* which do not construct any intersection objects, from *intersections* which construct the intersection objects.

Tests:

- Function *do_intersect* tests if the input primitives are intersected by the query. This function is fast as it involves only predicates and stops after the first encountered intersection.
- Function *number_of_intersected_primitives* counts all intersected primitives.
- Function *all_intersected_primitives* enumerates all intersected primitives ids without constructing the corresponding intersection objects.
- Function *any_intersected_primitive* returns the first encountered intersecting primitive id (if any) without constructing the corresponding intersection object, and stops after the first encountered intersection. Note that the traversal order of the tree is such that first herein does not refer to any particular ordering of the intersections with respect to the query.

Constructions:

- Function *all_intersections* detects and constructs all intersection objects with the input primitives.
- Function *any_intersection* detects and constructs the first encountered intersection and constructs the corresponding object. This function is fast as it stops after the first encountered intersection.

Distance. An AABB tree computes the closest point from a given point query to the input primitives through the function *closest_point(query)*. In addition, it can compute the id of the closest primitive from a given point query through the function *closest_point_and_primitive(query)*, i.e., the id of the primitive which realizes the minimum distance from the point query. The AABB tree uses a secondary search structure to speed up the distance queries. The construction of this secondary structure should be requested by the user by a call to *accelerate_distance_queries* before the first the distance computation. This data structure is not generated by default because it is used only for distance computations.

64.3 Examples

64.3.1 Tree of Triangles, for Intersection and Distance Queries

In the following example a set of 3D triangles is stored in a list. The AABB primitive wraps a triangle as *datum* and an iterator in the list as *id*. We compute the number of input triangles intersected by a ray query, as well as the closest point and the squared distance from a point query.

```
#include <iostream>
#include <list>

#include <CGAL/Simple_cartesian.h>
#include <CGAL/AABB_tree.h>
#include <CGAL/AABB_traits.h>
#include <CGAL/AABB_triangle_primitive.h>

typedef CGAL::Simple_cartesian<double> K;

typedef K::FT FT;
```

```
typedef K::Ray_3 Ray;
typedef K::Line_3 Line;
typedef K::Point_3 Point;
typedef K::Triangle_3 Triangle;

typedef std::list<Triangle>::iterator Iterator;
typedef CGAL::AABB_triangle_primitive<K,Iterator> Primitive;
typedef CGAL::AABB_traits<K, Primitive> AABB_triangle_traits;
typedef CGAL::AABB_tree<AABB_triangle_traits> Tree;

int main()
{
    Point a(1.0, 0.0, 0.0);
    Point b(0.0, 1.0, 0.0);
    Point c(0.0, 0.0, 1.0);
    Point d(0.0, 0.0, 0.0);

    std::list<Triangle> triangles;
    triangles.push_back(Triangle(a,b,c));
    triangles.push_back(Triangle(a,b,d));
    triangles.push_back(Triangle(a,d,c));

    // constructs AABB tree
    Tree tree(triangles.begin(),triangles.end());

    // counts #intersections
    Ray ray_query(a,b);
    std::cout << tree.number_of_intersected_primitives(ray_query)
        << " intersections(s) with ray query" << std::endl;

    // compute closest point and squared distance
    Point point_query(2.0, 2.0, 2.0);
    Point closest_point = tree.closest_point(point_query);
    std::cerr << "closest point is: " << closest_point << std::endl;
    FT sqd = tree.squared_distance(point_query);
    std::cout << "squared distance: " << sqd << std::endl;

    return EXIT_SUCCESS;
}
```

File: examples/AABB_tree/AABB_triangle_3_example.cpp

64.3.2 Tree of Polyhedron Triangle Facets for Intersection Queries

In the following example the AABB primitive wraps a facet handle of a triangle polyhedral surface as *id* and the corresponding 3D triangle as geometric object. From a segment query we test the intersections, then compute the number of intersections, compute the first encountered intersection (generally a point), compute all intersections (where each intersection is a pair of one CGAL object and one primitive id - here a face handle) and compute all intersected primitives. The latter involves only tests and no predicates and is hence faster than computing all intersections. We also compute the first encountered intersection with a plane query, which is generally a segment.

```
#include <iostream>

#include <CGAL/Simple_cartesian.h>
#include <CGAL/AABB_tree.h>
#include <CGAL/AABB_traits.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/AABB_polyhedron_triangle_primitive.h>

typedef CGAL::Simple_cartesian<double> K;
typedef K::Point_3 Point;
typedef K::Plane_3 Plane;
typedef K::Vector_3 Vector;
typedef K::Segment_3 Segment;
typedef CGAL::Polyhedron_3<K> Polyhedron;
typedef CGAL::AABB_polyhedron_triangle_primitive<K,Polyhedron> Primitive;
typedef CGAL::AABB_traits<K, Primitive> Traits;
typedef CGAL::AABB_tree<Traits> Tree;
typedef Tree::Object_and_primitive_id Object_and_primitive_id;
typedef Tree::Primitive_id Primitive_id;

int main()
{
    Point p(1.0, 0.0, 0.0);
    Point q(0.0, 1.0, 0.0);
    Point r(0.0, 0.0, 1.0);
    Point s(0.0, 0.0, 0.0);
    Polyhedron polyhedron;
    polyhedron.make_tetrahedron(p, q, r, s);

    // constructs AABB tree
    Tree tree(polyhedron.facets_begin(),polyhedron.facets_end());

    // constructs segment query
    Point a(-0.2, 0.2, -0.2);
    Point b(1.3, 0.2, 1.3);
    Segment segment_query(a,b);

    // tests intersections with segment query
    if(tree.do_intersect(segment_query))
        std::cout << "intersection(s)" << std::endl;
    else
        std::cout << "no intersection" << std::endl;

    // computes #intersections with segment query
    std::cout << tree.number_of_intersected_primitives(segment_query)
        << " intersection(s)" << std::endl;

    // computes first encountered intersection with segment query
    // (generally a point)
    boost::optional<Object_and_primitive_id> intersection =
        tree.any_intersection(segment_query);
    if(intersection)
    {
```

```
        // gets intersection object
        Object_and_primitive_id op = *intersection;
        CGAL::Object object = op.first;
        Point point;
        if(CGAL::assign(point,object))
            std::cout << "intersection object is a point" << std::endl;
    }

    // computes all intersections with segment query (as pairs object -
   primitive_id)
    std::list<Object_and_primitive_id> intersections;
    tree.all_intersections(segment_query,
   std::back_inserter(intersections));

    // computes all intersected primitives with segment query as
   primitive ids
    std::list<Primitive_id> primitives;
    tree.all_intersected_primitives(segment_query,
   std::back_inserter(primitives));

    // constructs plane query
    Vector vec(0.0,0.0,1.0);
    Plane plane_query(a,vec);

    // computes first encountered intersection with plane query
    // (generally a segment)
    intersection = tree.any_intersection(plane_query);
    if(intersection)
    {
        // gets intersection object
        Object_and_primitive_id op = *intersection;
        CGAL::Object object = op.first;
        Segment segment;
        if(CGAL::assign(segment,object))
            std::cout << "intersection object is a segment" << std::endl;
    }

    return EXIT_SUCCESS;
}
```

File: examples/AABB_tree/AABB_polyhedron_facet_intersection_example.cpp

64.3.3 Tree of Polyhedron Triangle Facets for Distance Queries

In the following example the AABB primitive wraps a facet handle of a triangle polyhedral surface as *id* and the corresponding 3D triangle as geometric object. From a point query we compute the squared distance, the closest point as well as the closest point and primitive id. The latter returns a pair composed of a point and a face handle.

```
// Author(s) : Pierre Alliez
```

```
#include <iostream>

64.3.4 Tree of Segments for Intersection and Distance Queries

In the following example the segments are stored into a list, and the AABB primitive wraps a segment as *datum* and an iterator in the list as *id*. We compute the number of intersections with plane and triangles queries, and the closest point from a point query.

```
#include <iostream>
#include <list>

#include <CGAL/Simple_cartesian.h>
#include <CGAL/AABB_tree.h>
#include <CGAL/AABB_traits.h>
#include <CGAL/AABB_segment_primitive.h>

typedef CGAL::Simple_cartesian<double> K;

typedef K::FT FT;
typedef K::Point_3 Point;
typedef K::Plane_3 Plane;
typedef K::Segment_3 Segment;
typedef K::Triangle_3 Triangle;

64.3.5 Tree of Polyhedron Edge Segments for Intersection and Distance Queries

In the following example the AABB primitive wraps a halfedge handle as *id* and generates a 3D segment on the fly, each time its method *datum* is called. We compute the number of intersections with a triangle query and the closest point from a point query.

```
#include <iostream>

#include <CGAL/Simple_cartesian.h>
#include <CGAL/AABB_tree.h>
#include <CGAL/AABB_traits.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/AABB_polyhedron_segment_primitive.h>

typedef CGAL::Simple_cartesian<double> K;
typedef K::FT FT;
typedef K::Point_3 Point;
typedef K::Triangle_3 Triangle;
typedef CGAL::Polyhedron_3<K> Polyhedron;
typedef CGAL::AABB_polyhedron_segment_primitive<K,Polyhedron> Primitive;
typedef CGAL::AABB_traits<K, Primitive> Traits;
typedef CGAL::AABB_tree<Traits> Tree;

int main()
{
    Point p(1.0, 0.0, 0.0);
    Point q(0.0, 1.0, 0.0);
    Point r(0.0, 0.0, 1.0);
    Point s(0.0, 0.0, 0.0);
    Polyhedron polyhedron;
    polyhedron.make_tetrahedron(p, q, r, s);

    // constructs the AABB tree and the internal search tree for
```

```
    // efficient distance queries.
    Tree tree(polyhedron.edges_begin(),polyhedron.edges_end());
    tree.accelerate_distance_queries();

    // counts #intersections with a triangle query
    Triangle triangle_query(p,q,r);
    std::cout << tree.number_of_intersected_primitives(triangle_query)
        << " intersections(s) with triangle" << std::endl;

    // computes the closest point from a query point
    Point point_query(2.0, 2.0, 2.0);
    Point closest = tree.closest_point(point_query);

    std::cerr << "closest point is: " << closest << std::endl;
    return EXIT_SUCCESS;
}
```

File: examples/AABB_tree/AABB_polyhedron_edge_example.cpp

64.3.6 Incremental Insertion of Primitives

The AABB tree is a static data structure, but it allows to insert primitives, and will internally rebuild triggered by the first query, or because the user calls the *build* method. The following example illustrates this for two polyhedral surfaces.

```
#include <iostream>

#include <CGAL/Simple_cartesian.h>
#include <CGAL/AABB_tree.h>
#include <CGAL/AABB_traits.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/AABB_polyhedron_triangle_primitive.h>

typedef CGAL::Simple_cartesian<double> K;
typedef K::FT FT;
typedef K::Point_3 Point;
typedef K::Segment_3 Segment;
typedef CGAL::Polyhedron_3<K> Polyhedron;
typedef CGAL::AABB_polyhedron_triangle_primitive<K,Polyhedron> Primitive;
typedef CGAL::AABB_traits<K, Primitive> Traits;
typedef CGAL::AABB_tree<Traits> Tree;
typedef Tree::Object_and_primitive_id Object_and_primitive_id;
typedef Tree::Point_and_primitive_id Point_and_primitive_id;

int main()
{
    Point p(1.0, 0.0, 0.0);
    Point q(0.0, 1.0, 0.0);
    Point r(0.0, 0.0, 1.0);
    Point s(0.0, 0.0, 0.0);
    Polyhedron polyhedron1;
    polyhedron1.make_tetrahedron(p, q, r, s);
```

```
    Point p2(11.0, 0.0, 0.0);
    Point q2(10.0, 1.0, 0.0);
    Point r2(10.0, 0.0, 1.0);
    Point s2(10.0, 0.0, 0.0);
    Polyhedron polyhedron2;
    polyhedron2.make_tetrahedron(p2, q2, r2, s2);
    // constructs AABB tree and computes internal KD-tree
    // data structure to accelerate distance queries
    Tree tree(polyhedron1.facets_begin(),polyhedron1.facets_end());

    tree.accelerate_distance_queries();

    tree.insert(polyhedron2.facets_begin(),polyhedron2.facets_end());

    // query point
    Point query(0.0, 0.0, 3.0);

    // computes squared distance from query
    FT sqd = tree.squared_distance(query);
    std::cout << "squared distance: " << sqd << std::endl;

    return EXIT_SUCCESS;
}
```

File: examples/AABB_tree/AABB_insertion_example.cpp

64.3.7 Trees of Custom Primitives

The AABB tree example folder contains three examples of trees constructed with customize primitives. In *AABB_custom_example.cpp* the primitive contains triangles which are defined by three pointers to custom points. In *AABB_custom_triangle_soup_example.cpp* all input triangles are stored into a single array so as to form a triangle soup. The primitive internally uses a *boost::iterator_adaptor* so as to provide the three functions (*id()*, *datum()*, *reference_point()*) required by the primitive concept. In *AABB_custom_indexed_triangle_set_example.cpp* the input is an indexed triangle set stored through two arrays: one array of points and one array of indices which refer to the point array. Here also the primitive internally uses a *boost::iterator_adaptor*.

64.4 Performances

We provide some performance numbers for the case where the AABB tree contains a set of polyhedron triangle facets. We measure the tree construction time, the memory occupancy and the number of queries per second for a variety of intersection and distance queries. The machine used is a PC running Windows XP64 with an Intel CPU Core2 Extreme clocked at 3.06 GHz with 4GB of RAM. By default the kernel used is *Simple_cartesian< double>* (the fastest in our experiments). The program has been compiled with Visual C++ 2005 compiler with the O2 option which maximizes speed.

64.4.1 Construction

The surface triangle mesh chosen for benchmarking the tree construction is the knot model (14,400 triangles) depicted by Figure 64.4.3. We measure the tree construction time (both AABB tree alone and AABB tree with internal KD-tree) for this model as well as for three denser versions subdivided through the Loop subdivision scheme which multiplies the number of triangles by four.

Number of triangles	Construction (in ms)	Construction with internal KD-tree (in ms)
14,400	156	157
57,600	328	328
230,400	1,141	1,437
921,600	4,813	5,953

64.4.2 Memory

When using the polyhedron triangle facet primitive (defined in *AABB_polyhedron_triangle_primitive.h*) the AABB tree occupies approximately 61 bytes per primitive (without constructing the internal KD-tree). It increases to approximately 150 bytes per primitive when constructing the internal KD-tree with one reference point per primitive (the default mode when calling the function *tree.accelerate_distance_queries()*). Note that the polyhedron facet primitive primitive stores only one facet handle as primitive id and computes on the fly a 3D triangle from the facet handle stored internally. When explicitly storing a 3D triangle in the primitive the tree occupies approximately 140 bytes per primitive instead of 60 (without constructing the internal KD-tree).

The following table provides orders of memory occupancy in MBytes for an increasing number of triangles. As the internal KD-tree used to accelerate the distance queries dominates the memory occupancy, we recommend to specify for large models a lower number of reference point (evenly distributed) to construct the internal KD-tree through the function *tree.accelerate_distance_queries(begin,end)* which takes an iterator range as input.

Number of triangles	AABB tree (in MBytes)	AABB tree with internal KD-tree (in MBytes)
18,400	1.10	2.76
102,400	6.33	14.73
1,022,400	59.56	151.31
1,822,400	108.34	291.84

64.4.3 Intersections

The following table measures the number of intersection queries per second on the 14,400 triangle version of the knot mesh model for ray, line, segment and plane queries. Each ray query is generated by choosing a random source point within the mesh bounding box and a random vector. A line or segment query is generated by choosing two random points inside the bounding box. A plane query is generated by picking a random point inside the bounding box and a random normal vector. Note that a plane query generally intersects many triangles of the input surface mesh. This explains the low performance numbers for the intersection functions which enumerate all intersections.

Function	Segment	Ray	Line	Plane
do_intersect()	187,868	185,649	206,096	377,969
any_intersected_primitive()	190,684	190,027	208,941	360,337
any_intersection()	147,468	143,230	148,235	229,336
number_of_intersected_primitives()	64,389	52,943	54,559	7,906
all_intersected_primitives()	65,553	54,838	53,183	5,693
all_intersections()	46,507	38,471	36,374	2,644

Curve 64.4.3 plots the number of queries per second (here the *all_intersections* function with random segment queries) against the number of input triangles for the knot triangle surface mesh.

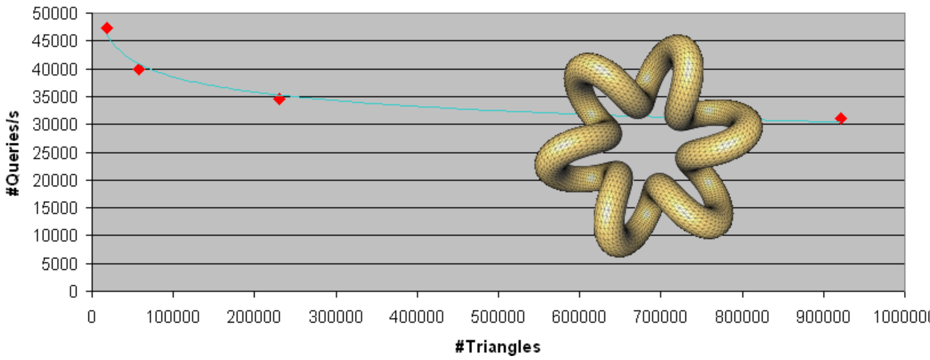

Figure 64.2: Number of queries per second against number of triangles for the knot model with 14K (shown), 57K, 230K and 921K triangles. We call the *all_intersections* function with segment queries randomly chosen within the bounding box.

The following table measures the number of *all_intersections()* queries per second against several kernels. We use the 14,400 triangle version of the knot mesh model for random segment queries. Note how the *Simple_cartesian* kernel is substantially faster than the *Cartesian* kernel.

Kernel	Queries/s (all_intersections() with segment queries)
Simple_cartesian<double>	46,507
Simple_cartesian<float>	43,187
Cartesian<double>	5,335
Cartesian<float>	5,522
Exact_predicates_inexact_constructions	18,411

64.4.4 Distances

The surface triangle mesh chosen for benchmarking distances is again the knot model in four increasing resolutions obtained through Loop subdivision. In the following table we first measure the tree construction time (which includes the construction of the internal KD-tree data structure used to accelerate the distance queries by up to one order of magnitude in our experiments). We then measure the number of queries per second for the three types distance queries (*closest_point*, *squared_distance* and *closest_point_and_primitive*) from point queries randomly chosen inside the bounding box.

Nb triangles	Construction (ms)	Closest_point()	squared_distance()	closest_point_and_primitive()
14,400	157	45,132	45,626	45,770
57,600	328	21,589	21,312	21,137
230,400	1,437	11,063	10,962	11,086
921,600	5,953	5,636	5,722	5,703

64.4.5 Summary

The experiments described above are neither exhaustive nor conclusive as we have chosen one specific case where the input primitives are the facets of a triangle surface polyhedron. Nevertheless we now provide some general observations and advices about how to put the AABB tree to use with satisfactory performances. While the tree construction times and memory occupancy do not fluctuate much in our experiments depending on the input surface triangle mesh, the performance expressed in number of queries varies greatly depending on a complex combination of criteria: type of kernel, number of input primitives, distribution of primitives in space, type of function queried, type of query and location of query in space.

- Kernel: The type of CGAL kernel turns out to dominate the final execution times, the maximum performances being obtained with the simple Cartesian kernel parameterized with the double precision number type. In applications where the intersection and distance execution times are crucial it is possible to use this kernel for the AABB tree in combination with a more robust kernel for the main data structure.
- Primitives: Although the number of input primitives plays an obvious role in the final performance, their distribution in space is at least equally important in order to obtain a well-balanced AABB tree. Ideally the primitives must be evenly distributed in space and the long primitives spanning the bounding box of the tree root node must be avoided as much as possible. It is often beneficial to split these long primitives into smaller ones before constructing the tree, e.g., through recursive longest edge bisection for triangle surface meshes.
- Function: The type of function queried plays another important role. Obviously the "exhaustive" functions, which list all intersections, are slower than the ones stopping after the first intersection. Within each of these functions the ones which call only intersection tests (do_intersect(), number_of_intersected_primitives(), any_intersected_primitive(), all_intersected_primitives()) are faster than the ones which explicitly construct the intersections (any_intersection() and all_intersections()).
- Query: The type of query (e.g., line, ray, segment or plane used above) plays another role, strongly correlated with the type of function (exhaustive or not, and whether or not it constructs the intersections). When all intersection constructions are needed, the final execution times highly depend on the complexity of the general intersection object. For example a plane query generally intersects a surface triangle mesh into many segments while a segment query generally intersects a surface triangle mesh into few points. Finally, the location of the query in space also plays an obvious role in the performances, especially for the distance queries. Assuming the internal KD-tree constructed through the function *tree.accelerate_distance_queries()*, it is preferable to specify a query point already close to the surface triangle mesh so that the query traverses only few AABBs of the tree. For a large number of primitive data (greater than 2M faces in our experiments) however we noticed that it is not necessary (and sometimes even slower) to use all reference points when constructing the KD-tree. In these cases we recommend to specify trough the function *tree.accelerate_distance_queries(begin,end)* fewer reference points (typically not more than 100K) evenly distributed over the input primitives.

64.5 Implementation Details

The AABB tree construction is initialized by computing the AABB of the whole set of input primitives. All primitives are then sorted along the longest coordinate axis of this box, and the primitives are separated into two equal size sets. This procedure is applied recursively until an AABB contains a single primitive. The tree is leafless as presented in OPCODE [Ter05]. An intersection query traverses the tree by computing intersection tests only with respect to the AABBs during traversal, and with respect to the input primitives at the end of traversal (in the leafs of the tree).

The reference id is not used internally but simply used by the AABB tree to refer to the primitive in the results provided to the user. It follows that, while in most cases each reference id corresponds to a unique primitive, this is not a requirement of the component. This way a user may use these reference ids as labels, each of them being shared by several geometric object.

A distance query between a query point q and the input primitives is turned into a *ball* query centered at q. The ball traverses the tree while recursively querying intersections with the AABBs, and computes the closest point p from the query point to the input primitives at the leafs of the tree. The ball radius is then shrunk to the distance between p and q for all remaining recursive traversals of the tree. Efficiency is achieved through setting the initial ball radius to a small value still guaranteed to intersect the input primitives. This is achieved by constructing through the function *accelerate_distance_queries* an internal secondary data structure which provides a good hint to the algorithm at the beginning of the traversal.

64.6 Design and Implementation History

Camille Wormser and Pierre Alliez started working on a data structure for efficient collision detection in 2007. The generic design for implementing both intersection and distance queries, and for generic queries and primitives was developed by Camille Wormser. In 2009, Pierre Alliez, Stéphane Tayeb and Camille Wormser made the implementation CGAL-compliant, with the help of Laurent Rineau for optimizing the tree construction. The authors wish to thank Andreas Fabri, Jane Tournois, Mariette Yvinec and Sylvain Lefèbvre for helpful comments and discussions.

3D Fast Intersection and Distance Computation (AABB Tree) Reference Manual

64.7 Classified Reference Pages

Concepts

Classes

64.8 Alphabetical List of Reference Pages

Class

CGAL::AABB_tree<AT>

Definition

Class *AABB_tree<AT>* is a static data structure for efficient intersection and distance computations in 3D. It builds a hierarchy of axis-aligned bounding boxes (an AABB tree) from a set of 3D geometric objects, and can receive intersection and distance queries, provided that the corresponding predicates are implemented in the traits class AT. The template parameter AT stands for a traits class which must be a model of the concept *AABBTraits*.

#include <CGAL/AABB_tree.h>

Types

AABB_tree<AT>:: size_type;		Unsigned integral size type.
typedef AT::FT	*FT;*	Number type returned by the distance queries.
typedef AT::Point_3	*Point;*	Type of 3D point.
typedef AT::Primitive	*Primitive;*	Type of input primitive.
typedef AT::Bounding_box	*Bounding_box;*	Type of bounding box.
typedef std::pair<Point, Primitive::Id>	*Point_and_primitive_id;*	
typedef std::pair<CGAL::Object, Primitive::Id>	*Object_and_primitive_id;*	

Creation

AABB_tree<AT> tree; Constructs an empty tree.

template < class InputIterator>
AABB_tree<AT> tree(InputIterator begin, InputIterator beyond);

Builds the AABB tree data structure. Type *InputIterator* can be any const iterator such that *Primitive* has a constructor taking a *InputIterator* as argument. The tree stays empty if the memory allocation is not successful.

Operations

template < class InputIterator>
void *tree.rebuild(InputIterator begin, InputIterator beyond)*

Clears the current tree and rebuilds it from scratch. See constructor above for the parameters.

void *tree.clear()* Clears the AABB tree.

template <class InputIterator>
void *tree.insert(InputIterator begin, InputIterator beyond)*

Add a sequence of primitives to the set of primitive of the AABB tree. Type *InputIterator* can be any const iterator such that *Primitive* has a constructor taking an InputIterator as argument.

void *tree.insert(const Primitive p)*

Add a primitive to the set of primitives of the AABB tree.

advanced

void *tree.build()* After one or more calls to *insert*, the internal data structure of *AABB_tree<AT>* must be reconstructed. This procedure has a complexity of *O(n log(n))*, where n is the number of primitives of the tree. This procedure is called implicitly at the first call to a query member function. You can call *build()* explicitly to ensure that the next call to query functions will not trigger the reconstruction of the data structure.

advanced

Bounding_box *tree.bbox() const* Returns the axis-aligned bounding box of the whole tree.
size_type *tree.size() const* Returns the number of primitives in the tree.
bool *tree.empty() const* Returns *true*, iff tree contains no primitive.

Intersection Tests

template <class Query>
bool *tree.do_intersect(Query query) const*

Returns *true*, iff the query intersects at least one of the input primitives. Type *Query* must be a type for which *do_intersect* predicates are defined in the *AT* class.

template <class Query>
size_type *tree.number_of_intersected_primitives(Query query) const*

Returns the number of primitives intersected by the query. Type *Query* must be a type for which *do_intersect* predicates are defined in the *AT* class.

template <class Query, class OutputIterator>
OutputIterator *tree.all_intersected_primitives(Query query, OutputIterator out) const*

Outputs to the iterator the list of all intersected primitives ids. This function does not compute the intersection points and is hence faster than the function *all_intersections* function below. Type *Query* must be a type for which *do_intersect* predicates are defined in the *AT* class.

template <class Query>

boost::optional<Primitive::Id>

tree.any_intersected_primitive(Query query) const

Returns the first encountered intersected primitive id, iff the query intersects at least one of the input primitives. No particular order is guaranteed over the tree traversal, such that, e.g, the primitive returned is not necessarily the closest from the source point of a ray query. Type *Query* must be a type for which *do_intersect* predicates are defined in the *AT* class.

Intersections

template <class Query, class OutputIterator>
OutputIterator *tree.all_intersections(Query query, OutputIterator out) const*

Outputs to the iterator the list of all intersections between the query and input data, as objects of type *Object_and_primitive_id*. Type *Query* must be a type for which *do_intersect* predicates and intersections are defined in the *AT* class.

template <class Query>
boost::optional<Object_and_primitive_id>

tree.any_intersection(Query query) const

Returns the first encountered intersection, iff the query intersects at least one of the input primitives. No particular order is guaranteed over the tree traversal, such that, e.g, the primitive returned is not necessarily the closest from the source point of a ray query. Type *Query* must be a type for which *do_intersect* predicates and intersections are defined in the *AT* class.

Distance Queries

FT *tree.squared_distance(Point query) const*

Returns the minimum squared distance between the query point and all input primitives. Method *accelerate_distance_queries* should be called before the first distance query, so that an internal secondary search structure is build, for improving performance.

Point *tree.closest_point(Point query) const*

Returns the point in the union of all input primitives which is closest to the query. In case there are several closest points, one arbitrarily chosen closest point is returned. Method *accelerate_distance_queries* should be called before the first distance query, so that an internal secondary search structure is build, for improving performance.

Point_and_primitive_id

tree.closest_point_and_primitive(Point query) const

Returns a *Point_and_primitive_id* which realizes the smallest distance between the query point and all input primitives. Method *accelerate_distance_queries* should be called before the first distance query, so that an internal secondary search structure is build, for improving performance.

Accelerating the Distance Queries

bool *tree.accelerate_distance_queries() const*

Constructs an internal data structure for accelerating distance queries. This method should be called once, before the first distance query. Returns *true*, iff the memory allocation is successful.

advanced

In the following paragraphs, we discuss details of the implementation of the distance queries. We explain the internal use of hints, how the user can pass his own hints to the tree, and how the user can influence the construction of the secondary data structure used for accelerating distance queries.

Internally, the distance queries algorithms are initialized with some hint, which has the same type as the return type of the query, and this value is refined along a traversal of the tree, until it is optimal, that is to say until it realizes the shortest distance to the primitives. In particular, the exact specification of these internal algorithms is that they minimize the distance to the object composed of the union of the primitives and the hint.

It follows that

- in order to return the exact distance to the set of primitives, the algorithms need the hint to be exactly on the primitives;
- if this is not the case, and if the hint happens to be closer to the query point than any of the primitives, then the hint is returned.

This second observation is reasonable, in the sense that providing a hint to the algorithm means claiming that this hint belongs to the union of the primitives. These considerations about the hints being exactly on the primitives or not are important: in the case where the set of primitives is a triangle soup, and if some of the primitives are large, one may want to provide a much better hint than a vertex of the triangle soup could be. It could be, for example, the barycenter of one of the triangles. But, except with the use of an exact constructions kernel, one cannot easily construct points other than the vertices, that lie exactly on a triangle soup. Hence, providing a good hint sometimes means not being able to provide it exactly on the primitives. In rare occasions, this hint can be returned as the closest point.

In order to accelerate distance queries significantly, the AABB tree builds an internal KD-tree containing a set of potential hints, when the method *accelerate_distance_queries* is called. This KD-tree provides very good hints that allow the algorithms to run much faster than with a default hint (such as the *reference_point* of the first primitive). The set of potential hints is a sampling of the union of the primitives, which is obtained, by default, by calling the method *reference_point* of each of the primitives. However, such a sampling with one point per primitive may not be the most relevant one: if some primitives are very large, it helps inserting more than one sample on them. Conversely, a sparser sampling with less than one point per input primitive is relevant in some cases.

For this reason, the user can provide his own set of sample points:

template <class InputIterator>
bool *tree.accelerate_distance_queries(InputIterator begin, InputIterator beyond) const*

Constructs an internal KD-tree containing the specified point set, to be used as the set of potential hints for accelerating the distance queries. *InputIterator* is an iterator with value type *Point_and_primitive_id*.

Note that, in some cases, the user is not able to provide ids of the primitives on which the points lie. In these cases, providing a default value for the ids of the hints is possible. Still, the user should be aware that if she uses the *closest_point_and_primitive* method, there is a (tiny) chance that a hint is returned, along with this default value as corresponding primitive id. Hence, the validity of the returned primitive id should be checked in these cases.

As an alternative to using the KD-tree, the user can also provide the hints directly, by using the following methods:

FT *tree.squared_distance(Point query, Point hint) const*

Returns the minimum squared distance between the query point and all input primitives. The internal KD-tree is not used.

Point *tree.closest_point(Point query, Point hint) const*

Returns the point in the union of all input primitives which is closest to the query. In case there are several closest points, one arbitrarily chosen closest point is returned. The internal KD-tree is not used.

Point_and_primitive_id

tree.closest_point_and_primitive(Point query, Point_and_primitive_id hint) const

Returns a *Point_and_primitive_id* which realizes the smallest distance between the query point and all input primitives. The internal KD-tree is not used.

AABBGeomTraits

Concept

Definition

The concept AABBGeomTraits defines the requirements for the first template parameter of the class *AABB_traits<GeomTraits, Primitive>*. It provides predicates and constructors to detect and compute intersections between query objects and the primitives stored in the AABB tree. In addition, it contains predicates and constructors to compute distances between a point query and the primitives stored in the AABB tree.

Types

AABBGeomTraits:: Bbox_3	Bounding box type.
AABBGeomTraits:: Sphere_3	Sphere type, that should be consistent with the distance function chosen for the distance queries, namely the *Squared_distance_3* functor.
AABBGeomTraits:: Point_3	Point type.
AABBGeomTraits:: Do_intersect_3	A functor object to detect intersections between two geometric objects. Provides the operators: *bool operator()(const Type_1& type_1, const Type_2& type_2);* where *Type_1* and *Type_2* are relevant types among *Ray_3*, *Segment_3*, *Line_3*, *Triangle_3*, *Plane_3* and *Bbox_3*. Relevant herein means that a line primitive (ray, segment, line) is tested against a planar or solid primitive (plane, triangle, box), and a solid primitive is tested against another solid primitive (box against box). The operator returns *true* iff *type_1* and *type_2* have a non empty intersection.
AABBGeomTraits:: Intersect_3	A functor object to construct the intersection between two geometric objects. Provides the operators: *CGAL::Object operator()(const Type_1& type_1, const Type_2& type_2);* where *Type_1* and *Type_2* are any relevant types among *Ray_3*, *Segment_3*, *Line_3*, *Triangle_3*, *Plane_3* and *Bbox_3*. Relevant herein means that a line primitive (ray, segment, line) is tested against a planar or solid primitive (plane, triangle, box). The operator computes a *CGAL::Object* which is the intersection between the objects *type_1* and *type_2*.
AABBGeomTraits:: Construct_sphere_3	A functor object to construct the sphere centered at one point and passing through another one. Provides the operator: *Sphere_3 operator()(const Point_3& p, const Point_3 & q);* which returns the sphere centered at *p* and passing through *q*.
AABBGeomTraits:: Compute_closest_point_3	A functor object to compute the point on a geometric primitive which is closest from a query. Provides the operator: *Point_3 operator()(const Point_3& p, const Type_2& type_2);* where *Type_2* is any type among *Segment_3* and *Triangle_3*. The operator returns the point on *type_2* which is closest to *p*.

AABBGeomTraits:: Has_on_bounded_side_3 A functor object to detect if a point lies inside a sphere or not. Provides the operator: *bool operator()(const Sphere_3& s, const Point_3& p);* which returns *true* iff the closed volume bounded by *s* contains *p*.

AABBGeomTraits:: Compute_squared_radius_3

A functor object to compute the squared radius of a sphere. Provides the operator: *FT operator()(const Sphere_3& s);* which returns the squared radius of *s*.

Creation

Operations

Do_intersect_3 *geomtraits.do_intersect_3_object()*

Returns the intersection detection functor.

Intersect_3 *geomtraits.intersect_3_object()*

Returns the intersection constructor.

Construct_sphere_3 *geomtraits.construct_sphere_3_object()*

Returns the distance comparison functor.

Compute_closest_point_3

geomtraits.compute_closest_point_3_object()

Returns the closest point constructor.

Has_on_bounded_side_3

geomtraits.has_on_bounded_side_3_object()

Returns the closest point constructor.

Compute_squared_radius_3

geomtraits.compute_squared_radius_3_object()

Returns the squared radius functor.

Has Models

Any instantiation of *CGAL::Kernel* is a model of this traits concept.

AABB_traits<GeomTraits,AABBPrimitive>.

Concept

AABBPrimitive

Definition

The concept AABBPrimitive describes the requirements for the primitives stored in the AABB tree data structure. The concept encapsulates a type for the input datum (a geometric object) and an identifier (id) type through which those primitives are referred to. The concept AABBPrimitive also refines the concepts DefaultConstructible and Assignable.

Types

AABBPrimitive:: Point	3D point type.
AABBPrimitive:: Datum	Type of input datum.
AABBPrimitive:: Id	Type of identifiers through which the input objects are referred to. It must be a model of the concepts DefaultConstructible and Assignable.

Operations

Datum	*primitive.datum()*	Returns the datum (geometric object) represented by the primitive.
Id	*primitive.id()*	Returns the corresponding identifier. This identifier is only used as a reference for the objects in the output of the *AABB_tree* methods.
Point	*primitive.reference_point()*	Returns a 3D point located on the geometric object represented by the primitive. This function is used to sort the primitives during the AABB tree construction as well as to construct the search KD-tree internal to the AABB tree used to accelerate distance queries.

See Also

AABB_tree<AT>

Example

The *Primitive* type can be, e.g., a wrapper around a *Handle*. Assume for instance that the input objects are the triangle faces of a mesh stored as a *CGAL::Polyhedron*. The *Datum* would be a *Triangle_3* and the *Id* would be a polyhedron *Face_handle*. Method *datum()* can return either a *Triangle_3* constructed on the fly from the face handle or a *Triangle_3* stored internally. This provides a way for the user to trade memory for efficiency.

Has Models

AABB_polyhedron_triangle_primitive<GeomTraits,Polyhedron>,
AABB_polyhedron_segment_primitive<GeomTraits,Polyhedron>.

Class

CGAL::AABB_polyhedron_triangle_primitive<GeomTraits,Polyhedron>

Definition

The class *AABB_polyhedron_triangle_primitive<GeomTraits,Polyhedron>* is a model of the concept *AABBPrimitive*. It wraps a facet handle of a polyhedron, which is used as id, and allows the construction of the datum on the fly. Since only the facet handle is stored in this primitive, the polyhedron from which the AABB tree is built should not be deleted while the AABB tree is in use.

Parameters

The template parameter *GeomTraits* provides a *Point_3* type, used as *Point*, and a *Triangle_3* type, used as *Datum* and constructible from three arguments of type *Point*. The template parameter *Polyhedron* should be a *CGAL::Polyhedron* whose points have type *Point*.

#include <CGAL/AABB_polyhedron_triangle_primitive.h>

Types

typedef GeomTraits::Triangle_3 *Datum;*	Geometric data type.
typedef Polyhedron::Facet_handle *Id;*	Id type.

Class

Definition

The class *AABB_polyhedron_segment_primitive<GeomTraits,Polyhedron>* is a model of the concept *AABBPrimitive*. It wraps a halfedge handle of a polyhedron, which is used as id, and allows the construction of the datum on the fly. Since only the halfedge handle is stored in this primitive, the polyhedron from which the AABB tree is built should not be deleted while the AABB tree is in use.

Parameters

The template parameter *GeomTraits* provides a *Point_3* type, used as *Point*, and a *Segment_3* type, used as *Datum* and constructible from two arguments of type *Point*. The template parameter *Polyhedron* should be a *CGAL::Polyhedron* whose points have type *Point*.

#include <CGAL/AABB_polyhedron_segment_primitive.h>

Types

typedef GeomTraits::Segment_3 *Datum;*	Geometric data type.
typedef Polyhedron::Halfedge_handle *Id;*	Id type.

AABBTraits

Definition

The concept AABBTraits provides the geometric primitive types and methods for the class *AABB_tree<AT>*.

Types

AABBTraits:: FT — Value type of the *Squared_distance* functor.

AABBTraits:: Point_3 — Type of a 3D point.

AABBTraits:: Primitive — Type of primitive. Must be a model of the concept *AABBPrimitive*.

AABBTraits:: Bounding_box — Bounding box type.

AABBTraits:: enum Axis { X_AXIS, Y_AXIS, Z_AXIS }

typedef std::pair<Point_3, Primitive::Id>

Point_and_primitive_id;

typedef std::pair<Object, Primitive::Id>

Object_and_primitive_id;

During the construction of the *AABB_tree*, the primitives are sorted according to some comparison functions related to the x, y or z coordinate axis:

AABBTraits:: Split_primitives_along_x_axis — A functor object to split a range of primitives into two sub-ranges along the X-axis. Provides the operator: *void operator()(InputIterator first, InputIterator beyond);* Iterator *InputIterator* must be a model of RandomAccessIterator and have *Primitive* as value type. The operator is used for determining the primitives assigned to the two children nodes of a given node, assuming that the goal is to split the X-dimension of the bounding box of the node. The primitives assigned to this node are passed as argument to the operator. It should modify the iterator range in such a way that its first half and its second half correspond to the two children nodes.

AABBTraits:: Split_primitives_along_y_axis — A functor object to split a range of primitives into two sub-ranges along the Y-axis. See *Split_primitives_along_x_axis* for the detailed description.

AABBTraits:: Split_primitives_along_z_axis — A functor object to split a range of primitives into two sub-ranges along the Z-axis. See *Split_primitives_along_x_axis* for the detailed description.

AABBTraits:: Compute_bbox — A functor object to compute the bounding box of a set of primitives. Provides the operator: *Bounding_box operator()(Input_iterator begin, Input_iterator beyond);* Iterator *InputIterator* must have *Primitive* as value type.

AABBTraits:: Splitting_direction — A functor object to specify the direction along which the bounding box should be split: *Axis operator()(const Bounding_box& bbox);* which returns the direction used for splitting *bbox*. It is usually the axis aligned with the longest edge of *bbox*.

The following predicates are required for each type *Query* for which the class *AABB_tree<AT>* may receive an intersection detection or computation query.

AABBTraits:: Do_intersect — A functor object to compute intersection predicates between the query and the nodes of the tree. Provides the operators: *bool operator()(const Query & q, const Bounding_box & box);* which returns *true* iff the query intersects the bounding box, and *bool operator()(const Query & q, const Primitive & primitive);* which returns *true* iff the query intersects the primitive.

AABBTraits:: Intersect — A functor object to compute the intersection of a query and a primitive. Provides the operator: *boost::optional<Object_and_primitive_id> operator()(const Query & q, const Primitive& primitive);* which returns the intersection as a pair composed of an object and a primitive id, iff the query intersects the primitive.

The following predicates are required for each type *Query* for which the class *AABB_tree<AT>* may receive a distance query.

AABBTraits:: Compare_distance — A functor object to compute distance comparisons between the query and the nodes of the tree. Provides the operators: *bool operator()(const Query & query, const Bounding_box& box, const Point & closest);* which returns *true* iff the bounding box is closer to *query* than *closest* is, and *bool operator()(const Query & query, const Primitive & primitive, const Point & closest);* which returns *true* iff *primitive* is closer to the *query* than *closest* is.

AABBTraits:: Closest_point — A functor object to compute closest point from the query on a primitive. Provides the operator: *Point_3 operator()(const Query& query, const Primitive& primitive, const Point_3 & closest);* which returns the closest point to *query*, among *closest* and all points of the primitive.

AABBTraits:: Squared_distance — A functor object to compute the squared distance between the query and a point. Provides the operator: *FT operator()(const Query& query, const Point_3 & p);* which returns the squared distance between *query* and *p*.

Operations

Split_primitives_along_x_axis

traits.split_primitives_along_x_axis_object()

Returns the primitive splitting functor for the X axis.

Split_primitives_along_y_axis

traits.split_primitives_along_y_axis_object()

Returns the primitive splitting functor for the Y axis.

Split_primitives_along_z_axis

traits.split_primitives_along_z_axis_object()

Returns the primitive splitting functor for the Z axis.

Compute_bbox *traits.compute_bbox_object()*

Returns the bounding box constructor.

Do_intersect *traits.do_intersect_object()*

Returns the intersection detection functor.

Intersect *traits.intersect_object()*

Returns the intersection constructor.

Compare_distance *traits.compare_distance_object()*

Returns the distance comparison functor.

Closest_point *traits.closest_point_object()*

Returns the closest point constructor.

Has Models

CGAL::AABB_traits<GeomTraits,Primitive>

Definition

The class *AABB_traits<GeomTraits,Primitive>* is a model of the concept *AABBTraits*. This traits class handles any type of 3D geometric primitives provided that the proper intersection tests and constructions are implemented. It handles points, rays, lines and segments as query types for intersection detection and computations, and it handles points as query type for distance queries.

Parameters

The template parameter *GeomTraits* provides the geometric types as well as the intersection tests and computations required. This type must be a model of the concept *AABBGeomTraits*. The template parameter *Primitive* provides the type of primitives stored in the AABB tree. This parameter must be a model of the concept *AABBPrimitive*.

#include <CGAL/AABB_traits.h>

Types

typedef GeomTraits::Point_3

Point_3; — Point query type.

typedef GeomTraits::Ray_3

Ray_3; — Ray query type.

typedef GeomTraits::Line_3

Line_3; — Line query type.

typedef GeomTraits::Segment_3

Segment_3; — Segment query type.

AABB_traits<GeomTraits,Primitive>:: size_type

Unsigned integral type.

AABB_traits<GeomTraits,Primitive> traits(GeomTraits gt = GeomTraits());

Default constructor.

Chapter 65

Spatial Sorting

Christophe Delage and Olivier Devillers

Contents

65.1 Introduction

Many geometric algorithms implemented in CGAL are incremental, and thus their speed is dependent on the order of insertion. This package provides sorting algorithms that may considerably improve running times of such algorithms.

The rationale is to sort objects along a space-filling curve so that two objects close geometrically will be close in the insertion order with high probability. That way, parts of a data structure that will be looked at during an insertion will probably have been looked at in a recent insertion, and thus probably will be in cache memory instead of main memory. As another side-effect, these sorting functions usually improve memory locality of the data structures produced by incremental algorithms, sometimes leading to speed ups in other algorithm using these data structures.

Some algorithms have a good complexity under randomized hypotheses which contradicts the idea of sorting the input using any sorting criterion. In such a case, it is possible to introduce just a bit of randomness to be able to combine the good randomized complexity and the good effects of locality [ACR03].

The predicates used by this package are comparisons between coordinates, thus there is no robustness issue involved here, for example to choose the arithmetic of the kernel.

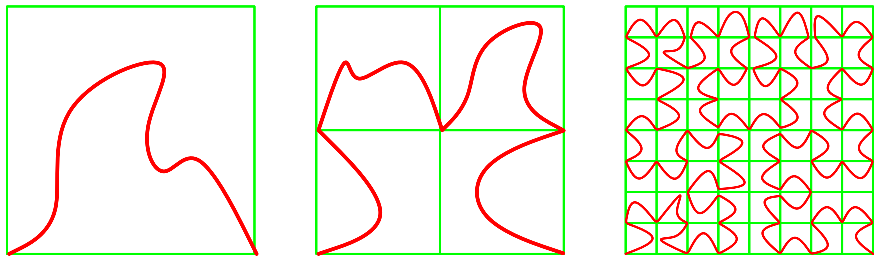

Figure 65.1: Hilbert mapping

65.2 Hilbert Sorting

In 2D, one can construct a space filling curve, that is a mapping f of $[0,1]$ to the unit square $[0,1]^2$, such that $f(0) = (0,0)$ and $f(1) = (1,0)$ in the following way: the unit square is subdivided in four such that

$f([0,\frac{1}{4}]) = [0,\frac{1}{2}]^2$, $f([\frac{1}{4},\frac{1}{2}]) = [0,\frac{1}{2}] \times [\frac{1}{2},1]$, $f([\frac{1}{2},\frac{3}{4}]) = [\frac{1}{2},1]^2$, and $f([\frac{3}{4},1]) = [\frac{1}{2},1] \times [0,\frac{1}{2}]$.
$f(\frac{1}{4}) = (0,\frac{1}{2})$
$f(\frac{1}{2}) = (\frac{1}{2},\frac{1}{2})$, and $f(\frac{3}{4}) = (1,\frac{1}{2})$.

Then each square is subdivided in the same way recursively. Figure 65.1 illustrates this process.

Now given a set of 2D points, they can be sorted in the order they have on such a space filling curve as illustrated in Figure 65.2 :

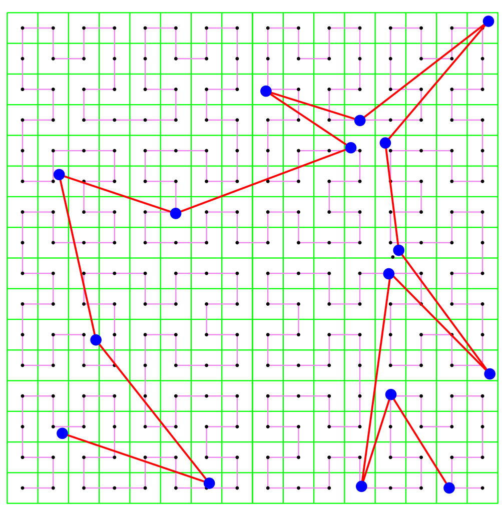

Figure 65.2: Hilbert sort with middle policy

65.2.1 Examples

The code to use Hilbert sort is as simple as the following example:

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/hilbert_sort.h>
#include <iostream>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2                                          Point;
typedef CGAL::Creator_uniform_2<double,Point>               Creator;

int main ()
{
  std::size_t size = 16;
  std::vector<Point> v; v.reserve(size);
  CGAL::points_on_square_grid_2(3.0, size,           // generate points
                               std::back_inserter(v), Creator());

  CGAL::hilbert_sort (v.begin(), v.end());           // sort

  for(std::size_t i=0; i<size; ++i)std::cout<<v[i]<<std::endl;//output
  return 0;
}
```

File: `examples/Spatial_sorting/hilbert.cpp`

If instead of subdividing the square in a fixed way at its middle point, as above, we subdivide it by splitting at the median point (in x or y directions alternating), we construct a 2-d tree adapted to the point set. This tree can be visited in a similar manner and we get also a suitable ordering of the points (see Figure 65.3).

CGAL provides Hilbert sorting for points in 2D, 3D and higher dimensions, in the middle and the median policies.

The middle policy is easier to analyze, and is interesting in practice for well distributed set of points in small dimension (if the number of points is really smaller than 2^d). The median policy should be prefered for high dimension or if the point set distribution is not regular (or unknown). Since the median policy cannot be much worse than the middle policy, while the converse can happen, the median policy is the default behavior. Most theoretical results are using the middle policy [ACR03, But71, BG89, PB89].

This other example illustrates the use of the two different policies

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/hilbert_sort.h>
#include <iostream>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2                                          Point;

int main ()
```

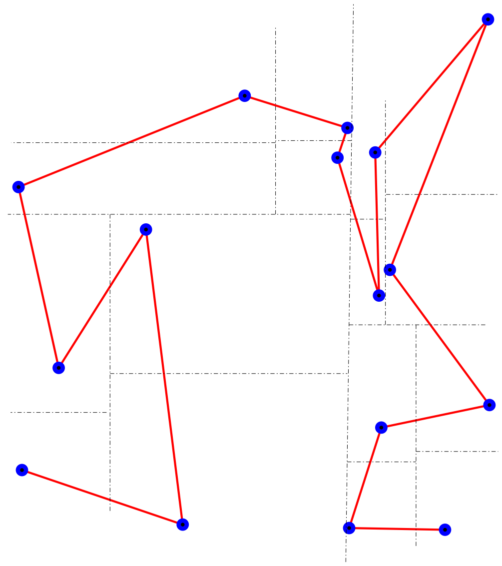

Figure 65.3: Hilbert sort with median policy

```
{
  std::vector<Point> v; v.reserve(4);
  v.push_back( Point(0.0,0.0)) ;
  v.push_back( Point(1.0,1.0)) ;
  v.push_back( Point(0.1,0.1)) ;
  v.push_back( Point(0.2,0.8)) ;

  std::cout << "Hilbert sort (middle policy)." << std::endl;
  CGAL::hilbert_sort (v.begin(), v.end(),
   CGAL::Hilbert_sort_middle_policy());
  std::cout<<v[0]<<"; "<<v[1]<<"; "<<v[2]<<"; "<<v[3]<<"; "<<std::endl;
  std::cout << "Hilbert sort (median policy)." << std::endl;
  CGAL::hilbert_sort (v.begin(), v.end(),
   CGAL::Hilbert_sort_median_policy());
  std::cout<<v[0]<<"; "<<v[1]<<"; "<<v[2]<<"; "<<v[3]<<"; "<<std::endl;
  return 0;
}
```

File: `examples/Spatial_sorting/hilbert_policies.cpp`

65.3 Spatial Sorting

Hilbert sort cannot be used directly before feeding a randomized algorithm. Thus, the trick is to organize the point set in random buckets of increasing sizes, Hilbert sort being used only inside a bucket.

It has been proved, in the context of Delaunay triangulation, that such an order provides enough randomness to combine the advantages of a random order and a space filling curve order [ACR03].

CGAL provides spatial sorting for points in 2D, 3D and higher dimensions, with the middle and the median policies for Hilbert sort in the buckets.

65.3.1 Basic Example

The following example shows that, on particular input, spatial sort runs much faster than a bad order or than Hilbert sort (below results with release mode compilation on a 1.8GHz processor).

```
$ ./small_example_delaunay_2
10000 points on a parabola
  Delaunay without spatial sort...        done in 6.33443 seconds.
  Delaunay with median hilbert sort...    done in 0.822975 seconds.
  Delaunay with median spatial sort...    done in 0.022415 seconds.
```

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/spatial_sort.h>
#include <CGAL/Timer.h>
#include <iostream>
#include <vector>
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Delaunay_triangulation_2<K> DT;
void compute_delaunay(std::vector<K::Point_2>::iterator it,
                      std::vector<K::Point_2>::iterator e){
    DT dt;
    DT::Face_handle hint;
    for( ;it!=e; ++it)  hint = dt.insert(*it, hint)->face();
}
int main ()
{   int size = 1000;
    std::vector<K::Point_2> v;
    v.reserve(size);
    CGAL::Timer cost;
    std::cout <<size<< " points on a parabola" << std::endl;
    for (int i=0; i< size; ++i) {
      double x= -size +i;
      v.push_back( K::Point_2( x, x*x ));
    }
    cost.reset();cost.start();
    std::cout << "  Delaunay without spatial sort... "<< std::flush;
    compute_delaunay(v.begin(),v.end());cost.stop();
    std::cout << "done in "<<cost.time()<<" seconds." << std::endl;
    cost.reset();cost.start();
    std::cout << "  Delaunay with Hilbert sort...    " << std::flush;
    CGAL::hilbert_sort(v.begin(),v.end());
    compute_delaunay(v.begin(),v.end());cost.stop();
    std::cout << "done in "<<cost.time()<<" seconds." << std::endl;
    cost.reset();cost.start();
    std::cout << "  Delaunay with spatial sort...    " << std::flush;
    CGAL::spatial_sort(v.begin(),v.end());
    compute_delaunay(v.begin(),v.end());cost.stop();
    std::cout << "done in "<<cost.time()<<" seconds." << std::endl;
```

```
    return 0;
}
```

File: examples/Spatial_sorting/small_example_delaunay_2.cpp

65.3.2 Using Your Own Point Type

If you want to sort points of your own point type, you only have to provide functors that compare the *x* and *y* coordinates of your points. Note that in case you simply want to associate an extra information to your point you might consider the example of Section 65.3.3 as an alternative.

```
#include <CGAL/spatial_sort.h>

struct MyPoint {
  double x,y;
  int color;
  MyPoint()
    : x(0), y(0),color(0)
  {}

  MyPoint(double x, double y, int color=0)
    : x(x), y(y), color(color)
  {}
};

struct MyLessX {

  bool operator()(const MyPoint& p, const MyPoint& q) const
  {
    return p.x < q.x;
  }

};

struct MyLessY {

  bool operator()(const MyPoint& p, const MyPoint& q) const
  {
    return p.y < q.y;
  }

};

struct MySpatialSortingTraits {

  typedef MyPoint Point_2;

  typedef MyLessX Less_x_2;
  typedef MyLessY Less_y_2;

  Less_x_2 less_x_2_object() const
```

```
  {
    return Less_x_2();
  }

  Less_y_2 less_y_2_object() const
  {
    return Less_y_2();
  }
};

int main()
{
  std::vector< MyPoint > points;

  points.push_back(MyPoint(14,12, 3));
  points.push_back(MyPoint(1,2  , 0));
  points.push_back(MyPoint(414,2, 5));
  points.push_back(MyPoint(4,21 , 1));
  points.push_back(MyPoint(7,74 , 2));
  points.push_back(MyPoint(74,4 , 4));

  MySpatialSortingTraits sst;
  CGAL::spatial_sort(points.begin(), points.end(), sst);

  for (std::vector< MyPoint >::iterator
   it=points.begin();it!=points.end();++it)
    std::cout << it->color << " ";
  std::cout << "\n";

  std::cerr << "done" << std::endl;
  return 0;
}
```

File: examples/Spatial_sorting/myPoint.cpp

65.3.3 Sorting Arbitrary Types

The spatial sorting traits class provides a point type and functors for comparing, for example, the *x*-coordinates of two points. If you want to sort something else than just points, for example a sequence of tuples containing a point, or a sequence of indices in a vector of points, you need another level of indirection. We provide the spatial sorting traits class adapters which are templated by another spatial sorting traits class, and a property map. which allows to obtain a point from whatever you want to sort.

The following examples illustrate the usage of these traits class adapters.

Sorting Using Pairs of Points and Integers

In this example program, the sorted sequence of points is retrieved using a vector of pairs of points and integers.

```
#include <CGAL/Simple_cartesian.h>
```

```
#include <CGAL/spatial_sort.h>
#include <CGAL/Spatial_sort_traits_adapter_2.h>
#include <vector>

typedef CGAL::Simple_cartesian<double>       Kernel;
typedef Kernel::Point_2                      Point_2;
typedef std::pair<Point_2,int>               Point_with_info;
typedef std::vector< Point_with_info >       Data_vector;

//property map
struct First_of_pair{
  //classical typedefs
  typedef Point_with_info key_type;
  typedef Point_2 value_type;
  typedef const Point_2& reference;
  typedef boost::readable_property_map_tag category;
};
//get function for property map
First_of_pair::reference
get(const First_of_pair&, const First_of_pair::key_type& k) {
  return k.first;
}

typedef CGAL::Spatial_sort_traits_adapter_2<Kernel,First_of_pair>
    Search_traits_2;

int main()
{
  Data_vector points;
  points.push_back(std::make_pair(Point_2(14,12) , 3));
  points.push_back(std::make_pair(Point_2(1,2)   , 0));
  points.push_back(std::make_pair(Point_2(414,2) , 5));
  points.push_back(std::make_pair(Point_2(4,21)  , 1));
  points.push_back(std::make_pair(Point_2(7,74)  , 2));
  points.push_back(std::make_pair(Point_2(74,4)  , 4));

  Search_traits_2 traits;
  CGAL::spatial_sort(points.begin(), points.end(), traits);
  for (Data_vector::iterator it=points.begin();it!=points.end();++it)
    std::cout << it->second << " ";
  std::cout << "\n";

  std::cout << "done" << std::endl;

  return 0;
}
```

File: examples/Spatial_sorting/sp_sort_using_property_map_2.cpp

Sorting Using Indices of Points

In this example program, the sorted sequence of points is retrieved using the indices of the points in a vector of points.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/spatial_sort.h>
#include <CGAL/Spatial_sort_traits_adapter_3.h>
#include <vector>
#include <boost/iterator/counting_iterator.hpp>

typedef CGAL::Simple_cartesian<double>                        Kernel;
typedef Kernel::Point_3                                       Point_3;
//using a pointer as a special property map type
typedef
  CGAL::Spatial_sort_traits_adapter_3<Kernel,Point_3*>   Search_traits_3;

int main()
{
  std::vector<Point_3> points;
  points.push_back(Point_3(1,3,11));
  points.push_back(Point_3(14,34,46));
  points.push_back(Point_3(414,34,4));
  points.push_back(Point_3(4,2,56));
  points.push_back(Point_3(744,4154,43));
  points.push_back(Point_3(74,44,1));

  std::vector<std::ptrdiff_t> indices;
  indices.reserve(points.size());

  std::copy(boost::counting_iterator<std::ptrdiff_t>(0),
            boost::counting_iterator<std::ptrdiff_t>(points.size()),
            std::back_inserter(indices));

  CGAL::spatial_sort(
   indices.begin(),indices.end(),Search_traits_3(&(points[0])) );

  for (std::vector<std::ptrdiff_t>::iterator
   it=indices.begin();it!=indices.end();++it)
    std::cout << points[*it] << "\n";

  std::cout << "done" << std::endl;

  return 0;
}
```

Sorting Using Indices of Pairs of Points and Integers

In this example program, the sorted sequence of points is retrieved using the indices of the points in a vector of pairs of points and integers.

```
#include <CGAL/Cartesian_d.h>
#include <CGAL/spatial_sort.h>
#include <CGAL/Spatial_sort_traits_adapter_d.h>
#include <boost/iterator/counting_iterator.hpp>
#include <vector>

typedef CGAL::Cartesian_d<double>          Kernel;
typedef Kernel::Point_d                    Point_d;
typedef std::pair<Point_d,int>             Point_with_info;
typedef std::vector< Point_with_info >     Data_vector;

//property map and get as friend
// to be allowed to use private member
class Vect_ppmap{
  const Data_vector& points;
public:
  //classical typedefs
  typedef Data_vector::size_type key_type;
  typedef Point_d value_type;
  typedef const value_type& reference;
  typedef boost::readable_property_map_tag category;

  Vect_ppmap(const Data_vector& points_):points(points_){}

  friend reference get(const Vect_ppmap& vmap, key_type i) {
    return vmap.points[i].first;
  }
};

typedef CGAL::Spatial_sort_traits_adapter_d<Kernel,Vect_ppmap>
   Search_traits_d;

int main()
{
  double coords[] ={ 1.0, 1.0, 1.0, 1.0,
                     2.0, 2.0, 2.0, 2.0 };

  Data_vector points;
  points.push_back(std::make_pair(Point_d(4,coords  ,coords+4) , 1));
  points.push_back(std::make_pair(Point_d(4,coords+4,coords+8) , 2));

  std::vector<Vect_ppmap::key_type> indices;
  indices.reserve(points.size());

  std::copy(
    boost::counting_iterator<Vect_ppmap::key_type>(0),
    boost::counting_iterator<Vect_ppmap::key_type>(points.size()),
    std::back_inserter(indices) );

  CGAL::spatial_sort(
    indices.begin(),
    indices.end(),
    Search_traits_d(Vect_ppmap(points)) );
```

```
  std::vector<Vect_ppmap::key_type>::iterator it=indices.begin();
  for (;it!=indices.end();++it)
    std::cout << points[*it].second << " ";
  std::cout << std::endl;

  std::cout << "done" << std::endl;

  return 0;
}
```

CGAL::spatial_sort

Function

Definition

The function *spatial_sort* sorts an iterator range of points in a way that improves space locality. Two points close in the order will be close geometrically, and two points close geometrically will have a high probability of being close in the order.

#include <CGAL/spatial_sort.h>

```
template <class RandomAccessIterator, class Traits, class PolicyTag>
void              spatial_sort( RandomAccessIterator begin,
                                RandomAccessIterator end,
                                Traits traits = Default_traits,
                                PolicyTag policy = Default_policy,
                                std::ptrdiff_t threshold_hilbert=default,
                                std::ptrdiff_t threshold_multiscale=default,
                                double ratio=default)
```

sorts the range [*begin*,*end*) in place.

The default traits class *Default_traits* is the kernel in which the type *RandomAccessIterator::value_type* is defined.

The default policy is *Hilbert_sort_median_policy()* and the other option is *Hilbert_sort_middle_policy()*.

The default values for the thresholds and the ratio depends on the dimension.

Requirements

1. *RandomAccessIterator::value_type* is convertible to *Traits::Point_2*, *Traits::Point_3*, or *Traits::Point_d*.
2. *Traits* is a model for concept *SpatialSortingTraits_2*, *SpatialSortingTraits_3*, or *SpatialSortingTraits_d*.

Implementation

Creates an instance of *Multiscale_sort<Hilbert_sort>* where *Hilbert_sort* is an Hilbert sorting object, and calls its *operator()*.

The *threshold_hilbert* is the minimal size of a point set to be subdivided recursively during Hilbert sorting, otherwise random order is used. The *threshold_multiscale* value is the minimal size for a sample to call Hilbert sort, otherwise random order is used. The *ratio* value is used to split the original set in two subsets, spatial sort is applied on the first subset of size *ratio* times the original size of the set, Hilbert sort is applied on the second subset.

CGAL::hilbert_sort

Definition

The function *hilbert_sort* sorts an iterator range of points along a Hilbert curve.

#include <CGAL/hilbert_sort.h>

template <class RandomAccessIterator, class Traits, class PolicyTag>
void hilbert_sort(RandomAccessIterator begin,
RandomAccessIterator end,
Traits traits = Default_traits,
PolicyTag policy = Default_policy)

sorts the range [*begin*,*end*) in place.

The default traits class *Default_traits* is the kernel in which the type *RandomAccessIterator::value_type* is defined. The default policy is *Hilbert_sort_median_policy()* and the other option is *Hilbert_sort_middle_policy()*.

Requirements

1. *RandomAccessIterator::value_type* is convertible to *Traits::Point_2*, *Traits::Point_3*, or *Traits::Point_d*.
2. *Traits* is a model for concept *SpatialSortingTraits_2*, *SpatialSortingTraits_3*, or *SpatialSortingTraits_d*.

Implementation

Creates an instance of *Hilbert_sort_2<Traits, PolicyTag>*, *Hilbert_sort_3<Traits, PolicyTag>*, or *Hilbert_sort_d<Traits, PolicyTag>* and calls its *operator()*.

SpatialSortingTraits_2

Concept

Definition

All 2D spatial sorting algorithms provided in CGAL are parameterized by a traits class *Traits*, which defines the primitives (objects and predicates) that the sorting algorithms use. SpatialSortingTraits_2 defines the complete set of primitives required in these functions and functors.

Types

SpatialSortingTraits_2:: Point_2 — The point type on which the sorting algorithms operate.

SpatialSortingTraits_2:: Compute_x_2

Functor object type returning the x coordinate of a *Point_2*. Must provide *FT operator()(Point_2 p)* where *FT* can be used as argument of *CGAL::to_double*.

SpatialSortingTraits_2:: Compute_y_2

Functor object type returning the y coordinate of a *Point_2*. Must provide *FT operator()(Point_2 p)* where *FT* can be used as argument of *CGAL::to_double*.

SpatialSortingTraits_2:: Less_x_2 — Binary predicate object type comparing *Point_2*s along the x coordinate. Must provide *bool operator()(Point_2 p, Point_2 q)* where *true* is returned iff $p_x < q_x$, where p_x and q_x denote x coordinate of point p and q, respectively.

SpatialSortingTraits_2:: Less_y_2 — Binary predicate object type comparing *Point_2*s along the y coordinate. Must provide *bool operator()(Point_2 p, Point_2 q)* where *true* is returned iff $p_y < q_y$, where p_y and q_y denote y coordinate of point p and q, respectively.

Creation

Only a copy constructor is required.

SpatialSortingTraits_2 traits(t);

Operations

The following member functions to create instances of the above predicate object types must exist.

Compute_x_2	*traits.compute_x_2_object()*
Compute_y_2	*traits.compute_y_2_object()*
Less_x_2	*traits.less_x_2_object()*
Less_y_2	*traits.less_y_2_object()*

Has Models

Any CGAL kernel.
CGAL::Spatial_sort_traits_adapter_2<Base_traits,PointPropertyMap>.

CGAL::Hilbert_sort_2<Traits, PolicyTag>

Functor
Class

Definition

The function object *Hilbert_sort_2<Traits, PolicyTag>* sorts iterator ranges of *Traits::Point_2* along a Hilbert curve by recursively subdividing at the median or the middle depending on the *PolicyTag*.

Requirements

Traits is a model for *SpatialSortingTraits*.

Creation

Hilbert_sort_2<Traits, PolicyTag> o(const Traits &traits = Traits());

constructs an instance with *traits* as traits class instance.

Operations

template <class RandomAccessIterator>
void *o.operator()(RandomAccessIterator begin, RandomAccessIterator end) const*

sorts the range [*begin*, *end*).
Requirement: *RandomAccessIterator::value_type* equals to *Traits::Point_2*.

SpatialSortingTraits_3

Definition

All 3D spatial sorting algorithms provided in CGAL are parameterized by a traits class *Traits*, which defines the primitives (objects and predicates) that the sorting algorithms use. SpatialSortingTraits_3 defines the complete set of primitives required in these functions and functors.

Types

SpatialSortingTraits_3:: Point_3 — The point type on which the sorting algorithms operate.

SpatialSortingTraits_3:: Compute_x_3

Functor object type returning the x coordinate of a *Point_3*. Must provide *FT operator()(Point_3 p)* where *FT* can be used as argument of *CGAL::to_double*.

SpatialSortingTraits_3:: Compute_y_3

Functor object type returning the y coordinate of a *Point_3*. Must provide *FT operator()(Point_3 p)* where *FT* can be used as argument of *CGAL::to_double*.

SpatialSortingTraits_3:: Compute_z_3

Functor object type returning the z coordinate of a *Point_3*. Must provide *FT operator()(Point_3 p)* where *FT* can be used as argument of *CGAL::to_double*.

SpatialSortingTraits_3:: Less_x_3 — Binary predicate object type comparing *Point_3*s along the x coordinate. Must provide *bool operator()(Point_3 p, Point_3 q)* where *true* is returned iff $p_x < q_x$, where p_x and q_x denote x coordinate of point p and q, respectively.

SpatialSortingTraits_3:: Less_y_3 — Binary predicate object type comparing *Point_3*s along the y coordinate. Must provide *bool operator()(Point_3 p, Point_3 q)* where *true* is returned iff $p_y < q_y$, where p_y and q_y denote y coordinate of point p and q, respectively.

SpatialSortingTraits_3:: Less_z_3 — Binary predicate object type comparing *Point_3*s along the z coordinate. Must provide *bool operator()(Point_3 p, Point_3 q)* where *true* is returned iff $p_z < q_z$, where p_z and q_z denote z coordinate of point p and q, respectively.

Creation

Only a copy constructor is required.

SpatialSortingTraits_3 traits(t);

Operations

The following member functions to create instances of the above predicate object types must exist.

Compute_x_3	*traits.compute_x_3_object()*
Compute_y_3	*traits.compute_y_3_object()*
Compute_z_3	*traits.compute_z_3_object()*
Less_x_3	*traits.less_x_3_object()*
Less_y_3	*traits.less_y_3_object()*
Less_z_3	*traits.less_z_3_object()*

Has Models

Any CGAL kernel.
CGAL::Spatial_sort_traits_adapter_3<Base_traits,PointPropertyMap>.

Functor
Class

CGAL::Hilbert_sort_3<Traits, PolicyTag>

Definition

The function object *Hilbert_sort_3<Traits, PolicyTag>* sorts iterator ranges of *Traits::Point_3* along a Hilbert curve by recursively subdividing at the median or the middle depending on the *PolicyTag*.

Requirements

Traits is a model for *SpatialSortingTraits_3*.

Creation

Hilbert_sort_3<Traits, PolicyTag> o(const Traits &traits = Traits());

constructs an instance with *traits* as traits class instance.

Operations

template <class RandomAccessIterator>
void *o.operator()(RandomAccessIterator begin, RandomAccessIterator end) const*

sorts the range [*begin*, *end*).
Requirement: *RandomAccessIterator::value_type* equals to *Traits::Point_3*.

SpatialSortingTraits_d

Definition

All higher dimensional spatial sorting algorithms provided in CGAL are parameterized by a traits class *Traits*, which defines the primitives (objects and predicates) that the sorting algorithms use. SpatialSortingTraits_d defines the complete set of primitives required in these functions and functors.

Types

SpatialSortingTraits_d:: Point_d — The point type on which the sorting algorithms operate.

SpatialSortingTraits_d:: Point_dimension_d — Functor object type returning the dimension of a *Point_d*. Must provide *int operator()(Point_d p)* returning the dimension of p.

SpatialSortingTraits_d:: Compute_coordinate_d

Functor object type returning the coordinates of a *Point_d*. Must provide *FT operator()(Point_d p, int i)* returning the ith coordinate of p. *FT* is a type that can be used as argument of *CGAL::to_double*.

SpatialSortingTraits_d:: Less_coordinate_d — Binary predicate object type comparing *Point_d*s along some coordinate. Must provide *bool operator()(Point_d p, Point_d q, int i)* where *true* is returned iff $p_i < q_i$, where p_i and q_i denote ith coordinate of point p and q, respectively.

Creation

Only a copy constructor is required.

SpatialSortingTraits_d traits(t);

Operations

The following member functions to create instances of the above predicate object types must exist.

Point_dimension_d — *traits.point_dimension_d_object()*

Compute_coordinate_d

traits.compute_coordinate_d_object()

Less_coordinate_d — *traits.less_coordinate_d_object()*

Has Models

Any CGAL d dimensional kernel.
CGAL::Spatial_sort_traits_adapter_d<Base_traits,PointPropertyMap>.

Functor Class

CGAL::Hilbert_sort_d<Traits, PolicyTag>

Definition

The function object *Hilbert_sort_d<Traits, PolicyTag>* sorts iterator ranges of *Traits::Point_d* along a Hilbert curve by recursively subdividing at the median or the middle depending on the *PolicyTag*.

Requirements

Traits is a model for *SpatialSortingTraits_d*.

Creation

Hilbert_sort_d<Traits, PolicyTag> o(const Traits &traits = Traits());

constructs an instance with *traits* as traits class instance.

Operations

template <class RandomAccessIterator>
void *o.operator()(RandomAccessIterator begin, RandomAccessIterator end) const*

sorts the range [*begin*, *end*).
Requirement: *RandomAccessIterator::value_type* equals to *Traits::Point_d*.

CGAL::Multiscale_sort<Sort>

Functor
Class

Definition

The class *Multiscale_sort<Sort>* represents a sorting algorithm adaptor. Given a range of n points:

1. it applies *Sort* on the last $(1-ratio) \times n$ points,
2. it recurses on the first $ratio \times n$ points, stopping when there are less than *threshold* points.

Creation

Multiscale_sort<Sort> o(const Sort &sort = Sort(), std::ptrdiff_t threshold = 1, double ratio = 0.5);

constructs an instance with *traits* as traits class instance.

Operations

template <class RandomAccessIterator>
void *o.operator()(RandomAccessIterator begin, RandomAccessIterator end) const*

sorts the range [*begin*, *end*).
Requirement: *Sort::operator()(RandomAccessIterator begin, RandomAccessIterator end)* is defined.

Class

CGAL::Median

Definition

Median is a tag class. It can be used to parameterize a strategy policy in order to specify the strategy for spatial sorting. *Hilbert_policy<Median>* can be passed to as parameter to *hilbert_sort* to choose the sorting policy.

CGAL::Spatial_sort_traits_adapter_2<Base_traits,PointPropertyMap>

Class

Definition

Given a property map associating a key to a point, the class *Spatial_sort_traits_adapter_2<Base_traits,PointPropertyMap>* induces a spatial reorder of the keys instead of the points, the comparisons being done on the associated points. In other words, the traits provides to a spatial sort algorithm a point type which is a key, while the actual point type is *Base_traits::Point_2*.

Requirements

Base_traits is a model for *SpatialSortingTraits_2*. *PointPropertyMap* is a model of boost::ReadablePropertyMap with *Base_traits::Point_2* as *value_type*.

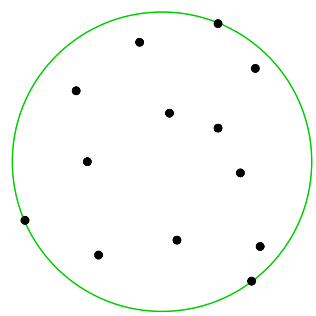
Part XIV

Geometric Optimization

Chapter 66

Bounding Volumes

Kaspar Fischer, Bernd Gärtner, Thomas Herrmann, Michael Hoffmann, and Sven Schönherr



This chapter describes algorithms which for a given point set compute the "best" circumscribing object from a specific class. If the class consists of all spheres in d-dimensional Euclidean space and "best" is defined as having smallest radius, then we obtain the smallest enclosing sphere problem already mentioned above.

In the following example a smallest enclosing circle (*CGAL::Min_circle_2<Traits>*) is constructed from points on a line and written to standard output. The example shows that it is advisable to switch on random shuffling in order to deal with a 'bad' order of the input points.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Min_circle_2.h>
#include <CGAL/Min_circle_2_traits_2.h>
#include <iostream>

// typedefs
typedef  CGAL::Exact_predicates_exact_constructions_kernel K;
typedef  CGAL::Min_circle_2_traits_2<K>  Traits;
typedef  CGAL::Min_circle_2<Traits>      Min_circle;

typedef  K::Point_2                      Point;

int
main( int, char**)
{
    const int n = 100;
    Point P[n];
```

```
    for ( int i = 0; i < n; ++i)
        P[ i] = Point( (i%2 == 0 ? i : -i), 0);
    // (0,0), (-1,0), (2,0), (-3,0), ...

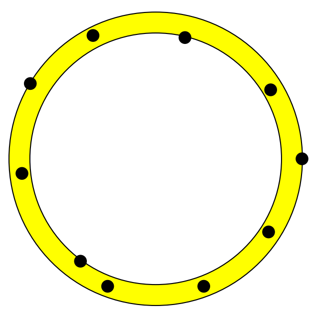
    Min_circle  mc1( P, P+n, false);    // very slow
    Min_circle  mc2( P, P+n, true);     // fast

    CGAL::set_pretty_mode( std::cout);
    std::cout << mc2;

    return 0;
}
```

File: examples/Min_circle_2/min_circle_2.cpp

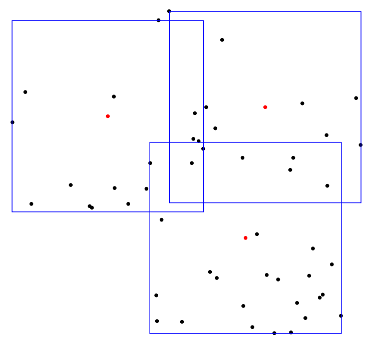
Other classes for which we provide solutions are ellipses (*CGAL::Min_ellipse_2<Traits>*), rectangles (*CGAL::min_rectangle_2*), parallelograms (*CGAL::min_parallelogram_2*) and strips (*CGAL::min_strip_2*) in the plane, with appropriate optimality criteria. For arbitrary dimensions we provide smallest enclosing spheres for points (*CGAL::Min_sphere_d<Traits>*) and spheres for spheres (*CGAL::Min_sphere_of_spheres_d<Traits>*), smallest enclosing annuli (*CGAL::Min_annulus_d<Traits>*), and approximate minimum-volume enclosing ellipsoid with user-specified approximation ratio (*CGAL::Approximate_min_ellipsoid_d<Traits>*).



Bounding volumes can be used to obtain simple approximations of complicated objects. For example, consider the problem of deciding whether two moving polygons currently intersect. An obvious solution is to discretize time and perform a full intersection test for any time step. If the polygons are far apart most of the time, this is unnecessary. Instead, simple bounding volumes (for examples, circles) are computed for both polygons at their initial positions. At subsequent time steps, an intersection test between the moving bounding circles replaces the actual intersection test; only if the circles do intersect, the expensive intersection test between the polygons is performed. In practice, bounding volume hierarchies are often used on top of simple bounding volumes to approximate complicated objects more accurately.

Bounding volumes are also frequently applied to extract geometric properties of objects. For example, the smallest enclosing annulus of a point set can be used to test whether a set of points is approximately cospherical. Here, the width of the annulus (or its area, or still another criterion that we use) is a good measure for this property. The largest area triangle is for example used in heuristics for matching archaeological aerial photographs. Largest perimeter triangles are used in scoring cross country soaring flights, where the goal is basically to fly as far as possible, but still return to the departure airfield. To score simply based on the total distance flown is not a good measure, since circling in thermals allows to increase it easily.

Bounding volumes also define geometric “center points” of objects. For example, if two objects are to be matched (approximately), one approch is to first apply the translation that maps the centers of their smallest enclosing spheres onto each other. Simpler centers are possible, of course (center of gravity, center of bounding box), but more advanced bounding volumes might give better results in some cases. It can also make sense to consider several center points instead of just one. For example, we provide algorithms to cover a planar point set with between two and four minimal boxes (*CGAL::rectangular_p_center_2*). Below is an example covering with three boxes; the center points are shown in red.



Bounded Volumes Reference Manual

Kaspar Fischer, Bernd Gärtner, Thomas Herrmann, Michael Hoffmann, and Sven Schönherr

This chapter describes concepts, classes, and functions for bounding areas and volumes.

These are Smallest enclosing circle and ellipse (2D), smallest enclosing rectangle, parallelogram, and strip (2D), rectangular p-center (2D), smallest enclosing sphere and annulus (dD), approximate minimum-volume enclosing ellipsoid with user-specified approximation ratio (dD).

Assertions

The optimization code uses infix *OPTIMISATION* in the assertions, e.g. defining the compiler flag *CGAL_OPTIMISATION_NO_PRECONDITIONS* switches precondition checking off, cf. Section 2.8.

CGAL::Min_circle_2<Traits>

Definition

An object of the class *Min_circle_2<Traits>* is the unique circle of smallest area enclosing a finite (multi)set of points in two-dimensional Euclidean space $\mathbb{E}^2$. For a point set P we denote by $mc(P)$ the smallest circle that contains all points of P. Note that $mc(P)$ can be degenerate, i.e. $mc(P) = \emptyset$ if $P = \emptyset$ and $mc(P) = \{p\}$ if $P = \{p\}$.

An inclusion-minimal subset S of P with $mc(S) = mc(P)$ is called a *support set*, the points in S are the *support points*. A support set has size at most three, and all its points lie on the boundary of $mc(P)$. In general, neither the support set nor its size are necessarily unique.

The underlying algorithm can cope with all kinds of input, e.g. P may be empty or points may occur more than once. The algorithm computes a support set S which remains fixed until the next insert or clear operation.

Please note: This class is (almost) obsolete. The class *CGAL::Min_sphere_of_spheres_d<Traits>* solves a more general problem and is faster then *Min_circle_2<Traits>* even if used only for points in two dimensions as input. Most importantly, *CGAL::Min_sphere_of_spheres_d<Traits>* has a specialized implementation for floating-point arithmetic which ensures correct results in a large number of cases (including highly degenerate ones). In contrast, *Min_circle_2<Traits>* is not tuned for floating-point computations. The only advantage of *Min_circle_2<Traits>* over *CGAL::Min_sphere_of_spheres_d<Traits>* is that the former can deal with points in homogeneous coordinates, in which case the algorithm is division-free. Thus, *Min_circle_2<Traits>* might still be an option in case your input number type cannot (efficiently) divide.

#include <CGAL/Min_circle_2.h>

Requirements

The template parameter *Traits* is a model for *MinCircle2Traits*.

We provide the model *CGAL::Min_circle_2_traits_2* using the two-dimensional CGAL kernel.

Types

Min_circle_2<Traits>:: Point typedef to *Traits::Point*.

Min_circle_2<Traits>:: Circle typedef to *Traits::Circle*.

Min_circle_2<Traits>:: Point_iterator

non-mutable model of the STL concept *BidirectionalIterator* with value type *Point*. Used to access the points of the smallest enclosing circle.

Min_circle_2<Traits>:: Support_point_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the support points of the smallest enclosing circle.

Creation

A *Min_circle_2<Traits>* object can be created from an arbitrary point set P and by specialized construction methods expecting no, one, two or three points as arguments. The latter methods can be useful for reconstructing $mc(P)$ from a given support set S of P.

template < class InputIterator >
Min_circle_2<Traits> min_circle(InputIterator first, InputIterator last, bool randomize, Random& random = CGAL::default_random, Traits traits = Traits())

initializes *min_circle* to $mc(P)$ with P being the set of points in the range [*first*,*last*). If *randomize* is *true*, a random permutation of P is computed in advance, using the random numbers generator *random*. Usually, this will not be necessary, however, the algorithm's efficiency depends on the order in which the points are processed, and a bad order might lead to extremely poor performance (see example below).
Requirement: The value type of *first* and *last* is *Point*.

Min_circle_2<Traits> min_circle(Traits traits = Traits());

initializes *min_circle* to $mc(\emptyset)$, the empty set.
Postcondition: *min_circle.is_empty() = true*.

Min_circle_2<Traits> min_circle(Point p, Traits traits = Traits());

initializes *min_circle* to $mc(\{p\})$, the set $\{p\}$.
Postcondition: *min_circle.is_degenerate() = true*.

Min_circle_2<Traits> min_circle(Point p1, Point p2, Traits traits = Traits());

initializes *min_circle* to $mc(\{p1,p2\})$, the circle with diameter equal to the segment connecting $p1$ and $p2$.

Min_circle_2<Traits> min_circle(Point p1, Point p2, Point p3, Traits traits = Traits());

initializes *min_circle* to $mc(\{p1,p2,p3\})$.

Access Functions

int *min_circle.number_of_points() const*

returns the number of points of *min_circle*, i.e. $|P|$.

int *min_circle.number_of_support_points() const*

returns the number of support points of *min_circle*, i.e. $|S|$.

Point_iterator
min_circle.points_begin() const
returns an iterator referring to the first point of *min_circle*.

Point_iterator
min_circle.points_end() const returns the corresponding past-the-end iterator.

Support_point_iterator
min_circle.support_points_begin() const
returns an iterator referring to the first support point of *min_circle*.

Support_point_iterator
min_circle.support_points_end() const
returns the corresponding past-the-end iterator.

Point *min_circle.support_point(int i) const*

returns the i-th support point of *min_circle*. Between two modifying operations (see below) any call to *min_circle.support_point(i)* with the same i returns the same point.
Precondition: $0 \leq i <$ *min_circle.number_of_support_points()*.

Circle *min_circle.circle() const* returns the current circle of *min_circle*.

Predicates

By definition, an empty *Min_circle_2<Traits>* has no boundary and no bounded side, i.e. its unbounded side equals the whole space $\mathbb{E}^2$.

CGAL::Bounded_side

min_circle.bounded_side(Point p) const

returns *CGAL::ON_BOUNDED_SIDE*, *CGAL::ON_BOUNDARY*, or *CGAL::ON_UNBOUNDED_SIDE* iff p lies properly inside, on the boundary of, or properly outside of *min_circle*, resp.

bool *min_circle.has_on_bounded_side(Point p) const*

returns *true*, iff p lies properly inside *min_circle*.

bool *min_circle.has_on_boundary(Point p) const*

returns *true*, iff p lies on the boundary of *min_circle*.

bool *min_circle.has_on_unbounded_side(Point p) const*

returns *true*, iff p lies properly outside of *min_circle*.

bool *min_circle.is_empty() const* returns *true*, iff *min_circle* is empty (this implies degeneracy).

bool *min_circle.is_degenerate() const*

returns *true*, iff *min_circle* is degenerate, i.e. if *min_circle* is empty or equal to a single point, equivalently if the number of support points is less than 2.

Modifiers

New points can be added to an existing *min_circle*, allowing to build $mc(P)$ incrementally, e.g. if P is not known in advance. Compared to the direct creation of $mc(P)$, this is not much slower, because the construction method is incremental itself.

void *min_circle.insert(Point p)* inserts *p* into *min_circle* and recomputes the smallest enclosing circle.

template < class InputIterator >
void *min_circle.insert(InputIterator first, InputIterator last)*

inserts the points in the range [*first*,*last*) into *min_circle* and recomputes the smallest enclosing circle by calling *insert(p)* for each point *p* in [*first*,*last*).
Requirement: The value type of *first* and *last* is *Point*.

void *min_circle.clear()* deletes all points in *min_circle* and sets *min_circle* to the empty set.
Postcondition: *min_circle.is_empty() = true*.

Validity Check

An object *min_circle* is valid, iff

- *min_circle* contains all points of its defining set *P*,
- *min_circle* is the smallest circle spanned by its support set *S*, and
- *S* is minimal, i.e. no support point is redundant.

bool *min_circle.is_valid(bool verbose = false, int level = 0) const*

returns *true*, iff *min_circle* is valid. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

Miscellaneous

const Traits&

min_circle.traits() const returns a const reference to the traits class object.

I/O

std::ostream&

std::ostream& os << min_circle

writes *min_circle* to output stream *os*.
Requirement: The output operator is defined for *Point* (and for *Circle*, if pretty printing is used).

std::istream&

std::istream& is >> min_circle&

reads *min_circle* from input stream *is*.
Requirement: The input operator is defined for *Point*.

MinCircle2Traits . . . . page 3809

Implementation

We implement the incremental algorithm of Welzl, with move-to-front heuristic [Wel91]. The whole implementation is described in [GS98a].

If randomization is chosen, the creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point might take up to linear time, but substantially less than computing the new smallest enclosing circle from scratch. The clear operation and the check for validity each takes linear time.

Example

To illustrate the creation of *Min_circle_2<Traits>* and to show that randomization can be useful in certain cases, we give an example.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Min_circle_2.h>
#include <CGAL/Min_circle_2_traits_2.h>
#include <iostream>

// typedefs
typedef  CGAL::Exact_predicates_exact_constructions_kernel K;
typedef  CGAL::Min_circle_2_traits_2<K>   Traits;
typedef  CGAL::Min_circle_2<Traits>       Min_circle;
```

```
typedef  K::Point_2                      Point;

int
main( int, char**)
{
    const int n = 100;
    Point P[n];

    for ( int i = 0; i < n; ++i)
        P[ i] = Point( (i%2 == 0 ? i : -i), 0);
    // (0,0), (-1,0), (2,0), (-3,0), ...

    Min_circle  mc1( P, P+n, false);    // very slow
    Min_circle  mc2( P, P+n, true);     // fast

    CGAL::set_pretty_mode( std::cout);
    std::cout << mc2;

    return 0;
}
```

Class

CGAL::Min_circle_2_traits_2<K>

Definition

The class *Min_circle_2_traits_2<K>* is a traits class for *Min_circle_2<Traits>* using the two-dimensional CGAL kernel.

#include <CGAL/Min_circle_2_traits_2.h>

Requirements

The template parameter *K* is a model for *Kernel*.

Is Model for the Concepts

MinCircle2Traits . . . . page 3809

Types

Min_circle_2_traits_2<K>:: Point typedef to *K::Point_2*.

Min_circle_2_traits_2<K>:: Circle internal type.

Creation

Min_circle_2_traits_2<K> traits; default constructor.

Min_circle_2_traits_2<K> traits(Min_circle_2_traits_2<K>);

copy constructor.

Operations

CGAL::Orientation *traits.orientation(Point p, Point q, Point r) const*

returns *CGAL::orientation(p, q, r)*.

MinCircle2Traits

Concept

Definition

This concept defines the requirements for traits classes of *CGAL::Min_circle_2<Traits>*.

Types

MinCircle2Traits:: Point	The point type must provide default and copy constructor, assignment and equality test.
MinCircle2Traits:: Circle	The circle type must fulfill the requirements listed below in the next section.

Variables

Circle	*circle;*	The current circle. This variable is maintained by the algorithm, the user should neither access nor modify it directly.

Creation

Only default and copy constructor are required.

MinCircle2Traits traits;

MinCircle2Traits traits(MinCircle2Traits);

Operations

The following predicate is only needed, if the member function *is_valid* of *Min_circle_2* is used.

CGAL::Orientation *traits.orientation(Point p, Point q, Point r) const*

returns constants *CGAL::LEFT_TURN*, *CGAL::COLLINEAR*, or *CGAL::RIGHT_TURN* iff r lies properly to the left of, on, or properly to the right of the oriented line through p and q, resp.

Has Models

CGAL::Min_circle_2_traits_2<K> . . . . page 3808

See Also

CGAL::Min_circle_2<Traits> . . . . page 3802

Circle Type (*Circle*)

Definition

An object of the class *Circle* is a circle in two-dimensional Euclidean plane $\mathbb{E}^2$. Its boundary splits the plane into a bounded and an unbounded side. By definition, an empty *Circle* has no boundary and no bounded side, i.e. its unbounded side equals the whole plane $\mathbb{E}^2$. A *Circle* containing exactly one point p has no bounded side, its boundary is $\{p\}$, and its unbounded side equals $\mathbb{E}^2 \setminus \{p\}$.

Types

Circle:: Point	Point type.

The following type is only needed, if the member function *is_valid* of *Min_circle_2* is used.

Circle:: Distance	Distance type. The function *squared_radius* (see below) returns an object of this type.

Creation

void	*circle.set()*	sets *circle* to the empty circle.
void	*circle.set(Point p)*	sets *circle* to the circle containing exactly $\{p\}$.
void	*circle.set(Point p, Point q)*	sets *circle* to the circle with diameter equal to the segment connecting p and q. The algorithm guarantees that *set* is never called with two equal points.
void	*circle.set(Point p, Point q, Point r)*	sets *circle* to the circle through p,q,r. The algorithm guarantees that *set* is never called with three collinear points.

Predicates

bool	*circle.has_on_unbounded_side(Point p) const*	returns *true*, iff p lies properly outside of *circle*.

Each of the following predicates is only needed, if the corresponding predicate of *Min_circle_2* is used.

CGAL::Bounded_side	*circle.bounded_side(Point p) const*	returns *CGAL::ON_BOUNDED_SIDE*, *CGAL::ON_BOUNDARY*, or *CGAL::ON_UNBOUNDED_SIDE* iff p lies properly inside, on the boundary, or properly outside of *circle*, resp.

bool *circle.has_on_bounded_side(Point p) const*

returns *true*, iff *p* lies properly inside *circle*.

bool *circle.has_on_boundary(Point p) const*

returns *true*, iff *p* lies on the boundary of *circle*.

bool *circle.is_empty() const* returns *true*, iff *circle* is empty (this implies degeneracy).

bool *circle.is_degenerate() const* returns *true*, iff *circle* is degenerate, i.e. if *circle* is empty or equal to a single point.

Additional Operations for Checking

The following operations are only needed, if the member function *is_valid* of *Min_circle_2* is used.

bool *circle == circle2* returns *true*, iff *circle* and *circle2* are equal.

Point *circle.center() const* returns the center of *circle*.

Distance *circle.squared_radius() const*

returns the squared radius of *circle*.

I/O

The following I/O operator is only needed, if the corresponding I/O operator of *Min_circle_2* is used.

std::ostream&

std::ostream& os << circle writes *circle* to output stream *os*.

Class

CGAL::Min_ellipse_2<Traits>

Definition

An object of the class *Min_ellipse_2<Traits>* is the unique ellipse of smallest area enclosing a finite (multi)set of points in two-dimensional euclidean space $\mathbb{E}^2$. For a point set P we denote by $me(P)$ the smallest ellipse that contains all points of P. Note that $me(P)$ can be degenerate, i.e. $me(P) = \emptyset$ if $P = \emptyset$, $me(P) = \{p\}$ if $P = \{p\}$, and $me(P) = \{(1-\lambda)p + \lambda q \mid 0 \leq \lambda \leq 1\}$ if $P = \{p,q\}$.

An inclusion-minimal subset S of P with $me(S) = me(P)$ is called a *support set*, the points in S are the *support points*. A support set has size at most five, and all its points lie on the boundary of $me(P)$. In general, neither the support set nor its size are necessarily unique.

The underlying algorithm can cope with all kinds of input, e.g. P may be empty or points may occur more than once. The algorithm computes a support set S which remains fixed until the next insert or clear operation.

#include <CGAL/Min_ellipse_2.h>

Requirements

The template parameter *Traits* is a model for *MinEllipse2Traits*.

We provide the model *CGAL::Min_ellipse_2_traits_2<K>* using the two-dimensional CGAL kernel.

Types

Min_ellipse_2<Traits>:: Point — Typedef to *Traits::Point*.

Min_ellipse_2<Traits>:: Ellipse — Typedef to *Traits::Ellipse*. If you are using the predefined traits class *CGAL::Min_ellipse_2_traits_2<K>*, you can access the coefficients of the ellipse, see the documentation of *CGAL::Min_ellipse_2_traits_2<K>* and the example below.

Min_ellipse_2<Traits>:: Point_iterator

Non-mutable model of the STL concept *BidirectionalIterator* with value type *Point*. Used to access the points of the smallest enclosing ellipse.

Min_ellipse_2<Traits>:: Support_point_iterator

Non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the support points of the smallest enclosing ellipse.

Creation

A *Min_ellipse_2<Traits>* object can be created from an arbitrary point set P and by specialized construction methods expecting no, one, two, three, four or five points as arguments. The latter methods can be useful for reconstructing $me(P)$ from a given support set S of P.

template < class InputIterator >
Min_ellipse_2<Traits> min_ellipse(InputIterator first, InputIterator last, bool randomize, Random& random = default_random, Traits traits = Traits())

initializes *min_ellipse* to $me(P)$ with P being the set of points in the range [*first*,*last*). If *randomize* is *true*, a random permutation of P is computed in advance, using the random numbers generator *random*. Usually, this will not be necessary, however, the algorithm's efficiency depends on the order in which the points are processed, and a bad order might lead to extremely poor performance (see example below).
Requirement: The value type of *first* and *last* is *Point*.

Min_ellipse_2<Traits> min_ellipse(Traits traits = Traits());

creates a variable *min_ellipse* of type *Min_ellipse_2<Traits>*. It is initialized to $me(\emptyset)$, the empty set.
Postcondition: *min_ellipse.is_empty() = true*.

Min_ellipse_2<Traits> min_ellipse(Point p, Traits traits = Traits());

initializes *min_ellipse* to $me(\{p\})$, the set $\{p\}$.
Postcondition: *min_ellipse.is_degenerate() = true*.

Min_ellipse_2<Traits> min_ellipse(Point p, Point q, Traits traits = Traits());

initializes *min_ellipse* to $me(\{p,q\})$,
the set $\{(1-\lambda)p+\lambda q \mid 0 \leq \lambda \leq 1\}$.
Postcondition: *min_ellipse.is_degenerate() = true*.

Min_ellipse_2<Traits> min_ellipse(Point p1, Point p2, Point p3, Traits traits = Traits());

initializes *min_ellipse* to $me(\{p1,p2,p3\})$.

Min_ellipse_2<Traits> min_ellipse(Point p1, Point p2, Point p3, Point p4, Traits traits = Traits());

initializes *min_ellipse* to $me(\{p1,p2,p3,p4\})$.

Min_ellipse_2<Traits> min_ellipse(Point p1, Point p2, Point p3, Point p4, Point p5, Traits traits = Traits());

initializes *min_ellipse* to $me(\{p1,p2,p3,p4,p5\})$.

Access Functions

int *min_ellipse.number_of_points() const*

returns the number of points of *min_ellipse*, i.e. $|P|$.

int *min_ellipse.number_of_support_points() const*

returns the number of support points of *min_ellipse*, i.e. $|S|$.

Point_iterator
min_ellipse.points_begin() const
returns an iterator referring to the first point of *min_ellipse*.

Point_iterator
min_ellipse.points_end() const returns the corresponding past-the-end iterator.

Support_point_iterator
min_ellipse.support_points_begin() const
returns an iterator referring to the first support point of *min_ellipse*.

Support_point_iterator
min_ellipse.support_points_end() const
returns the corresponding past-the-end iterator.

Point *min_ellipse.support_point(int i) const*

returns the i-th support point of *min_ellipse*. Between two modifying operations (see below) any call to *min_ellipse.support_point(i)* with the same i returns the same point.
Precondition: $0 \leq i <$ *min_ellipse.number_of_support_points()*.

Ellipse *min_ellipse.ellipse() const* returns the current ellipse of *min_ellipse*.

Predicates

By definition, an empty *Min_ellipse_2<Traits>* has no boundary and no bounded side, i.e. its unbounded side equals the whole space $\mathbb{E}^2$.

CGAL::Bounded_side

min_ellipse.bounded_side(Point p) const

returns *CGAL::ON_BOUNDED_SIDE*, *CGAL::ON_BOUNDARY*, or *CGAL::ON_UNBOUNDED_SIDE* iff p lies properly inside, on the boundary of, or properly outside of *min_ellipse*, resp.

bool *min_ellipse.has_on_bounded_side(Point p) const*

returns *true*, iff p lies properly inside *min_ellipse*.

bool *min_ellipse.has_on_boundary(Point p) const*

returns *true*, iff *p* lies on the boundary of *min_ellipse*.

bool *min_ellipse.has_on_unbounded_side(Point p) const*

returns *true*, iff *p* lies properly outside of *min_ellipse*.

bool *min_ellipse.is_empty() const* returns *true*, iff *min_ellipse* is empty (this implies degeneracy).

bool *min_ellipse.is_degenerate() const*

returns *true*, iff *min_ellipse* is degenerate, i.e. if *min_ellipse* is empty, equal to a single point or equal to a segment, equivalently if the number of support points is less than 3.

Modifiers

New points can be added to an existing *min_ellipse*, allowing to build $me(P)$ incrementally, e.g. if P is not known in advance. Compared to the direct creation of $me(P)$, this is not much slower, because the construction method is incremental itself.

void *min_ellipse.insert(Point p)* inserts *p* into *min_ellipse* and recomputes the smallest enclosing ellipse.

template < class InputIterator >
void *min_ellipse.insert(InputIterator first, InputIterator last)*

inserts the points in the range [*first*,*last*) into *min_ellipse* and recomputes the smallest enclosing ellipse by calling *insert(p)* for each point *p* in [*first*,*last*).
Requirement: The value type of *first* and *last* is *Point*.

void *min_ellipse.clear()* deletes all points in *min_ellipse* and sets *min_ellipse* to the empty set.
Postcondition: *min_ellipse.is_empty()* = *true*.

Validity Check

An object *min_ellipse* is valid, iff

- *min_ellipse* contains all points of its defining set *P*,
- *min_ellipse* is the smallest ellipse spanned by its support set *S*, and
- *S* is minimal, i.e. no support point is redundant.

Note: In this release only the first item is considered by the validity check.

bool *min_ellipse.is_valid(bool verbose = false, int level = 0) const*

returns *true*, iff *min_ellipse* contains all points of its defining set *P*. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

Miscellaneous

const Traits&

min_ellipse.traits() const returns a const reference to the traits class object.

I/O

std::ostream&

std::ostream& os << min_ellipse

writes *min_ellipse* to output stream *os*.
Requirement: The output operator is defined for *Point* (and for *Ellipse*, if pretty printing is used).

std::istream&

std::istream& is >> min_ellipse&

reads *min_ellipse* from input stream *is*.
Requirement: The input operator is defined for *Point*.

CGAL::Min_ellipse_2_traits_2<K> . . . . page 3819
MinEllipse2Traits . . . . page 3821

Implementation

We implement the incremental algorithm of Welzl, with move-to-front heuristic [Wel91], using the primitives as described in [GS97a, GS97b]. The whole implementation is described in [GS98b].

If randomization is chosen, the creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point might take up to linear time, but substantially less than computing the new smallest enclosing ellipse from scratch. The clear operation and the check for validity each takes linear time.

Example

To illustrate the usage of *Min_ellipse_2<Traits>* and to show that randomization can be useful in certain cases, we give an example. The example also shows how the coefficents of the constructed ellipse can be accessed.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Min_ellipse_2.h>
#include <CGAL/Min_ellipse_2_traits_2.h>
#include <CGAL/Gmpq.h>

#include <cassert>

typedef  CGAL::Gmpq                       NT;
typedef  CGAL::Cartesian<NT>              K;
typedef  CGAL::Point_2<K>                 Point;
typedef  CGAL::Min_ellipse_2_traits_2<K>  Traits;
typedef  CGAL::Min_ellipse_2<Traits>      Min_ellipse;

int
main( int, char**)
{
    const int n = 200;
    Point     P[n];

    for ( int i = 0; i < n; ++i)
        P[ i] = Point( i % 2 ? i : -i , 0);
    // (0,0), (-1,0), (2,0), (-3,0)

    std::cout << "Computing ellipse (without randomization)...";
    std::cout.flush();
    Min_ellipse  me1( P, P+n, false);    // very slow
    std::cout << "done." << std::endl;

    std::cout << "Computing ellipse (with randomization)...";
    std::cout.flush();
    Min_ellipse  me2( P, P+n, true);     // fast
    std::cout << "done." << std::endl;

    // because all input points are collinear, the ellipse is
    // degenerate and equals a line segment; the ellipse has
    // two support points
    assert(me2.is_degenerate());
    assert(me2.number_of_support_points()==2);

    // prettyprinting
    CGAL::set_pretty_mode( std::cout);
    std::cout << me2;

    // in general, the ellipse is not explicitly representable
    // over the input number type NT; when you use the default
    // traits class CGAL::Min_ellipse_2_traits_2<K>, you can
    // get double approximations for the coefficients of the
    // underlying conic curve. NOTE: this curve only exists
    // in the nondegenerate case!
```

```
    me2.insert(Point(0,1)); // resolves the degeneracy
    assert(!me2.is_degenerate());

    // get the coefficients
    double r,s,t,u,v,w;
    me2.ellipse().double_coefficients( r, s, t, u, v, w);
    std::cout << "ellipse has the equation " <<
      r << " x^2 + " <<
      s << " y^2 + " <<
      t << " xy + " <<
      u << " x + " <<
      v << " y + " <<
      w << " = 0." << std::endl;

    return 0;
}
```

CGAL::Min_ellipse_2_traits_2<K>

Class

Definition

The class *Min_ellipse_2_traits_2<K>* is a traits class for *CGAL::Min_ellipse_2<Traits>* using the two-dimensional CGAL kernel.

#include <CGAL/Min_ellipse_2_traits_2.h>

Requirements

The template parameter *K* is a model for *Kernel*.

Is Model for the Concepts

MinEllipse2Traits . . . . page 3821

Types

Min_ellipse_2_traits_2<K>:: Point	typedef to *K::Point_2*.
Min_ellipse_2_traits_2<K>:: Ellipse	internal type.

The Ellipse type provides the following access methods not required by the concept *MinEllipse2Traits*.

bool	*ellipse.is_circle()*	tests whether the ellipse is a circle.
void	*ellipse.double_coefficients(double &r, double &s, double &t, double &u, double &v, double &w)*	gives a double approximation of the ellipse's conic equation. If *K* is a Cartesian kernel, the ellipse is the set of all points (x,y) satisfying $rx^2+sy^2+txy+ux+vy+w=0$. In the Homogeneous case, the ellipse is the set of points (hx,hy,hw) satisfying $r(hx)^2+s(hy)^2+t(hx)(hy)+u(hx)(hw)+v(hy)(hw)+w(hw)^2=0$.

Creation

Min_ellipse_2_traits_2<K> traits; default constructor.

Min_ellipse_2_traits_2<K> traits(Min_ellipse_2_traits_2<K>);

copy constructor.

MinEllipse2Traits

Concept

Definition

This concept defines the requirements for traits classes of *CGAL::Min_ellipse_2<Traits>*.

Types

MinEllipse2Traits:: Point	The point type must provide default and copy constructor, assignment and equality test.
MinEllipse2Traits:: Ellipse	The ellipse type must fulfill the requirements listed below in the next section.

Variables

Ellipse	*ellipse;*	The current ellipse. This variable is maintained by the algorithm, the user should neither access nor modify it directly.

Creation

Only default and copy constructor are required.

MinEllipse2Traits traits;

MinEllipse2Traits traits(Traits);

Has Models

CGAL::Min_ellipse_2_traits_2<K> . . . . page 3819

See Also

CGAL::Min_ellipse_2<Traits> . . . . page 3812

Ellipse Type (*Ellipse*)

Definition

An object of the class *Ellipse* is an ellipse in two-dimensional Euclidean plane $\mathbb{E}^2$. Its boundary splits the plane into a bounded and an unbounded side. By definition, an empty *Ellipse* has no boundary and no bounded side, i.e. its unbounded side equals the whole plane $\mathbb{E}^2$.

Types

Ellipse:: Point — Point type.

Creation

void *ellipse.set()* — sets *ellipse* to the empty ellipse.

void *ellipse.set(Point p)* — sets *ellipse* to the ellipse containing exactly $\{p\}$.

void *ellipse.set(Point p, Point q)*

sets *ellipse* to the ellipse containing exactly the segment connecting p and q. The algorithm guarantees that *set* is never called with two equal points.

void *ellipse.set(Point p, Point q, Point r)*

sets *ellipse* to the smallest ellipse through p,q,r. The algorithm guarantees that *set* is never called with three collinear points.

void *ellipse.set(Point p, Point q, Point r, Point s)*

sets *ellipse* to the smallest ellipse through p,q,r,s. The algorithm guarantees that this ellipse exists.

void *ellipse.set(Point p, Point q, Point r, Point s, Point t)*

sets *ellipse* to the unique conic through p,q,r,s,t. The algorithm guarantees that this conic is an ellipse.

Predicates

bool *ellipse.has_on_unbounded_side(Point p) const*

returns *true*, iff p lies properly outside of *ellipse*.

Each of the following predicates is only needed, if the corresponding predicate of *Min_ellipse_2* is used.

CGAL::Bounded_side

ellipse.bounded_side(Point p) const

returns *CGAL::ON_BOUNDED_SIDE*, *CGAL::ON_BOUNDARY*, or *CGAL::ON_UNBOUNDED_SIDE* iff *p* lies properly inside, on the boundary, or properly outside of *ellipse*, resp.

bool *ellipse.has_on_bounded_side(Point p) const*

returns *true*, iff *p* lies properly inside *ellipse*.

bool *ellipse.has_on_boundary(Point p) const*

returns *true*, iff *p* lies on the boundary of *ellipse*.

bool *ellipse.is_empty() const*

returns *true*, iff *ellipse* is empty (this implies degeneracy).

bool *ellipse.is_degenerate() const*

returns *true*, iff *ellipse* is degenerate, i.e. if *ellipse* is empty or equal to a single point.

I/O

The following I/O operator is only needed, if the corresponding I/O operator of *Min_ellipse_2* is used.

ostream& *ostream& os << ellipse*

writes *ellipse* to output stream *os*.

Function

CGAL::min_rectangle_2

Definition

The function computes a minimum area enclosing rectangle $R(P)$ of a given convex point set P. Note that $R(P)$ is not necessarily axis-parallel, and it is in general not unique. The focus on convex sets is no restriction, since any rectangle enclosing P – as a convex set – contains the convex hull of P. For general point sets one has to compute the convex hull as a preprocessing step.

#include <CGAL/min_quadrilateral_2.h>

template < class ForwardIterator, class OutputIterator, class Traits >
OutputIterator *min_rectangle_2(*
ForwardIterator points_begin,
ForwardIterator points_end,
OutputIterator o,
Traits& t = Default_traits)

computes a minimum area enclosing rectangle of the point set described by [*points_begin*, *points_end*), writes its vertices (counterclockwise) to *o*, and returns the past-the-end iterator of this sequence.
If the input range is empty, *o* remains unchanged.
If the input range consists of one element only, this point is written to *o* four times.

Precondition: The points denoted by the range [*points_begin*, *points_end*) form the boundary of a simple convex polygon P in counterclockwise orientation.

The geometric types and operations to be used for the computation are specified by the traits class parameter *t*. The parameter can be omitted, if *ForwardIterator* refers to a two-dimensional point type from one the CGAL kernels. In this case, a default traits class (*Min_quadrilateral_default_traits_2<K>*) is used.

Requirement:

1. If *Traits* is specified, it is a model for *MinQuadrilateralTraits_2* and the value type *VT* of *ForwardIterator* is *Traits::Point_2*. Otherwise *VT* is *CGAL::Point_2<K>* for some kernel *K*.
2. *OutputIterator* accepts *VT* as value type.

CGAL::min_strip_2 . . . page 3828
MinQuadrilateralTraits_2 . . . page 3834
CGAL::Min_quadrilateral_default_traits_2<K> . . . page 3830

Implementation

We use a rotating caliper algorithm [Tou83] with worst case running time linear in the number of input points.

Example

The following code generates a random convex polygon P with 20 vertices and computes the minimum enclosing rectangle of P.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>
#include <CGAL/min_quadrilateral_2.h>
#include <iostream>

struct Kernel : public CGAL::Cartesian<double> {};

typedef Kernel::Point_2                           Point_2;
typedef Kernel::Line_2                            Line_2;
typedef CGAL::Polygon_2<Kernel>                   Polygon_2;
typedef CGAL::Random_points_in_square_2<Point_2>  Generator;

int main()
{
  // build a random convex 20-gon p
  Polygon_2 p;
  CGAL::random_convex_set_2(20, std::back_inserter(p), Generator(1.0));
  std::cout << p << std::endl;

  // compute the minimal enclosing rectangle p_m of p
  Polygon_2 p_m;
  CGAL::min_rectangle_2(
    p.vertices_begin(), p.vertices_end(), std::back_inserter(p_m));
  std::cout << p_m << std::endl;

  return 0;
}
```

Function

CGAL::min_parallelogram_2

Definition

The function computes a minimum area enclosing parallelogram $A(P)$ of a given convex point set P. Note that $R(P)$ is not necessarily axis-parallel, and it is in general not unique. The focus on convex sets is no restriction, since any parallelogram enclosing P – as a convex set – contains the convex hull of P. For general point sets one has to compute the convex hull as a preprocessing step.

#include <CGAL/min_quadrilateral_2.h>

```
template < class ForwardIterator, class OutputIterator, class Traits >
OutputIterator        min_parallelogram_2(
                              ForwardIterator points_begin,
                              ForwardIterator points_end,
                              OutputIterator o,
                              Traits& t = Default_traits)
```

computes a minimum area enclosing parallelogram of the point set described by [*points_begin*, *points_end*), writes its vertices (counterclockwise) to *o* and returns the past-the-end iterator of this sequence. If the input range is empty, *o* remains unchanged.
If the input range consists of one element only, this point is written to *o* four times.

Precondition: The points denoted by the range [*points_begin*, *points_end*) form the boundary of a simple convex polygon P in counterclockwise orientation.

The geometric types and operations to be used for the computation are specified by the traits class parameter *t*. The parameter can be omitted, if *ForwardIterator* refers to a two-dimensional point type from one the CGAL kernels. In this case, a default traits class (*Min_quadrilateral_default_traits_2<K>*) is used.

Requirement:

1. If *Traits* is specified, it is a model for *MinQuadrilateralTraits_2* and the value type *VT* of *ForwardIterator* is *Traits::Point_2*. Otherwise *VT* is *CGAL::Point_2<K>* for some kernel *K*.
2. *OutputIterator* accepts *VT* as value type.

Implementation

We use a rotating caliper algorithm [STV+95, Vai90] with worst case running time linear in the number of input points.

Example

The following code generates a random convex polygon P with 20 vertices and computes the minimum enclosing parallelogram of P.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>
#include <CGAL/min_quadrilateral_2.h>
#include <iostream>

struct Kernel : public CGAL::Cartesian<double> {};

typedef Kernel::Point_2                          Point_2;
typedef Kernel::Line_2                           Line_2;
typedef CGAL::Polygon_2<Kernel>                  Polygon_2;
typedef CGAL::Random_points_in_square_2<Point_2> Generator;

int main()
{
  // build a random convex 20-gon p
  Polygon_2 p;
  CGAL::random_convex_set_2(20, std::back_inserter(p), Generator(1.0));
  std::cout << p << std::endl;

  // compute the minimal enclosing parallelogram p_m of p
  Polygon_2 p_m;
  CGAL::min_parallelogram_2(
    p.vertices_begin(), p.vertices_end(), std::back_inserter(p_m));
  std::cout << p_m << std::endl;

  return 0;
}
```

File: examples/Min_quadrilateral_2/minimum_enclosing_parallelogram_2.cpp

Function

CGAL::min_strip_2

Definition

The function computes a minimum width enclosing strip $S(P)$ of a given convex point set P. A strip is the closed region bounded by two parallel lines in the plane. Note that $S(P)$ is not unique in general. The focus on convex sets is no restriction, since any parallelogram enclosing P – as a convex set – contains the convex hull of P. For general point sets one has to compute the convex hull as a preprocessing step.

#include <CGAL/min_quadrilateral_2.h>

template < class ForwardIterator, class OutputIterator, class Traits >
OutputIterator *min_strip_2(*
ForwardIterator points_begin,
ForwardIterator points_end,
OutputIterator o,
Traits& t = Default_traits)

computes a minimum enclosing strip of the point set described by [*points_begin*, *points_end*), writes its two bounding lines to *o* and returns the past-the-end iterator of this sequence.
If the input range is empty or consists of one element only, *o* remains unchanged.

Precondition: The points denoted by the range [*points_begin*, *points_end*) form the boundary of a simple convex polygon P in counterclockwise orientation.

The geometric types and operations to be used for the computation are specified by the traits class parameter *t*. The parameter can be omitted, if *ForwardIterator* refers to a two-dimensional point type from one the CGAL kernels. In this case, a default traits class (*Min_quadrilateral_default_traits_2<K>*) is used.

Requirement:

1. If *Traits* is specified, it is a model for *MinQuadrilateralTraits_2* and the value type *VT* of *ForwardIterator* is *Traits::Point_2*. Otherwise *VT* is *CGAL::Point_2<K>* for some kernel *K*.
2. *OutputIterator* accepts *Traits::Line_2* as value type.

CGAL::Min_quadrilateral_default_traits_2<K>

Definition

The class *Min_quadrilateral_default_traits_2<K>* is a traits class for the functions *min_rectangle_2*, *min_parallelogram_2* and *min_strip_2* using a two-dimensional CGAL kernel.

Requirements

The template parameter *K* is a model for *Kernel*.

#include <CGAL/Min_quadrilateral_traits_2.h>

Is Model for the Concepts

Min_quadrilateral_default_traits_2<K>:: Area_less_rectangle_2

AdaptableBinaryFunction class
op: *Rectangle_2* $\times$ *Rectangle_2* $\rightarrow$ *bool*.
op(r1,r2) returns true, iff the area of $r1$ is strictly less than the area of $r2$.

Min_quadrilateral_default_traits_2<K>:: Area_less_parallelogram_2

AdaptableBinaryFunction class
op: *Parallelogram_2* $\times$ *Parallelogram_2* $\rightarrow$ *bool*.
op(p1,p2) returns true, iff the area of $p1$ is strictly less than the area of $p2$.

Min_quadrilateral_default_traits_2<K>:: Width_less_strip_2

AdaptableBinaryFunction class
op: *Strip_2* $\times$ *Strip_2* $\rightarrow$ *bool*.
op(s1,s2) returns true, iff the width of $s1$ is strictly less than the width of $s2$.

Constructions

Min_quadrilateral_default_traits_2<K>:: Construct_vector_2

Kernel::Construct_vector_2 . . . . page **??**.

Min_quadrilateral_default_traits_2<K>:: Construct_vector_from_direction_2

AdaptableFunctor
op: *Direction_2* $\rightarrow$ *Vector_2*.
op(d) returns a vector in direction d.

Min_quadrilateral_default_traits_2<K>:: Construct_perpendicular_vector_2

Kernel::Construct_perpendicular_vector_2 . . . . page **??**.

Min_quadrilateral_default_traits_2<K>:: Construct_direction_2

Kernel::Construct_direction_2 . . . . page **??**.

Min_quadrilateral_default_traits_2<K>:: Construct_opposite_direction_2

Kernel::Construct_opposite_direction_2 . . . . . . page **??**.

Min_quadrilateral_default_traits_2<K>:: Construct_line_2

Kernel::Construct_line_2 . . . . page **??**.

Min_quadrilateral_default_traits_2<K>:: Construct_rectangle_2

Function class
op: $Point\_2 \times Direction\_2 \times Point\_2 \times Point\_2 \times Point\_2 \rightarrow Rectangle\_2$.
If the points $p1, p2, p3, p4$ form the boundary of a convex polygon (oriented counterclockwise), *op(p1,d,p2,p3,p4)* returns the rectangle with one of the points on each side and one sides parallel to d.

Min_quadrilateral_default_traits_2<K>:: Construct_parallelogram_2

Function class
op: $Point\_2 \times Direction\_2 \times Point\_2 \times Direction\_2 \times Point\_2 \times Point\_2 \rightarrow Rectangle\_2$.
If the points $p1, p2, p3, p4$ form the boundary of a convex polygon (oriented counterclockwise), *op(p1,d1,p2,d2,p3,p4)* returns the parallelogram with one of the points on each side and one side parallel to each of $d1$ and $d2$.

Min_quadrilateral_default_traits_2<K>:: Construct_strip_2

Function class
op: $Point\_2 \times Direction\_2 \times Point\_2 \rightarrow Strip\_2$.
op(p1,d,p2) returns the strip bounded by the lines through $p1$ resp. $p2$ with direction d.

Operations

template < class OutputIterator >

OutputIterator *t.copy_rectangle_vertices_2(const Rectangle_2& r, OutputIterator o) const*

copies the four vertices of *r* in counterclockwise order to *o*.

template < class OutputIterator >
OutputIterator *t.copy_parallelogram_vertices_2(const Parallelogram_2& p, OutputIterator o) const*

copies the four vertices of *p* in counterclockwise order to *o*.

template < class OutputIterator >
OutputIterator *t.copy_strip_lines_2(const Strip_2& s, OutputIterator o) const*

copies the two lines bounding *s* to *o*.

Additionally, for each of the predicate and construction functor types listed above, there is a member function that requires no arguments and returns an instance of that functor type. The name of the member function is the uncapitalized name of the type returned with the suffix *_object* appended. For example, for the functor type *Construct_vector_2* the following member function exists:

Construct_vector_2

t.construct_vector_2_object() const

MinQuadrilateralTraits_2

Definition

The concept MinQuadrilateralTraits_2 defines types and operations needed to compute minimum enclosing quadrilaterals of a planar point set using the functions *min_rectangle_2*, *min_parallelogram_2* and *min_strip_2*.

Types

MinQuadrilateralTraits_2:: Point_2	type for representing points.
MinQuadrilateralTraits_2:: Vector_2	type for representing vectors.
MinQuadrilateralTraits_2:: Direction_2	type for representing directions.
MinQuadrilateralTraits_2:: Line_2	type for representing lines.
MinQuadrilateralTraits_2:: Rectangle_2	type for representing (not necessarily axis-parallel) rectangles.
MinQuadrilateralTraits_2:: Parallelogram_2	type for representing parallelograms.
MinQuadrilateralTraits_2:: Strip_2	type for representing strips, that is the closed region bounded by two parallel lines.

Predicates

MinQuadrilateralTraits_2:: Equal_2 — a model for Kernel::Equal_2 . . . . page 996.

MinQuadrilateralTraits_2:: Less_xy_2 — a model for Kernel::Less_xy_2 . . . . page **??**.

MinQuadrilateralTraits_2:: Less_yx_2 — a model for Kernel::Less_yx_2 . . . . page **??**.

MinQuadrilateralTraits_2:: Has_on_negative_side_2

a model for Kernel::Has_on_negative_side_2 . . . . . page **??**.

MinQuadrilateralTraits_2:: Compare_angle_with_x_axis_2

a model for Kernel::Compare_angle_with_x_axis_2page **??**.

MinQuadrilateralTraits_2:: Area_less_rectangle_2

AdaptableFunctor
op: $Rectangle\_2 \times Rectangle\_2 \rightarrow bool$.
op(r1,r2) returns true, iff the area of $r1$ is strictly less than the area of $r2$.

MinQuadrilateralTraits_2:: Area_less_parallelogram_2

AdaptableFunctor
op: *Parallelogram_2* × *Parallelogram_2* → *bool*.
op(p1,p2) returns true, iff the area of $p1$ is strictly less than the area of $p2$.

MinQuadrilateralTraits_2:: Width_less_strip_2

AdaptableFunctor
op: *Strip_2* × *Strip_2* → *bool*.
op(s1,s2) returns true, iff the width of $s1$ is strictly less than the width of $s2$.

The following type is used for expensive precondition checking only.

MinQuadrilateralTraits_2:: Orientation_2

a model for Kernel::Orientation_2 . . . . page 1034.

Constructions

MinQuadrilateralTraits_2:: Construct_vector_2

a model for Kernel::Construct_vector_2 . . . . page **??**.

MinQuadrilateralTraits_2:: Construct_vector_from_direction_2

AdaptableFunctor
op: *Direction_2* → *Vector_2*.
op(d) returns a vector in direction d.

MinQuadrilateralTraits_2:: Construct_perpendicular_vector_2

a model for Kernel::Construct_perpendicular_vector_2 page **??**.

MinQuadrilateralTraits_2:: Construct_direction_2

a model for Kernel::Construct_direction_2 . . . . page **??**.

MinQuadrilateralTraits_2:: Construct_opposite_direction_2

a model for Kernel::Construct_opposite_direction_2 page **??**.

MinQuadrilateralTraits_2:: Construct_line_2

a model for Kernel::Construct_line_2 . . . . page **??**.

MinQuadrilateralTraits_2:: Construct_rectangle_2

Function class
op: $Point\_2 \times Direction\_2 \times Point\_2 \times Point\_2 \times Point\_2 \rightarrow Rectangle\_2$.
If the points $p1, p2, p3, p4$ form the boundary of a convex polygon (oriented counterclockwise), *op(p1,d,p2,p3,p4)* returns the rectangle with one of the points on each side and one sides parallel to d.

MinQuadrilateralTraits_2:: Construct_parallelogram_2

Function class
op: $Point\_2 \times Direction\_2 \times Point\_2 \times Direction\_2 \times Point\_2 \times Point\_2 \rightarrow Rectangle\_2$.
If the points $p1, p2, p3, p4$ form the boundary of a convex polygon (oriented counterclockwise), *op(p1,d1,p2,d2,p3,p4)* returns the parallelogram with one of the points on each side and one side parallel to each of $d1$ and $d2$.

MinQuadrilateralTraits_2:: Construct_strip_2

Function class
op: $Point\_2 \times Direction\_2 \times Point\_2 \rightarrow Strip\_2$.
op(p1,d,p2) returns the strip bounded by the lines through $p1$ resp. $p2$ with direction d.

Operations

template < class OutputIterator >
OutputIterator *t.copy_rectangle_vertices_2(const Rectangle_2& r, OutputIterator o) const*

copies the four vertices of r in counterclockwise order to o.

template < class OutputIterator >
OutputIterator *t.copy_parallelogram_vertices_2(const Parallelogram_2& p, OutputIterator o) const*

copies the four vertices of p in counterclockwise order to o.

template < class OutputIterator >
OutputIterator *t.copy_strip_lines_2(const Strip_2& s, OutputIterator o) const*

copies the two lines bounding s to o.

Additionally, for each of the predicate and construction functor types listed above, there must exist a member function that requires no arguments and returns an instance of that functor type. The name of the member function is the uncapitalized name of the type returned with the suffix *_object* appended. For example, for the functor type *Construct_vector_2* the following member function must exist:

Construct_vector_2

t.construct_vector_2_object() const

Function

CGAL::rectangular_p_center_2

Definition

The function *rectangular_p_center_2* computes rectilinear p-centers of a planar point set, i.e. a set of p points such that the maximum minimal L_∞-distance between both sets is minimized.

More formally the problem can be defined as follows.

Given a finite set $\mathcal{P}$ of points, compute a point set $\mathcal{C}$ with $|\mathcal{C}| \leq p$ such that the p-radius of $\mathcal{P}$,

$$rad_p(\mathcal{P}) := \max_{P \in \mathcal{P}} \min_{Q \in \mathcal{C}} ||P - Q||_\infty$$

is minimized. We can interpret $\mathcal{C}$ as the best approximation (with respect to the given metric) for $\mathcal{P}$ with at most p points.

#include <CGAL/rectangular_p_center_2.h>

```
template < class ForwardIterator, class OutputIterator, class FT, class Traits >
OutputIterator        rectangular_p_center_2(
                              ForwardIterator f,
                              ForwardIterator l,
                              OutputIterator o,
                              FT& r,
                              int p,
                              Traits t = Default_traits)
```

computes rectilinear p-centers for the point set described by the range $[f, l)$, sets r to the corresponding p-radius, writes the at most p center points to o and returns the past-the-end iterator of this sequence.

Precondition: $2 \leq p \leq 4$.

The geometric types and operations to be used for the computation are specified by the traits class parameter t. This parameter can be omitted if *ForwardIterator* refers to a point type from the 2D-Kernel. In this case, a default traits class (*Rectangular_p_center_default_traits_2<K>*) is used.

Requirement:

1. *Either: (if no traits parameter is given)* Value type of *ForwardIterator* is *CGAL::Point_2<K>* for some representation class *K* and *FT* is equivalent to *K::FT*,
2. *Or: (if a traits parameter is specified) Traits* is a model for *RectangularPCenterTraits_2*.
3. *OutputIterator* accepts the value type of *ForwardIterator* as value type.

See Also

RectangularPCenterTraits_2 . . . . page 3843
CGAL::Rectangular_p_center_default_traits_2<K> . . . . page 3840
CGAL::sorted_matrix_search . . . . page 465

Implementation

The runtime is linear for $p \in \{2,3\}$ and $O(n \cdot \log n)$ for $p = 4$ where n is the number of input points. These runtimes are worst case optimal. The 3-center algorithm uses a prune-and-search technique described in [Hof99]. The 4-center implementation uses sorted matrix search [FJ83, FJ84] and fast algorithms for piercing rectangles [SW96].

Example

The following code generates a random set of ten points and computes its two-centers.

```
#include <CGAL/Cartesian.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/rectangular_p_center_2.h>

Class

CGAL::Rectangular_p_center_default_traits_2<K>

Definition

The class *Rectangular_p_center_default_traits_2<K>* defines types and operations needed to compute rectilinear p-centers of a planar point set using the function *rectangular_p_center_2*.

Requirements

The template parameter K is a model for *Kernel*.

Is Model for the Concepts

RectangularPCenterTraits_2 . . . . page 3843

Types

Rectangular_p_center_default_traits_2<K>:: FT

typedef to *K::FT*.

Rectangular_p_center_default_traits_2<K>:: Point_2

typedef to *K::Point_2*.

Rectangular_p_center_default_traits_2<K>:: Iso_rectangle_2

typedef to *K::Iso_rectangle_2*.

Rectangular_p_center_default_traits_2<K>:: Less_x_2

typedef to *K::Less_x_2*.

Rectangular_p_center_default_traits_2<K>:: Less_y_2

typedef to *K::Less_y_2*.

Rectangular_p_center_default_traits_2<K>:: Construct_vertex_2

typedef to *K::Construct_vertex_2*.

Rectangular_p_center_default_traits_2<K>:: Construct_iso_rectangle_2

typedef to *K::Construct_iso_rectangle_2*.

Rectangular_p_center_default_traits_2<K>:: Signed_x_distance_2

adaptable binary function class: $Point\_2 \times Point\_2 \rightarrow FT$ returns the signed distance of two points' x-coordinates.

Rectangular_p_center_default_traits_2<K>:: Signed_y_distance_2

adaptable binary function class: $Point\_2 \times Point\_2 \rightarrow FT$ returns the signed distance of two points' y-coordinates.

Rectangular_p_center_default_traits_2<K>:: Infinity_distance_2

adaptable binary function class: $Point\_2 \times Point\_2 \rightarrow FT$ returns the $||\cdot||_\infty$ distance of two points.

Rectangular_p_center_default_traits_2<K>:: Signed_infinity_distance_2

adaptable binary function class: $Point\_2 \times Point\_2 \rightarrow FT$ returns the signed $||\cdot||_\infty$ distance of two points.

Rectangular_p_center_default_traits_2<K>:: Construct_point_2_below_left_implicit_point_2

3-argument function class: $Point\_2 \times Point\_2 \times FT \rightarrow Point\_2$. For arguments (p,q,r) it returns the lower-left corner of the iso-oriented square with sidelength r and upper-right corner at the intersection of the vertical line through p and the horizontal line through q.

Rectangular_p_center_default_traits_2<K>:: Construct_point_2_below_right_implicit_point_2

3-argument function class: $Point\_2 \times Point\_2 \times FT \rightarrow Point\_2$. For arguments (p,q,r) it returns the lower-right corner of the iso-oriented square with sidelength r and upper-left corner at the intersection of the vertical line through p and the horizontal line through q.

Rectangular_p_center_default_traits_2<K>:: Construct_point_2_above_right_implicit_point_2

3-argument function class: $Point\_2 \times Point\_2 \times FT \rightarrow Point\_2$. For arguments (p,q,r) it returns the upper-right corner of the iso-oriented square with sidelength r and lower-left corner at the intersection of the vertical line through p and the horizontal line through q.

Rectangular_p_center_default_traits_2<K>:: Construct_point_2_above_left_implicit_point_2

3-argument function class: $Point\_2 \times Point\_2 \times FT \rightarrow Point\_2$. For arguments (p,q,r) it returns the upper-left corner of the iso-oriented square with sidelength r and lower-right corner at the intersection of the vertical line through p and the horizontal line through q.

Class

CGAL::Min_sphere_d<Traits>

Definition

An object of the class *Min_sphere_d<Traits>* is the unique sphere of smallest volume enclosing a finite (multi)set of points in d-dimensional Euclidean space $\mathbb{E}^d$. For a set P we denote by $ms(P)$ the smallest sphere that contains all points of P. $ms(P)$ can be degenerate, i.e. $ms(P) = \emptyset$ if $P = \emptyset$ and $ms(P) = \{p\}$ if $P = \{p\}$.

An inclusion-minimal subset S of P with $ms(S) = ms(P)$ is called a *support set*, the points in S are the *support points*. A support set has size at most $d+1$, and all its points lie on the boundary of $ms(P)$. In general, neither the support set nor its size are unique.

The algorithm computes a support set S which remains fixed until the next insert or clear operation.

Please note: This class is (almost) obsolete. The class *CGAL::Min_sphere_of_spheres_d<Traits>* solves a more general problem and is faster then *Min_sphere_d<Traits>* even if used only for points as input. Most importantly, *CGAL::Min_sphere_of_spheres_d<Traits>* has a specialized implementation for floating-point arithmetic which ensures correct results in a large number of cases (including highly degenerate ones). In contrast, *Min_sphere_d<Traits>* is not reliable under floating-point computations. The only advantage of *Min_sphere_d<Traits>* over *CGAL::Min_sphere_of_spheres_d<Traits>* is that the former can deal with points in homogeneous coordinates, in which case the algorithm is division-free. Thus, *Min_sphere_d<Traits>* might still be an option in case your input number type cannot (efficiently) divide.

#include <CGAL/Min_sphere_d.h>

Requirements

The class *Min_sphere_d<Traits>* expects a model of the concept *OptimisationDTraits* as its template argument. We provide the models *CGAL::Optimisation_d_traits_2*, *CGAL::Optimisation_d_traits_3* and *CGAL::Optimisation_d_traits_d* for two-, three-, and d-dimensional points respectively.

Types

Min_sphere_d<Traits>:: Traits

Min_sphere_d<Traits>:: FT — typedef to *Traits::FT*.

Min_sphere_d<Traits>:: Point — typedef to *Traits::Point*.

Min_sphere_d<Traits>:: Point_iterator — non-mutable model of the STL concept *BidirectionalIterator* with value type *Point*. Used to access the points used to build the smallest enclosing sphere.

Min_sphere_d<Traits>:: Support_point_iterator — non-mutable model of the STL concept *BidirectionalIterator* with value type *Point*. Used to access the support points defining the smallest enclosing sphere.

Creation

Min_sphere_d<Traits> min_sphere(Traits traits = Traits());

creates a variable of type *Min_sphere_d<Traits>* and initializes it to $ms(\emptyset)$. If the traits parameter is not supplied, the class *Traits* must provide a default constructor.

template < class InputIterator >
Min_sphere_d<Traits> min_sphere(InputIterator first, InputIterator last, Traits traits = Traits());

creates a variable *min_sphere* of type *Min_sphere_d<Traits>*. It is initialized to $ms(P)$ with P being the set of points in the range [*first*,*last*).
Requirement: The value type of *first* and *last* is *Point*. If the traits parameter is not supplied, the class *Traits* must provide a default constructor.
Precondition: All points have the same dimension.

int *min_sphere.number_of_points() const*

returns the number of points of *min_sphere*, i.e. $|P|$.

int *min_sphere.number_of_support_points() const*

returns the number of support points of *min_sphere*, i.e. $|S|$.

Point_iterator *min_sphere.points_begin() const*
returns an iterator referring to the first point of *min_sphere*.

Point_iterator *min_sphere.points_end() const*
returns the corresponding past-the-end iterator.

Support_point_iterator *min_sphere.support_points_begin() const*
returns an iterator referring to the first support point of *min_sphere*.

Support_point_iterator *min_sphere.support_points_end() const*
returns the corresponding past-the-end iterator.

int *min_sphere.ambient_dimension() const*

returns the dimension of the points in P. If *min_sphere* is empty, the ambient dimension is -1.

Point *min_sphere.center() const*

returns the center of *min_sphere*.
Precondition: *min_sphere* is not empty.

FT *min_sphere.squared_radius() const*

returns the squared radius of *min_sphere*.
Precondition: *min_sphere* is not empty.

Predicates

By definition, an empty *Min_sphere_d<Traits>* has no boundary and no bounded side, i.e. its unbounded side equals the whole space $\mathbb{E}^d$.

Bounded_side *min_sphere.bounded_side(Point p) const*

returns *CGAL::ON_BOUNDED_SIDE*, *CGAL::ON_BOUNDARY*, or *CGAL::ON_UNBOUNDED_SIDE* iff *p* lies properly inside, on the boundary, or properly outside of *min_sphere*, resp.
Precondition: if *min_sphere* is not empty, the dimension of *p* equals *ambient_dimension()*.

bool *min_sphere.has_on_bounded_side(Point p) const*

returns *true*, iff *p* lies properly inside *min_sphere*.
Precondition: if *min_sphere* is not empty, the dimension of *p* equals *ambient_dimension()*.

bool *min_sphere.has_on_boundary(Point p) const*

returns *true*, iff *p* lies on the boundary of *min_sphere*.
Precondition: if *min_sphere* is not empty, the dimension of *p* equals *ambient_dimension()*.

bool *min_sphere.has_on_unbounded_side(Point p) const*

returns *true*, iff *p* lies properly outside of *min_sphere*.
Precondition: if *min_sphere* is not empty, the dimension of *p* equals *ambient_dimension()*.

bool *min_sphere.is_empty() const*

returns *true*, iff *min_sphere* is empty (this implies degeneracy).

bool *min_sphere.is_degenerate() const*

returns *true*, iff *min_sphere* is degenerate, i.e. if *min_sphere* is empty or equal to a single point, equivalently if the number of support points is less than 2.

Modifiers

void *min_sphere.clear()*

resets *min_sphere* to $ms(\emptyset)$.

template < class InputIterator >

void *min_sphere.set(InputIterator first, InputIterator last)*

sets *min_sphere* to the $ms(P)$, where P is the set of points in the range [*first*,*last*).
Requirement: The value type of *first* and *last* is *Point*.
Precondition: All points have the same dimension.

void *min_sphere.insert(Point p)*

inserts p into *min_sphere*. If p lies inside the current sphere, this is a constant-time operation, otherwise it might take longer, but usually substantially less than recomputing the smallest enclosing sphere from scratch.
Precondition: The dimension of p equals *ambient_dimension()* if *min_sphere* is not empty.

template < class InputIterator >
void *min_sphere.insert(InputIterator first, InputIterator last)*

inserts the points in the range [*first*,*last*) into *min_sphere* and recomputes the smallest enclosing sphere, by calling *insert* for all points in the range.
Requirement: The value type of *first* and *last* is *Point*.
Precondition: All points have the same dimension. If *min_sphere* is not empty, this dimension must be equal to *ambient_dimension()*.

Validity Check

An object *min_sphere* is valid, iff

- *min_sphere* contains all points of its defining set P,
- *min_sphere* is the smallest sphere containing its support set S, and
- S is minimal, i.e. no support point is redundant.

Note: Under inexact arithmetic, the result of the validation is not realiable, because the checker itself can suffer from numerical problems.

bool *min_sphere.is_valid(bool verbose = false, int level = 0) const*

returns *true*, iff *min_sphere* is valid. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

Miscellaneous

const Traits&　　*min_sphere.traits() const*

returns a const reference to the traits class object.

I/O

std::ostream&　　*std::ostream& os << min_sphere*

writes *min_sphere* to output stream *os*.
Requirement: The output operator is defined for *Point*.

std::istream&　　*std::istream& is >> min_sphere&*

reads *min_sphere* from input stream *is*.
Requirement: The input operator is defined for *Point*.

CGAL::Min_sphere_of_spheres_d<Traits> . . . . page 3867
CGAL::Min_annulus_d<Traits> . . . . page 3860

Implementation

We implement the algorithm of Welzl with move-to-front heuristic [Wel91] for small point sets, combined with a new efficient method for large sets, which is particularly tuned for moderately large dimension ($d \leq 20$) [Gär99]. The creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point might take up to linear time, but substantially less than computing the new smallest enclosing sphere from scratch. The clear operation and the check for validity each take linear time.

Example

```
#include <CGAL/Cartesian_d.h>
#include <iostream>
#include <cstdlib>
#include <CGAL/Random.h>
#include <CGAL/Min_sphere_annulus_d_traits_d.h>
#include <CGAL/Min_sphere_d.h>

typedef CGAL::Cartesian_d<double>              K;
typedef CGAL::Min_sphere_annulus_d_traits_d<K> Traits;
typedef CGAL::Min_sphere_d<Traits>             Min_sphere;
typedef K::Point_d                             Point;

const int n = 10;                         // number of points
```

```
const int d = 5;                               // dimension of points

int main ()
{
    Point          P[n];                       // n points
    double         coord[d];                   // d coordinates
    CGAL::Random   r;                          // random number generator

    for (int i=0; i<n; ++i) {
        for (int j=0; j<d; ++j)
            coord[j] = r.get_double();
        P[i] = Point(d, coord, coord+d); // random point
    }

    Min_sphere  ms (P, P+n);                   // smallest enclosing sphere

    CGAL::set_pretty_mode (std::cout);
    std::cout << ms;                           // output the sphere

    return 0;
}
```

File: examples/Min_sphere_d/min_sphere_d.cpp

MinSphereAnnulusDTraits

Definition

This concept defines the requirements for traits classes of d-dimensional min sphere and min annulus algorithms.

Types

MinSphereAnnulusDTraits:: Point_d point type used to represent the input points.

MinSphereAnnulusDTraits:: Rep_tag compile time tag to distinguish between Cartesian and homogeneous representation of the input points. *Rep_tag* has to be either *CGAL::Cartesian_tag* or *CGAL::Homogeneous_tag*.

MinSphereAnnulusDTraits:: RT number type used to represent the coordinates of the input points. It has to be a model for *RingNumberType*.

MinSphereAnnulusDTraits:: FT number type used to return either the squared radius of the smallest enclosing sphere or annulus, or the squared distance of the polytopes. *FT* has to be either *RT* or *CGAL::Quotient*<*RT*> if the input points have Cartesian or homogeneous representation, respectively (cf. *Rep_tag*).

MinSphereAnnulusDTraits:: Access_dimension_d

data accessor object used to access the dimension of the input points.

MinSphereAnnulusDTraits:: Access_coordinates_begin_d

data accessor object used to access the coordinates of the input points.

MinSphereAnnulusDTraits:: Construct_point_d

constructor object used to construct either the center of the smallest enclosing sphere or annulus, or the points realizing the distance between the two polytopes.

The following two number types are only needed for *CGAL::Min_annulus_d*<*Traits*> and *CGAL::Polytope_distance_d*<*Traits*>.

MinSphereAnnulusDTraits:: ET exact number type used to do the exact computations in the underlying solver for linear programs. It has to to be a model for *RingNumberType*. There must be an implicit conversion from *RT* to *ET* available.

MinSphereAnnulusDTraits:: NT fast (possibly inexact) number type used to speed up the pricing step in the underlying solver for linear programs. It has to be a model for *RingNumberType*. There must be implicit conversions from *RT* to *NT* and from *NT* to *ET* available.

Creation

Only default and copy constructor are required.

MinSphereAnnulusDTraits traits;

MinSphereAnnulusDTraits traits(MinSphereAnnulusDTraits);

Operations

The following functions just return the corresponding function class object.

Access_dimension_d	*traits.access_dimension_d_object() const*
Access_coordinates_begin_d	*traits.access_coordinates_begin_d_object() const*
Construct_point_d	*traits.construct_point_d_object() const*

Class

CGAL::Min_sphere_annulus_d_traits_2<K,ET,NT>

Definition

The class *Min_sphere_annulus_d_traits_2<K,ET,NT>* is a traits class for the d-dimensional optimisation algorithms using the two-dimensional CGAL kernel.

#include <CGAL/Min_sphere_annulus_d_traits_2.h>

Requirements

The template parameter *K* is a model for *Kernel*. Template parameters *ET* and *NT* are models for *RingNumberType*.

The second and third template parameter have default type *K::RT*.

Is Model for the Concepts

MinSphereAnnulusDTraits . . . . page 3907

Types

Min_sphere_annulus_d_traits_2<K,ET,NT>:: Point_d — typedef to *K::Point_2*.

Min_sphere_annulus_d_traits_2<K,ET,NT>:: Rep_tag — typedef to *K::Rep_tag*.

Min_sphere_annulus_d_traits_2<K,ET,NT>:: RT — typedef to *K::RT*.

Min_sphere_annulus_d_traits_2<K,ET,NT>:: FT — typedef to *K::FT*.

Min_sphere_annulus_d_traits_2<K,ET,NT>:: Access_dimension_d

typedef to *K::Access_dimension_2*.

Min_sphere_annulus_d_traits_2<K,ET,NT>:: Access_coordinates_begin_d

typedef to *K::Access_coordinates_begin_2*.

Min_sphere_annulus_d_traits_2<K,ET,NT>:: Construct_point_d

typedef to *K::Construct_point_2*.

Min_sphere_annulus_d_traits_2<K,ET,NT>:: ET — second template parameter (default is *K::RT*).

Min_sphere_annulus_d_traits_2<K,ET,NT>:: NT — third template parameter (default is *K::RT*).

Creation

Min_sphere_annulus_d_traits_2<K,ET,NT> traits; default constructor.

Min_sphere_annulus_d_traits_2<K,ET,NT> traits(Min_sphere_annulus_d_traits_2<K,ET,NT>);

copy constructor.

Operations

The following functions just return the corresponding function class object.

Access_dimension_d *traits.access_dimension_d_object() const*

Access_coordinates_begin_d *traits.access_coordinates_begin_d_object() const*

Construct_point_d *traits.construct_point_d_object() const*

CGAL::Min_sphere_annulus_d_traits_3<K,ET,NT>

Definition

The class *Min_sphere_annulus_d_traits_3<K,ET,NT>* is a traits class for the d-dimensional optimisation algorithms using the three-dimensional CGAL kernel.

#include <CGAL/Min_sphere_annulus_d_traits_3.h>

Requirements

The template parameter *K* is a model for *Kernel*. Template parameters *ET* and *NT* are models for *RingNumberType*.

The second and third template parameter have default type *K::RT*.

Is Model for the Concepts

MinSphereAnnulusDTraits . . . . page 3907

Types

Min_sphere_annulus_d_traits_3<K,ET,NT>:: Point_d	typedef to *K::Point_3*.
Min_sphere_annulus_d_traits_3<K,ET,NT>:: Rep_tag	typedef to *K::Rep_tag*.
Min_sphere_annulus_d_traits_3<K,ET,NT>:: RT	typedef to *K::RT*.
Min_sphere_annulus_d_traits_3<K,ET,NT>:: FT	typedef to *K::FT*.
Min_sphere_annulus_d_traits_3<K,ET,NT>:: Access_dimension_d	typedef to *K::Access_dimension_3*.
Min_sphere_annulus_d_traits_3<K,ET,NT>:: Access_coordinates_begin_d	typedef to *K::Access_coordinates_begin_3*.
Min_sphere_annulus_d_traits_3<K,ET,NT>:: Construct_point_d	typedef to *K::Construct_point_3*.
Min_sphere_annulus_d_traits_3<K,ET,NT>:: ET	second template parameter (default is *K::RT*).
Min_sphere_annulus_d_traits_3<K,ET,NT>:: NT	third template parameter (default is *K::RT*).

Creation

Min_sphere_annulus_d_traits_3<K,ET,NT> traits; default constructor.

Min_sphere_annulus_d_traits_3<K,ET,NT> traits(Min_sphere_annulus_d_traits_3<K,ET,NT>);

copy constructor.

Operations

The following functions just return the corresponding function class object.

Access_dimension_d *traits.access_dimension_d_object() const*

Access_coordinates_begin_d *traits.access_coordinates_begin_d_object() const*

Construct_point_d *traits.construct_point_d_object() const*

Class

CGAL::Min_sphere_annulus_d_traits_d<K,ET,NT>

Definition

The class *Min_sphere_annulus_d_traits_d<K,ET,NT>* is a traits class for the d-dimensional optimisation algorithms using the d-dimensional CGAL kernel.

#include <CGAL/Min_sphere_annulus_d_traits_d.h>

Requirements

The template parameter *K* is a model for *Kernel*. Template parameters *ET* and *NT* are models for *RingNumberType*.

The second and third template parameter have default type *K::RT*.

Is Model for the Concepts

MinSphereAnnulusDTraits . . . . page 3907

Types

Min_sphere_annulus_d_traits_d<K,ET,NT>:: Point_d	typedef to *K::Point_d*.
Min_sphere_annulus_d_traits_d<K,ET,NT>:: Rep_tag	typedef to *K::Rep_tag*.
Min_sphere_annulus_d_traits_d<K,ET,NT>:: RT	typedef to *K::RT*.
Min_sphere_annulus_d_traits_d<K,ET,NT>:: FT	typedef to *K::FT*.
Min_sphere_annulus_d_traits_d<K,ET,NT>:: Access_dimension_d	typedef to *K::Access_dimension_d*.
Min_sphere_annulus_d_traits_d<K,ET,NT>:: Access_coordinates_begin_d	typedef to *K::Access_coordinates_begin_d*.
Min_sphere_annulus_d_traits_d<K,ET,NT>:: Construct_point_d	typedef to *K::Construct_point_d*.
Min_sphere_annulus_d_traits_d<K,ET,NT>:: ET	second template parameter (default is *K::RT*).
Min_sphere_annulus_d_traits_d<K,ET,NT>:: NT	third template parameter (default is *K::RT*).

Creation

Min_sphere_annulus_d_traits_d<K,ET,NT> traits; default constructor.

Min_sphere_annulus_d_traits_d<K,ET,NT> traits(Min_sphere_annulus_d_traits_d<K,ET,NT>);

copy constructor.

Operations

The following functions just return the corresponding function class object.

Access_dimension_d	*traits.access_dimension_d_object() const*
Access_coordinates_begin_d	*traits.access_coordinates_begin_d_object() const*
Construct_point_d	*traits.construct_point_d_object() const*

Class

CGAL::Min_annulus_d<Traits>

Definition

An object of the class *Min_annulus_d<Traits>* is the unique annulus (region between two concentric spheres with radii r and R, $r \leq R$) enclosing a finite set of points in d-dimensional Euclidean space $\mathbb{E}^d$, where the difference $R^2 - r^2$ is minimal. For a point set P we denote by $ma(P)$ the smallest annulus that contains all points of P. Note that $ma(P)$ can be degenerate, i.e. $ma(P) = \emptyset$ if $P = \emptyset$ and $ma(P) = \{p\}$ if $P = \{p\}$.

An inclusion-minimal subset S of P with $ma(S) = ma(P)$ is called a *support set*, the points in S are the *support points*. A support set has size at most $d+2$, and all its points lie on the boundary of $ma(P)$. In general, the support set is not necessarily unique.

The underlying algorithm can cope with all kinds of input, e.g. P may be empty or points may occur more than once. The algorithm computes a support set S which remains fixed until the next set, insert, or clear operation.

#include <CGAL/Min_annulus_d.h>

Requirements

The template parameter *Traits* is a model for *OptimisationDTraits*.

We provide the models *Optimisation_d_traits_2*, *Optimisation_d_traits_3*, and *Optimisation_d_traits_d* using the two-, three-, and d-dimensional CGAL kernel, respectively.

Types

Min_annulus_d<Traits>:: Point — typedef to *Traits::Point_d*. Point type used to represent the input points.

Min_annulus_d<Traits>:: FT — typedef to *Traits::FT*. Number type used to return the squared radii of the smallest enclosing annulus.

Min_annulus_d<Traits>:: ET — typedef to *Traits::ET*. Number type used to do the exact computations in the underlying solver for quadratic programs (cf. **Implementation**).

Min_annulus_d<Traits>:: Point_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the points of the smallest enclosing annulus.

Min_annulus_d<Traits>:: Support_point_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the support points of the smallest enclosing annulus.

Min_annulus_d<Traits>:: Inner_support_point_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the inner support points of the smallest enclosing annulus.

Min_annulus_d<Traits>:: Outer_support_point_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the outer support points of the smallest enclosing annulus.

Min_annulus_d<Traits>:: Coordinate_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *ET*. Used to access the coordinates of the center of the smallest enclosing annulus.

Creation

Min_annulus_d<Traits> min_annulus(Traits traits = Traits(), int verbose = 0, std::ostream& stream = std::cout)

initializes *min_annulus* to $ma(\emptyset)$.

template < class InputIterator >
Min_annulus_d<Traits> min_annulus(InputIterator first, InputIterator last, Traits traits = Traits(), int verbose = 0, std::ostream& stream = std::cout)

initializes *min_annulus* to $ma(P)$ with P being the set of points in the range [*first*,*last*).
Requirement: The value type of *InputIterator* is *Point*.
Precondition: All points have the same dimension.

Access Functions

int min_annulus.ambient_dimension() const

returns the dimension of the points in P. If *min_annulus* is empty, the ambient dimension is -1.

int min_annulus.number_of_points() const

returns the number of points of *min_annulus*, i.e. $|P|$.

int min_annulus.number_of_support_points() const

returns the number of support points of *min_annulus*, i.e. $|S|$.

int *min_annulus.number_of_inner_support_points() const*

returns the number of support points of *min_annulus* which lie on the inner sphere.

int *min_annulus.number_of_outer_support_points() const*

returns the number of support points of *min_annulus* which lie on the outer sphere.

Point_iterator
min_annulus.points_begin() const
returns an iterator referring to the first point of *min_annulus*.

Point_iterator
min_annulus.points_end() const
returns the corresponding past-the-end iterator.

Support_point_iterator
min_annulus.support_points_begin() const
returns an iterator referring to the first support point of *min_annulus*.
Precondition: $ma(P)$ is not degenerate, i.e., *number_of_support_points()* is at least one.

Support_point_iterator
min_annulus.support_points_end() const
returns the corresponding past-the-end iterator.
Precondition: $ma(P)$ is not degenerate, i.e., *number_of_support_points()* is at least one.

Inner_support_point_iterator
min_annulus.inner_support_points_begin() const
returns an iterator referring to the first inner support point of *min_annulus*.

Inner_support_point_iterator
min_annulus.inner_support_points_end() const
returns the corresponding past-the-end iterator.

Outer_support_point_iterator
min_annulus.outer_support_points_begin() const
returns an iterator referring to the first outer support point of *min_annulus*.

Outer_support_point_iterator
min_annulus.outer_support_points_end() const
returns the corresponding past-the-end iterator.

Point *min_annulus.center() const*
returns the center of *min_annulus*.
Requirement: An implicit conversion from *ET* to *RT* is available.
Precondition: *min_annulus* is not empty.

FT *min_annulus.squared_inner_radius() const*

returns the squared inner radius of *min_annulus*.
Requirement: An implicit conversion from *ET* to *RT* is available.
Precondition: *min_annulus* is not empty.

FT *min_annulus.squared_outer_radius() const*

returns the squared outer radius of *min_annulus*.
Requirement: An implicit conversion from *ET* to *RT* is available.
Precondition: *min_annulus* is not empty.

Coordinate_iterator
min_annulus.center_coordinates_begin() const
returns an iterator referring to the first coordinate of the center of *min_annulus*.
Note: The coordinates have a rational representation, i.e. the first d elements of the iterator range are the numerators and the $(d+1)$-st element is the common denominator.

Coordinate_iterator
min_annulus.center_coordinates_end() const
returns the corresponding past-the-end iterator.

ET *min_annulus.squared_inner_radius_numerator() const*

returns the numerator of the squared inner radius of *min_annulus*.

ET *min_annulus.squared_outer_radius_numerator() const*

returns the numerator of the squared outer radius of *min_annulus*.

ET *min_annulus.squared_radii_denominator() const*

returns the denominator of the squared radii of *min_annulus*.

Predicates

The bounded area of the smallest enclosing annulus lies between the inner and the outer sphere. The boundary is the union of both spheres. By definition, an empty annulus has no boundary and no bounded side, i.e. its unbounded side equals the whole space $\mathbb{E}^d$.

CGAL::Bounded_side

min_annulus.bounded_side(Point p) const

returns *CGAL::ON_BOUNDED_SIDE*, *CGAL::ON_BOUNDARY*, or *CGAL::ON_UNBOUNDED_SIDE* iff p lies properly inside, on the boundary, or properly outside of *min_annulus*, resp.
Precondition: The dimension of p equals *min_annulus.ambient_dimension()* if *min_annulus* is not empty.

bool *min_annulus.has_on_bounded_side(Point p) const*

returns *true*, iff p lies properly inside *min_annulus*.
Precondition: The dimension of p equals *min_annulus.ambient_dimension()* if *min_annulus* is not empty.

bool *min_annulus.has_on_boundary(Point p) const*

returns *true*, iff *p* lies on the boundary of *min_annulus*.
Precondition: The dimension of *p* equals *min_annulus.ambient_dimension()* if *min_annulus* is not empty.

bool *min_annulus.has_on_unbounded_side(Point p) const*

returns *true*, iff *p* lies properly outside of *min_annulus*.
Precondition: The dimension of *p* equals *min_annulus.ambient_dimension()* if *min_annulus* is not empty.

bool *min_annulus.is_empty() const*

returns *true*, iff *min_annulus* is empty (this implies degeneracy).

bool *min_annulus.is_degenerate() const*

returns *true*, iff *min_annulus* is degenerate, i.e. if *min_annulus* is empty or equal to a single point.

Modifiers

void *min_annulus.clear()* resets *min_annulus* to $ma(\emptyset)$.

template < class InputIterator >
void *min_annulus.set(InputIterator first, InputIterator last)*

sets *min_annulus* to $ma(P)$, where P is the set of points in the range [*first*,*last*).
Requirement: The value type of *InputIterator* is *Point*.
Precondition: All points have the same dimension.

void *min_annulus.insert(Point p)*

inserts *p* into *min_annulus*.
Precondition: The dimension of *p* equals *min_annulus.ambient_dimension()* if *min_annulus* is not empty.

template < class InputIterator >
void *min_annulus.insert(InputIterator first, InputIterator last)*

inserts the points in the range [*first*,*last*) into *min_annulus* and recomputes the smallest enclosing annulus.
Requirement: The value type of *InputIterator* is *Point*.
Precondition: All points have the same dimension. If *min_annulus* is not empty, this dimension must be equal to *min_annulus.ambient_dimension()*.

Validity Check

An object *min_annulus* is valid, iff

- *min_annulus* contains all points of its defining set *P*,
- *min_annulus* is the smallest annulus containing its support set *S*, and
- *S* is minimal, i.e. no support point is redundant.

Note: In this release only the first item is considered by the validity check.

bool *min_annulus.is_valid(bool verbose = false, int level = 0) const*

returns *true*, iff *min_annulus* is valid. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

Miscellaneous

const Traits&

min_annulus.traits() const returns a const reference to the traits class object.

I/O

std::ostream&

std::ostream& os << *min_annulus*

writes *min_annulus* to output stream *os*.
Requirement: The output operator is defined for *Point*.

std::istream&

std::istream& is >> *min_annulus&*

reads *min_annulus* from input stream *is*.
Requirement: The input operator is defined for *Point*.

Implementation

The problem of finding the smallest enclosing annulus of a finite point set can be formulated as an optimization problem with linear constraints and a linear objective function. The solution is obtained using our exact solver for linear and quadratic programs [GS00].

The creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point takes almost always linear time. The clear operation and the check for validity each take linear time.

CGAL::Min_sphere_of_spheres_d<Traits>

Class

Definition

An object of the class *Min_sphere_of_spheres_d<Traits>* is a data structure that represents the unique sphere of smallest volume enclosing a finite set of spheres in d-dimensional Euclidean space $\mathbb{E}^d$. For a set S of spheres we denote by $ms(S)$ the smallest sphere that contains all spheres of S; we call $ms(S)$ the *minsphere* of S. $ms(S)$ can be degenerate, i.e., $ms(S) = \emptyset$, if $S = \emptyset$ and $ms(S) = \{s\}$, if $S = \{s\}$. Any sphere in S may be degenerate, too, i.e., any sphere from S may be a point. Also, S may contain several copies of the same sphere.

An inclusion-minimal subset R of S with $ms(R) = ms(S)$ is called a *support set* for $ms(S)$; the spheres in R are the *support spheres*. A support set has size at most $d+1$, and all its spheres lie on the boundary of $ms(S)$. (A sphere s' is said to *lie on the boundary* of a sphere s, if s' is contained in s and if their boundaries intersect.) In general, the support set is not unique.

The algorithm computes the center and the radius of $ms(S)$, and finds a support set R (which remains fixed until the next *insert()*, *clear()* or *set()* operation). We also provide a specialization of the algorithm for the case when the center coordinates and radii of the input spheres are floating-point numbers. This specialized algorithm uses floating-point arithmetic only, is very fast and especially tuned for stability and robustness. Still, it's output may be incorrect in some (rare) cases; termination is guaranteed.

When default constructed, an instance of type *Min_sphere_of_spheres_d<Traits>* represents the set $S = \emptyset$, together with its minsphere $ms(S) = \emptyset$. You can add spheres to the set S by calling *insert()*. Querying the minsphere is done by calling the routines *is_empty()*, *radius()* and *center_cartesian_begin()*, among others.

In general, the radius and the Euclidean center coordinates of $ms(S)$ need not be rational. Consequently, the algorithm computing the exact minsphere will have to deal with algebraic numbers. Fortunately, both the radius and the coordinates of the minsphere are numbers of the form $a_i + b_i\sqrt{t}$, where $a_i, b_i, t \in \mathbb{Q}$ and where $t \geq 0$ is the same for all coordinates and the radius. Thus, the exact minsphere can be described by the number t, which is called the sphere's *discriminant*, and by $d+1$ pairs $(a_i, b_i) \in \mathbb{Q}^2$ (one for the radius and d for the center coordinates).

#include <CGAL/Min_sphere_of_spheres_d.h>

Note: This class (almost) replaces *CGAL::Min_sphere_d<Traits>*, which solves the less general problem of finding the smallest enclosing ball of a set of *points*. *Min_sphere_of_spheres_d<Traits>* is faster than *CGAL::Min_sphere_d<Traits>*, and in contrast to the latter provides a specialized implementation for floating-point arithmetic which ensures correct results in a large number of cases (including highly degenerate ones). The only advantage of *CGAL::Min_sphere_d<Traits>* over *Min_sphere_of_spheres_d<Traits>* is that the former can deal with points in homogeneous coordinates, in which case the algorithm is division-free. Thus, *CGAL::Min_sphere_d<Traits>* might still be an option in case your input number type cannot (efficiently) divide.

Requirements

The class *Min_sphere_of_spheres_d<Traits>* expects a model of the concept *MinSphereOfSpheresTraits* as its template argument.

Types

Min_sphere_of_spheres_d<Traits>:: Sphere is a typedef to *Traits::Sphere*.

Min_sphere_of_spheres_d<Traits>:: FT is a typedef to *Traits::FT*.

Min_sphere_of_spheres_d<Traits>:: Result is the type of the radius and of the center coordinates of the computed minsphere: When *FT* is an inexact number type (*double*, for instance), then *Result* is simply *FT*. However, when *FT* is an exact number type, then *Result* is a typedef to a derived class of *std::pair<FT,FT>*; an instance of this type represents the number $a+b\sqrt{t}$, where a is the first and b the second element of the pair and where the number t is accessed using the member function *discriminant()* of class *Min_sphere_of_spheres_d<Traits>*.

Min_sphere_of_spheres_d<Traits>:: Algorithm is either *CGAL::LP_algorithm* or *CGAL::Farthest_first_heuristic*. As is described in the documentation of concept *MinSphereOfSpheresTraits*, the type *Algorithm* reflects the method which is used to compute the minsphere. (Normally, *Algorithm* coincides with *Traits::Algorithm*. However, if the method *Traits::Algorithm* should not be supported anymore in a future release, then *Algorithm* will have another type.)

Min_sphere_of_spheres_d<Traits>:: Support_iterator

non-mutable model of the STL concept *BidirectionalIterator* with value type *Sphere*. Used to access the support spheres defining the smallest enclosing sphere.

Min_sphere_of_spheres_d<Traits>:: Cartesian_const_iterator

non-mutable model of the STL concept *BidirectionalIterator* to access the center coordinates of the minsphere.

Creation

Min_sphere_of_spheres_d<Traits> minsphere(Traits traits = Traits());

creates a variable of type *Min_sphere_of_spheres_d<Traits>* and initializes it to $ms(\emptyset)$. If the traits parameter is not supplied, the class *Traits* must provide a default constructor.

template < typename InputIterator >
Min_sphere_of_spheres_d<Traits> minsphere(InputIterator first, InputIterator last, Traits traits = Traits());

creates a variable *minsphere* of type *Min_sphere_of_spheres_d<Traits>* and inserts (cf. *insert()*) the spheres from the range [*first*,*last*).
Requirement: The value type of *first* and *last* is *Sphere*. If the traits parameter is not supplied, the class *Traits* must provide a default constructor.

Access Functions

Support_iterator *minsphere.support_begin() const*

returns an iterator referring to the first support sphere of *minsphere*.

Support_iterator *minsphere.support_end() const*

returns the corresponding past-the-end iterator.

FT *minsphere.discriminant() const*

returns the discriminant of *minsphere*. This number is undefined when *FT* is an inexact number type. When *FT* is exact, the center coordinates and the radius of the minsphere are numbers of the form $a+b\sqrt{t}$, where t is the discriminant of the minsphere as returned by this function.
Precondition: *minsphere* is not empty, and *FT* is an exact number type.

Result *minsphere.radius() const*

returns the radius of *minsphere*. If *FT* is an exact number type then the radius of the minsphere is the real number $a+b\sqrt{t}$, where t is the minsphere's discriminant, a is the first and b the second component of the pair returned by *radius()*.
Precondition: *minsphere* is not empty.

Cartesian_const_iterator

minsphere.center_cartesian_begin() const

returns a const-iterator to the first of the *Traits::D* center coordinates of *minsphere*. The iterator returns objects of type *Result*. If *FT* is an exact number type, then a center coordinate is represented by a pair (a,b) describing the real number $a+b\sqrt{t}$, where t is the minsphere's discriminant (cf. *discriminant()*).
Precondition: *minsphere* is not empty.

Cartesian_const_iterator

minsphere.center_cartesian_end() const

returns the corresponding past-the-end iterator, i.e. *center_cartesian_begin()+Traits::D*.
Precondition: *minsphere* is not empty.

Predicates

bool *minsphere.is_empty() const*

returns *true*, iff *minsphere* is empty, i.e. iff $ms(S) = \emptyset$.

Modifiers

void *minsphere.clear()* resets *minsphere* to $ms(\emptyset)$, with $S := \emptyset$.

template < class InputIterator >
void *minsphere.set(InputIterator first, InputIterator last)*

sets *minsphere* to the $ms(S)$, where S is the set of spheres in the range [*first*,*last*).
Requirement: The value type of *first* and *last* is *Sphere*.

void *minsphere.insert(Sphere s)*

inserts the sphere *s* into the set S of instance *minsphere*.

template < class InputIterator >
void *minsphere.insert(InputIterator first, InputIterator last)*

inserts the spheres in the range [*first*,*last*) into the set S of instance *minsphere*.
Requirement: The value type of *first* and *last* is *Sphere*.

Validity Check

An object *minsphere* is valid, iff

- *minsphere* contains all spheres of its defining set S,
- *minsphere* is the smallest sphere containing its support set R, and
- R is minimal, i.e., no support sphere is redundant.

bool *minsphere.is_valid() const*

returns *true*, iff *minsphere* is valid. When *FT* is inexact, this routine always returns *true*.

Miscellaneous

const Traits& *minsphere.traits() const*

returns a const reference to the traits class object.

CGAL::Min_circle_2<Traits> . . . page 3802

Implementation

We implement two algorithms, the LP-algorithm and a heuristic [MSW92]. As described in the documentation of concept *MinSphereOfSpheresTraits*, each has its advantages and disadvantages: Our implementation of the LP-algorithm has maximal expected running time $O(2^d n)$, while the heuristic comes without any complexity guarantee. In particular, the LP-algorithm runs in linear time for fixed dimension d. (These running times hold for the arithmetic model, so they count the number of operations on the number type *FT*.)

On the other hand, the LP-algorithm is, for inexact number types *FT*, much worse at handling degeneracies and should therefore not be used in such a case. (For exact number types *FT*, both methods handle all kinds of degeneracies.)

Currently, we require *Traits::FT* to be either an exact number type or *double* or *float*; other inexact number types are not supported at this time. Also, the current implementation only handles spheres with Cartesian coordinates; homogenous representation is not supported yet.

Example

```
#include <CGAL/Cartesian_d.h>
#include <CGAL/Random.h>
#include <CGAL/Gmpq.h>
#include <CGAL/Min_sphere_of_spheres_d.h>
#include <vector>

const int N = 1000;                       // number of spheres
const int D = 3;                          // dimension of points
const int LOW = 0, HIGH = 10000;          // range of coordinates and
    radii

typedef CGAL::Gmpq                        FT;
//typedef double                          FT;
typedef CGAL::Cartesian_d<FT>             K;
typedef CGAL::Min_sphere_of_spheres_d_traits_d<K,FT,D> Traits;
typedef CGAL::Min_sphere_of_spheres_d<Traits> Min_sphere;
typedef K::Point_d                        Point;
typedef Traits::Sphere                    Sphere;

int main () {
  std::vector<Sphere> S;                  // n spheres
  FT coord[D];                            // d coordinates
  CGAL::Random r;                         // random number generator

  for (int i=0; i<N; ++i) {
    for (int j=0; j<D; ++j)
      coord[j] = r.get_int(LOW,HIGH);
    Point p(D,coord,coord+D);             // random center...
    S.push_back(Sphere(p,r.get_int(LOW,HIGH))); // ...and random radius
```

```
  }

  Min_sphere ms(S.begin(),S.end());       // check in the spheres
  CGAL_assertion(ms.is_valid());
}
```

MinSphereOfSpheresTraits

Definition

A model of concept *MinSphereOfSpheresTraits* must provide the following constants, types, predicates and operations.

Has Models

CGAL::Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>
CGAL::Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>
CGAL::Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>

Constants

MinSphereOfSpheresTraits:: D — specifies the dimension of the spheres you want to compute the minsphere of.

Types

MinSphereOfSpheresTraits:: Sphere — is a typedef to to some class representing a sphere. (The package will compute the minsphere of spheres of type *Sphere*.) The type *Sphere* must provide a copy constructor.

MinSphereOfSpheresTraits:: FT — is a (exact or inexact) field number type.
Requirement: Currently, *FT* must either be *double* or *float*, or an exact field number type. (An *exact* number type is one which evaluates arithmetic expressions involving the four basic operations and comparisions with infinite precision, that is, like in $\mathbb{R}$.)

MinSphereOfSpheresTraits:: Cartesian_const_iterator

non-mutable model of the STL concept *ForwardIterator* with value type *FT*. Used to access the center coordinates of a sphere.

MinSphereOfSpheresTraits:: Use_square_roots

must typedef to either *CGAL::Tag_true* or *CGAL::Tag_false*. The algorithm uses (depending on the type *MinSphereOfSpheresTraits::Algorithm*) floating-point arithmetic internally for some intermediate computations. The type *Use_square_roots* affects how these calculations are done: When *Use_square_roots* is *Tag_true*, the algorithm computing the minsphere will perform square-root operations on *double*s and *float*s where appropriate. On the other hand, if *Use_square_roots* is *CGAL::Tag_false*, the algorithm will work without doing square-roots.
Note: On some platforms the algorithm is much faster when square-roots are disabled (due to lacking hardware support).

MinSphereOfSpheresTraits:: Algorithm

selects the method to compute the minsphere with. It must typedef to either *CGAL::Default_algorithm*, *CGAL::LP_algorithm* or *CGAL::Farthest_first_heuristic*. The recommended choice is the first, which is a synonym to the one of the other two methods which we consider "the best in practice." In case of *CGAL::LP_algorithm*, the minsphere will be computed using the LP-algorithm [MSW92], which in our implementation has maximal expected running time $O(2^d n)$ (in the number of operations on the number type *FT*). In case of *CGAL::Farthest_first_heuristic*, a simple heuristic will be used instead which seems to work fine in practice, but comes without a guarantee on the running time. For an inexact number type *FT* we strongly recommend *CGAL::Default_algorithm*, or, if you want, *CGAL::Farthest_first_heuristic*, since these handle most degeneracies in a satisfying manner. Notice that this compile-time flag is taken as a hint only. Should one of the methods not be available anymore in a future release, then the default algorithm will be chosen.

Access Functions

FT *traits.radius(Sphere s)*

returns the radius of sphere *s*.
Postcondition: The returned number is greater or equal to 0.

Cartesian_const_iterator

traits.center_cartesian_begin(Sphere s)

returns an iterator referring to the first of the *D* Cartesian coordinates of the center of *s*.

CGAL::Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>

Definition

The class *Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>* is a model for concept *MinSphereOfSpheresTraits*. It uses the CGAL type *Point_2* to represent circles.

Is Model for the Concepts

MinSphereOfSpheresTraits

Parameters

The last two template parameters, *UseSqrt* and *Algorithm*, have default arguments, namely *CGAL::Tag_false* and *CGAL::Default_algorithm*, respectively.

The template parameters of class *Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>* must fulfill the following requirements:

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: K

is a model for *Kernel*.

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: FT

is a number type, which fulfills the requirements of type *FT* of concept *MinSphereOfSpheresTraits*: It must be either *double* or *float*, or an exact number type.

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: UseSqrt

fulfills the requirements of type *Use_square_roots* of concept *MinSphereOfSpheresTraits*: It must be either *Tag_true* or *Tag_false*.

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: Algorithm

fulfills the requirements of type *Algorithm* of concept *MinSphereOfSpheresTraits*: It must be either *Default_algorithm*, *LP_algorithm* or *Farthest_first_heuristic*.

Constants

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: D

is the constant 2, i.e. the dimension of $\mathbb{R}^2$.

Types

In addition to the types required by the concept *MinSphereOfSpheresTraits*, this model also defines the types *Radius* and *Point*. Here's the complete list of defined types:

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: FT

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: Use_square_roots

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: Algorithm

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: Radius

is a typedef to the template parameter *FT*

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: Point

is a typedef to *K::Point_2*.

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: Sphere

is a typedef to *std::pair<Point,Radius>*.

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: Cartesian_const_iterator

is a typedef to *K::Cartesian_const_iterator_2*.

Access Functions

The class provides the access functions required by the concept *MinSphereOfSpheresTraits*; they simply map to the corresponding routines of class *K::Point_2*:

FT *traits.radius(Sphere s)*

maps to *s.second*.

Cartesian_const_iterator

traits.center_cartesian_begin(Sphere s)

maps to *s.first.cartesian_begin()*.

CGAL::Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>

Class

Definition

The class *Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>* is a model for concept *MinSphereOfSpheresTraits*. It uses the CGAL type *Point_3* to represent circles.

Is Model for the Concepts

MinSphereOfSpheresTraits

Parameters

The last two template parameters, *UseSqrt* and *Algorithm*, have default arguments, namely *CGAL::Tag_false* and *CGAL::Default_algorithm*, respectively.

The template parameters of class *Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>* must fulfill the following requirements:

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: K

is a model for *Kernel*.

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: FT

is a number type, which fulfills the requirements of type *FT* of concept *MinSphereOfSpheresTraits*: It must be either *double* or *float*, or an exact number type.

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: UseSqrt

fulfills the requirements of type *Use_square_roots* of concept *MinSphereOfSpheresTraits*: It must be either *Tag_true* or *Tag_false*.

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: Algorithm

fulfills the requirements of type *Algorithm* of concept *MinSphereOfSpheresTraits*: It must be either *Default_algorithm*, *LP_algorithm* or *Farthest_first_heuristic*.

Constants

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: D

is the constant 3, i.e. the dimension of $\mathbb{R}^3$.

Types

In addition to the types required by the concept *MinSphereOfSpheresTraits*, this model also defines the types *Radius* and *Point*. Here's the complete list of defined types:

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: FT

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: Use_square_roots

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: Algorithm

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: Radius

is a typedef to the template parameter *FT*

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: Point

is a typedef to *K::Point_3*.

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: Sphere

is a typedef to *std::pair<Point,Radius>*.

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: Cartesian_const_iterator

is a typedef to *K::Cartesian_const_iterator_2*.

Access Functions

The class provides the access functions required by the concept *MinSphereOfSpheresTraits*; they simply map to the corresponding routines of class *K::Point_3*:

FT *traits.radius(Sphere s)*

maps to *s.second*.

Cartesian_const_iterator

traits.center_cartesian_begin(Sphere s)

maps to *s.first.cartesian_begin()*.

CGAL::Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>

Class

Definition

The class *Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>* is a model for concept *MinSphereOfSpheresTraits*. It uses the CGAL type *Point_d* to represent circles.

Is Model for the Concepts

MinSphereOfSpheresTraits

Parameters

The last two template parameters, *UseSqrt* and *Algorithm*, have default arguments, namely *CGAL::Tag_false* and *CGAL::Default_algorithm*, respectively.

The template parameters of class *Min_sphere_of_spheres_d_traits_d<K,FT,UseSqrt,Algorithm>* must fulfill the following requirements:

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: K

is a model for *Kernel*.

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: FT

is a number type, which fulfills the requirements of type *FT* of concept *MinSphereOfSpheresTraits*: It must be either *double* or *float*, or an exact number type.

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: UseSqrt

fulfills the requirements of type *Use_square_roots* of concept *MinSphereOfSpheresTraits*: It must be either *Tag_true* or *Tag_false*.

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: Algorithm

fulfills the requirements of type *Algorithm* of concept *MinSphereOfSpheresTraits*: It must be either *Default_algorithm*, *LP_algorithm* or *Farthest_first_heuristic*.

Constants

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: D

is the constant *Dim*.

Types

In addition to the types required by the concept *MinSphereOfSpheresTraits*, this model also defines the types *Radius* and *Point*. Here's the complete list of defined types:

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: FT

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: Use_square_roots

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: Algorithm

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: Radius

is a typedef to the template parameter *FT*

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: Point

is a typedef to *K::Point_d*.

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: Sphere

is a typedef to *std::pair<Point,Radius>*.

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: Cartesian_const_iterator

is a typedef to *K::Cartesian_const_iterator_d*.

Access Functions

The class provides the access functions required by the concept *MinSphereOfSpheresTraits*; they simply map to the corresponding routines of class *K::Point_d*:

FT *traits.radius(Sphere s)*

maps to *s.second*.

Cartesian_const_iterator

traits.center_cartesian_begin(Sphere s)

maps to *s.first.cartesian_begin()*.

CGAL::Min_sphere_of_points_d_traits_2<K,FT,UseSqrt,Algorithm>

Definition

The class *Min_sphere_of_points_d_traits_2<K,FT,UseSqrt,Algorithm>* is a model for concept *MinSphereOfSpheresTraits*. It uses the CGAL type *Point_2* to represent circles.

Is Model for the Concepts

MinSphereOfSpheresTraits

Parameters

The last two template parameters, *UseSqrt* and *Algorithm*, have default arguments, namely *CGAL::Tag_false* and *CGAL::Default_algorithm*, respectively.

The template parameters of class *Min_sphere_of_points_d_traits_2<K,FT,UseSqrt,Algorithm>* must fulfill the following requirements:

Min_sphere_of_points_d_traits_2<K,FT,UseSqrt,Algorithm>:: K

is a model for *Kernel*.

Min_sphere_of_points_d_traits_2<K,FT,UseSqrt,Algorithm>:: FT

is a number type, which fulfills the requirements of type *FT* of concept *MinSphereOfSpheresTraits*: It must be either *double* or *float*, or an exact number type.

Min_sphere_of_points_d_traits_2<K,FT,UseSqrt,Algorithm>:: UseSqrt

fulfills the requirements of type *Use_square_roots* of concept *MinSphereOfSpheresTraits*: It must be either *Tag_true* or *Tag_false*.

Min_sphere_of_points_d_traits_2<K,FT,UseSqrt,Algorithm>:: Algorithm

fulfills the requirements of type *Algorithm* of concept *MinSphereOfSpheresTraits*: It must be either *Default_algorithm*, *LP_algorithm* or *Farthest_first_heuristic*.

Constants

Min_sphere_of_points_d_traits_2<K,FT,UseSqrt,Algorithm>:: D

is the constant 2, i.e. the dimension of $\mathbb{R}^2$.

Types

maps to *s.cartesian_begin()*.

CGAL::Approximate_min_ellipsoid_d<Traits>

Class

Definition

An object of class *Approximate_min_ellipsoid_d<Traits>* is an approximation to the ellipsoid of smallest volume enclosing a finite multiset of points in d-dimensional Euclidean space $\mathbb{E}^d$, $d \geq 2$.

An *ellipsoid* in $\mathbb{E}^d$ is a Cartesian pointset of the form $\{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}$, where E is some positive definite matrix from the set $\mathbb{R}^{d \times d}$, e is some real d-vector, and $\eta \in \mathbb{R}$. A pointset $P \subseteq \mathbb{E}^d$ is called *full-dimensional* if its affine hull has dimension d. For a finite, full-dimensional pointset P we denote by $\text{MEL}(P)$ the smallest ellipsoid that contains all points of P; this ellipsoid exists and is unique.

For a given finite and full-dimensional pointset $P \subset \mathbb{E}^d$ and a real number $\varepsilon \geq 0$, we say that an ellipsoid $\mathcal{E} \subset \mathbb{E}^d$ is an $(1+\varepsilon)$-*appoximation* to $\text{MEL}(P)$ if $P \subset \mathcal{E}$ and $\text{VOL}(\mathcal{E}) \leq (1+\varepsilon)\,\text{VOL}(\text{MEL}(P))$. In other words, an $(1+\varepsilon)$-approximation to $\text{MEL}(P)$ is an enclosing ellipsoid whose volume is by at most a factor of $1+\varepsilon$ larger than the volume of the smallest enclosing ellipsoid of P.

Given this notation, an object of class *Approximate_min_ellipsoid_d<Traits>* represents an $(1+\varepsilon)$-approximation to $\text{MEL}(P)$ for a given finite and full-dimensional multiset of points $P \subset \mathbb{E}^d$ and a real constant $\varepsilon > 0$.[1] When an *Approximate_min_ellipsoid_d<Traits>* object is constructed, an iterator over the points P and the number ε have to be specified; the number ε defines the *desired approximation ratio* $1+\varepsilon$. The underlying algorithm will then try to compute an $(1+\varepsilon)$-approximation to $\text{MEL}(P)$, and one of the following two cases takes place.

- The algorithm determines that P is not full-dimensional (see *is_full_dimensional()* below).

  Important note: due to rounding errors, the algorithm cannot in all cases decide correctly whether P is full-dimensional or not. If *is_full_dimensional()* returns *false*, the points lie in such a "thin" subspace of $\mathbb{E}^d$ that the algorithm is incapable of computing an approximation to $\text{MEL}(P)$. More precisely, if *is_full_dimensional()* returns *false*, there exist two parallel hyperplanes in $\mathbb{E}^d$ with the points P in between so that the distance δ between the hyperplanes is very small, possible zero. (If $\delta = 0$ then P is not full-dimensional.)

  If P is not full-dimensional, linear algebra techniques should be used to determine an affine subspace S of $\mathbb{E}^d$ that contains the points P as a (w.r.t. S) full-dimensional pointset; once S is determined, the algorithm can be invoked again to compute an approximation to (the lower-dimensional) $\text{MEL}(P)$ in S. Since *is_full_dimensional()* might (due to rounding errors, see above) return *false* even though P is full-dimensional, the lower-dimensional subspace S containing P need not exist. Therefore, it might be more advisable to fit a hyperplane H through the pointset P, project P onto this affine subspace H, and compute an approximation to the minimum-volume enclosing ellipsoid of the projected points within H; the fitting can be done for instance using the *linear_least_squares_fitting()* function from the CGAL package *Principal_component_analysis*.

- The algorithm determines that P is full-dimensional. In this case, it provides an approximation $\mathcal{E}$ to $\text{MEL}(P)$, but depending on the input problem (i.e., on the pair (P, ε)), it may not have achieved the desired approximation ratio but merely some *worse* approximation ratio $1+\varepsilon' > 1+\varepsilon$. The achieved approximation ratio $1+\varepsilon'$ can be queried using *achieved_epsilon()*, which returns ε'. The ellipsoid $\mathcal{E}$ itself can be queried via the methods *defining_matrix()*, *defining_vector()*, and *defining_scalar()*.

The ellipsoid $\mathcal{E}$ computed by the algorithm satisfies the inclusions

$$\frac{1}{(1+\varepsilon')d}\mathcal{E} \subseteq \text{conv}(P) \subseteq \mathcal{E} \qquad (66.1)$$

[1] A *multiset* is a set where elements may have multiplicity greater than 1.

where $f\mathcal{E}$ denotes the ellipsoid $\mathcal{E}$ scaled by the factor $f \in \mathbb{R}^+$ with respect to its center, and where $\mathrm{conv}(A)$ denotes the *convex hull* of a pointset $A \subset \mathbb{E}^d$.

The underlying algorithm can cope with all kinds of inputs (multisets P, $\varepsilon \in [0,\infty)$) and terminates in all cases. There is, however, no guarantee that any desired approximation ratio is actually achieved; the performance of the algorithm in this respect highly depends on the input pointset. Values of at least 0.01 for ε are usually handled without problems.

Internally, the algorithm represents the input points' Cartesian coordinates as *double*'s. For this conversion to work, the input point coordinates must be convertible to *double*. Also, in order to compute the achieved epsilon ε' mentioned above, the algorithm requires a number type *ET* that provides *exact* arithmetic. (Both these aspects are discussed in the documentation of the concept *ApproximateMinEllipsoid_d_Traits_d*.)

#include <CGAL/Approximate_min_ellipsoid_d.h>

Requirements

The template parameter *Traits* is a model for *ApproximateMinEllipsoid_d_Traits_d*.

We provide the model *CGAL::Approximate_min_ellipsoid_d_traits_d<K>* using the *d*-dimensional CGAL kernel; the models *CGAL::Approximate_min_ellipsoid_d_traits_2<K>* and *CGAL::Approximate_min_ellipsoid_d_traits_3<K>* are for use with the 2- and 3-dimensional CGAL kernel, respectively.

Types

Approximate_min_ellipsoid_d<Traits>:: FT

typedef Traits::FT FT (which is always a typedef to *double*).

Approximate_min_ellipsoid_d<Traits>:: ET

typedef Traits::ET ET (which is an exact number type used for exact computation like for example in *achieved_epsilon()*).

Approximate_min_ellipsoid_d<Traits>:: Point

typedef Traits::Point Point

Approximate_min_ellipsoid_d<Traits>:: Cartesian_const_iterator

typedef Traits::Cartesian_const_iterator Cartesian_const_iterator

Approximate_min_ellipsoid_d<Traits>:: Center_coordinate_iterator

A model of STL concept *RandomAccessIterator* with value type *double* that is used to iterate over the Cartesian center coordinates of the computed ellipsoid, see *center_cartesian_begin()*.

Approximate_min_ellipsoid_d<Traits>:: Axes_lengths_iterator

A model of STL concept *RandomAccessIterator* with value type *double* that is used to iterate over the lengths of the semiaxes of the computed ellipsoid, see *axes_lengths_begin()*.

Approximate_min_ellipsoid_d<Traits>:: Axis_direction_iterator

A model of STL concept *RandomAccessIterator* with value type *double* that is used to iterate over the Cartesian coordinates of the direction of a fixed axis of the computed ellipsoid, see *axis_direction_cartesian_begin()*.

Creation

An object of type *Approximate_min_ellipsoid_d<Traits>* can be created from an arbitrary point set P and some nonnegative *double* value *eps*.

template < class Iterator >
Approximate_min_ellipsoid_d<Traits> ame(double eps, Iterator first, Iterator last, Traits traits = Traits());

initializes *ame* to an $(1+\varepsilon)$-approximation of $\textsc{mel}(P)$ with P being the set of points in the range [*first*,*last*). The number ε in this will be at most *eps*, if possible. However, due to the limited precision in the algorithm's underlying arithmetic, it can happen that the computed approximation ellipsoid has a worse approximation ratio (and ε can thus be larger than *eps* in general). In any case, the number ε (and with this, the achived approximation $1+\varepsilon$) can be queried by calling the routine *achieved_epsilon()* discussed below.
Requirement: *Iterator* must be a model for concept *InputIterator* with value type *Point*.
Precondition: The dimension d of the input points must be at least 2, and $\varepsilon > 0$.

Access Functions

The following methods can be used to query the achieved approximation ratio $1+\varepsilon'$ and the computed ellipsoid $\mathcal{E} = \{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}$. The methods *defining_matrix()*, *defining_vector()*, and *defining_scalar()* do not return E, e, and η directly but yield multiples of these quantities that are exactly representable using the *double* type. (This is necessary because the parameters E, e, and η of the computed approximation ellipsoid $\mathcal{E}$ might not be exactly representable as *double* numbers.)

unsigned int *ame.number_of_points() const*

returns the number of points of *ame*, i.e., $|P|$.

double *ame.achieved_epsilon() const*

returns a number ε' such that the computed approximation is (under exact arithmetic) guaranteed to be an $(1+\varepsilon')$-approximation to $\text{MEL}(P)$.
Precondition: *ame.is_full_dimensional() == true*.
Postcondition: $\varepsilon' > 0$.

double *ame.defining_matrix(int i, int j) const*

gives access to the (i, j)th entry of the matrix E in the representation $\{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}$ of the computed approximation ellipsoid $\mathcal{E}$. The number returned by this routine is $(1+\varepsilon')(d+1)\,E_{ij}$, where ε' is the number returned by *achieved_epsilon()*.
Precondition: $0 \leq i, j \leq d$, where d is the dimension of the points P, and *ame.is_full_dimensional() == true*.

double *ame.defining_vector(int i) const*

gives access to the ith entry of the vector e in the representation $\{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}$ of the computed approximation ellipsoid $\mathcal{E}$. The number returned by this routine is $(1+\varepsilon')(d+1)\,e_i$, where ε' is the number returned by *achieved_epsilon()*.
Precondition: $0 \leq i \leq d$, where d is the dimension of the points P, and *ame.is_full_dimensional() == true*.

double *ame.defining_scalar() const*

gives access to the scalar η from the representation $\{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}$ of the computed approximation ellipsoid $\mathcal{E}$. The number returned by this routine is $(1+\varepsilon')(d+1)\,(\eta+1)$, where ε' is the number returned by *achieved_epsilon()*.
Precondition: *ame.is_full_dimensional() == true*.

Traits *ame.traits() const* returns a const reference to the traits class object.

int *ame.dimension() const*

returns the dimension of the ambient space, i.e., the dimension of the points P.

In order to access the center and semiaxes of the computed approximation ellipsoid, the functions *center_cartesian_begin()*, *axes_lengths_begin()*, and *axis_direction_cartesian_begin()* can be used. In constrast to the above access functions *achieved_epsilon()*, *defining_matrix()*, *defining_vector()*, and *defining_scalar()*, which return the described quantities exactly, the routines below return *numerical approximations* to the real center and real semiaxes of the computed ellipsoid; the comprised relative error may be larger than zero, and there are no guarantees for the returned quantities.

Center_coordinate_iterator
ame.center_cartesian_begin()

returns an iterator pointing to the first of the d Cartesian coordinates of the computed ellipsoid's center.
The returned point is a floating-point approximation to the ellipsoid's exact center; no guarantee is given w.r.t. the involved relative error.
Precondition: *ame.is_full_dimensional() == true*.

Center_coordinate_iterator
ame.center_cartesian_end()

returns the past-the-end iterator corresponding to *center_cartesian_begin()*.
Precondition: *ame.is_full_dimensional() == true*.

Axes_lengths_iterator
ame.axes_lengths_begin()

returns an iterator pointing to the first of the d descendantly sorted lengths of the computed ellipsoid's axes. The d returned numbers are floating-point approximations to the exact axes-lengths of the computed ellipsoid; no guarantee is given w.r.t. the involved relative error. (See also method *axes_direction_cartesian_begin()*.)
Precondition: *ame.is_full_dimensional() == true*, and $d \in \{2,3\}$.

Axes_lengths_iterator
ame.axes_lengths_end()

returns the past-the-end iterator corresponding to *axes_lengths_begin()*.
Precondition: *ame.is_full_dimensional() == true*, and $d \in \{2,3\}$.

Axes_direction_coordinate_iterator
ame.axis_direction_cartesian_begin(int i)

returns an iterator pointing to the first of the d Cartesian coordinates of the computed ellipsoid's ith axis direction (i.e., unit vector in direction of the ellipsoid's ith axis). The direction described by this iterator is a floating-point approximation to the exact axis direction of the computed ellipsoid; no guarantee is given w.r.t. the involved relative error. An approximation to the length of axis i is given by the ith entry of *axes_lengths_begin()*.
Precondition: *ame.is_full_dimensional() == true*, and $d \in \{2,3\}$, and $0 \leq i < d$.

Axes_direction_coordinate_iterator
ame.axis_direction_cartesian_end(int i)

returns the past-the-end iterator corresponding to *axis_direction_cartesian_begin()*.
Precondition: *ame.is_full_dimensional() == true*, and $d \in \{2,3\}$, and $0 \leq i < d$.

Predicates

bool *ame.is_full_dimensional() const*

returns whether P is full-dimensional or not, i.e., returns *true* if and only if P is full-dimensional.
Note: due to the limited precision in the algorithm's underlying arithmetic, the result of this method is not always correct. Rather, a return value of *false* means that the points P are contained in a "very thin" linear subspace of $\mathbb{E}^d$, and as a consequence, the algorithm cannot compute an approximation. More precisely, a return value of *false* means that the points P are contained between two parallel hyperplanes in $\mathbb{E}^d$ that are very close to each other (possibly at distance zero) — so close, that the algorithm could not compute an approximation ellipsoid. Similarly, a return value of *true* does not guarantee P to be full-dimensional; but there exists an input pointset P' such that the points P' and P have almost identical coordinates and P' is full-dimensional.

Validity Check

An object *ame* is valid iff

- *ame* contains all points of its defining set P,
- *ame* is an $(1+\varepsilon')$-approximation to the smallest ellipsoid $\mathrm{MEL}(P)$ of P,
- The ellipsoid represented by *ame* fulfills the inclusion (66.1).

bool *ame.is_valid(bool verbose = false) const*

returns *true* iff *ame* is valid according to the above definition. If *verbose* is *true*, some messages concerning the performed checks are written to the standard error stream.

Miscellaneous

void *ame.write_eps(const std::string& name) const*

Writes the points P and the computed approximation to $\mathrm{MEL}(P)$ as an EPS-file under pathname *name*.
Precondition: The dimension of points P must be 2.
Note: this routine is provided as a debugging routine; future version of CGAL might not provide it anymore.
Precondition: *ame.is_full_dimensional() == true*.

Implementation

We implement Khachyian's algorithm for rounding polytopes [Kha96]. Internally, we use *double*-arithmetic and (initially a single) Cholesky-decomposition. The algorithm's running time is $O(nd^2(\varepsilon^{-1}+\ln d+\ln\ln(n)))$, where $n=|P|$ and $1+\varepsilon$ is the desired approximation ratio.

Example

To illustrate the usage of *Approximate_min_ellipsoid_d<Traits>* we give two examples in 2D. The first program generates a random set $P\subset\mathbb{E}^2$ and outputs the points and a 1.01-approximation of $\mathrm{MEL}(P)$ as an EPS-file, which you can view using gv, for instance. (In both examples you can change the variables n and d to experiment with the code.)

```
#include <CGAL/Cartesian_d.h>
#include <CGAL/MP_Float.h>
#include <CGAL/point_generators_d.h>
#include <CGAL/Approximate_min_ellipsoid_d.h>
```

```
#include <CGAL/Approximate_min_ellipsoid_d_traits_d.h>

#include <vector>
#include <iostream>

typedef CGAL::Cartesian_d<double>                              Kernel;
typedef CGAL::MP_Float                                         ET;
typedef CGAL::Approximate_min_ellipsoid_d_traits_d<Kernel, ET> Traits;
typedef Traits::Point                                          Point;
typedef std::vector<Point>
   Point_list;
typedef CGAL::Approximate_min_ellipsoid_d<Traits>              AME;

int main()
{
  const int    n = 1000;                // number of points
  const int    d = 2;                   // dimension
  const double eps = 0.01;              // approximation ratio is
    (1+eps)

  // create a set of random points:
  Point_list P;
  CGAL::Random_points_in_cube_d<Point> rpg(d,100.0);
  for (int i = 0; i < n; ++i) {
    P.push_back(*rpg);
    ++rpg;
  }

  // compute approximation:
  Traits traits;
  AME ame(eps, P.begin(), P.end(), traits);

  // write EPS file:
  if (ame.is_full_dimensional() && d == 2)
    ame.write_eps("example.eps");

  // output center coordinates:
  std::cout << "Cartesian center coordinates: ";
  for (AME::Center_coordinate_iterator c_it =
   ame.center_cartesian_begin();
       c_it != ame.center_cartesian_end();
       ++c_it)
    std::cout << *c_it << ' ';
  std::cout << ".\n";

  if (d == 2 || d == 3) {
    // output  axes:
    AME::Axes_lengths_iterator axes = ame.axes_lengths_begin();
    for (int i = 0; i < d; ++i) {
      std::cout << "Semiaxis " << i << " has length " << *axes++  << "\n"
                << "and Cartesian coordinates ";
      for (AME::Axes_direction_coordinate_iterator
             d_it = ame.axis_direction_cartesian_begin(i);
           d_it != ame.axis_direction_cartesian_end(i); ++d_it)
```

```
        std::cout << *d_it << ' ';
      std::cout << ".\n";
    }
  }
}
```

Concept

ApproximateMinEllipsoid_d_Traits_d

Definition

This concept defines the requirements for traits classes of *CGAL::Approximate_min_ellipsoid_d<Traits>*.

Refines

DefaultConstructible
CopyConstructible
Assignable

Types

ApproximateMinEllipsoid_d_Traits_d:: FT — *typedef double FT*

ApproximateMinEllipsoid_d_Traits_d:: ET — Some model of concept *RingNumberType* that provides exact arithmetic, meaning that *CGAL::Number_type_traits<ET> ::Has_exact_ring_operations* must be *CGAL::Tag_true*. In addition, *ET* must be able to exactly represent any finite *double* value. (An example for such a type is *CGAL::MP_Float*.).
The type *ET* is to be used by the *Approximate_min_ellipsoid_d<Traits>* class for internal, exact computations.

ApproximateMinEllipsoid_d_Traits_d:: Point — Type of the input points. *Point* must provide the default and copy constructor, and must be a model of *DefaultConstructible*, *CopyConstructible*, and *Assignable*.

ApproximateMinEllipsoid_d_Traits_d:: Cartesian_const_iterator

Model for the STL concept *RandomAccessIterator* whose value type must be convertible to *double*. This type is used to iterate over the Cartesian coordinates of an instance of type *Point*, see *cartesian_begin()* below.

Access Functions

int *traits.dimension(Point p)*

returns the dimension of a point *p*.

Cartesian_const_iterator

traits.cartesian_begin(Point p)

returns an input iterator over the Euclidean coordinates of the point *p*. The range of the iterator must have size *dimension(p)*.

Class

CGAL::Approximate_min_ellipsoid_d_traits_2<K,ET>

Definition

The class *Approximate_min_ellipsoid_d_traits_2<K,ET>* is a traits class for *CGAL::Approximate_min_ellipsoid_d<Traits>* using the 2-dimensional CGAL kernel. In order to use this class, an exact number-type *ET* has to be provided which *Approximate_min_ellipsoid_d<Traits>* will use for its internal exact computations.

#include <CGAL/Approximate_min_ellipsoid_d_traits_2.h>

Requirements

The template parameter *K* must be a model for concept *Kernel*. The template parameter *ET* must be a model for concept *RingNumberType* with exact arithmetic operations, i.e., the type *CGAL::Number_type_traits<ET> ::Has_exact_ring_operations* must be *CGAL::Tag_true*. In addition, *ET* must be able to exactly represent any finite *double* value. (Examples of such a number-type are *CGAL::MP_Float*, *CORE::Expr*, and *CGAL::Gmpq*.)

Is Model for the Concepts

ApproximateMinEllipsoid_d_Traits_d

Types

Approximate_min_ellipsoid_d_traits_2<K,ET>:: FT — *typedef double FT*. The kernel's number type *K::RT* must be convertible to *double*.

Approximate_min_ellipsoid_d_traits_2<K,ET>:: ET — typedef to the second template argument, *ET*.

Approximate_min_ellipsoid_d_traits_2<K,ET>:: Point

typedef K::Point_2 Point

Approximate_min_ellipsoid_d_traits_2<K,ET>:: Cartesian_const_iterator

typedef K::Cartesian_const_iterator_2 Cartesian_const_iterator

CGAL::Min_sphere_annulus_d_traits_2<K,ET,NT>

Class

Definition

The class *Min_sphere_annulus_d_traits_2<K,ET,NT>* is a traits class for the d-dimensional optimisation algorithms using the two-dimensional CGAL kernel.

#include <CGAL/Min_sphere_annulus_d_traits_2.h>

Requirements

The template parameter *K* is a model for *Kernel*. Template parameters *ET* and *NT* are models for *RingNumberType*.

The second and third template parameter have default type *K::RT*.

Is Model for the Concepts

MinSphereAnnulusDTraits . . . . page 3907

Types

Min_sphere_annulus_d_traits_2<K,ET,NT>:: Point_d	typedef to *K::Point_2*.
Min_sphere_annulus_d_traits_2<K,ET,NT>:: Rep_tag	typedef to *K::Rep_tag*.
Min_sphere_annulus_d_traits_2<K,ET,NT>:: RT	typedef to *K::RT*.
Min_sphere_annulus_d_traits_2<K,ET,NT>:: FT	typedef to *K::FT*.
Min_sphere_annulus_d_traits_2<K,ET,NT>:: Access_dimension_d	typedef to *K::Access_dimension_2*.
Min_sphere_annulus_d_traits_2<K,ET,NT>:: Access_coordinates_begin_d	typedef to *K::Access_coordinates_begin_2*.
Min_sphere_annulus_d_traits_2<K,ET,NT>:: Construct_point_d	typedef to *K::Construct_point_2*.
Min_sphere_annulus_d_traits_2<K,ET,NT>:: ET	second template parameter (default is *K::RT*).
Min_sphere_annulus_d_traits_2<K,ET,NT>:: NT	third template parameter (default is *K::RT*).

Creation

Min_sphere_annulus_d_traits_2<K,ET,NT> traits; default constructor.

Min_sphere_annulus_d_traits_2<K,ET,NT> traits(Min_sphere_annulus_d_traits_2<K,ET,NT>);

copy constructor.

Operations

The following functions just return the corresponding function class object.

Access_dimension_d	*traits.access_dimension_d_object() const*
Access_coordinates_begin_d	*traits.access_coordinates_begin_d_object() const*

CGAL::Min_sphere_annulus_d_traits_d<K,ET,NT>

Class

Definition

The class *Min_sphere_annulus_d_traits_d<K,ET,NT>* is a traits class for the d-dimensional optimisation algorithms using the d-dimensional CGAL kernel.

#include <CGAL/Min_sphere_annulus_d_traits_d.h>

Requirements

The template parameter *K* is a model for *Kernel*. Template parameters *ET* and *NT* are models for *RingNumberType*.

The second and third template parameter have default type *K::RT*.

Is Model for the Concepts

MinSphereAnnulusDTraits . . . . page 3907

Types

Min_sphere_annulus_d_traits_d<K,ET,NT>:: Point_d	typedef to *K::Point_d*.
Min_sphere_annulus_d_traits_d<K,ET,NT>:: Rep_tag	typedef to *K::Rep_tag*.
Min_sphere_annulus_d_traits_d<K,ET,NT>:: RT	typedef to *K::RT*.
Min_sphere_annulus_d_traits_d<K,ET,NT>:: FT	typedef to *K::FT*.
Min_sphere_annulus_d_traits_d<K,ET,NT>:: Access_dimension_d	typedef to *K::Access_dimension_d*.
Min_sphere_annulus_d_traits_d<K,ET,NT>:: Access_coordinates_begin_d	typedef to *K::Access_coordinates_begin_d*.
Min_sphere_annulus_d_traits_d<K,ET,NT>:: Construct_point_d	typedef to *K::Construct_point_d*.
Min_sphere_annulus_d_traits_d<K,ET,NT>:: ET	second template parameter (default is *K::RT*).
Min_sphere_annulus_d_traits_d<K,ET,NT>:: NT	third template parameter (default is *K::RT*).

Creation

Min_sphere_annulus_d_traits_d<K,ET,NT> traits; default constructor.

Min_sphere_annulus_d_traits_d<K,ET,NT> traits(Min_sphere_annulus_d_traits_d<K,ET,NT>);

copy constructor.

Operations

The following functions just return the corresponding function class object.

Access_dimension_d	*traits.access_dimension_d_object() const*
Access_coordinates_begin_d	*traits.access_coordinates_begin_d_object() const*
Construct_point_d	*traits.construct_point_d_object() const*

MinSphereAnnulusDTraits . . . . page 3907

Concept

MinSphereAnnulusDTraits

Definition

This concept defines the requirements for traits classes of d-dimensional min sphere and min annulus algorithms.

Types

MinSphereAnnulusDTraits:: Point_d — point type used to represent the input points.

MinSphereAnnulusDTraits:: Rep_tag — compile time tag to distinguish between Cartesian and homogeneous representation of the input points. *Rep_tag* has to be either *CGAL::Cartesian_tag* or *CGAL::Homogeneous_tag*.

MinSphereAnnulusDTraits:: RT — number type used to represent the coordinates of the input points. It has to be a model for *RingNumberType*.

MinSphereAnnulusDTraits:: FT — number type used to return either the squared radius of the smallest enclosing sphere or annulus, or the squared distance of the polytopes. *FT* has to be either *RT* or *CGAL::Quotient*<*RT*> if the input points have Cartesian or homogeneous representation, respectively (cf. *Rep_tag*).

MinSphereAnnulusDTraits:: Access_dimension_d

data accessor object used to access the dimension of the input points.

MinSphereAnnulusDTraits:: Access_coordinates_begin_d

data accessor object used to access the coordinates of the input points.

MinSphereAnnulusDTraits:: Construct_point_d

constructor object used to construct either the center of the smallest enclosing sphere or annulus, or the points realizing the distance between the two polytopes.

The following two number types are only needed for *CGAL::Min_annulus_d*<*Traits*> and *CGAL::Polytope_distance_d*<*Traits*>.

MinSphereAnnulusDTraits:: ET — exact number type used to do the exact computations in the underlying solver for linear programs. It has to to be a model for *RingNumberType*. There must be an implicit conversion from *RT* to *ET* available.

MinSphereAnnulusDTraits:: NT — fast (possibly inexact) number type used to speed up the pricing step in the underlying solver for linear programs. It has to be a model for *RingNumberType*. There must be implicit conversions from *RT* to *NT* and from *NT* to *ET* available.

Creation

Only default and copy constructor are required.

MinSphereAnnulusDTraits traits;

MinSphereAnnulusDTraits traits(MinSphereAnnulusDTraits);

Operations

The following functions just return the corresponding function class object.

Access_dimension_d	*traits.access_dimension_d_object() const*
Access_coordinates_begin_d	*traits.access_coordinates_begin_d_object() const*
Construct_point_d	*traits.construct_point_d_object() const*

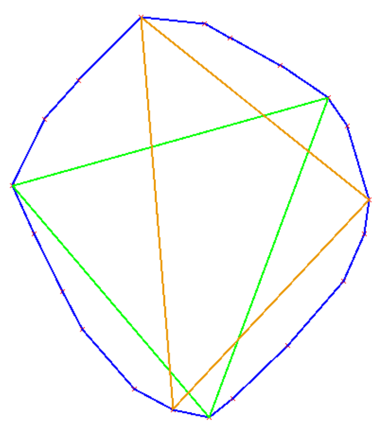
Chapter 67

Inscribed Areas

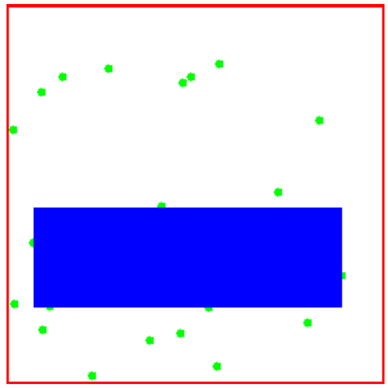
Michael Hoffmann and Eli Packer

This chapter describes algorithms which for a given point set compute the "best" inscribed object from a specific class. We provide algorithms for computing maximal inscribed k-gons (triangles, quadrilaterals, ...) of a planar point set P. Maximal k-gons are convex, and it is known that their vertices can be chosen to be vertices of the convex hull of P. Hence, the functions *CGAL::maximum_area_inscribed_k_gon_2* and *CGAL::maximum_perimeter_inscribed_k_gon_2* operate on convex polygons only. The example below shows that the largest area triangle (green) and the largest perimeter triangle (orange, containing the top point) of a point set are different in general.



We further provide an algorithm for computing the maximal area inscribed axis parallel rectangle

Given a set of points in the plane, the class *CGAL::Largest_empty_iso_rectangle_2<T>* is a data structure that maintains an iso-rectangle with the largest area among all iso-rectangles that are inside a given iso-rectangles, and that do not contain any point of the point set.



Inscribed volumes are also frequently applied to extract geometric properties of objects. The largest area triangle is for example used in heuristics for matching archaeological aerial photographs. Largest perimeter triangles are used in scoring cross country soaring flights, where the goal is basically to fly as far as possible, but still return to the departure airfield. To score simply based on the total distance flown is not a good measure, since circling in thermals allows to increase it easily.

Inscribed Areas
Reference Manual

Michael Hoffmann and Eli Packer

This chapter describes concepts, classes, and functions for maximum area and perimeter inscribed k-gon (2D), extremal inscribed k-gon (2D), largest empty isorectangle (2D).

Assertions

The optimization code uses infix *OPTIMISATION* in the assertions, e.g. defining the compiler flag *CGAL_OPTIMISATION_NO_PRECONDITIONS* switches precondition checking off, cf. Section 2.8.

Function

CGAL::maximum_area_inscribed_k_gon_2

Definition

The function *maximum_area_inscribed_k_gon_2* computes a maximum area k-gon P_k that can be inscribed into a given convex polygon P. Note that

- P_k is not unique in general, but it can be chosen in such a way that its vertices form a subset of the vertex set of P and
- the vertices of a maximum area k-gon, where the k vertices are to be drawn from a planar point set S, lie on the convex hull of S i.e. a convex polygon.

#include <CGAL/extremal_polygon_2.h>

```
template < class RandomAccessIterator, class OutputIterator >
OutputIterator        maximum_area_inscribed_k_gon_2(
                          RandomAccessIterator points_begin,
                          RandomAccessIterator points_end,
                          int k,
                          OutputIterator o)
```

computes a maximum area inscribed k-gon of the convex polygon described by [*points_begin*, *points_end*), writes its vertices to o and returns the past-the-end iterator of this sequence.

Precondition:

1. the – at least three – points denoted by the range [*points_begin*, *points_end*) form the boundary of a convex polygon (oriented clock– or counterclockwise).
2. $k \geq 3$.

Requirement:

1. Value type of *RandomAccessIterator* is *K::Point_2* where K is a model for *Kernel*.
2. *OutputIterator* accepts the value type of *RandomAccessIterator* as value type.

CGAL::extremal_polygon_2 . . . . page 3916
CGAL::monotone_matrix_search . . . . page 458

Implementation

The implementation uses monotone matrix search [AKM+87] and has a worst case running time of $O(k \cdot n + n \cdot \log n)$, where n is the number of vertices in P.

Example

The following code generates a random convex polygon p with ten vertices and computes the maximum area inscribed five-gon of p.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>
#include <CGAL/extremal_polygon_2.h>
#include <iostream>
#include <vector>

typedef double                                         FT;

typedef CGAL::Cartesian<FT>                            Kernel;

typedef Kernel::Point_2                                Point;
typedef std::vector<int>                               Index_cont;
typedef CGAL::Polygon_2<Kernel>                        Polygon_2;
typedef CGAL::Random_points_in_square_2<Point>         Generator;

int main() {

  int n = 10;
  int k = 5;

  // generate random convex polygon:
  Polygon_2 p;
  CGAL::random_convex_set_2(n, std::back_inserter(p), Generator(1));
  std::cout << "Generated Polygon:\n" << p << std::endl;

  // compute maximum area incribed k-gon of p:
  Polygon_2 k_gon;
  CGAL::maximum_area_inscribed_k_gon_2(
    p.vertices_begin(), p.vertices_end(), k, std::back_inserter(k_gon));
  std::cout << "Maximum area " << k << "-gon:\n"
            << k_gon << std::endl;

  return 0;
}
```

Function

CGAL::maximum_perimeter_inscribed_k_gon_2

Definition

The function *maximum_perimeter_inscribed_k_gon_2* computes a maximum perimeter k-gon P_k that can be inscribed into a given convex polygon P. Note that

- P_k is not unique in general, but it can be chosen in such a way that its vertices form a subset of the vertex set of P and
- the vertices of a maximum perimeter k-gon, where the k vertices are to be drawn from a planar point set S, lie on the convex hull of S i.e. a convex polygon.

#include <CGAL/extremal_polygon_2.h>

```
template < class RandomAccessIterator, class OutputIterator >
OutputIterator      maximum_perimeter_inscribed_k_gon_2(
                           RandomAccessIterator points_begin,
                           RandomAccessIterator points_end,
                           int k,
                           OutputIterator o)
```

computes a maximum perimeter inscribed k-gon of the convex polygon described by [*points_begin*, *points_end*), writes its vertices to o and returns the past-the-end iterator of this sequence.

Precondition:

1. the – at least three – points denoted by the range [*points_begin*, *points_end*) form the boundary of a convex polygon (oriented clock– or counterclockwise).
2. $k \geq 2$.

Requirement:

1. Value type of *RandomAccessIterator* is *K::Point_2* where K is a model for *Kernel*.
2. There is a global function *K::FT CGAL::sqrt(K::FT)* defined that computes the squareroot of a number.
3. *OutputIterator* accepts the value type of *RandomAccessIterator* as value type.

Function

CGAL::extremal_polygon_2

advanced

Definition

The function *extremal_polygon_2* computes a maximal k-gon that can be inscribed into a given convex polygon. The criterion for maximality and some basic operations have to be specified in an appropriate traits class parameter.

#include <CGAL/extremal_polygon_2.h>

```
template < class RandomAccessIterator, class OutputIterator, class Traits >
OutputIterator      extremal_polygon_2(
                        RandomAccessIterator points_begin,
                        RandomAccessIterator points_end,
                        int k,
                        OutputIterator o,
                        Traits t)
```

computes a maximal (as specified by t) inscribed k-gon of the convex polygon described by [*points_begin*, *points_end*), writes its vertices to o and returns the past-the-end iterator of this sequence.

Precondition:

1. the – at least three – points denoted by the range [*points_begin*, *points_end*) form the boundary of a convex polygon (oriented clock– or counterclockwise).
2. $k \geq t.min\_k()$.

Requirement:

1. *Traits* is a model for *ExtremalPolygonTraits_2*.
2. Value type of *RandomAccessIterator* is *Traits::Point_2*.
3. *OutputIterator* accepts *Traits::Point_2* as value type.

ExtremalPolygonTraits_2

advanced

Definition

The concept ExtremalPolygonTraits_2 provides the types and operations needed to compute a maximal k-gon that can be inscribed into a given convex polygon.

Types

ExtremalPolygonTraits_2:: FT	model for FieldNumberType . . . . page 149.
ExtremalPolygonTraits_2:: Point_2	model for Kernel::Point_2 . . . . page 794.
ExtremalPolygonTraits_2:: Less_xy_2	model for Kernel::Less_xy_2 . . . . page **??**.
ExtremalPolygonTraits_2:: Orientation_2	model for Kernel::Orientation_2 . . . . page 1034.
ExtremalPolygonTraits_2:: Operation	AdaptableBinaryFunction class *op*: $Point\_2 \times Point\_2 \rightarrow FT$. Together with *init* this operation recursively defines the objective function to maximize. Let p and q be two vertices of a polygon P such that q precedes p in the oriented vertex chain of P starting with vertex $root$. Then *op(p,q)* returns the value by which an arbitrary sub-polygon of P with vertices from $[root, q]$ increases when p is added to it. E.g. in the maximum area case this is the area of the triangle $(root, q, p)$.

Operations

int *t.min_k() const*

returns the minimal k for which a maximal k-gon can be computed. (e.g. in the maximum area case this is three.)

FT *t.init(const Point_2& p, const Point_2& q) const*

returns the value of the objective function for a polygon consisting of the two points p and q. (e.g. in the maximum area case this is *FT(0)*.)

Operation *t.operation(const Point_2& p) const*

return *Operation* where p is the fixed *root* point.

template < class RandomAccessIterator, class OutputIterator >

Concept

OutputIterator	*t.compute_min_k_gon(*	*RandomAccessIterator points_begin,* *RandomAccessIterator points_end,* *FT& max_area,* *OutputIterator o) const*

writes the points of [*points_begin*, *points_end*) forming a *min_k()*-gon rooted at *points_begin[0]* of maximal value to o and returns the past-the-end iterator for that sequence (== *o* + *min_k()*).

Less_xy_2	*t.less_xy_2_object()*
Orientation_2	*t.orientation_2_object()*

Notes

- *::Less_xy_2* and *::Orientation_2* are used for (expensive) precondition checking only. Therefore, they need not to be specified, in case that precondition checking is disabled.

CGAL::Largest_empty_iso_rectangle_2<T>

Class

Definition

Given a set of points in the plane, the class *Largest_empty_iso_rectangle_2<T>* is a data structure that maintains an iso-rectangle with the largest area among all iso-rectangles that are inside a given bounding box(iso-rectangle), and that do not contain any point of the point set.

The class *Largest_empty_iso_rectangle_2<T>* expects a model of the concept *LargestEmptyIsoRectangleTraits_2* as its template argument.

#include <CGAL/Largest_empty_iso_rectangle_2.h>

Types

The class *Largest_empty_iso_rectangle_2<T>* defines the following types:

typedef T *Traits;*

typedef Traits::Point_2

Point_2;

typedef Traits::Iso_rectangle_2

Iso_rectangle_2;

The following iterator allows to enumerate the points. It is non mutable, bidirectional and its value type is *Point_2*. It is invalidated by any insertion or removal of a point.

Largest_empty_iso_rectangle_2<T>:: const_iterator

Iterator over the points.

Creation

Largest_empty_iso_rectangle_2<T> l(Iso_rectangle_2 b);

Constructor. The iso-rectangle b is the bounding rectangle.

Largest_empty_iso_rectangle_2<T> l(const Point_2 p, const Point_2 q);

Constructor. The iso-rectangle whose lower left and upper right points are p and q respectively is the bounding rectangle.

Largest_empty_iso_rectangle_2<T> l;

Constructor. The iso-rectangle whose lower left point and upper right points are (0,0) and (1,1) respectively is the bounding rectangle.

Largest_empty_iso_rectangle_2<T> l(const Largest_empty_iso_rectangle_2<Traits> tr);

Copy constructor.

Operations

Assignment

Largest_empty_iso_rectangle_2<T>

l = tr

Access Functions

Traits	*l.traits() const*	Returns a const reference to the traits object.
const_iterator	*l.begin() const*	Returns an iterator to the beginning of the point set.
const_iterator	*l.end() const*	Returns a past-the-end iterator for the point set.

Queries

Quadruple<Point_2, Point_2, Point_2, Point_2>

l.get_left_bottom_right_top()

Returns the four points that define the largest empty iso-rectangle. (Note that these points are not necessarily on a corner of an iso-rectangle.)

Iso_rectangle_2

l.get_largest_empty_iso_rectangle()

Returns the largest empty iso-rectangle. (Note that the two points defining the iso-rectangle are not necessarily part of the point set.)

Iso_rectangle_2

l.get_bounding_box() Returns the iso-rectangle passed in the constructor.

Insertion

void	*l.insert(Point_2 p)*	Inserts point p in the point set, if it is not already in the set.
void	*l.push_back(Point_2 p)*	Inserts point p in the point set, if it is not already in the set.

template < class InputIterator >

int *l.insert(InputIterator first, InputIterator last)*

Inserts the points in the range [*first*, *last*). Returns the number of inserted points.

Requirements

The *value_type* of *first* and *last* is *Point*.

Removal

bool	*l.remove(Point_2 p)*	Removes point p. Returns false iff p is not in the point set.
void	*l.clear()*	Removes all points of l.

Implementation

The algorithm is an implementation of [Orl90]. The runtime of an insertion or a removal is $O(\log n)$. A query takes $O(n^2)$ worst case time and $O(n \log n)$ expected time. The working storage is $O(n)$.

Concept

LargestEmptyIsoRectangleTraits_2

Definition

The concept LargestEmptyIsoRectangleTraits_2 describes the set of requirements to be fulfilled by any class used to instantiate the template parameter of the class *Largest_empty_iso_rectangle_2<T>*. This concept provides the types of the geometric primitives used in this class and some function object types for the required predicates on those primitives.

Types

LargestEmptyIsoRectangleTraits_2:: Point_2 — The point type.

LargestEmptyIsoRectangleTraits_2:: Iso_rectangle_2

The iso rectangle type.

LargestEmptyIsoRectangleTraits_2:: Compare_x_2

Predicate object. Must provide the operator *Comparison_result operator()(Point_2 p, Point_2 q)* which returns *SMALLER, EQUAL* or *LARGER* according ding to the x-ordering of points p and q.

LargestEmptyIsoRectangleTraits_2:: Compare_y_2

Predicate object. Must provide the operator *Comparison_result operator()(Point_2 p, Point_2 q)* which returns *SMALLER, EQUAL* or *LARGER* according to the y-ordering of points p and q.

LargestEmptyIsoRectangleTraits_2:: Less_x_2 — Predicate object. Must provide the operator *bool operator()(Point_2 p, Point_2 q)* which returns whether p is less than q according to their x-ordering.

LargestEmptyIsoRectangleTraits_2:: Less_y_2 — Predicate object. Must provide the operator *bool operator()(Point_2 p, Point_2 q)* which returns whether p is less than q according to their y-ordering.

Creation

Only a default constructor, copy constructor and an assignement operator are required. Note that further constructors can be provided.

LargestEmptyIsoRectangleTraits_2 traits; — Default constructor.

LargestEmptyIsoRectangleTraits_2 traits(LargestEmptyIsoRectangleTraits_2);

Copy constructor

LargestEmptyIsoRectangleTraits_2

traits = gtr — Assignment operator.

Predicate functions

The following functions give access to the predicate and constructor objects.

Compare_x_2	*traits.compare_x_2_object()*
Compare_y_2	*traits.compare_y_2_object()*
Less_x_2	*traits.less_x_2_object()*
Less_y_2	*traits.less_y_2_object()*

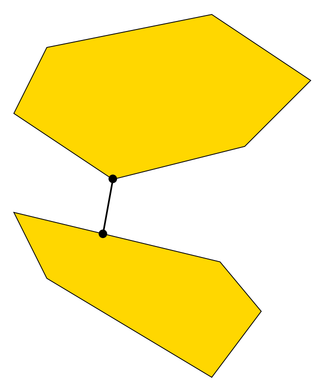
Chapter 68

Optimal Distances

Kaspar Fischer, Bernd Gärtner, Thomas Herrmann, Michael Hoffmann, and Sven Schönherr

This chapter describes how to compute the distance between the convex hulls of two given point sets in d-dimensional Euclidean space (*CGAL::Polytope_distance_d<Traits>*). Moreover, it is possible to compute the width of a point set in three dimensions (*CGAL::Width_3<Traits>*).



The obvious application is collision detection between convex bodies in space. In the spirit of the bounding volume application above, it also makes sense for nonconvex objects: a full intersection test between complicated objects could in a first stage be approximated with the test between the convex hulls of the objects. Only if the hulls intersect, a full intersection test is necessary.

To dampen fears concerning the performance of the distance computation, we want to mention that the convex hulls of the input point sets are not explicitly computed. This avoids a runtime which grows exponentially in d. In fact, the runtime is almost always linear in the size of the two point sets.

Optimal Distances
Reference Manual

Kaspar Fischer, Bernd Gärtner, Thomas Herrmann, Michael Hoffmann, and Sven Schönherr

This chapter describes concepts, classes, and functions for 2D all furthest neigbors, 3D width of a point set, and dD polytope distance.

Assertions

The optimization code uses infix *OPTIMISATION* in the assertions, e.g. defining the compiler flag *CGAL_OPTIMISATION_NO_PRECONDITIONS* switches precondition checking off, cf. Section 2.8.

CGAL::all_furthest_neighbors_2

Function

Definition

The function *all_furthest_neighbors_2* computes all furthest neighbors for the vertices of a convex polygon P, i.e. for each vertex v of P a vertex f_v of P such that the distance between v and f_v is maximized.

#include <CGAL/all_furthest_neighbors_2.h>

template < class RandomAccessIterator, class OutputIterator, class Traits >
OutputIterator all_furthest_neighbors_2(
RandomAccessIterator points_begin,
RandomAccessIterator points_end,
OutputIterator o,
Traits t = Default_traits)

computes all furthest neighbors for the vertices of the convex polygon described by the range [*points_begin*, *points_end*), writes their indices (relative to *points_begin*) to *o*[1] and returns the past-the-end iterator of this sequence.

Precondition: The points denoted by the non-empty range [*points_begin*, *points_end*) form the boundary of a convex polygon P (oriented clock– or counterclockwise).

The geometric types and operations to be used for the computation are specified by the traits class parameter t. This parameter can be omitted if *RandomAccessIterator* refers to a point type from a *Kernel*. In this case, the kernel is used as default traits class.

Requirement:

1. If t is specified explicitly, *Traits* is a model for *AllFurthestNeighborsTraits_2*.
2. Value type of *RandomAccessIterator* is *Traits::Point_2* or – if t is not specified explicitly – *K::Point_2* where K is a model for *Kernel*.
3. *OutputIterator* accepts *int* as value type.

See Also

AllFurthestNeighborsTraits_2 . . . . page 3935
CGAL::monotone_matrix_search . . . . page 458

Implementation

The implementation uses monotone matrix search[AKM+87]. Its runtime complexity is linear in the number of vertices of P.

[1] i.e. the furthest neighbor of *points_begin*[i] is *points_begin*[*i*-th number written to *o*]

Example

The following code generates a random convex polygon *p* with ten vertices, computes all furthest neighbors and writes the sequence of their indices (relative to *points_begin*) to *cout* (e.g. a sequence of *4788911224* means the furthest neighbor of *points_begin[0]* is *points_begin[4]*, the furthest neighbor of *points_begin[1]* is *points_begin[7]* etc.).

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>
#include <CGAL/all_furthest_neighbors_2.h>
#include <CGAL/IO/Ostream_iterator.h>
#include <iostream>
#include <vector>

typedef double                                          FT;

typedef CGAL::Cartesian<FT>                             Kernel;

typedef Kernel::Point_2                                 Point;
typedef std::vector<int>                                Index_cont;
typedef CGAL::Polygon_2<Kernel>                         Polygon_2;
typedef CGAL::Random_points_in_square_2<Point>          Generator;
typedef CGAL::Ostream_iterator<int,std::ostream>        Oiterator;

int main()
{
  // generate random convex polygon:
  Polygon_2 p;
  CGAL::random_convex_set_2(10, std::back_inserter(p), Generator(1));

  // compute all furthest neighbors:
  CGAL::all_furthest_neighbors_2(p.vertices_begin(), p.vertices_end(),
                                 Oiterator(std::cout));
  std::cout << std::endl;

  return 0;
}
```

Concept

AllFurthestNeighborsTraits_2

Definition

The concept AllFurthestNeighborsTraits_2 defines types and operations needed to compute all furthest neighbors for the vertices of a convex polygon using the function *all_furthest_neighbors_2*.

Types

AllFurthestNeighborsTraits_2:: FT	model for FieldNumberType . . . . page 149.
AllFurthestNeighborsTraits_2:: Point_2	model for Kernel::Point_2 . . . . page 794.
AllFurthestNeighborsTraits_2:: Compute_squared_distance_2	
	model for Kernel::Compute_squared_distance_2 . . . page **??**.
AllFurthestNeighborsTraits_2:: Less_xy_2	model for Kernel::Less_xy_2 . . . . page **??**.
AllFurthestNeighborsTraits_2:: Orientation_2	model for Kernel::Orientation_2 . . . . page 1034.

Operations

The following member functions return function objects of the types listed above.

Compute_squared_distance_2	
	t.compute_squared_distance_2_object()
Less_xy_2	*t.less_xy_2_object()*
Orientation_2	*t.orientation_2_object()*

Has Models

Cartesian<FieldNumberType> . . . . page **??**, *Homogeneous<RingNumberType>* . . . . page **??**,
Simple_cartesian<FieldNumberType> . . . . . . page **??**, *Simple_homogeneous<RingNumberType>* . . . . . . page **??**.

See Also

CGAL::all_furthest_neighbors_2 . . . . page 3933

Notes

- *::Less_xy_2* and *::Orientation_2* are used for (expensive) precondition checking only. Therefore, they need not to be specified, in case that precondition checking is disabled.

CGAL::Width_3<Traits>

Definition

Given a set of points $\mathcal{S} = \{p_1, \ldots, p_n\}$ in $\mathbb{R}^3$. The width of $\mathcal{S}$, denoted as $\mathcal{W}(\mathcal{S})$, is defined as the minimum distance between two parallel planes of support of $conv(\mathcal{S})$; where $conv(\mathcal{S})$ denotes the convex hull of $\mathcal{S}$. The width in direction $\mathbf{d}$, denoted as $\mathcal{W}_d(\mathcal{S})$, is the distance between two parallel planes of support of $conv(\mathcal{S})$, which are orthogonal to $\mathbf{d}$.

Subject to the applications of the width algorithm, several objects might be interesting:

1. The two parallel planes of support such that the distance between them is as small as possible. These planes are called width-planes in further considerations.
2. The width $\mathcal{W}(\mathcal{S})$, i.e., the distance between the width-planes.
3. The direction $\mathbf{d}_{opt}$ such that $\mathcal{W}(\mathcal{S}) = \mathcal{W}_{d_{opt}}(\mathcal{S})$

Note: There might be several optimal build directions. Hence neither the width-planes nor the direction $\mathbf{d}_{opt}$ are unique – only the width is.

#include <CGAL/Width_3.h>

Requirements

The template parameter *Traits* is a model for *WidthTraits_3*. We provide the model *Width_default_traits_3< Kernel>* based on a three-dimensional CGAL kernel.

Types

Width_3<Traits>:: Traits		traits class.
typedef typename Traits::Point_3	*Point_3;*	point type.
typedef typename Traits::Plane_3	*Plane_3;*	plane type.
typedef typename Traits::Vector_3	*Vector_3;*	vector type.
typedef typename Traits::RT	*RT;*	algebraic ring type.
typedef typename Traits::ChullTraits	*ChullTraits;*	traits class for the 3D convex hull algorithm.

Creation

template < class InputIterator >
Width_3<Traits> width(InputIterator first, InputIterator beyond);

creates a variable *width* initialized to the width of $\mathcal{S}$ – with $\mathcal{S}$ being the set of points in the range [*first*,*beyond*).
Requirement: The value type of *InputIterator* is *Point_3*.

template < class Polyhedron >
Width_3<Traits> width(Polyhedron& P);

creates a variable *width* initialized to the width of the polyhedron P. Note that the vertex point coordinates are altered!
Precondition: P is a convex polyhedron.
Requirement: *Polyhedron* is a *CGAL::Polyhedron_3* with facets supporting plane equations where *Polyhedron::Point_3* $\equiv$ *Point_3* and *Polyhedron::Plane_3* $\equiv$ *Plane_3*.

Access Functions

void *width.get_squared_width(RT& width_num, RT& width_denom)*

returns the squared width. For the reason of exact computation not the width itself is stored, but the *squared* width as a fraction: The numerator in *width_num* and the denominator in *width_denom*. The width of the point set $\mathcal{S}$ is $\sqrt{\frac{width\_num}{width\_denom}}$.

void *width.get_width_planes(Plane_3& e1, Plane_3& e2)*

The planes *e1* and *e2* are the two parallel supporting planes, which distance is minimal (among all such planes).

void *width.get_width_coefficients(RT& A, RT& B, RT& C, RT& D, RT& K)*

The returned coefficients *A,B,C,D,K* have the property that width-plane *e1* is given by the equation $Ax+By+Cz+D=0$ and width-plane *e2* by $Ax+By+Cz+K=0$.

Vector_3 *width.get_build_direction()*

returns a direction $\mathbf{d}_{opt}$ such that the width-planes *e1* and *e2* are perpendicular to $\mathbf{d}_{opt}$. The width of the point set is minimal in this direction.

void *width.get_all_build_directions(std::vector<Vector_3>& dir)*

All the build directions are stored in the vector *dir*. It might happen that a certain body has several different build directions, but it is also possible to have only one build direction.

int *width.get_number_of_optimal_solutions()*

returns the number of optimal solutions, i.e., the number of optimal build directions.

See Also

CGAL::Width_default_traits_3<K> . . . . page 3940
WidthTraits_3 . . . . page 3942

Implementation

Since the width of the point set $\mathcal{S}$ and the width of the convex hull of $\mathcal{S}$ ($conv(\mathcal{S})$) is the same, the algorithm uses the 3D convex hull algorithm CGAL provides.

The width-algorithm is not incremental and therefore inserting and erasing points cause not an 'automatic' update of the width. Instead you have to run the width-algorithm again even if the point set is extended by only one new point.

advanced

Large Numbers. Because there is no need for dividing values during the algorithm, the numbers can get really huge (all the computations are made using a lot of multiplications). Therefore it is strongly recommended to use a number type that can handle numbers of arbitrary length (e.g., *leda_integer* in combination with the homogeneous representation of the points). But these large numbers have a disadvantage: Operations on them are slower as greater the number gets. Therefore it is possible to shorten the numbers by using the compiler flag -DSIMPLIFY. For using this option it is required that the underlying number type provides the 'modulo' operation.

Information Output during the Computations. If during the algorithm the program should output some information (e.g., during the debugging phase) you can turn on the output information by giving the compiler flag DEBUG. In the file `width_assertions.h` you can turn on/off the output of some functions and additional informations by changing the defined values from 0 (no output) to 1 (output available). But then it is required that the <<-operator has to been overloaded for *Point_3*, *Plane_3*, *Vector_3* and *RT*.

Class

CGAL::Width_default_traits_3<K>

Definition

The class *Width_default_traits_3<K>* is a traits class for *Width_3<Traits>* using the three-dimensional CGAL kernel.

#include <CGAL/Width_default_traits_3.h>

Requirements

The template parameter *K* is a model for *Kernel*

Is Model for the Concepts

WidthTraits_3 . . . . page 3942

Types

typedef typename K::Point_3	*Point_3;*
typedef typename K::Plane_3	*Plane_3;*
typedef typename K::Vector_3	*Vector_3;*
typedef typename K::RT	*RT;*
typedef Convex_hull_traits_3<K>	*ChullTraits;*

Creation

Width_default_traits_3<K> traits; default constructor.

Operations

RT *traits.get_hx(Point_3 p) const*
returns the homogeneous x-coordinate of point p.

RT *traits.get_hy(Point_3 p) const*
returns the homogeneous y-coordinate of point p.

RT *traits.get_hz(Point_3 p) const*
returns the homogeneous z-coordinate of point p.

RT *traits.get_hw(Point_3 p) const*
returns the homogenizing coordinate of point p.

void *traits.get_point_coordinates(Point_3 p, RT& px, RT& py, RT& pz, RT& ph) const*
returns all homogeneous coordinates of point p at once.

RT *traits.get_a(Plane_3 f) const*
returns the first coefficient of plane f.

RT *traits.get_b(Plane_3 f) const*
returns the second coefficient of plane f.

RT	*traits.get_c(Plane_3 f) const*	
		returns the third coefficient of plane f.
RT	*traits.get_d(Plane_3 f) const*	
		returns the fourth coefficient of plane f.
void	*traits.get_plane_coefficients(Plane_3 f, RT& a, RT& b, RT& c, RT& d) const*	
		returns all four plane coefficients of f at once.
Point_3	*traits.make_point(RT hx, RT hy, RT hz, RT hw) const*	
		returns a point of type *Point_3* with homogeneous coordinates *hx*, *hy*, *hz* and *hw*.
Plane_3	*traits.make_plane(RT a, RT b, RT c, RT d) const*	
		returns a plane of type *Plane_3* whose coefficients are *a*, *b*, *c* and *d*.
Vector	*traits.make_vector(RT a, RT b, RT c) const*	
		returns a vector of type *Vector_3* with the four coefficients *a*, *b*, *c* and 1.

WidthTraits_3 . . . . page 3942

Concept

WidthTraits_3

Definition

This concept defines the requirements for traits classes of *Width_3<Traits>*.

Types

WidthTraits_3:: Point_3	The point type. The (in)equality tests must be available. Access to the point coordinates is done via the *get_()* functions. Constructing a point is done with the *make_point( )* operation.
WidthTraits_3:: Plane_3	The plane type. Access to the coefficients of the plane is made via the *get_()* functions. Constructing a plane is done with the *make_plane()* operation.
WidthTraits_3:: Vector_3	The vector type. There is no need to access the coefficients of a vector; only constructing is required and is done with the *make_vector* operation.
WidthTraits_3:: ChullTraits	The traits class for using the convex hull algorithm. It must be a model of the concept ConvexHullTraits_3. This class is used only if the width is computed from a set of points.
WidthTraits_3:: RT	Ring type numbers. Internally all numbers are treated as ring type numbers, i.e., neither $/$-operator nor $\sqrt{.}$ nor other inexact operations are used. But because the algorithm does not use any divisions, but multiplication instead, the numbers can get really big. Therefore it is recommended to use a ring type number, that provides values of arbitrary length. Furthermore it is assumed that the underlying number type of *Point_3*, *Plane_3* and *Vector_3* equals *RT*.

Notes: If you want to compute the width of a *polyhedron* then you have to make sure that the point type in the traits class and the point type in the polyhedron class are the same! The same holds for *Traits::Plane_3* and *Polyhedron::Plane_3*.

Creation

Only a default constructor is required.

WidthTraits_3 traits;

Operations

Whatever the coordinates of the points are, it is required for the width-algorithm to have access to the homogeneous representation of points.

RT	*get_hx(Point_3 p) const*	returns the homogeneous x-coordinate of point p.
RT	*get_hy(Point_3 p) const*	returns the homogeneous y-coordinate of point p.
RT	*get_hz(Point_3 p) const*	returns the homogeneous z-coordinate of point p.
RT	*get_hw(Point_3 p) const*	returns the homogenizing coordinate of point p.
void	*get_point_coordinates(Point_3 p, RT& px, RT& py, RT& pz, RT& ph) const*	returns all homogeneous coordinates of point p at once.
RT	*get_a(Plane_3 f) const*	returns the first coefficient of plane f.
RT	*get_b(Plane_3 f) const*	returns the second coefficient of plane f.

RT	*get_c(Plane_3 f) const*	returns the third coefficient of plane f.
RT	*get_d(Plane_3 f) const*	returns the fourth coefficient of plane f.
void	*get_plane_coefficients(Plane_3 f, RT& a, RT& b, RT& c, RT& d) const*	returns all four plane coefficients of f at once.
Point_3	*make_point(RT hx, RT hy, RT hz, RT hw) const*	returns a point of type *Point_3* with homogeneous coordinates hx, hy, hz and hw.
Plane_3	*make_plane(RT a, RT b, RT c, RT d) const*	returns a plane of type *Plane_3* with coefficients a, b, c and d.
Vector_3	*make_vector(RT a, RT b, RT c) const*	returns a vector of type *Vector_3* with the four homogeneous coefficients a, b, c and 1.

Class

CGAL::Polytope_distance_d<Traits>

Definition

An object of the class *Polytope_distance_d<Traits>* represents the (squared) distance between two convex polytopes, given as the convex hulls of two finite point sets in d-dimensional Euclidean space $\mathbb{E}^d$. For point sets P and Q we denote by $pd(P,Q)$ the distance between the convex hulls of P and Q. Note that $pd(P,Q)$ can be degenerate, i.e. $pd(P,Q) = \infty$ if P or Q is empty.

Two inclusion-minimal subsets S_P of P and S_Q of Q with $pd(S_P,S_Q) = pd(P,Q)$ are called *pair of support sets*, the points in S_P and S_Q are the *support points*. A pair of support sets has size at most $d+2$ (by size we mean $|S_P| + |S_Q|$). The distance between the two polytopes is *realized* by a pair of points p and q lying in the convex hull of S_P and S_Q, repectively, i.e. $\sqrt{||p-q||} = pd(P,Q)$. In general, neither the support sets nor the realizing points are necessarily unique.

The underlying algorithm can cope with all kinds of input, e.g. P and Q may be in non-convex position or points may occur more than once. The algorithm computes a pair of support sets S_P and S_Q with realizing points p and q which remain fixed until the next set, insert, or clear operation.

#include <CGAL/Polytope_distance_d.h>

Requirements

The template parameter *Traits* is a model for *OptimisationDTraits*.

We provide the models *Optimisation_d_traits_2*, *Optimisation_d_traits_3*, and *Optimisation_d_traits_d* using the two-, three-, and d-dimensional CGAL kernel, respectively.

Types

Polytope_distance_d<Traits>:: Point	typedef to *Traits::Point_d*. Point type used to represent the input points.
Polytope_distance_d<Traits>:: FT	typedef to *Traits::FT*. Number type used to return the squared distance between the two polytopes.
Polytope_distance_d<Traits>:: ET	typedef to *Traits::ET*. Number type used to do the exact computations in the underlying solver for quadratic programs (cf. **Implementation**).

Polytope_distance_d<Traits>:: Point_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the points of the two polytopes.

Polytope_distance_d<Traits>:: Support_point_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the support points.

Polytope_distance_d<Traits>:: Support_point_index_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *int*. Used to access the indices of the support points in the provided input order (starting from 0 in both point sets).

Polytope_distance_d<Traits>:: Coordinate_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *ET*. Used to access the coordinates of the realizing points.

Creation

Polytope_distance_d<Traits> poly_dist(Traits traits = Traits(), int verbose = 0, std::ostream& stream = std::cout)

initializes *poly_dist* to $pd(\emptyset,\emptyset)$.

template < class InputIterator1, class InputIterator2 >
Polytope_distance_d<Traits> poly_dist(InputIterator1 p_first, InputIterator1 p_last, InputIterator2 q_first, InputIterator2 q_last, Traits traits = Traits(), int verbose = 0, std::ostream& stream = std::cout)

initializes *poly_dist* to $pd(P,Q)$ with P and Q being the sets of points in the range [*p_first*,*p_last*) and [*q_first*,*q_last*), respectively.
Requirement: The value type of *InputIterator1* and *InputIterator2* is *Point*.
Precondition: All points have the same dimension.

advanced

If *verbose* is set to 1, 2, or 3 then some, more, or full verbose output of the underlying solver for quadratic programs is written to *stream*, resp.

advanced

Access Functions

int *poly_dist.ambient_dimension() const*

returns the dimension of the points in P and Q. If *poly_dist* is $pd(\emptyset,\emptyset)$, the ambient dimension is -1.

int *poly_dist.number_of_points() const*
returns the number of all points of *poly_dist*, i.e. $|P| + |Q|$.

int *poly_dist.number_of_points_p() const*
returns the number of points in P.

int *poly_dist.number_of_points_q() const*
returns the number of points in Q.

int *poly_dist.number_of_support_points() const*
returns the number of support points of *poly_dist*, i.e. $|S_P| + |S_Q|$.

int *poly_dist.number_of_support_points_p() const*
returns the number of support points in S_P.

int *poly_dist.number_of_support_points_q() const*
returns the number of support points in S_Q.

Point_iterator *poly_dist.points_p_begin() const*
returns an iterator referring to the first point in P.

Point_iterator *poly_dist.points_p_end() const*
returns the corresponding past-the-end iterator.

Point_iterator *poly_dist.points_q_begin() const*
returns an iterator referring to the first point in Q.

Point_iterator *poly_dist.points_q_end() const*
returns the corresponding past-the-end iterator.

Support_point_iterator
poly_dist.support_points_p_begin() const
returns an iterator referring to the first support point in S_P.

Support_point_iterator
poly_dist.support_points_p_end() const
returns the corresponding past-the-end iterator.

Support_point_iterator
poly_dist.support_points_q_begin() const
returns an iterator referring to the first support point in S_Q.

Support_point_iterator
poly_dist.support_points_q_end() const
returns the corresponding past-the-end iterator.

Support_point_index_iterator
poly_dist.support_points_p_indices_begin() const
returns an iterator referring to the index of the first support point in P.

Support_point_index_iterator
poly_dist.support_points_p_indices_end() const
returns the corresponding past-the-end iterator.

Support_point_index_iterator
poly_dist.support_points_q_indices_begin() const
returns an iterator referring to the index of the first support point in Q.

Support_point_index_iterator

poly_dist.support_points_q_indices_end() const

returns the corresponding past-the-end iterator.

Point *poly_dist.realizing_point_p() const*

returns the realizing point of P.
Requirement: An implicit conversion from *ET* to *RT* is available.
Precondition: $pd(P,Q)$ is finite.

Point *poly_dist.realizing_point_q() const*

returns the realizing point of Q.
Requirement: An implicit conversion from *ET* to *RT* is available.
Precondition: $pd(P,Q)$ is finite.

FT *poly_dist.squared_distance() const*

returns the squared distance of *poly_dist*, i.e. $(pd(P,Q))^2$.
Requirement: An implicit conversion from *ET* to *RT* is available.
Precondition: $pd(P,Q)$ is finite.

Coordinate_iterator *poly_dist.realizing_point_p_coordinates_begin() const*

returns an iterator referring to the first coordinate of the realizing point of P.
Note: The coordinates have a rational representation, i.e. the first d elements of the iterator range are the numerators and the $(d+1)$-st element is the common denominator.

Coordinate_iterator *poly_dist.realizing_point_p_coordinates_end() const*

returns the corresponding past-the-end iterator.

Coordinate_iterator *poly_dist.realizing_point_q_coordinates_begin() const*

returns an iterator referring to the first coordinate of the realizing point of Q.
Note: The coordinates have a rational representation, i.e. the first d elements of the iterator range are the numerators and the $(d+1)$-st element is the common denominator.

Coordinate_iterator *poly_dist.realizing_point_q_coordinates_end() const*

returns the corresponding past-the-end iterator.

ET *poly_dist.squared_distance_numerator() const*

returns the numerator of the squared distance of *poly_dist*.

ET *poly_dist.squared_distance_denominator() const*

returns the denominator of the squared distance of *poly_dist*.

Predicates

bool *poly_dist.is_finite() const*

returns *true*, if $pd(P,Q)$ is finite, i.e. none of the two polytopes is empty.

bool *poly_dist.is_zero() const*

returns *true*, if $pd(P,Q)$ is zero, i.e. the two polytopes intersect (this implies degeneracy).

bool *poly_dist.is_degenerate() const*

returns *true*, iff $pd(P,Q)$ is degenerate, i.e. $pd(P,Q)$ is not finite.

Modifiers

void *poly_dist.clear()* resets *poly_dist* to $pd(\emptyset,\emptyset)$.

template < class InputIterator1, class InputIterator2 >
void *poly_dist.set(InputIterator1 p_first,*
InputIterator1 p_last,
InputIterator2 q_first,
InputIterator2 q_last)

sets *poly_dist* to $pd(P,Q)$ with P and Q being the sets of points in the ranges [*p_first*,*p_last*) and [*q_first*,*q_last*), respectively.
Requirement: The value type of *InputIterator1* and *InputIterator2* is *Point*.
Precondition: All points have the same dimension.

template < class InputIterator >
void *poly_dist.set_p(InputIterator p_first, InputIterator p_last)*

sets *poly_dist* to $pd(P,Q)$ with P being the set of points in the range [*p_first*,*p_last*) (Q remains unchanged).
Requirement: The value type of *InputIterator* is *Point*.
Precondition: All points in P have dimension *poly_dist.ambient_dimension()* if Q is not empty.

template < class InputIterator >
void *poly_dist.set_q(InputIterator q_first, InputIterator q_last)*

sets *poly_dist* to $pd(P,Q)$ with Q being the set of points in the range [*q_first*,*q_last*) (P remains unchanged).
Requirement: The value type of *InputIterator* is *Point*.
Precondition: All points in Q have dimension *poly_dist.ambient_dimension()* if P is not empty.

void *poly_dist.insert_p(Point p)*

inserts p into P.
Precondition: The dimension of p equals *poly_dist.ambient_dimension()* if *poly_dist* is not $pd(\emptyset,\emptyset)$.

void *poly_dist.insert_q(Point q)*

inserts q into Q.
Precondition: The dimension of q equals *poly_dist.ambient_dimension()* if *poly_dist* is not $pd(\emptyset,\emptyset)$.

template < class InputIterator1, class InputIterator2 >
void *poly_dist.insert(InputIterator1 p_first, InputIterator1 p_last, InputIterator2 q_first, InputIterator2 q_last)*

inserts the points in the range [*p_first*,*p_last*) and [*q_first*,*q_last*) into P and Q, respectively, and recomputes the (squared) distance.
Requirement: The value type of *InputIterator1* and *InputIterator2* is *Point*.
Precondition: All points have the same dimension. If *poly_dist* is not $pd(\emptyset,\emptyset)$, this dimension must be equal to *poly_dist.ambient_dimension()*.

template < class InputIterator >
void *poly_dist.insert_p(InputIterator p_first, InputIterator p_last)*

inserts the points in the range [*p_first*,*p_last*) into P and recomputes the (squared) distance (Q remains unchanged).
Requirement: The value type of *InputIterator* is *Point*.
Precondition: All points have the same dimension. If *poly_dist* is not empty, this dimension must be equal to *poly_dist.ambient_dimension()*.

template < class InputIterator >
void *poly_dist.insert_q(InputIterator q_first, InputIterator q_last)*

inserts the points in the range [*q_first*,*q_last*) into Q and recomputes the (squared) distance (P remains unchanged).
Requirement: The value type of *InputIterator* is *Point*.
Precondition: All points have the same dimension. If *poly_dist* is not empty, this dimension must be equal to *poly_dist.ambient_dimension()*.

Validity Check

An object *poly_dist* is valid, iff ...

- *poly_dist* contains all points of its defining set *P*,
- *poly_dist* is the smallest sphere containing its support set *S*, and
- *S* is minimal, i.e. no support point is redundant.

bool *poly_dist.is_valid(bool verbose = false, int level = 0) const*

returns *true*, iff *poly_dist* is valid. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

Miscellaneous

const Traits& *poly_dist.traits() const*

returns a const reference to the traits class object.

I/O

std::ostream& *std::ostream& os << poly_dist*

writes *poly_dist* to output stream *os*.
Requirement: The output operator is defined for *Point_d*.

std::istream& *std::istream& is >> poly_dist&*

reads *poly_dist* from input stream *is*.
Requirement: The input operator is defined for *Point_d*.

Implementation

The problem of finding the distance between two convex polytopes given as the convex hulls of two finite point sets can be formulated as an optimization problem with linear constraints and a convex quadratic objective function. The solution is obtained using our exact solver for quadratic programs [GS00].

The creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point might take up to linear time. The clear operation and the check for validity each take linear time.

PolytopeDistanceDTraits

Definition

This concept defines the requirements for traits classes of d-dimensional optimisation algorithms.

Types

PolytopeDistanceDTraits:: Point_d — point type used to represent the input points.

PolytopeDistanceDTraits:: Rep_tag — compile time tag to distinguish between Cartesian and homogeneous representation of the input points. *Rep_tag* has to be either *CGAL::Cartesian_tag* or *CGAL::Homogeneous_tag*.

PolytopeDistanceDTraits:: RT — number type used to represent the coordinates of the input points. It has to be a model for *RingNumberType*.

PolytopeDistanceDTraits:: FT — number type used to return either the squared radius of the smallest enclosing sphere or annulus, or the squared distance of the polytopes. *FT* has to be either *RT* or *CGAL::Quotient*<*RT*> if the input points have Cartesian or homogeneous representation, respectively (cf. *Rep_tag*).

PolytopeDistanceDTraits:: Access_dimension_d

data accessor object used to access the dimension of the input points.

PolytopeDistanceDTraits:: Access_coordinates_begin_d

data accessor object used to access the coordinates of the input points.

PolytopeDistanceDTraits:: Construct_point_d

constructor object used to construct either the center of the smallest enclosing sphere or annulus, or the points realizing the distance between the two polytopes.

The following two number types are only needed for *CGAL::Min_annulus_d*<*Traits*> and *CGAL::Polytope_distance_d*<*Traits*>.

PolytopeDistanceDTraits:: ET — exact number type used to do the exact computations in the underlying solver for linear programs. It has to to be a model for *RingNumberType*. There must be an implicit conversion from *RT* to *ET* available.

PolytopeDistanceDTraits:: NT — fast (possibly inexact) number type used to speed up the pricing step in the underlying solver for linear programs. It has to be a model for *RingNumberType*. There must be implicit conversions from *RT* to *NT* and from *NT* to *ET* available.

Creation

Only default and copy constructor are required.

PolytopeDistanceDTraits traits;

PolytopeDistanceDTraits traits(PolytopeDistanceDTraits);

Operations

The following functions just return the corresponding function class object.

Access_dimension_d	*traits.access_dimension_d_object() const*
Access_coordinates_begin_d	*traits.access_coordinates_begin_d_object() const*
Construct_point_d	*traits.construct_point_d_object() const*

Chapter 69

Principal Component Analysis

Pierre Alliez, Sylvain Pion and Ankit Gupta

Contents

This package provides functions to analyze sets of objects in 2D and 3D. It provides the computation of axis-aligned bounding boxes, centers of mass and principal component analysis for all bounded objects, as well as barycenters for sets of weighted points. Note that unlike most of the CGAL packages, this package uses approximation methods (in particular for linear least squares fitting) and is not intended to provide an exact canonical result in any sense.

69.1 Definitions

A *bounding box* for a set of objects is a cuboid that contains the set. An *axis-aligned bounding box* captures the maximum extents of all objects from the set within their coordinate system, i.e., a bounding box aligned with the axes of the coordinate system. Axis-aligned bounding boxes are frequently used in geometric algorithms as an indication of the general location of a data set, for either display, first-approximation spatial query, or spatial indexing purposes.

A *centroid* of a set of objects is their center of mass, i.e., the point whose coordinates are computed by means of coordinates of all points composing the objects. Note that although the general definition of center of mass incorporates a density function (and hence weighted means), the current implementation assumes a uniform density (see barycenter below defined for weighted points). For a point set $\{X_1, X_2, \ldots, X_N\}$ the centroid $\bar{X}$ is computed as

$$\bar{X} = \frac{1}{N}\sum_{i=1}^{N} X_i.$$

For a set of segments $\{S_1, S_2, ..., S_N\}$ the centroid $\bar{X}$ is computed as

$$\bar{X} = \frac{1}{\sum_{i=1}^{N}|S_i|}\sum_{i=1}^{N}|S_i|\,\bar{S}_i,$$

where $|S_i|$ stands for the length of a segment and $\bar{S}_i$ stands for its uniform barycenter (midpoint). For a set of triangles $\{T_1, T_2, ..., T_N\}$ the centroid $\bar{X}$ is computed as

$$\bar{X} = \frac{1}{\sum_{i=1}^{N}|T_i|}\sum_{i=1}^{N}|T_i|\,\bar{T}_i,$$

where $|T_i|$ stands for the area of a triangle and $\bar{T}_i$ stands for its uniform barycenter. Such definition still holds for more general objects where the Lebesgue measure (length in 1D, area in 2D, volume in 3D) is used for weighting the object barycenters. Centers of mass are used to summarize data sets for either approximation, spatial query or spatial indexing purposes.

A *barycenter* of a set of weighted points is the point whose coordinates are computed by means of weighted coordinates of all weighted points from the set. When all weights are equal the barycenter coincides with the centroid.

Given a set of objects, *linear least squares fitting* amounts to finding the linear sub-space which minimizes the sum of squared distances from all points composing the objects of the set, to their projection onto this linear sub-space. Such linear sub-space is obtained by so-called principal component analysis (PCA). PCA is defined as a transformation that transforms the objects to a new coordinate system such that the greatest variance by orthogonal projection of the objects comes to lie on the first coordinate (called the first principal component), the second greatest variance on the second coordinate, and so on. PCA is often used in geometric applications to reduce data sets to lower dimensions for analysis or approximation. Figure below illustrates (least squares) fitting of a line to a 2D point set, fitting of a line and a plane to a 3D point set and fitting of a plane to a set of 3D triangles.

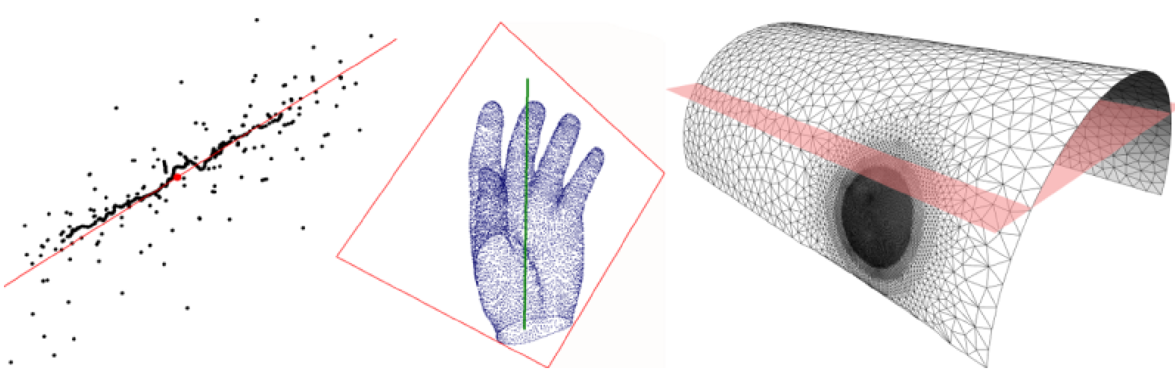

Figure 69.1: Left: fitting a line to a 2D point set (centroid dotted in red). Middle: fitting a line and a plane to a 3D point set. Right: fitting a plane to a set of 3D triangles.

69.2 Examples

69.2.1 Bounding Box of 2D and 3D Point Sets

In the following example we use STL containers of 2D points and 3D points, and compute their axis-aligned bounding box.

```
#include <CGAL/Cartesian.h>
#include <CGAL/bounding_box.h>

#include <list>
#include <iostream>

typedef double             FT;
typedef CGAL::Cartesian<FT> K;
typedef K::Point_2          Point_2;
typedef K::Point_3          Point_3;

int main()
{
  // axis-aligned bounding box of 2D points
  std::list<Point_2> points_2;
  points_2.push_back(Point_2(1.0, 0.0));
  points_2.push_back(Point_2(2.0, 2.0));
  points_2.push_back(Point_2(3.0, 5.0));

  K::Iso_rectangle_2 c2 = CGAL::bounding_box(points_2.begin(),
   points_2.end());
  std::cout << c2 << std::endl;

  // axis-aligned bounding box of 3D points
  std::list<Point_3> points_3;
  points_3.push_back(Point_3(1.0, 0.0, 0.5));
  points_3.push_back(Point_3(2.0, 2.0, 1.2));
  points_3.push_back(Point_3(3.0, 5.0, 4.5));

  K::Iso_cuboid_3 c3 = CGAL::bounding_box(points_3.begin(),
   points_3.end());
  std::cout << c3 << std::endl;

  return 0;
}
```

File: examples/Principal_component_analysis/bounding_box.cpp

69.2.2 Centroid of 2D and 3D Objects

In the following example we use STL containers of 2D, 3D points and 3D triangles, and compute their centroid. The dimension tag indicates the dimension of the objects being fitted (0 for points, 2 for triangles). Note that it is also possible to compute the centroid of the triangle edges (3D segments) by specifying 1 as dimension tag, and to compute the centroid of the triangle vertices (3D points) by specifying 0 as dimension tag.

```
#include <CGAL/Cartesian.h>
#include <CGAL/centroid.h>

#include <list>
#include <iostream>

typedef double                    FT;
typedef CGAL::Cartesian<FT>  K;
typedef K::Point_2           Point_2;
typedef K::Point_3           Point_3;
typedef K::Triangle_3        Triangle_3;

int main()
{
  // centroid of 2D points
  std::list<Point_2> points_2;
  points_2.push_back(Point_2(1.0, 0.0));
  points_2.push_back(Point_2(2.0, 2.0));
  points_2.push_back(Point_2(3.0, 5.0));
  Point_2 c2 = CGAL::centroid(points_2.begin(),
   points_2.end(),CGAL::Dimension_tag<0>());
  std::cout << c2 << std::endl;

  // centroid of 3D points
  std::list<Point_3> points_3;
  points_3.push_back(Point_3(1.0, 0.0, 0.5));
  points_3.push_back(Point_3(2.0, 2.0, 1.2));
  points_3.push_back(Point_3(3.0, 5.0, 4.5));
  Point_3 c3 = CGAL::centroid(points_3.begin(),
   points_3.end(),CGAL::Dimension_tag<0>());
  std::cout << c3 << std::endl;

  // centroid of 3D triangles
  std::list<Triangle_3> triangles_3;
  Point_3 p(1.0, 0.0, 0.0);
  Point_3 q(1.0, 2.0, 0.0);
  Point_3 r(0.0, 1.0, 3.0);
  Point_3 s(0.0, 2.0, 5.0);
  triangles_3.push_back(Triangle_3(p,q,r));
  triangles_3.push_back(Triangle_3(p,q,s));
  c3 = CGAL::centroid(triangles_3.begin(),
   triangles_3.end(),CGAL::Dimension_tag<2>());
  std::cout << c3 << std::endl;

  return 0;
}
```

File: examples/Principal_component_analysis/centroid.cpp

69.2.3 Barycenter of a Set of Weighted Points

In the following example we use STL containers of 2D and 3D weighted points, and compute their barycenter.

```
#include <CGAL/Cartesian.h>
#include <CGAL/barycenter.h>

#include <list>
#include <iostream>
#include <utility>

typedef double                   FT;
typedef CGAL::Cartesian<FT>  K;
typedef K::Point_2               Point_2;
typedef K::Point_3               Point_3;

int main()
{
  // barycenter of 2D weighted points
  std::list<std::pair<Point_2, FT> > points_2;
  points_2.push_back(std::make_pair(Point_2(1.0, 0.0),  1.0));
  points_2.push_back(std::make_pair(Point_2(2.0, 2.0),  2.0));
  points_2.push_back(std::make_pair(Point_2(3.0, 5.0), -2.0));

  Point_2 c2 = CGAL::barycenter(points_2.begin(), points_2.end());
  std::cout << c2 << std::endl;

  // barycenter of 3D weighted points
  std::list<std::pair<Point_3, FT> > points_3;
  points_3.push_back(std::make_pair(Point_3(1.0, 0.0, 0.5),  1.0));
  points_3.push_back(std::make_pair(Point_3(2.0, 2.0, 1.2),  2.0));
  points_3.push_back(std::make_pair(Point_3(3.0, 5.0, 4.5), -5.0));

  Point_3 c3 = CGAL::barycenter(points_3.begin(), points_3.end());
  std::cout << c3 << std::endl;

  return 0;
}
```

69.2.4 Least Squares Fitting of a Line to a 2D Point Set

In the following example we use a STL container of 2D points, and compute the best fitting line in the least squares sense.

```
#include <CGAL/Cartesian.h>
#include <CGAL/linear_least_squares_fitting_2.h>
#include <list>

typedef double                   FT;
```

```
typedef CGAL::Cartesian<FT>  K;
typedef K::Line_2            Line;
typedef K::Point_2           Point;

int main()
{
  std::list<Point> points;
  points.push_back(Point(1.0,2.0));
  points.push_back(Point(3.0,4.0));
  points.push_back(Point(5.0,6.0));

  // fit line
  Line line;

   linear_least_squares_fitting_2(points.begin(),points.end(),line,CGAL::Dimension_tag<0>

  return 0;
}
```

File: examples/Principal_component_analysis/linear_least_squares_fitting_points_2.cpp

69.2.5 Least Squares Fitting of a Line and a Plane to a 3D Triangle Set

In the following example we use a STL container of 3D triangles, and compute the best fitting line and plane in the least squares sense. Note that we can fit either the whole triangles, the triangle edges or the triangle vertices.

```
#include <CGAL/Cartesian.h>
#include <CGAL/linear_least_squares_fitting_3.h>
#include <list>

typedef double               FT;
typedef CGAL::Cartesian<FT>  K;
typedef K::Line_3            Line;
typedef K::Plane_3           Plane;
typedef K::Point_3           Point;
typedef K::Triangle_3        Triangle;

int main(void)
{
  std::list<Triangle> triangles;
  Point a(1.0,2.0,3.0);
  Point b(4.0,0.0,6.0);
  Point c(7.0,8.0,9.0);
  Point d(8.0,7.0,6.0);
  Point e(5.0,3.0,4.0);
  triangles.push_back(Triangle(a,b,c));
  triangles.push_back(Triangle(a,b,d));
  triangles.push_back(Triangle(d,e,c));

  Line line;
  Plane plane;

```

```
  // fit plane to whole triangles

   linear_least_squares_fitting_3(triangles.begin(),triangles.end(),plane,CGAL::Dimension

  // fit line to triangle vertices
  linear_least_squares_fitting_3(triangles.begin(),triangles.end(),line,
   CGAL::Dimension_tag<0>());

  return 0;
}
```

Principal Component Analysis Reference Manual

Pierre Alliez, Sylvain Pion and Ankit Gupta

This CGAL component provides functions to compute global information about the shape of a set of 2D or 3D objects. It provides the computation of axis-aligned bounding boxes for point sets, and barycenters of weighted point sets. In addition, it provides computation of centroids (center of mass) and linear least squares fitting for point sets as well as for sets of other bounded objects. More specifically, it is possible to fit 2D lines to 2D segments, circles, disks, iso-rectangles and triangles, as well as to fit 3D lines or 3D planes to 3D segments, triangles, iso-cuboids, tetrahedra, spheres and balls. The interface to these functions takes an iterator range of objects.

Functions

69.4 Alphabetical List of Reference Pages

Function

CGAL::bounding_box

Definition

The function *bounding_box* computes the axis-aligned bounding box of a set of 2D or 3D points. The bounding box is returned either as an iso rectangle in 2D or as an iso cuboid in 3D, the type being deduced automatically from the value type of the iterator range.

#include <CGAL/bounding_box.h>

There is a set of overloaded *bounding_box* functions for 2D and 3D points. The user can also optionally pass an explicit kernel, in case the default, based on *Kernel_traits* is not sufficient. The dimension is also deduced automatically.

template < typename InputIterator >
K::Iso_rectangle_2 *bounding_box(InputIterator first, InputIterator beyond)*

computes the bounding box of a non-empty set of 2D points. *K* is *Kernel_traits<std::iterator_traits<InputIterator> ::value_type>::Kernel*. The value type must be *K::Point_2*.
Precondition: first != beyond.

template < typename InputIterator, typename K >
K::Iso_rectangle_2 *bounding_box(InputIterator first, InputIterator beyond, K k)*

computes the bounding box of a non-empty set of 2D points. The value type must be *K::Point_2*.
Precondition: first != beyond.

template < typename InputIterator >
K::Iso_cuboid_3 *bounding_box(InputIterator first, InputIterator beyond)*

computes the bounding box of a non-empty set of 3D points. *K* is *Kernel_traits<std::iterator_traits<InputIterator> ::value_type>::Kernel*. The value type must be *K::Point_3*.
Precondition: first != beyond.

template < typename InputIterator, typename K >
K::Iso_cuboid_3 *bounding_box(InputIterator first, InputIterator beyond, K k)*

computes the bounding box of a non-empty set of 3D points. The value type must be *K::Point_3*.
Precondition: first != beyond.

CGAL::centroid

Function

Definition

The function *centroid* computes the (uniform) center of mass of a set of 2D or 3D bounded objects. In 2D these objects include points, segments, triangles, iso rectangles, circles and disks. In 3D these objects include points, segments, triangles, iso cuboids, spheres, balls and tetrahedra.

#include <CGAL/centroid.h>

There is a set of overloaded *centroid* functions for 2D and 3D objects. The user can also optionally pass an explicit kernel, in case the default based on *Kernel_traits* is not sufficient. The default dimension tag is deduced automatically, although the user can pass a *tag* specifying the dimension of the objects to be considered for the centroid computation. For example, the default dimension of a tetrahedron is 3, but specifying a dimension 0 computes the centroid of the tetrahedron vertices (3D points), specifying a dimension 1 computes the centroid of the tetrahedron edges (3D segments) and specifying a dimension 2 computes the centroid of the tetrahedron facets (3D triangles).

template < typename InputIterator, typename Tag >
K::Point_2 *centroid(InputIterator first, InputIterator beyond, Tag t)*

computes the centroid of a non-empty set of 2D objects. The tag is used to specify the dimension to be considered from the objects. *K* is *Kernel_traits<std::iterator_traits<InputIterator>::value_type>::Kernel*. The value type must be either *K::Point_2*, *K::Segment_2*, *K::Triangle_2*, *K::Rectangle_2* or *K::Circle_2*. To fit a set of disks the user must call the function with value type *K::Circle_2* and with dimension tag of 2. The tag must range between *CGAL::Dimension_tag<0>* and *CGAL::Dimension_tag<2>*.
Precondition: first != beyond.

template < typename InputIterator, typename K, typename Tag >
K::Point_2 *centroid(InputIterator first, InputIterator beyond, K k, Tag t)*

computes the centroid of a non-empty set of 2D objects. The tag is used to specify the dimension to be considered from the objects. *K* is *Kernel_traits<std::iterator_traits<InputIterator>::value_type>::Kernel*. The value type must be either *K::Point_2*, *K::Segment_2*, *K::Triangle_2*, *K::Rectangle_2* or *K::Circle_2*. To fit a set of disks the user must call the function with value type *K::Circle_2* and with dimension tag of 2. The tag must range between *CGAL::Dimension_tag<0>* and *CGAL::Dimension_tag<2>*.
Precondition: first != beyond.

template < typename InputIterator, typename Tag >

K::Point_3 *centroid(InputIterator first, InputIterator beyond, Tag t)*

computes the centroid of a non-empty set of 3D objects. The tag is used to specify the dimension to be considered from the objects. *K* is *Kernel_traits<std::iterator_traits< InputIterator>::value_type>::Kernel*. The value type must be either *K::Point_3*, *K::Segment_3*, *Triangle_3*, *Cuboid_3*, *Sphere_3* or *Tetrahedron_3*. To fit a set of balls the user must call the function with value type *K::Sphere_3* and with dimension tag of 3. The tag must range between *CGAL::Dimension_tag<0>* and *CGAL::Dimension_tag<3>*.
Precondition: first != beyond.

template < typename InputIterator, typename K, typename Tag >
K::Point_3 *centroid(InputIterator first, InputIterator beyond, K k, Tag t)*

computes the centroid of a non-empty set of 3D objects. The tag is used to specify the dimension to be considered from the objects. *K* is *Kernel_traits<std::iterator_traits< InputIterator>::value_type>::Kernel*. The value type must be either *K::Point_3*, *K::Segment_3*, *Triangle_3*, *Cuboid_3*, *Sphere_3* or *Tetrahedron_3*. To fit a set of balls the user must call the function with value type *K::Sphere_3* and with dimension tag of 3. The tag must range between *CGAL::Dimension_tag<0>* and *CGAL::Dimension_tag<3>*.
Precondition: first != beyond.

CGAL::barycenter

Function

Definition

The function *barycenter* computes the barycenter (weighted center of mass) of a set of 2D or 3D weighted points. The weight associated to each point is specified using a *std::pair* storing the point and its weight.

#include <CGAL/barycenter.h>

There is a set of overloaded *barycenter* functions for 2D and 3D weighted points. The user can also optionally pass an explicit kernel, in case the default, based on *Kernel_traits* is not sufficient. The dimension is also deduced automatically.

template < typename InputIterator >
K::Point_2 *barycenter(InputIterator first, InputIterator beyond)*

computes the barycenter of a non-empty set of 2D weighted points. *K* is *Kernel_traits<std::iterator_traits<InputIterator> ::value_type::first_type>::Kernel*. The value type must be *std::pair<K::Point_2, K::FT>*.
Precondition: first != beyond, and the sum of the weights is non-zero.

template < typename InputIterator, typename K >
K::Point_2 *barycenter(InputIterator first, InputIterator beyond, K k)*

computes the barycenter of a non-empty set of 2D weighted points. The value type must be *std::pair<K::Point_2, K::FT>*.
Precondition: first != beyond, and the sum of the weights is non-zero.

template < typename InputIterator >
K::Point_3 *barycenter(InputIterator first, InputIterator beyond)*

computes the barycenter of a non-empty set of 3D weighted points. *K* is *Kernel_traits<std::iterator_traits<InputIterator> ::value_type::first_type>::Kernel*. The value type must be *std::pair<K::Point_3, K::FT>*.
Precondition: first != beyond, and the sum of the weights is non-zero.

template < typename InputIterator, typename K >
K::Point_3 *barycenter(InputIterator first, InputIterator beyond, K k)*

computes the barycenter of a non-empty set of 3D weighted points. The value type must be *std::pair<K::Point_3, K::FT>*.
Precondition: first != beyond, and the sum of the weights is non-zero.

CGAL::linear_least_squares_fitting_2

Function

Definition

The function *linear_least_squares_fitting_2* computes the 2D best fitting line (in the least squares sense) of a set of 2D objects such as points, segments, triangles, iso rectangles, circles or disks.

The best fitting line minimizes the sum of squared distances from all points comprising these objects to their orthogonal projections onto the line. It can be shown that this line goes through the centroid of the set. This problem is equivalent to search for the linear sub-space which maximizes the variance of projected points (sum of squared distances to the centroid). Internally we solve this problem by eigen decomposition of the covariance matrix of the whole set. Note that the 2×2 covariance matrix is computed internally in closed form and not by point sampling the objects. Eigenvectors corresponding to large eigenvalues are the directions in which the data has strong component, or equivalently large variance. If one eigenvalue is null the fit is perfect as the sum of squared distance from all points to their projection onto the best line is null. If the two eigenvalues are the same there is no preferable sub-space and all lines going through the centroid share the same fitting property.

#include <CGAL/linear_least_squares_fitting_2.h>

```
template < typename InputIterator, typename K, typename Tag >
typename K::FT      linear_least_squares_fitting_2( InputIterator first,
                                                    InputIterator beyond,
                                                    typename K::Line_2 & line,
                                                    typename K::Point_2 & centroid,
                                                    Tag tag,
                                                    K k)
```

computes the best fitting 2D line of a 2D object set in the range [*first*,*beyond*). The value returned is a fitting quality between 0 and 1, where 0 means that the variance is the same along any line (a horizontal line going through the centroid is output by default), and 1 means that the variance is null orthogonally to the best fitting line (hence the fit is perfect).
Precondition: first != beyond.

The tag *tag* identifies the dimension to be considered from the objects. For point sets it should be 0. For segments it can be 1 or 0 according to whether one wants to fit the whole segment or just their end points. For triangles it can range from 0 to 2 according to whether one wants to fit either the triangle points, the segments or the whole triangles. For rectangles it can range from 0 to 2 according to whether one wants to fit either the corner points, the segments, or the whole rectangles. For circles it can be 1 or 2 according to whether one wants to fit either the circles or the whole discs. For triangles it ranges from 0 to 2 according to whether one wants to fit either the points, the segments or the whole triangles.

The class *K* is the kernel in which the type *InputIterator::value_type* is defined. It can be omitted and deduced automatically from the value type.

Requirements

1. *InputIterator::value_type* is equivalent to *K::Point_2* or *K::Segment_2* or *K::Triangle_2* or *K::Rectangle_2* or *K::Circle_2*.

2. *line* is the best fitting line computed.

3. *centroid* is the centroid computed. This parameter is optional and can be omitted.

4. *tag* is the tag identifying the dimension to be considered from the objects. It should be one of *Dimension_tag<0>*, *Dimension_tag<1>* or *Dimension_tag<2>*. Also, it should not be of dimension greater than the geometry of the object. For example, a *Segment* can not have a *Dimension_tag<2>* tag.

CGAL::linear_least_squares_fitting_3

Function

Definition

Function *linear_least_squares_fitting_3* computes the best fitting 3D line or plane (in the least squares sense) of a set of 3D objects such as points, segments, triangles, spheres, balls, cuboids or tetrahedra.

The best fitting linear sub-space (here line or plane) minimizes the sum of squared distances from all points comprising these objects to their orthogonal projections onto this linear subspace. It can be shown that the best line or plane goes through the centroid of the set. This problem is equivalent to search for the linear sub-space which maximizes the variance of projected points (sum of squared distances to the centroid). Internally we solve this problem by eigen decomposition of the covariance matrix of the whole set. Note that the 3×3 covariance matrix is computed internally in closed form and not by point sampling the objects. Eigenvectors corresponding to large eigenvalues are the directions in which the data has strong component, or equivalently large variance.

The fitting quality property is characterized by the values of the three eigenvalues. When all three values are distinct the best linear subspace is uniquely determined, be it a line or a plane. When all three eigenvalues are equal there is no preferable sub-space and any line or plane going through the centroid share the same fitting property (a horizontal plane or a line along the x axis are returned by default). A best fitting line is uniquely determined as soon as the largest eigenvalue is different from the two others, otherwise all lines contained in the best fitting plane share the same fitting property. A best fitting plane is uniquely determined as soon as the smallest eigenvalue is different from the two others, otherwise all planes going through the best fitting line share the same fitting property.

#include <CGAL/linear_least_squares_fitting_3.h>

```
template < typename InputIterator, typename K, typename Tag >
typename K::FT     linear_least_squares_fitting_3( InputIterator first,
                                                   InputIterator beyond,
                                                   typename K::Line_3& line,
                                                   typename K::Point_3& centroid,
                                                   Tag tag,
                                                   K k)
```

computes the best fitting 3D line of a 3D object set in the range [*first*,*beyond*). The value returned is a fitting quality between 0 and 1, where 0 means that the variance is the same along any line contained within the best fitting plane, and 1 means that the variance is null orthogonally to the best fitting line (hence the fit is perfect).

The tag *tag* identifies the dimension to be considered from the objects. For point sets it should be 0. For segment sets it could be 1 or 0 according to whether one wants to fit the entire segments or just the end points. For triangle sets it can range from 0 to 2 according to whether one wants to fit either the corner points, the segments or the whole triangles. For cuboid sets it can range from 0 to 3 according to whether one wants to fit either the corners, the segments, the faces or the whole solid cuboids. For sphere sets it can be 2 or 3 according to whether one wants to fit either the surface of the spheres or the whole solid balls. For tetrahedron sets it can range from 0 to

3 according to whether one wants to fit either the points, the segments, the surface triangles or the whole solid tetrahedra.

The class *K* is the kernel in which the type *InputIterator::value_type* is defined. It can be omitted and deduced automatically from the value type.

Requirements

1. *InputIterator::value_type* can be either *K::Point_3*, *K::Segment_3*, *Triangle_3*, *Cuboid_3*, *Sphere_3* or *Tetrahedron_3*.
2. *line* is the best fitting line computed.
3. *centroid* is the centroid computed. This parameter is optional and can be omitted.
4. *tag* is the tag identifying the dimension to be considered from the objects. It should range from *Dimension_tag<0>* to *Dimension_tag<3>*. Also, it should not be of a dimension greater nor smaller than the geometry of the object. For example, a *Triangle* can not have a *Dimension_tag<3>* tag. A *Segment* can not have a *Dimension_tag<2>* nor a *Dimension_tag<3>* tag. A *Sphere* can not have a *Dimension_tag<0>* nor a *Dimension_tag<1>* tag.

template < typename InputIterator, typename K, typename Tag >
typename K::FT linear_least_squares_fitting_3(InputIterator first, InputIterator beyond, typename K::Plane_3& plane, typename K::Point_3& centroid, Tag tag, K k)

computes the best fitting 3D plane of a 3D object set in the range [*first*,*beyond*). The value returned is a fitting quality between 0 and 1, where 0 means that the variance is the same along any plane going through the best fitting line, and 1 means that the variance is null orthogonally to the best fitting plane (hence the fit is perfect).

The class *K* is the kernel in which the type *InputIterator::value_type* is defined. It can be omitted and deduced automatically from the value type. The tag *tag* identifies the dimension to be considered from the objects (see above).

Requirements

1. *InputIterator::value_type* can either be *K::Point_3*, *K::Segment_3*, *Triangle_3*, *Cuboid_3*, *Sphere_3* or *Tetrahedron_3*.
2. *plane* is the best fitting plane computed.
3. *centroid* is the centroid computed. This parameter is optional and can be omitted.
4. *tag* is the tag identifying the dimension to be considered from the objects. It should range from *Dimension_tag<0>* to *Dimension_tag<3>*. Also, it should not be of a dimension greater nor smaller than the geometry of the object. For example, a *Triangle* can not have a *Dimension_tag<3>* tag. A *Segment* can not have a *Dimension_tag<2>* nor a *Dimension_tag<3>* tag. A *Sphere* can not have a *Dimension_tag<0>* nor a *Dimension_tag<1>* tag.

Part XV

Interpolation

Chapter 70

2D and Surface Function Interpolation

Julia Flötotto

Contents

This chapter describes CGAL's interpolation package which implements natural neighbor coordinate functions as well as different methods for scattered data interpolation most of which are based on natural neighbor coordinates. The functions for computing natural neighbor coordinates in Euclidean space are described in Section 70.1, the functions concerning the coordinate and neighbor computation on surfaces are discussed in Section 70.2. In Section 70.3, we describe the different interpolation functions.

Scattered data interpolation solves the following problem: given measures of a function on a set of discrete data points, the task is to interpolate this function on an arbitrary query point. More formally, let $\mathcal{P} = \{\mathbf{p_1}, \ldots, \mathbf{p_n}\}$ be a set of n points in $\mathbb{R}^2$ or $\mathbb{R}^3$ and Φ be a scalar function defined on the convex hull of $\mathcal{P}$. We assume that the function values are known at the points of $\mathcal{P}$, i.e. to each $\mathbf{p_i} \in \mathcal{P}$, we associate $z_i = \Phi(\mathbf{p_i})$. Sometimes, the gradient of Φ is also known at $\mathbf{p_i}$. It is denoted $\mathbf{g_i} = \nabla\Phi(\mathbf{p_i})$. The interpolation is carried out for an arbitrary query point $\mathbf{x}$ on the convex hull of $\mathcal{P}$.

70.1 Natural Neighbor Coordinates

70.1.1 Introduction

Natural neighbor interpolation has been introduced by Sibson [Sib81] to interpolate multivariate scattered data. Given a set of data points $\mathcal{P}$, the natural neighbor coordinates associated to $\mathcal{P}$ are defined from the Voronoi diagram of $\mathcal{P}$. When simulating the insertion of a query point $\mathbf{x}$ into the Voronoi diagram of $\mathcal{P}$, the potential Voronoi cell of $\mathbf{x}$ "steals" some parts from the existing cells.

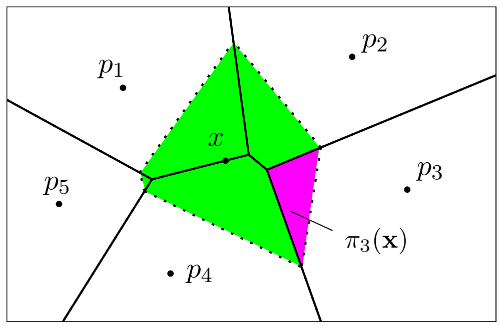

Figure 70.1: $2D$ example: $\mathbf{x}$ has five natural neighbors $\mathbf{p_1},\ldots,\mathbf{p_5}$. The natural neighbor coordinate $\lambda_3(\mathbf{x})$ is the ratio of the area of the pink polygon, $\pi_3(\mathbf{x})$, over the area of the total highlighted zone.

Let $\pi(\mathbf{x})$ denote the volume of the potential Voronoi cell of $\mathbf{x}$ and $\pi_i(\mathbf{x})$ denote the volume of the sub-cell that would be stolen from the cell of $\mathbf{p_i}$ by the cell of $\mathbf{x}$. The natural neighbor coordinate of $\mathbf{x}$ with respect to the data point $\mathbf{p_i} \in \mathcal{P}$ is defined by

$$\lambda_i(\mathbf{x}) = \frac{\pi_i(\mathbf{x})}{\pi(\mathbf{x})}.$$

A two-dimensional example is depicted in Figure 70.1.

Various papers ([Sib80], [Far90], [Pip93], [Bro97], [HS00]) show that the natural neighbor coordinates have the following properties:

1. $\mathbf{x} = \sum_{i=1}^{n} \lambda_i(\mathbf{x})\mathbf{p_i}$ (barycentric coordinate property).
2. For any $i, j \leq n, \lambda_i(\mathbf{p_j}) = \delta_{ij}$, where δ_{ij} is the Kronecker symbol.
3. $\sum_{i=1}^{n} \lambda_i(\mathbf{x}) = 1$ (partition of unity property).

For the case where the query point x is located on the envelope of the convex hull of $\mathcal{P}$, the potential Voronoi cell of x becomes infinite and :

$\pi(\mathbf{x}) = \infty$

$\lambda_i(\mathbf{x}) = 0$ for all data point $\mathbf{p_i}$ of $\mathcal{P}$ except for the two endpoints, let's say $\mathbf{p}$ and $\mathbf{q}$,of the edge where x lies.

The natural neighbor coordinate of $\mathbf{x}$ with respect to these endpoints $\mathbf{p}$ and $\mathbf{q}$ will be :

$\lambda_p(\mathbf{x}) = \frac{\|\mathbf{x}-\mathbf{q}\|}{\|\mathbf{q}-\mathbf{p}\|}$

$\lambda_q(\mathbf{x}) = \frac{\|\mathbf{x}-\mathbf{p}\|}{\|\mathbf{q}-\mathbf{p}\|}$

Furthermore, Piper [Pip93] shows that the coordinate functions are continuous in the convex hull of $\mathcal{P}$ and continuously differentiable except on the data points $\mathcal{P}$.

The interpolation package of CGAL provides functions to compute natural neighbor coordinates for $2D$ and $3D$ points with respect to Voronoi diagrams as well as with respect to power diagrams (only $2D$), i.e. for weighted points. Refer to the reference pages *natural_neighbor_coordinates_2*, *natural_neighbor_coordinates_3* and *regular_neighbor_coordinates_2*.

In addition, the package provides functions to compute natural neighbor coordinates on well sampled point set surfaces. See Section 70.2 and the reference page *surface_neighbor_coordinates_3* for further information.

70.1.2 Implementation

Given a Delaunay triangulation or a Regular triangulation, the vertices in conflict with the query point are determined. The areas $\pi_i(\mathbf{x})$ are computed by triangulating the Voronoi sub-cells. The normalization factor $\pi(\mathbf{x})$ is also returned. If the query point is already located and/or the boundary edges of the conflict zone are already determined, alternative functions allow to avoid the re-computation.

70.1.3 Example for Natural Neighbor Coordinates

The signature of all coordinate computation functions is about the same.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/natural_neighbor_coordinates_2.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Delaunay_triangulation_2<K>
   Delaunay_triangulation;
typedef std::vector< std::pair< K::Point_2, K::FT  > >

   Point_coordinate_vector;

int main()
{
  Delaunay_triangulation dt;

  for (int y=0 ; y<3 ; y++)
    for (int x=0 ; x<3 ; x++)
      dt.insert(K::Point_2(x,y));

  //coordinate computation
  K::Point_2 p(1.2, 0.7);
  Point_coordinate_vector coords;
  CGAL::Triple<
    std::back_insert_iterator<Point_coordinate_vector>,
    K::FT, bool> result =
    CGAL::natural_neighbor_coordinates_2(dt, p,
                                         std::back_inserter(coords));
  if(!result.third){
    std::cout << "The coordinate computation was not successful."
```

```
                << std::endl;
    std::cout << "The point (" <<p << ") lies outside the convex hull."
                << std::endl;
  }
  K::FT  norm = result.second;
  std::cout << "Coordinate computation successful." << std::endl;
  std::cout << "Normalization factor: " <<norm << std::endl;

70.1.4 Example for Regular Neighbor Coordinates

For regular neighbor coordinates, it is sufficient to replace the name of the function and the type of triangulation passed as parameter. A special traits class is needed.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Regular_triangulation_2.h>
#include <CGAL/Regular_triangulation_euclidean_traits_2.h>
#include <CGAL/regular_neighbor_coordinates_2.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Regular_triangulation_euclidean_traits_2<K> Gt;
typedef CGAL::Regular_triangulation_2<Gt>
   Regular_triangulation;
typedef Regular_triangulation::Weighted_point Weighted_point;
typedef std::vector< std::pair< Weighted_point, K::FT  > >

   Point_coordinate_vector;

int main()
{
  Regular_triangulation rt;

  for (int y=0 ; y<3 ; y++)
    for (int x=0 ; x<3 ; x++)
      rt.insert(Weighted_point(K::Point_2(x,y), 0));

  //coordinate computation
  Weighted_point wp(K::Point_2(1.2, 0.7),2);
  Point_coordinate_vector  coords;
  CGAL::Triple<
    std::back_insert_iterator<Point_coordinate_vector>,
    K::FT, bool> result =
    CGAL::regular_neighbor_coordinates_2(rt, wp,
                                         std::back_inserter(coords));
  if(!result.third){
    std::cout << "The coordinate computation was not successful."
                << std::endl;
```

```
    std::cout << "The point (" <<wp.point() << ") lies outside the convex
    hull."
              << std::endl;
  }
  K::FT  norm = result.second;
  std::cout << "Coordinate computation successful." << std::endl;
  std::cout << "Normalization factor: " <<norm << std::endl;

  std::cout << "done" << std::endl;
  return 0;
}
```

File: examples/Interpolation/rn_coordinates_2.cpp

For surface neighbor coordinates, the surface normal at the query point must be provided, see Section 70.2.

70.2 Surface Natural Neighbor Coordinates and Surface Neighbors

This section introduces the functions to compute natural neighbor coordinates and surface neighbors associated to a set of sample points issued from a surface $\mathcal{S}$ and given a query point $\mathbf{x}$ on $\mathcal{S}$. We suppose that $\mathcal{S}$ is a closed and compact surface of $\mathbb{R}^3$, and let $\mathcal{P} = \{\mathbf{p_1}, \ldots, \mathbf{p_n}\}$ be an ε-sample of $\mathcal{S}$ (refer to Amenta and Bern [AB99]). The concepts are based on the definition of Boissonnat and Flötotto [BF02], [Flö03b]. Both references contain a thorough description of the requirements and the mathematical properties.

70.2.1 Introduction

Two observations lead to the definition of surface neighbors and surface neighbor coordinates: First, it is clear that the tangent plane $\mathcal{T}_x$ of the surface $\mathcal{S}$ at the point $\mathbf{x} \in \mathcal{S}$ approximates $\mathcal{S}$ in the neighborhood of $\mathbf{x}$. It has been shown in [BF02] that, if the surface $\mathcal{S}$ is well sampled with respect to the curvature and the local thickness of $\mathcal{S}$, i.e. it is an ε-sample, the intersection of the tangent plane $\mathcal{T}_x$ with the Voronoi cell of $\mathbf{x}$ in the Voronoi diagram of $\mathcal{P} \cup \{\mathbf{x}\}$ has a small diameter. Consequently, inside this Voronoi cell, the tangent plane $\mathcal{T}_x$ is a reasonable approximation of $\mathcal{S}$. Furthermore, the second observation allows to compute this intersection diagram easily: one can show using Pythagoras' Theorem that the intersection of a three-dimensional Voronoi diagram with a plane $\mathcal{H}$ is a two-dimensional power diagram. The points defining the power diagram are the projections of the points in $\mathcal{P}$ onto $\mathcal{H}$, each point weighted with its negative square distance to $\mathcal{H}$. Algorithms for the computation of power diagrams via the dual regular triangulation are well known and for example provided by CGAL in the class *Regular_triangulation_2<Gt, Tds>*.

70.2.2 Implementation

Voronoi Intersection Diagrams

In CGAL, the regular triangulation dual to the intersection of a 3D Voronoi diagram with a plane $\mathcal{H}$ can be computed by instantiating the *Regular_triangulation_2<Gt, Tds>* class with the traits class *Voronoi_intersection_2_traits_3<K>*. This traits class contains a point and a vector as class member which define the plane $\mathcal{H}$. All predicates and constructions used by *Regular_triangulation_2<Gt, Tds>* are replaced by the corresponding operators on three-dimensional points. For example, the power test predicate (which takes three weighted $2D$ points p', q', r' of the regular triangulation and tests the power distance of a fourth point t' with respect to the power circle orthogonal to p, q, r) is replaced by a *Side_of_plane_centered_sphere_2_3* predicate that tests the position of a $3D$ point t with respect to the sphere centered on the plane $\mathcal{H}$ passing through the $3D$ points p, q, r. This approach allows to avoid the explicit constructions of the projected points and the weights which are very prone to rounding errors.

Natural Neighbor Coordinates on Surfaces

The computation of natural neighbor coordinates on surfaces is based upon the computation of regular neighbor coordinates with respect to the regular triangulation that is dual to $\mathrm{Vor}(\mathcal{P}) \cap \mathcal{T}_x$, the intersection of $\mathcal{T}_x$ and the Voronoi diagram of $\mathcal{P}$, via the function *regular_neighbor_coordinates_2*.

Of course, we might introduce all data points $\mathcal{P}$ into this regular triangulation. However, this is not necessary because we are only interested in the cell of $\mathbf{x}$. It is sufficient to guarantee that all surface neighbors of the query point $\mathbf{x}$ are among the input points that are passed as argument to the function. The sample points $\mathcal{P}$ can be filtered for example by distance, e.g. using range search or k-nearest neighbor queries, or with the help of the $3D$ Delaunay triangulation since the surface neighbors are necessarily a subset of the natural neighbors of the query point in this triangulation. CGAL provides a function that encapsulates the filtering based on the $3D$ Delaunay triangulation. For input points filtered by distance, functions are provided that indicate whether or not points that lie outside the input range (i.e. points that are further from $\mathbf{x}$ than the furthest input point) can still influence the result. This allows to iteratively enlarge the set of input points until the range is sufficient to certify the result.

Surface Neighbors

The surface neighbors of the query point are its neighbors in the regular triangulation that is dual to $\mathrm{Vor}(\mathcal{P}) \cap \mathcal{T}_x$, the intersection of $\mathcal{T}_x$ and the Voronoi diagram of $\mathcal{P}$. As for surface neighbor coordinates, this regular triangulation is computed and the same kind of filtering of the data points as well as the certification described above is provided.

70.2.3 Example for Surface Neighbor Coordinates

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/point_generators_3.h>
#include <CGAL/algorithm.h>
#include <CGAL/Origin.h>

#include <CGAL/surface_neighbor_coordinates_3.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::FT                           Coord_type;
typedef K::Point_3                      Point_3;
typedef K::Vector_3                     Vector_3;
typedef std::vector< std::pair< Point_3, K::FT  > >
                                        Point_coordinate_vector;
```

```
int main()
{

  int n=100;
  std::vector< Point_3> points;
  points.reserve(n);

  std::cout << "Generate " << n << " random points on a sphere."
            << std::endl;
  CGAL::Random_points_on_sphere_3<Point_3> g(1);
  CGAL::cpp0x::copy_n( g, n, std::back_inserter(points));

  Point_3 p(1, 0,0);
  Vector_3 normal(p-CGAL::ORIGIN);
  std::cout << "Compute surface neighbor coordinates for "
            << p << std::endl;
  Point_coordinate_vector coords;
  CGAL::Triple< std::back_insert_iterator<Point_coordinate_vector>,
    K::FT, bool> result =
    CGAL::surface_neighbor_coordinates_3(points.begin(), points.end(),
                                         p, normal,
                                         std::back_inserter(coords),
                                         K());
  if(!result.third){
    //Undersampling:
    std::cout << "The coordinate computation was not successful."
              << std::endl;
    return 0;
  }
  K::FT norm = result.second;

  std::cout << "Testing the barycentric property " << std::endl;
  Point_3 b(0, 0,0);
  for(std::vector< std::pair< Point_3, Coord_type  > >::const_iterator
        it = coords.begin(); it!=coords.end(); ++it)
    b = b + (it->second/norm)* (it->first - CGAL::ORIGIN);

  std::cout <<"    weighted barycenter: " << b <<std::endl;
  std::cout << "    squared distance: " <<
    CGAL::squared_distance(p,b) <<std::endl;

  std::cout << "done" << std::endl;
  return 0;
}
```

70.3 Interpolation Methods

70.3.1 Introduction

Linear Precision Interpolation

Sibson [Sib81] defines a very simple interpolant that re-produces linear functions exactly. The interpolation of $\Phi(\mathbf{x})$ is given as the linear combination of the neighbors' function values weighted by the coordinates:

$$Z^0(\mathbf{x}) = \sum_i \lambda_i(\mathbf{x}) z_i.$$

Indeed, if $z_i = a + \mathbf{b}^t \mathbf{p_i}$ for all natural neighbors of $\mathbf{x}$, we have

$$Z^0(\mathbf{x}) = \sum_i \lambda_i(\mathbf{x})(a + \mathbf{b}^t \mathbf{p_i}) = a + \mathbf{b}^t \mathbf{x}$$

by the barycentric coordinate property. The first example in Subsection 70.3.3 shows how the function is called.

Sibson's C^1 Continuous Interpolant

In [Sib81], Sibson describes a second interpolation method that relies also on the function gradient $\mathbf{g_i}$ for all $\mathbf{p_i} \in \mathcal{P}$. It is C^1 continuous with gradient $\mathbf{g_i}$ at $\mathbf{p_i}$. Spherical quadrics of the form $\Phi(\mathbf{x}) = a + \mathbf{b}^t\mathbf{x} + \gamma\, \mathbf{x}^t\mathbf{x}$ are reproduced exactly. The proof relies on the barycentric coordinate property of the natural neighbor coordinates and assumes that the gradient of Φ at the data points is known or approximated from the function values as described in [Sib81] (see Section 70.3.2).

Sibson's Z^1 interpolant is a combination of the linear interpolant Z^0 and an interpolant ξ which is the weighted sum of the first degree functions

$$\xi_i(\mathbf{x}) = z_i + \mathbf{g_i}^t(\mathbf{x} - \mathbf{p_i}), \qquad \xi(\mathbf{x}) = \frac{\sum_i \frac{\lambda_i(\mathbf{x})}{\|\mathbf{x}-\mathbf{p_i}\|}\xi_i(\mathbf{x})}{\sum_i \frac{\lambda_i(\mathbf{x})}{\|\mathbf{x}-\mathbf{p_i}\|}}.$$

Sibson observed that the combination of Z^0 and ξ reconstructs exactly a spherical quadric if they are mixed as follows:

$$Z^1(\mathbf{x}) = \frac{\alpha(\mathbf{x})Z^0(\mathbf{x}) + \beta(\mathbf{x})\xi(\mathbf{x})}{\alpha(\mathbf{x}) + \beta(\mathbf{x})} \text{ where } \alpha(\mathbf{x}) = \frac{\sum_i \lambda_i(\mathbf{x})\frac{\|\mathbf{x}-\mathbf{p_i}\|^2}{f(\|\mathbf{x}-\mathbf{p_i}\|)}}{\sum_i \frac{\lambda_i(\mathbf{x})}{f(\|\mathbf{x}-\mathbf{p_i}\|)}} \text{ and } \beta(\mathbf{x}) = \sum_i \lambda_i(\mathbf{x})\|\mathbf{x}-\mathbf{p_i}\|^2,$$

where in Sibson's original work, $f(\|\mathbf{x}-\mathbf{p_i}\|) = \|\mathbf{x}-\mathbf{p_i}\|$.

CGAL contains a second implementation with $f(\|\mathbf{x}-\mathbf{p_i}\|) = \|\mathbf{x}-\mathbf{p_i}\|^2$ which is less demanding on the number type because it avoids the square-root computation needed to compute the distance $\|\mathbf{x}-\mathbf{p_i}\|$. The theoretical guarantees are the same (see [Flö03b]). Simply, the smaller the slope of f around $f(0)$, the faster the interpolant approaches ξ_i as $\mathbf{x} \rightarrow \mathbf{p_i}$.

Farin's C^1 Continuous Interpolant

Farin [Far90] extended Sibson's work and realizes a C^1 continuous interpolant by embedding natural neighbor coordinates in the Bernstein-Bézier representation of a cubic simplex. If the gradient of Φ at the data points is known, this interpolant reproduces quadratic functions exactly. The function gradient can be approximated from the function values by Sibson's method [Sib81] (see Section 70.3.2) which is exact only for spherical quadrics.

Quadratic Precision Interpolants

Knowing the gradient $\mathbf{g_i}$ for all $\mathbf{p_i} \in \mathcal{P}$, we formulate a very simple interpolant that reproduces exactly quadratic functions. This interpolant is not C^1 continuous in general. It is defined as follows:

$$I^1(\mathbf{x}) = \sum_i \lambda_i(\mathbf{x})(z_i + \frac{1}{2}\mathbf{g_i}^t(\mathbf{x} - \mathbf{p_i}))$$

70.3.2 Gradient Fitting

Sibson describes a method to approximate the gradient of the function f from the function values on the data sites. For the data point $\mathbf{p_i}$, we determine

$$\mathbf{g_i} = \min_{\mathbf{g}} \sum_j \frac{\lambda_j(\mathbf{p_i})}{\|\mathbf{p_i} - \mathbf{p_j}\|^2} \left(z_j - (z_i + \mathbf{g}^t(\mathbf{p_j} - \mathbf{p_i}))\right),$$

where $\lambda_j(\mathbf{p_i})$ is the natural neighbor coordinate of $\mathbf{p_i}$ with respect to $\mathbf{p_i}$ associated to $\mathcal{P} \setminus \{\mathbf{p_i}\}$. For spherical quadrics, the result is exact.

CGAL provides functions to approximate the gradients of all data points that are inside the convex hull. There is one function for each type of natural neighbor coordinate (i.e. *natural_neighbor_coordinates_2*, *regular_neighbor_coordinates_2*).

70.3.3 Example for Linear Interpolation

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>

#include <CGAL/Interpolation_traits_2.h>
#include <CGAL/natural_neighbor_coordinates_2.h>
#include <CGAL/interpolation_functions.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Delaunay_triangulation_2<K>
   Delaunay_triangulation;
typedef CGAL::Interpolation_traits_2<K>               Traits;
typedef K::FT                                         Coord_type;
typedef K::Point_2                                    Point;

int main()
{
  Delaunay_triangulation T;
  std::map<Point, Coord_type, K::Less_xy_2> function_values;
  typedef CGAL::Data_access< std::map<Point, Coord_type, K::Less_xy_2 > >
                                                    Value_access;

  Coord_type a(0.25), bx(1.3), by(-0.7);

  for (int y=0 ; y<3 ; y++)
    for (int x=0 ; x<3 ; x++){
      K::Point_2 p(x,y);
```

```
      T.insert(p);
      function_values.insert(std::make_pair(p,a + bx* x+ by*y));
    }
  //coordinate computation
  K::Point_2 p(1.3,0.34);
  std::vector< std::pair< Point, Coord_type > > coords;
  Coord_type norm =
    CGAL::natural_neighbor_coordinates_2
    (T, p,std::back_inserter(coords)).second;

  Coord_type res =  CGAL::linear_interpolation(coords.begin(),
   coords.end(),
                                              norm,

   Value_access(function_values));

  std::cout << "   Tested interpolation on " << p << " interpolation: "
            << res << " exact: " << a + bx* p.x()+ by* p.y()<< std::endl;

  std::cout << "done" << std::endl;
  return 0;
}
```

  Coord_type norm =
    CGAL::natural_neighbor_coordinates_2(T, p,std::back_inserter
                                          (coords)).second;

  //Sibson interpolant: version without sqrt:
  std::pair<Coord_type, bool> res =
    CGAL::sibson_c1_interpolation_square
    (coords.begin(),
     coords.end(),norm,p,
     CGAL::Data_access<Point_value_map>(function_values),
     CGAL::Data_access<Point_vector_map>(function_gradients),
     Traits());
  if(res.second)
    std::cout << "   Tested interpolation on " << p
              << " interpolation: " << res.first << " exact: "
              << a + bx * p.x()+ by * p.y()+ c*(p.x()*p.x()+p.y()*p.y())
              << std::endl;
  else
    std::cout << "C^1 Interpolation not successful." << std::endl
              << " not all function_gradients are provided."  <<
   std::endl
              << " You may resort to linear interpolation." << std::endl;

  std::cout << "done" << std::endl;
  return 0;
}
```

File: examples/Interpolation/sibson_interpolation_2.cpp

An additional example in the distribution compares numerically the errors of the different interpolation functions with respect to a known function. It is distributed in the examples directory.

2D and Surface Function Interpolation Reference Manual

Julia Flötotto

Scattered data interpolation solves the following problem: given measures of a function on a set of discrete data points, the task is to interpolate this function on an arbitrary query point.

If the function is a linear function and given barycentric coordinates that allow to express the query point as the convex combination of some data points, the function can be exactly interpolated. If the function gradients are known, we can exactly interpolate quadratic functions given barycentric coordinates. Any further properties of these interpolation functions depend on the properties of the barycentric coordinates. They are provided in this package under the name *linear_interpolation* and *quadratic_interpolation*.

Natural neighbor interpolation

Natural neighbor coordinates are defined by Sibson in 1980 and are based on the Voronoi diagram of the data points. Interpolation methods based on natural neighbor coordinates are particularly interesting because they adapt easily to non-uniform and highly anisotropic data. This package contains Sibson's C^1 continuous interpolation method which interpolates exactly spherical quadrics (of the form $\Phi(\mathbf{x}) = a + \mathbf{b}^t\mathbf{x} + \gamma\,\mathbf{x}^t\mathbf{x}$) and Farin's C^1 continuous interpolation method based on Bernstein-Bézier techniques and interpolating exactly quadratic functions – assuming that the function gradient is known. In addition, Sibson defines a method to approximate the function gradients for data points that are in the interior of the convex hull. This method is exact for spherical quadrics.

This CGAL package implements Sibson's and Farin's interpolation functions as well as Sibson's function gradient fitting method. Furthermore, it provides functions to compute the natural neighbor coordinates with respect to a two-dimensional Voronoi diagram (i. e., from the Delaunay triangulation of the data points) and to a two-dimensional power diagram for weighted points (i. e., from their regular triangulation). Natural neighbor coordinates on closed and well-sampled surfaces can also be computed if the normal to the surface at the query point is known. The latter coordinates are only approximately barycentric, see [BF02].

For a more thorough introduction see the user manual.

CGAL::linear_interpolation

Function

Definition

The function *linear_interpolation* computes the weighted sum of the function values which must be provided via a functor.

#include <CGAL/interpolation_functions.h>

template < class ForwardIterator, class Functor>
typename Functor::result_type::first_type

linear_interpolation(ForwardIterator first,
ForwardIterator beyond,
typename std::iterator_traits<ForwardIterator>::value_type::second_type norm,
Functor function_values)

ForwardIterator::value_type is a pair associating a point to a (non-normalized) barycentric coordinate. *norm* is the normalization factor. Given a point, the functor *function_values* allows to access a pair of a function value and a Boolean. The Boolean indicates whether the function value could be retrieved correctly. This function generates the interpolated function value as the weighted sum of the values corresponding to each point of the point/coordinate pairs in the range $[first, beyond)$.
Precondition: $norm \neq 0$. *function_value(p).second* == *true* for all points p of the point/coordinate pairs in the range $[first, beyond)$.

Requirements

1. *ForwardIterator::value_type* is a pair of point/coordinate value, thus *ForwardIterator::value_type::first_type* is equivalent to a point and *ForwardIterator::value_type::second_type* is a field number type.
2. *Functor::argument_type* must be equivalent to *ForwardIterator::value_type::first_type* and *Functor::result_type* is a pair of the function value type and a Boolean value. The function value type must provide a multiplication and addition operation with the field number type *ForwardIterator::value_type::second_type* and a constructor with argument 0. A model of the functor is provided by the struct *Data_access*. It must be instantiated accordingly with an associative container (e.g. STL *std::map*) having the point type as *key_type* and the function value type as *mapped_type*.

Function

CGAL::sibson_c1_interpolation

Definition

The function *sibson_c1_interpolation* interpolates the function values and the gradients that are provided by functors following the method described in [Sib81].

Parameters

The template parameter *Traits* is to be instantiated with a model of *InterpolationTraits*. *ForwardIterator::value_type* is a pair associating a point to a (non-normalized) barycentric coordinate. *norm* is the normalization factor. The range [*first*,*beyond*) contains the barycentric coordinates for the query point *p*. The functor *function_value* allows to access the value of the interpolated function given a point. *function_gradient* allows to access the function gradient given a point.

#include <CGAL/interpolation_functions.h>

template < class ForwardIterator, class Functor, class GradFunctor, class Traits>
std::pair< typename Functor::result_type, bool>

sibson_c1_interpolation(ForwardIterator first,
ForwardIterator beyond,
typename std::iterator_traits<ForwardIterator>::value_type::second_type norm,
typename std::iterator_traits<ForwardIterator>::value_type:: first_type p,
Functor function_value,
GradFunctor function_gradient,
Traits traits)

This function generates the interpolated function value at the point *p* using Sibson's Z^1 interpolant [Sib81].
If the functor *function_gradient* cannot supply the gradient of a point, the function returns a pair where the Boolean is set to *false*. If the interpolation was successful, the pair contains the interpolated function value as first and *true* as second value.
Precondition: *norm* $\neq 0$. *function_value(p).second* == *true* for all points *p* of the point/coordinate pairs in the range [*first*, *beyond*).

Requirements

1. *Traits* is a model of the concept *InterpolationTraits*.
2. *ForwardIterator::value_type* is a point/coordinate pair. Precisely *ForwardIterator::value_type::first_type* is equivalent to *Traits::Point_d* and *ForwardIterator::value_type::second_type* is equivalent to *Traits::FT*.

3. *Functor::argument_type* must be equivalent to *Traits::Point_d* and *Functor::result_type* is a pair of the function value type and a Boolean. The function value type must provide a multiplication and addition operation with the type *Traits::FT* as well as a constructor with argument 0.

4. *GradFunctor::argument_type* must be equivalent to *Traits::Point_d* and *Functor::result_type* is a pair of the function's gradient type and a Boolean. The function gradient type must provide a multiplication operation with *Traits::Vector_d*.

5. A model of the functor types *Functor* (resp. *GradFunctor*) is provided by the struct *Data_access*. It must be instantiated accordingly with an associative container (e.g. STL *std::map*) having the point type as *key_type* and the function value type (resp. function gradient type) as *mapped_type*.

6. The number type *FT* provided by *Traits* must support the square root operation *sqrt()*.

template < class ForwardIterator, class Functor, class GradFunctor, class Traits>
typename Functor::result_type

sibson_c1_interpolation_square(ForwardIterator first,
ForwardIterator beyond,
typename std::iterator_traits<ForwardIterator> ::value_type::second_type norm,
typename std::iterator_traits<ForwardIterator> ::value_type::first_type p,
Functor function_value,
GradFunctor function_gradient,
Traits traits)

The same as above except that no square root operation is needed for *FT*.

Function

CGAL::farin_c1_interpolation

Definition

The function *farin_c1_interpolation* interpolates the function values and the gradients that are provided by functors using the method described in [Far90].

#include <CGAL/interpolation_functions.h>

Parameters

RandomAccessIterator::value_type is a pair associating a point to a (non-normalized) barycentric coordinate. See *sibson_c1_interpolation* for the other parameters.

template < class RandomAccessIterator, class Functor, class GradFunctor, class Traits>
typename Functor::result_type

farin_c1_interpolation(RandomAccessIterator first,
RandomAccessIterator beyond,
typename std::iterator_traits<RandomAccessIterator>::value_type::second_type norm,
typename std::iterator_traits<ForwardIterator>::value_type::first_type p,
Functor function_value,
GradFunctor function_gradient,
Traits traits)

generates the interpolated function value computed by Farin's interpolant [Far90]. See also *sibson_c1_interpolation*.
Precondition: $norm \neq 0$. *function_value(p).second == true* for all points p of the point/coordinate pairs in the range $[first, beyond)$.
Precondition: The range $[first, beyond)$ contains either one or more than three elements.

Requirements

Same requirements as for *sibson_c1_interpolation* only the iterator must provide random access and *Traits::FT* does not need to provide the square root operation.

Function

CGAL::quadratic_interpolation

Definition

The function *quadratic_interpolation* interpolates the function values and first degree functions defined from the function gradients. Both, function values and gradients, must be provided by functors.

#include <CGAL/interpolation_functions.h>

Parameters

See *sibson_c1_interpolation*.

template < class ForwardIterator, class Functor, class GradFunctor, class Traits>
typename Functor::result_type

quadratic_interpolation(ForwardIterator first,
ForwardIterator beyond,
typename std::iterator_traits<ForwardIterator>:: value_type::second_type norm,
typename std::iterator_traits<ForwardIterator>::value_type:: first_type p,
Functor function_value,
GradFunctor function_gradient,
Traits traits)

This function generates the interpolated function value as the weighted sum of the values plus a linear term in the gradient for each point of the point/coordinate pairs in the range [*first*, *beyond*). See also *sibson_c1_interpolation*.
Precondition: *norm* $\neq 0$ *function_value(p).second == true* for all points *p* of the point/coordinate pairs in the range [*first*, *beyond*).

Requirements

Same requirements as for *sibson_c1_interpolation* only that *Traits::FT* does not need to provide the square root operation.

CGAL::Data_access<Map>

Definition

The struct *Data_access<Map>* implements a functor that allows to retrieve data from an associative container. The functor keeps a reference to the container. Given an instance of the container's key type, it returns a pair of the container's value type and a Boolean indicating whether the retrieval was successful.

This class can be used to provide the values and gradients of the interpolation functions.

#include <CGAL/interpolation_functions.h>

Parameters

The class *Data_access<Map>* has the container type *Map* as template parameter.

Types

typedef Map::mapped_type

Data_type;

typedef Map::key_type

Key_type;

Creation

Data_access<Map> data_access(Map map); — Introduces a *Data_access* to the container *map*.

std::pair< Data_type, bool>

data_access(Key_type p)

If there is an entry for *p* in the container *map*, then the pair of *map.find(p)* and *true* is returned. Otherwise, the Boolean value of the pair is *false*.

InterpolationTraits

Concept

Definition

Most interpolation functions are parameterized by a traits class that defines the primitives used in the interpolation algorithms. The concept InterpolationTraits defines this common set of requirements.

Types

InterpolationTraits:: FT	The number type must follow the model *FieldNumberType*.
InterpolationTraits:: Point_d	The point type on which the function is defined and interpolated.
InterpolationTraits:: Vector_d	The corresponding vector type.
InterpolationTraits:: Construct_vector_d	A constructor object for *Vector_d*. Provides : *Vector_d operator() (Point_d a, Point_d b)* which produces the vector *b - a* and *Vector_d operator() (Null_vector NULL_VECTOR)* which introduces the null vector.
InterpolationTraits:: Construct_scaled_vector_d	Constructor object for *Vector_d*. Provides : *Vector_d operator() (Vector_d v,FT scale)* which produces the vector *v* scaled by a factor *scale*.
InterpolationTraits:: Compute_squared_distance_d	Constructor object for *FT*. Provides the operator: *FT operator() (Point_d a, Point_d b)* returning the squared distance between *a* and *b*.
InterpolationTraits traits;	default constructor.

Construction objects

The following functions that create instances of the above constructor object types must exist.

Construct_vector_d *traits.construct_vector_d_object()*

Construct_scaled_vector_d

traits.construct_scaled_vector_d_object()

Compute_squared_distance_d

traits.compute_squared_distance_d_object()

Function

CGAL::natural_neighbor_coordinates_2

Definition

The function *natural_neighbor_coordinates_2* computes natural neighbor coordinates, also called Sibson's coordinates, for 2D points provided a two-dimensional triangulation and a query point in the convex hull of the vertices of the triangulation.

#include <CGAL/natural_neighbor_coordinates_2.h>

template < class Dt, class OutputIterator >
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >

natural_neighbor_coordinates_2(Dt dt,
typename Dt::Geom_traits::Point_2 p,
OutputIterator out,
typename Dt::Face_handle start = typename Dt::Face_handle())

computes the natural neighbor coordinates for *p* with respect to the points in the two-dimensional Delaunay triangulation *dt*. The template class *Dt* should be of type *Delaunay_triangulation_2<Traits, Tds>*. The value type of the *OutputIterator* is a pair of *Dt::Point_2* and the coordinate value of type *Dt::Geom_traits::FT*. The sequence of point/coordinate pairs that is computed by the function is placed starting at *out*. The function returns a triple with an iterator that is placed past-the-end of the resulting sequence of point/coordinate pairs, the normalization factor of the coordinates and a Boolean value which is set to true iff the coordinate computation was successful.

template <class Dt, class OutputIterator, class EdgeIterator >
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >

natural_neighbor_coordinates_2(Dt dt,
typename Dt::Geom_traits::Point_2 p,
OutputIterator out,
EdgeIterator hole_begin,
EdgeIterator hole_end)

The same as above. *hole_begin* and *hole_end* determines the iterator range over the boundary edges of the conflict zone of *p* in the triangulation. It is the result of the function *T.get_boundary_of_conflicts(p,std::back_inserter(hole), start)*, see *Delaunay_triangulation_2<Traits, Tds>*.

template <class Dt, class OutputIterator>
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >

natural_neighbor_coordinates_2(Dt dt,

typename Dt::Vertex_handle vh,
OutputIterator out)

This function computes the natural neighbor coordinates of the point *vh->point()* with respect to the vertices of *dt* excluding *vh->point()*. The same as above for the remaining parameters.

Requirements

1. *Dt* are equivalent to the class *Delaunay_triangulation_2<Traits, Tds>*.
2. The traits class *Traits* of *Dt* is a model of the concept *DelaunayTriangulationTraits_2*. Only the following members of this traits class are used:
   - *Construct_circumcenter_2*
   - *FT*
   - *Point_2*
   - *construct_circumcenter_2_object*

   Additionally, *Traits* must meet the requirements for the traits class of the *polygon_area_2* function.
3. *OutputIterator::value_type* is equivalent to *std::pair<Dt::Point_2, Dt::Geom_traits::FT>*, i.e. a pair associating a point and its natural neighbor coordinate.

CGAL::surface_neighbor_coordinates_3 . . . . page 4016
CGAL::regular_neighbor_coordinates_2 . . . . page 4006

Implementation

This function computes the area of the sub-cells stolen from the Voronoi cells of the points in *dt* when inserting *p*. The total area of the Voronoi cell of *p* is also computed and returned by the function. If *p* lies outside the convex hull, the coordinate values cannot be computed and the third value of the result triple is set to *false*.

Function

CGAL::regular_neighbor_coordinates_2

Definition

The function *regular_neighbor_coordinates_2* computes natural neighbor coordinates, also called Sibson's coordinates, for weighted $2D$ points provided a two-dimensional regular triangulation and a (weighted) query point inside the convex hull of the vertices of the triangulation. We call these coordinates regular neighbor coordinates.

#include <CGAL/regular_neighbor_coordinates_2.h>

template < class Rt, class OutputIterator >
CGAL::Triple< OutputIterator, typename Rt::Geom_traits::FT, bool >

regular_neighbor_coordinates_2(Rt rt,
typename Rt::Weighted_point p,
OutputIterator out,
typename Rt::Face_handle start = typename Rt::Face_handle())

computes the regular neighbor coordinates for *p* with respect to the weighted points in the two-dimensional regular triangulation *rt*. The template class *Rt* should be of type *Regular_triangulation_2<Traits, Tds>*. The value type of the *OutputIterator* is a pair of *Rt::Weighted_point* and the coordinate value of type *Rt::Geom_traits::FT*. The sequence of point/-coordinate pairs that is computed by the function is placed starting at *out*. The function returns a triple with an iterator that is placed past-the-end of the resulting sequence of point/-coordinate pairs, the normalization factor of the coordinates and a Boolean value which is set to true iff the coordinate computation was successful, i.e. if *p* lies inside the convex hull of the points in *rt*.

template <class Rt, class OutputIterator, class EdgeIterator, class VertexIterator >
CGAL::Triple< OutputIterator, typename Traits::FT, bool >

regular_neighbor_coordinates_2(Rt rt,
typename Traits::Weighted_point p,
OutputIterator out,
EdgeIterator hole_begin,
EdgeIterator hole_end,
VertexIterator hidden_vertices_begin,

VertexIterator hidden_vertices_end)

The same as above. *hole_begin* and *hole_end* determines the iterator range over the boundary edges of the conflict zone of *p* in the triangulation *rt*. *hidden_vertices_begin* and *hidden_vertices_end* determines the iterator range over the hidden vertices of the conflict zone of *p* in*rt*. It is the result of the function *T.get_boundary_of_conflicts(p,std::back_inserter(hole), std::back_inserter(hidden_vertices), start)*, see *Regular_triangulation_2<Traits, Tds>*.

template <class Rt, class OutputIterator>
CGAL::Triple< OutputIterator, typename Rt::Geom_traits::FT, bool >

regular_neighbor_coordinates_2(Rt rt,
typename Rt::Vertex_handle vh,
OutputIterator out)

This function computes the regular neighbor coordinates of the point *vh->point()* with respect to the vertices of *rt* excluding *vh->point()*. The same as above for the remaining parameters.

Requirements

1. *Rt* are equivalent to the class *Regular_triangulation_2<Traits, Tds>*.
2. The traits class *Traits* of *Rt* is a model of the concept *RegularTriangulationTraits_2*. It provides the number type *FT* which is a model for *FieldNumberType* and it must meet the requirements for the traits class of the *polygon_area_2* function. A model of this traits class is *Regular_triangulation_euclidean_traits_2<K, Weight>*.
3. *OutputIterator::value_type* is equivalent to *std::pair<Rt::Weighted_point, Rt::Geom_traits::FT>*, i.e. a pair associating a point and its regular neighbor coordinate.

Implementation

This function computes the areas stolen from the Voronoi cells of points in *rt* by the insertion of *p*. The total area of the Voronoi cell of *p* is also computed and returned by the function. If *p* lies outside the convex hull, the coordinate values cannot be computed and the third value of the result triple is set to *false*.

Function

CGAL::sibson_gradient_fitting

Definition

The function *sibson_gradient_fitting* approximates the gradient of a function at a point p given natural neighbor coordinates for p and its neighbors' function values. The approximation method is described in [Sib81]. Further functions are provided to fit the gradient for all data points that lie inside the convex hull of the data points. One function exists for each type of natural neighbor coordinates.

#include <CGAL/sibson_gradient_fitting.h>

template < class ForwardIterator, class Functor, class Traits>
typename Traits::Vector_d

sibson_gradient_fitting(ForwardIterator first,
ForwardIterator beyond,
typename std::iterator_traits<ForwardIterator>::value_type::second_type norm,
typename std::iterator_traits<ForwardIterator>::value_type::first_type p,
Functor f,
Traits traits)

This function estimates the gradient of a function at the point p given natural neighbor coordinates of p in the range $[$ *first*, *beyond* $)$ and the function values of the neighbors provided by the functor f. *norm* is the normalization factor of the barycentric coordinates.

Requirements

1. *ForwardIterator::value_type* is a pair of point/coordinate value, thus *ForwardIterator::value_type::first_type* is equivalent to a point and *ForwardIterator::value_type::second_type* is a number type.

2. *Functor::argument_type* must be equivalent to *ForwardIterator::value_type::first_type* and *Functor::result_type* is the function value type. It must provide a multiplication and addition operation with the type *ForwardIterator::value_type::second_type*.

3. *Traits* is a model of the concept *GradientFittingTraits*.

template < class Dt, class OutputIterator, class Functor, class Traits>

OutputIterator *sibson_gradient_fitting_nn_2(Dt dt, OutputIterator out, Functor f, Traits traits)*

estimates the function gradients at all vertices of *dt* that lie inside the convex hull using the coordinates computed by the function *natural_neighbor_coordinates_2*. *OutputIterator::value_type* is a pair associating a point to a vector. The sequence of point/gradient pairs computed by this function is placed starting at *out*. The function returns an iterator that is placed past-the-end of the resulting sequence. The requirements are the same as above. The template class *Dt* must be equivalent to *Delaunay_triangulation_2<Gt, Tds>* .

template < class Rt, class OutputIterator, class Functor, class Traits>
OutputIterator *sibson_gradient_fitting_rn_2(Rt rt, OutputIterator out, Functor f, Traits traits)*

estimates the function gradients at all vertices of *rt* that lie inside the convex hull using the coordinates computed by the function *regular_neighbor_coordinates_2*. *OutputIterator::value_type* is a pair associating a point to a vector. The sequence of point/gradient pairs computed by this function is placed starting at *out*. The function returns an iterator that is placed past-the-end of the resulting sequence. The requirements are the same as above. The template class *Rt* must be equivalent to *Regular_triangulation_2<Gt, Tds>*.

Implementation

This function implements Sibson's gradient estimation method based on natural neighbor coordinates [Sib81].

Concept

GradientFittingTraits

Definition

The function *sibson_gradient_fitting* is parameterized by a traits class that defines the primitives used by the algorithm. The concept GradientFittingTraits defines this common set of requirements.

Types

GradientFittingTraits:: FT
The number type must follow the model *FieldNumberType*.

GradientFittingTraits:: Point_d
The point type on which the function is defined and interpolated.

GradientFittingTraits:: Vector_d
The corresponding vector type.

GradientFittingTraits:: Aff_transformation_d
defines a matrix type. Must provide the following member functions :
Aff_transformation tr.inverse () which gives the inverse transformation, and
Aff_transformation tr.transform(Vector v) which returns the multiplication of *tr* with *v*.

GradientFittingTraits:: Construct_vector_d
A constructor object for *Vector_d*. Provides :
Vector_d operator() (Point_d a, Point_d b) which produces the vector *b - a* and
Vector_d operator() (Null_vector NULL_VECTOR) which introduces the null vector.

GradientFittingTraits:: Construct_scaled_vector_d
Constructor object for *Vector_d*. Provides :
Vector_d operator() (Vector_d v,FT scale) which produces the vector *v* scaled by a factor *scale*.

GradientFittingTraits:: Construct_null_matrix_d
Constructor object for *Aff_transformation_d*. Provides :
Aff_transformation_d operator()() which introduces an affine transformation whose matrix has only zero entries.

GradientFittingTraits:: Construct_scaling_matrix_d
Constructor object for *Aff_transformation_d*. Provides :
Aff_transformation_d operator()(FT scale) which introduces a scaling by a scale factor *scale*.

GradientFittingTraits:: Construct_sum_matrix_d

Constructor object for *Aff_transformation_d*. Provides : *Aff_transformation_d operator()(Aff_transformation_d tr1, Aff_transformation_d tr2)* which returns the sum of the two matrices representing *tr1* and *tr2*.

GradientFittingTraits:: Construct_outer_product_d

Constructor object for *Aff_transformation_d*. Provides : *Aff_transformation_d operator()(Vector v)* which returns the outer product, i.e. the quadratic matrix $v^t v$.

Creation

GradientFittingTraits traits; default constructor.

Operations

The following functions that create instances of the above constructor object types must exist.

Construct_vector_d *traits.construct_vector_d_object()*

Construct_scaled_vector_d *traits.construct_scaled_vector_d_object()*

Construct_null_matrix_d *traits.construct_null_matrix_d_object()*

Construct_sum_matrix_d *traits.construct_sum_matrix_d_object()*

Construct_outer_product_d *traits.construct_outer_product_d_object()*

CGAL::Voronoi_intersection_2_traits_3<K>

Definition

Voronoi_intersection_2_traits_3<K> is a model for the concept *RegularTriangulationTraits_2* and *InterpolationTraits*. It can be used to instantiate the geometric traits class of a two-dimensional regular triangulation. A three-dimensional plane is defined by a point and a vector that are members of the traits class. The triangulation is defined on 3*D* points. It is the regular triangulation of the input points projected onto the plane and each weighted with the negative squared distance of the input point to the plane. It can be shown that it is dual to the power diagram obtained by intersecting the three-dimensional Voronoi diagram of the input points with the plane. All predicates and constructions used in the computation of the regular triangulation are formulated on the three dimensional points without explicitly constructing the projected points and the weights. This reduces the arithmetic demands. The traits class is templated by a kernel class *K*.

Function

CGAL::surface_neighbor_coordinates_3

Definition

The function *surface_neighbor_coordinates_3* computes natural neighbor coordinates for surface points associated to a finite set of sample points issued from the surface. The coordinates are computed from the intersection of the Voronoi cell of the query point p with the tangent plane to the surface at p. If the sampling is sufficiently dense, the coordinate system meets the properties described in the manual pages and in [BF02],[Flö03b]. The query point p needs to lie inside the convex hull of the projection of the sample points onto the tangent plane at p.

#include <CGAL/surface_neighbor_coordinates_3.h>

template <class OutputIterator, class InputIterator, class Kernel>
CGAL::Triple< OutputIterator, typename Kernel::FT, bool >

surface_neighbor_coordinates_3(InputIterator first,
InputIterator beyond,
typename Kernel::Point_3 p,
typename Kernel::Vector_3 normal,
OutputIterator out,
Kernel K)

The sample points $\mathcal{P}$ are provided in the range $[$*first*, *beyond*$)$. *InputIterator::value_type* is the point type *Kernel::Point_3*. The tangent plane is defined by the point p and the vector *normal*. The parameter K determines the kernel type that will instantiate the template parameter of *Voronoi_intersection_2_traits_3<K>*.
The natural neighbor coordinates for p are computed in the power diagram that results from the intersection of the $3D$ Voronoi diagram of $\mathcal{P}$ with the tangent plane. The sequence of point/coordinate pairs that is computed by the function is placed starting at *out*. The function returns a triple with an iterator that is placed past-the-end of the resulting sequence of point/coordinate pairs, the normalization factor of the coordinates and a Boolean value which is set to true iff the coordinate computation was successful, i.e. if p lies inside the convex hull of the projection of the points $\mathcal{P}$ onto the tangent plane.

template <class OutputIterator, class InputIterator, class ITraits>
CGAL::Triple< OutputIterator, typename ITraits::FT, bool >

surface_neighbor_coordinates_3(InputIterator first,
InputIterator beyond,
typename ITraits::Point_2 p,
OutputIterator out,

ITraits traits)

the same as above only that the traits class must be instantiated by the user. *ITraits* must be equivalent to *Voronoi_intersection_2_traits_3<K>*.

The next functions return, in addition, a second Boolean value (the fourth value of the quadruple) that certifies whether or not, the Voronoi cell of p can be affected by points that lie outside the input range, i.e. outside the ball centered on p passing through the furthest sample point from p in the range $[first, beyond)$. If the sample points are collected by a k-nearest neighbor or a range search query, this permits to check whether the neighborhood which has been considered is large enough.

template <class OutputIterator, class InputIterator, class Kernel>
CGAL::Quadruple< OutputIterator, typename Kernel::FT, bool, bool >

surface_neighbor_coordinates_certified_3(InputIterator first,
InputIterator beyond,
typename Kernel::Point_3 p,
typename Kernel::Vector_3 normal,
OutputIterator out,
Kernel K)

Similar to the first function. The additional fourth return value is *true* if the furthest point in the range $[first, beyond)$ is further away from p than twice the distance from p to the furthest vertex of the intersection of the Voronoi cell of p with the tangent plane defined by *(p,normal)*. It is *false* otherwise.

template <class OutputIterator, class InputIterator, class Kernel>
CGAL::Quadruple< OutputIterator, typename Kernel::FT, bool, bool >

surface_neighbor_coordinates_certified_3(InputIterator first,
InputIterator beyond,
typename Kernel::Point_3 p,
typename Kernel::FT max_distance,
OutputIterator out,
Kernel kernel)

The same as above except that this function takes the maximal distance from p to the points in the range $[first, beyond)$ as additional parameter.

template <class OutputIterator, class InputIterator, class ITraits>
CGAL::Quadruple< OutputIterator, typename ITraits::FT, bool, bool >

surface_neighbor_coordinates_certified_3(InputIterator first,
InputIterator beyond,
typename ITraits::Point_2 p,
OutputIterator out,
ITraits traits)

The same as above only that the traits class must be instantiated by the user and without the parameter *max_distance*. *ITraits* must be equivalent to *Voronoi_intersection_2_traits_3<K>*.

template <class OutputIterator, class InputIterator, class ITraits>
CGAL::Quadruple< OutputIterator, typename ITraits::FT, bool, bool >

surface_neighbor_coordinates_certified_3(InputIterator first, InputIterator beyond, typename ITraits::Point_2 p, typename ITraits::FT max_distance, OutputIterator out, ITraits traits)

The same as above with the parameter *max_distance*.

The next function allows to filter some potential neighbors of the query point p from $\mathcal{P}$ via its three-dimensional Delaunay triangulation. All surface neighbors of p are necessarily neighbors in the Delaunay triangulation of $\mathcal{P} \cup \{p\}$.

template < class Dt, class OutputIterator >
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >

surface_neighbor_coordinates_3(Dt dt, typename Dt::Geom_traits::Point_3 p, typename Dt::Geom_traits::Vector_3 normal, OutputIterator out, typename Dt::Cell_handle start = typename Dt::Cell_handle())

computes the surface neighbor coordinates with respect to the points that are vertices of the Delaunay triangulation *dt*. The type *Dt* must be equivalent to *Delaunay_triangulation_3<Gt, Tds>*. The optional parameter *start* is used as a starting place for the search of the conflict zone. It may be the result of the call *dt.locate(p)*. This function instantiates the template parameter *ITraits* to be *Voronoi_intersection_2_traits_3<Dt::Geom_traits>*.

template < class Dt, class OutputIterator, class ITraits>
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >

surface_neighbor_coordinates_3(Dt dt, typename Dt::Geom_traits::Point_3 p, OutputIterator out, ITraits traits, typename Dt::Cell_handle start = typename Dt::Cell_handle())

The same as above only that the parameter *traits* instantiates the geometric traits class. Its type *ITraits* must be equivalent to *Voronoi_intersection_2_traits_3<K>*.

Requirements

1. *Dt* is equivalent to the class *Delaunay_triangulation_3*.

2. *OutputIterator::value_type* is equivalent to *std::pair<Dt::Point_3, Dt::Geom_traits::FT>*, i.e. a pair associating a point and its natural neighbor coordinate.

3. *ITraits* is equivalent to the class *Voronoi_intersection_2_traits_3<K>*.

Implementation

This functions construct the regular triangulation of the input points instantiated with *Voronoi_intersection_2_traits_3<Kernel>* or *ITraits* if provided. They return the result of the function call *regular_neighbor_coordinates_2* with the regular triangulation and *p* as arguments.

CGAL::surface_neighbors_3

Definition

Given a set of sample points issued from a surface and a query point p, the function *surface_neighbors_3* computes the neighbors of p on the surface within the sample points. If the sampling is sufficiently dense, the neighbors are provably close to the point p on the surface (cf. the manual pages and [BF02],[Flö03b]). They are defined to be the neighbors of p in the regular triangulation dual to the power diagram which is equivalent to the intersection of the Voronoi cell of the query point p with the tangent plane to the surface at p.

#include <CGAL/surface_neighbors_3.h>

template <class OutputIterator, class InputIterator, class Kernel>
OutputIterator surface_neighbors_3(InputIterator first,
InputIterator beyond,
typename Kernel::Point_3 p,
typename Kernel::Vector_3 normal,
OutputIterator out,
Kernel K)

The sample points $\mathcal{P}$ are provided in the range $[$*first*, *beyond*$)$. *InputIterator::value_type* is the point type *Kernel::Point_3*. The tangent plane is defined by the point p and the vector *normal*. The parameter K determines the kernel type that will instantiate the template parameter of *Voronoi_intersection_2_traits_3<K>*.
The surface neighbors of p are computed which are the neighbors of p in the regular triangulation that is dual to the intersection of the $3D$ Voronoi diagram of $\mathcal{P}$ with the tangent plane. The point sequence that is computed by the function is placed starting at *out*. The function returns an iterator that is placed past-the-end of the resulting point sequence.

template <class OutputIterator, class InputIterator, class ITraits>
OutputIterator surface_neighbors_3(InputIterator first,
InputIterator beyond,
typename ITraits::Point_2 p,
OutputIterator out,
ITraits traits)

the same as above only that the traits class must be instantiated by the user. *ITraits* must be equivalent to *Voronoi_intersection_2_traits_3<K>*.

The next functions return, in addition, a Boolean value that certifies whether or not, the Voronoi cell of p can be affected by points that lie outside the input range, i.e. outside the ball centered on p passing through the furthest sample point from p in the range $[$*first*, *beyond*$)$. If the sample points are collected by a k-nearest neighbor or a range search query, this permits to verify that a large enough neighborhood has been considered.

template <class OutputIterator, class InputIterator, class Kernel>

std::pair< OutputIterator, bool >

surface_neighbors_certified_3(InputIterator first,
InputIterator beyond,
typename Kernel::Point_3 p,
typename Kernel::Vector_3 normal,
OutputIterator out,
Kernel K)

Similar to the first function. The additional third return value is *true* if the furthest point in the range $[first, beyond)$ is further away from p than twice the distance from p to the furthest vertex of the intersection of the Voronoi cell of p with the tangent plane defined be *(p,normal)*. It is *false* otherwise.

template <class OutputIterator, class InputIterator, class Kernel>
std::pair< OutputIterator, bool >

surface_neighbors_certified_3(InputIterator first,
InputIterator beyond,
typename Kernel::Point_3 p,
typename Kernel::Vector_3 normal,
typename Kernel::FT max_distance,
OutputIterator out,
Kernel kernel)

The same as above except that this function takes the maximal distance from p to the points in the range $[first, beyond)$ as additional parameter.

template <class OutputIterator, class InputIterator, class ITraits>
std::pair< OutputIterator, bool >

surface_neighbors_certified_3(InputIterator first,
InputIterator beyond,
typename ITraits::Point_2 p,
OutputIterator out,
ITraits traits)

The same as above only that the traits class must be instantiated by the user. *ITraits* must be equivalent to *Voronoi_intersection_2_traits_3<K>*. There is no parameter *max_distance*.

template <class OutputIterator, class InputIterator, class ITraits>
std::pair< OutputIterator, bool >

surface_neighbors_certified_3(InputIterator first,
InputIterator beyond,
typename ITraits::Point_2 p,
typename ITraits::FT max_distance,
OutputIterator out,

ITraits traits)

The same as above with the parameter *max_distance*.

The next function allows to filter some potential neighbors of the query point p from $\mathcal{P}$ via its three-dimensional Delaunay triangulation. All surface neighbors of p are necessarily neighbors in the Delaunay triangulation of $\mathcal{P} \cup \{p\}$.

template < class Dt, class OutputIterator >
OutputIterator surface_neighbors_3(Dt dt,
typename Dt::Geom_traits::Point_3 p,
typename Dt::Geom_traits::Vector_3 normal,
OutputIterator out,
typename Dt::Cell_handle start = typename Dt::Cell_handle())

computes the surface neighbor coordinates with respect to the points that are vertices of the Delaunay triangulation *dt*. The type *Dt* must be equivalent to *Delaunay_triangulation_3<Gt, Tds>*. The optional parameter *start* is used for the used as a starting place for the search of the conflict zone. It may be the result of the call *dt.locate(p)*. This function instantiates the template parameter *ITraits* to be *Voronoi_intersection_2_traits_3<Dt::Geom_traits>*.

template < class Dt, class OutputIterator, class ITraits>
OutputIterator surface_neighbors_3(Dt dt,
typename ITraits::Point_2 p,
OutputIterator out,
ITraits traits,
typename Dt::Cell_handle start = typename Dt::Cell_handle())

The same as above only that the parameter *traits* instantiates the geometric traits class. Its type *ITraits* must be equivalent to *Voronoi_intersection_2_traits_3<K>*.

Requirements

1. *Dt* is equivalent to the class *Delaunay_triangulation_3*.
2. *OutputIterator::value_type* is equivalent to *Dt::Point_3*, i.e. a point type.
3. *ITraits* is equivalent to the class *Voronoi_intersection_2_traits_3<K>*.

CGAL::surface_neighbor_coordinates_3 .... page 4016

Implementation

These functions compute the regular triangulation of the sample points and the point *p* using a traits class equivalent to *Voronoi_intersection_2_traits_3*<*K*>. They determine the neighbors of *p* in this triangulation. The functions which certify the result need to compute, in addition, the Voronoi vertices of the cell of *p* in this diagram.

Kinetic Data Structures

Chapter 71

Kinetic Data Structures

Daniel Russel

Contents

Lets say you want to maintain a sorted list of items (each item is associate with a real number key). You can imagine placing each of the items on the point on the real line corresponding to its key. Now, let the key for each item change continuously (i.e. no jumps are allowed). As long as no two (consecutive) items cross, the sorted order is intact. When two items cross, they need to be exchanged in the list and then the sorted order is once again correct. This is a trivial example of a kinetic data structure. The key observation is that the combinatorial structure which is maintained changes at discrete times (events) even though the basic building blocks are changing continuously.

This chapter describes a number of such kinetic data structures implemented using the Kinetic framework described in Chapter 72. We first, in Section 71.2 introduce kinetic data structures and sweepline algorithms. This section can be skipped if the reader is already familiar with the area. The next sections, Section 71.2.1 and Section 71.3 introduce the terms and give an overview of the framework. They are recommended reading for all readers, even if you are just using provided kinetic data structures. We then present kinetic data structures for Delaunay triangulations in two and three dimensions in Section 71.4.

If you are already familiar with kinetic data structures and know what you want to do, you might want to first take a look at the next section Section 71.1 which covers quick hints.

71.1 Quick Hints

This section gives quick answers to some questions people might have. It presumes knowledge of kinetic data structures and this framework.

How do I store extra information allow with, for example, a kinetic Point_2?

See the example *Kinetic_framework/defining_a_simulation_traits.cpp* to see how to define a new *SimulationTraits* class where the *ActiveObjectsTable* contains extra data along with the point.

Where is the best place to look if I want to write my own kinetic data structure?

We provide two simple kinetic data structures, first most trivial is *Kinetic_framework/trivial_kds.cpp* and a slightly more complicated one is:

#include <CGAL/Kinetic/Sort.h>

How can I use kinetic data structures to update Delaunay triangulations?

We are working on that one, but you will have to wait.

71.2 An Overview of Kinetic Data Structures and Sweep Algorithms

Kinetic data structures were first introduced in by Basch et. al. in 1997 [BGH97]. The idea stems from the observation that most, if not all, computational geometry structures are built using *predicates* — functions on quantities defining the geometric input (e.g. point coordinates), which return a discrete set of values. Many predicates reduce to determining the sign of a polynomial on the defining parameters of the primitive objects. For example, to test whether a point lies above or below a plane we compute the dot product of the point with the normal of the plane and subtract the plane's offset along the normal. If the result is positive, the point is above the plane, zero on the plane, negative below. The validity of many combinatorial structures built on top of geometric primitives can be verified by checking a finite number of predicates of the geometric primitives. These predicates, which collectively certify the correctness of the structure, are called *certificates*. For a Delaunay triangulation in three dimensions, for example, the certificates are one *InCircle* test per facet of the triangulation, plus a point plane orientation test for each facet or edge of the convex hull.

The kinetic data structures approach is built on top of this view of computational geometry. Let the geometric primitives move by replacing each of their defining quantities with a function of time (generally a polynomial). As time advances, the primitives trace out paths in space called *trajectories*. The values of the polynomial functions of the defining quantities used to evaluate the predicates now also become functions of time. We call these functions *certificate functions*. Typically, a geometric structure is valid when all predicates have a specific non-zero sign. In the kinetic setting, as long as the certificate functions maintain the correct sign as time varies, the corresponding predicates do not change values, and the original data structure remains correct. However, if one of the certificate functions changes sign, the original structure must be updated, as well as the set of certificate functions that verify it. We call such occurrences *events*.

Maintaining a kinetic data structure is then a matter of determining which certificate function changes sign next, i.e. determining which certificate function has the first real root that is greater than the current time, and then updating the structure and the set of certificate functions. In addition, the trajectories of primitives are allowed to change at any time, although C^0-continuity of the trajectories must be maintained. When a trajectory update occurs for a geometric primitive, all certificates involving that primitive must be updated. We call the collection of kinetic data structures, primitives, event queue and other support structures a *simulation*.

Sweepline algorithms for computing arrangements in d dimensions easily map on to kinetic data structures by taking one of the coordinates of the ambient space as the time variable. The kinetic data structure then maintains the arrangement of a set of objects defined by the intersection of a hyperplane of dimension $d-1$ with the objects whose arrangement is being computed.

Time is one of the central concepts in a kinetic simulation. Just as static geometric data structures divide the continuous space of all possible inputs (as defined by sets of coordinates) into a discrete set of combinatorial structures, kinetic data structures divide the continuous time domain into a set of disjoint intervals. In each interval the combinatorial structure does not change, so, in terms of the combinatorial structure, all times in the interval are equivalent. We capitalize on this equivalence in the framework in order to simplify computations. If the primitives move on polynomial trajectories and the certificates are polynomials in the coordinates, then events occur at real roots of polynomials of time. Real numbers, which define the endpoints of the interval, are more expensive to compute with than rational numbers, so performing computations at a rational number inside the interval is preferable whenever possible. See Section 72.1.4 for an example of where this equivalence is exploited.

71.2.1 Terms Used

primitive The basic geometric types, e.g., the points of a triangulation. A primitive has a set of *coordinates*.

combinatorial structure A structure built on top of the primitives. The structure does not depend directly on the coordinates of the primitives, only on relationships between them.

trajectory The path traced out by a primitive as time passes. In other words how the coordinates of a primitive change with time.

snapshot The position of all the primitives at a particular moment in time.

static Having to do with geometric data structures on non-moving primitives.

predicate A function which takes the coordinates of several primitives from a snapshot as input and produces one of a discrete set of outputs.

certificate One of a set of predicates which, when all having the correct values, ensure that the combinatorial structure is correct.

certificate function A function of time which is positive when the corresponding certificate has the correct value. When the certificate function changes sign, the combinatorial structure needs to be updated.

event When a certificate function changes sign and the combinatorial structure needs to be updated.

71.3 An Overview of the Kinetic Framework

The provided kinetic data structures are implemented on top of the Kinetic framework presented in Chapter 72. It is not necessary to know the details of the framework, but some familiarity is useful. Here we presented a quick overview of the framework.

The framework is structured around five main concepts. See Figure 71.1 for a schematic of how a kinetic data structure interacts with the various parts. The main concepts are

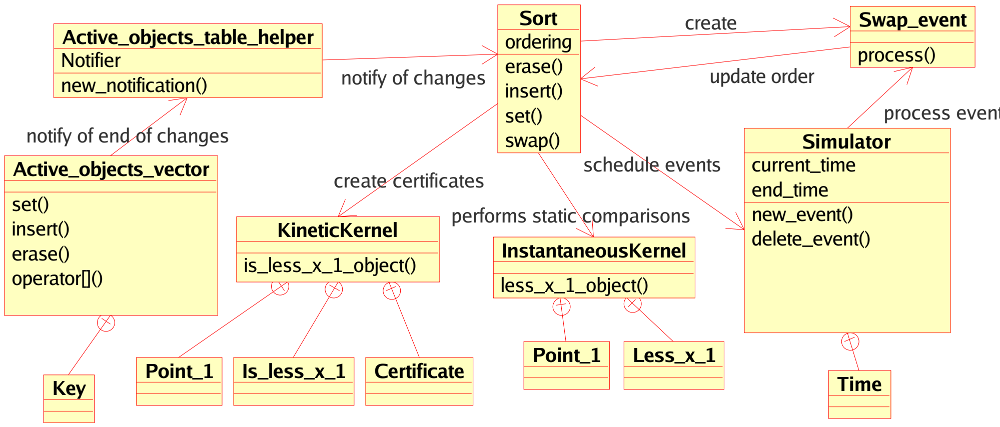

Figure 71.1: The figure shows the interaction between the *Kinetic::Sort<Traits, Visitor>* kinetic data structure and the various pieces of our package. Other, more complicated, kinetic data structures will also use the *Kinetic::InstantaneousKernel* in order to insert/remove geometric primitives and audit themselves. *Kinetic::Sort< Traits, Visitor>* uses the sorting functionality in the STL instead.

- the *Kinetic::Simulator*. Models of this concept process events in the correct order and audit kinetic data structures. There should be one instance of a model of this concept per simulation.
- the *Kinetic::Kernel*. The structure of a *Kinetic::Kernel* is analogous to the static CGAL (i.e., non-kinetic) kernels in that it defines a set of primitives and functors which generate certificates from the primitives.
- the *Kinetic::ActiveObjectsTable*. Models of this concept hold a collection of kinetic primitives in a centralized manner. This structure centralizes management of the primitives in order to properly disseminate notifications when trajectories change, new primitives are added or primitives are deleted. There is generally one instance of a model of this concept per simulation.
- the *Kinetic::InstantaneousKernel*. Models of this concept allow existing non-kinetic CGAL data structures to be used on a snapshot of kinetic data. As a result, pre-existing static structures can be used to initialize and audit kinetic data structures.
- the *Kinetic::FunctionKernel*. This concept is the computational kernel of our framework. Models of this concept are responsible for representing, generating and manipulating the motional and certificate functions and their roots. It is this concept that provides the kinetic data structures framework with the necessary algebraic operations for manipulating event times. The *Kinetic::FunctionKernel* is discussed in detail in Section 72.2.

For simplicity, we added an additional concept, that of *Kinetic::SimulationTraits*, which wraps together a particular set of choices for the above concepts and is responsible for creating instances of each of the models. As a user of existing kinetic data structures, this is the only framework object you will have to create. The addition of this concept reduces the choices the user has to make to picking the dimension of the ambient space and choosing between exact and inexact computations. The model of *Kinetic::SimulationTraits* creates an instance each of the *Kinetic::Simulator* and *Kinetic::ActiveObjectsTable*. Handles for these instances as well as instances of the *Kinetic::Kernel* and *Kinetic::InstantaneousKernel* can be requested from the simulation traits class. Both the *Kinetic::Kernel* and the *Kinetic::Simulator* use the *Kinetic::FunctionKernel*, the former to find certificate failure times and the later to operate on them. For technical reasons, each supplied model of *Kinetic::SimulationTraits* also picks out a particular type of kinetic primitive which will be used by the kinetic data structures.

71.4 Using Kinetic Data Structures

There are five provided kinetic data structures. They are

Kinetic::Sort<Traits, Visitor> maintain a list of points sorted by x-coordinate.

Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation> maintain the Delaunay triangulation of a set of two dimensional points

Kinetic::Delaunay_triangulation_3<Traits,Visitor, Triangulation> maintain the Delaunay triangulation of a set of three dimensional points.

Kinetic::Regular_triangulation_3<Traits, Visitor, Triangulation> maintain the regular triangulation of a set of waiting three dimensional points.

Kinetic::Enclosing_box_2<Traits>, *Kinetic::Enclosing_box_3<Traits>* restrict points to stay within a box by bouncing them off the walls.

71.4.1 A Simple Example

Using a kinetic data structure can be as simple as the following:

```
#include <CGAL/Kinetic/basic.h>

#include <CGAL/Kinetic/Exact_simulation_traits.h>
#include <CGAL/Kinetic/Insert_event.h>
#include <CGAL/Kinetic/Sort.h>

int main()
{
    typedef CGAL::Kinetic::Exact_simulation_traits Traits;

    typedef CGAL::Kinetic::Insert_event<Traits::Active_points_1_table>
   Insert_event;
    typedef Traits::Active_points_1_table::Data Moving_point;
    typedef CGAL::Kinetic::Sort<Traits> Sort;
    typedef Traits::Simulator::Time Time;

    Traits tr(0,100000);
    Sort sort(tr);
    Traits::Simulator::Handle sp= tr.simulator_handle();

    std::ifstream in("data/points_1");
    in  >> *tr.active_points_1_table_handle();

    while (sp->next_event_time() != sp->end_time()) {
        sp->set_current_event_number(sp->current_event_number()+1);
    }

    return EXIT_SUCCESS;
}
```

File: examples/Kinetic_data_structures/Kinetic_sort.cpp

Using the other kinetic data structures is substantially identical. Please see the appropriate files in the demo/Kinetic_data_structures directory.

In the example, first the *Kinetic::SimulationTraits* object is chosen (in this case one that supports exact computations). Then the kinetic data structure is defined using the chosen traits object and a visitor class which logs changes to the sorted list. Next, instances of the two are created and a set of points is read from a file. Then, the simulator is instructed to process all the events until the end of the simulation. Finally, a record of what happened is printed to the terminal.

Several important things happen behind the scenes in this example. First, the *Kinetic::ActiveObjectsTable* which holds the moving points notifies the kinetic data structure that new points have been added to the simulation. Second, the *Kinetic::Sort<Traits,Visitor>* kinetic data structure registers its events with the *Kinetic::Simulator* by providing a time and a proxy object for each event. When a particular event occurs, the *Kinetic::Simulator* calls a function on the proxy object which in turn updates the kinetic data structure.

The example illustrates how to monitor the supplied data structures as they evolve by using a *Kinetic::SortVisitor* object—a small class whose methods are called whenever the kinetic data structure changes. Hooks for such visitor concepts are provided for all of the shipped kinetic data structures. In the case of kinetic sorting, the visitor's methods are called every time a new point is inserted in the sorted list, when one is removed, or when two points are swapped in the sorted order.

The visitor concept is quite powerful, allowing us, for example, to implement a data structure for computing and storing two-dimensional arrangements of x-monotone curves on top of the *Kinetic::Sort<Traits, Visitor>* data structure using about 60 lines of code. This sweepline code is presented in Section 71.4.4.

71.4.2 Creating Kinetic Primitives

One key part of the framework not shown is how to create kinetic primitives (rather than just reading them in from a file). There are two ways to construction the necessary motion functions (which are models of *Kinetic::FunctionKernel::Function*). The first is to create an array of polynomial coeffients and simply call the constructor as in:

```
typedef Traits::Kinetic_kernel::Motion_function F;
std::vector<F::NT> coefs;
coefs.push_back(F::NT(1.0));
coefs.push_back(F::NT(2.0));
F x(coefs.begin(), coefs.end());
```

A slightly more flexible way is to use a *Kinetic::FunctionKernel::ConstructFunction* object. To do this do the following:

```
typedef Traits::Kinetic_kernel::Function_kernel::Construct_function
CF; typedef Traits::Kinetic_kernel::Motion_function F; CF cf; F
x=cf(F::NT(1.0), F::NT(2.0));
```

The *Kinetic::FunctionKernel::ConstructFunction* can be passed (almost) an number of arguments and will construct a polynomial with those arguments are coefficients.

Once the motion functions are constructed, constructing the primitive is just like constructing the corresponding static object.

```
typedef Traits::Kinetic_kernel::Point_1 Point_1;
Point_1 p(x);
```

71.4.3 Visualization of Kinetic Data Structures

The framework includes Qt widgets for displaying kinetic data structures in two and three dimensions. The following example shows using the two dimensional widget with a Delaunay triangulation:

```
#include <CGAL/Kinetic/Exact_simulation_traits.h>
#include <CGAL/Kinetic/Delaunay_triangulation_2.h>
#include <CGAL/Kinetic/Enclosing_box_2.h>
#include <CGAL/Kinetic/IO/Qt_moving_points_2.h>
#include <CGAL/Kinetic/IO/Qt_triangulation_2.h>
#include <CGAL/Kinetic/IO/Qt_widget_2.h>

int main(int argc, char *argv[]) {
    using namespace CGAL::Kinetic;
    typedef Exact_simulation_traits Traits;
    typedef Delaunay_triangulation_2<Traits> Del_2;
    typedef Enclosing_box_2<Traits> Box_2;
    typedef Qt_widget_2<Traits::Simulator> Qt_widget;
    typedef Qt_moving_points_2<Traits, Qt_gui> Qt_mps;
    typedef Qt_triangulation_2<Del_2, Qt_widget, Qt_mps> Qt_dt2;

    // create a simulation traits and add two KDSs:
    // a kinetic Delaunay triangulation and an enclosing box;
    // the moving points bounce against the walls of the enclosing box
    Traits tr;
    Box_2::Handle box = new Box_2(tr);
    Del_2::Handle kdel = new Del_2(tr);

    // register the simulator, set of moving points and
    // Delaunay triangulation with the kinetic Qt widget
    Qt_widget::Handle qt_w = new Qt_widget(argc, argv,
   tr.simulator_handle());
    Qt_mps::Handle qt_mps = new Qt_mps(qt_w, tr);
    Qt_dt2::Handle qt_dt2 = new Qt_dt2(kdel, qt_w, qt_mps);

    // read the trajectories of the moving points
    //  the simulation traits automatically inserts them in the two KDSs
    // and schedules the appropriate kinetic events; as in the kinetic
    // sorting example this is done with appropriate notifications
    std::ifstream in("data/points_2");
    in  >> *tr.active_points_2_table_handle();

    // run the interactive kinetic simulation
    return qt_w->begin_event_loop();
};
```

The example shows how to use a number of additional features of the framework. First, it shows that two kinetic data structures (*Kinetic::Delaunay_triangulation_2<Traits, Triangulation>* and *Kinetic::Enclosing_box_*

2<Traits>) can coexist on the same set of points without any extra effort. Both interact with the moving points through the active objects table, and never need to directly interact with one another. Second, objects (like `qt_w`, `qt_mps` and `qt_dt2`) are all stored by using reference counted handles (`Object::Handle`). This allows them to share references to one another without the user having to worry about memory management and order of deletion. For example, the *Kinetic::Qt_triangulation_2<KineticDelaunay_2, QtWidget_2, Qt_moving_points_2>* object needs a handle to the kinetic triangulation, in order to get the structure to display, and a handle to the *Active_points_1_table* to get the coordinates of the points.

Finally, the example shows how to use the graphical interface elements provided, see Figure 71.3. Our package includes `Qt` widgets for displaying kinetic geometry in two and three dimensions. In addition to being able to play and pause the simulation, the user can step through events one at a time and reverse the simulation to retrace what had happened. The three-dimensional visualization support is based on the Coin library http://www.coin3d.org.

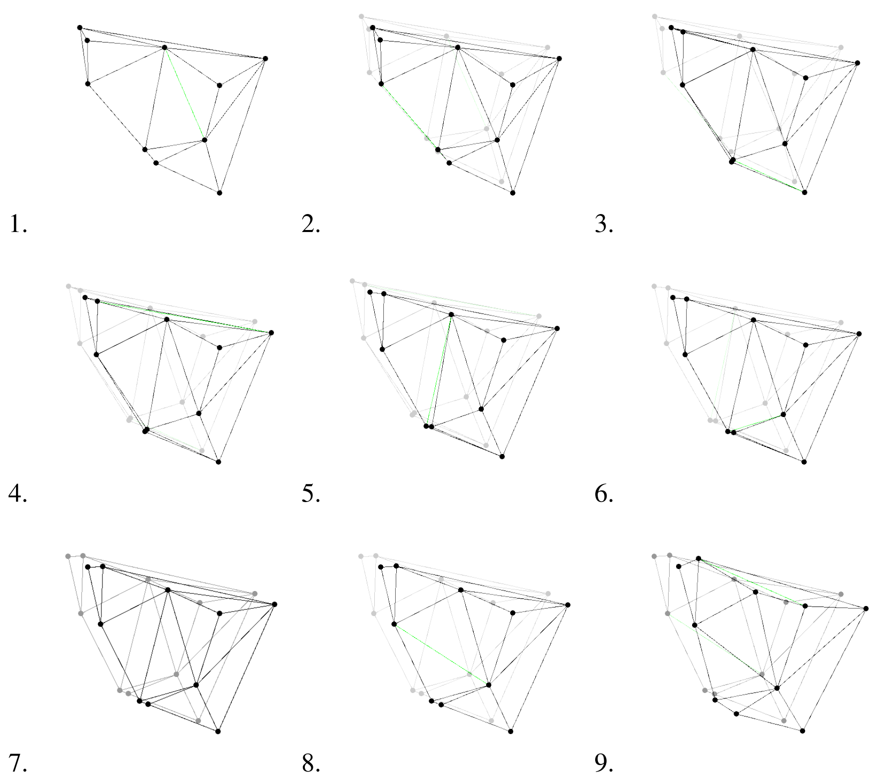

Figure 71.2: *Some events from a Delaunay triangulation kinetic data structure:* The state of the two dimensional Delaunay triangulation immediately following the first events is shown. Green edges are ones which were just created. The pictures are screen shots from *demo/Kinetic_data_structures/Kinetic_Delaunay_triangulation_2.cpp*.

71.4.4 Extending Kinetic Data Structures

Here we present a simple example that uses the *Kinetic::Sort<Traits, Visitor>* kinetic data structure to compute an arrangement of algebraic functions. It wraps the sorting data structure and uses a visitor to monitor changes and map them to corresponding features in the arrangement. To see an example using this kinetic data structure read the example at examples/Kinetic_data_structures/Kinetic_sweepline.cpp.

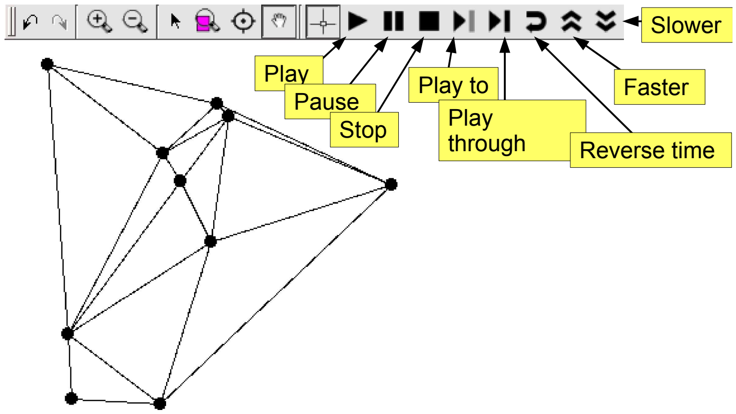

Figure 71.3: The figure shows the graphical user interface for controlling two-dimensional kinetic data structures. It is built on top of the *Qt_widget* and adds buttons to play, pause, step through and run the simulation backwards.

First we define the visitor class. An object of this type is passed to the *Kinetic::Sort<Traits, Visitor>* data structure and turns events into calls on the arrangement structure. This class has to be defined externally since the arrangement will inherit from the sorting structure.

```
template <class Arrangement>
struct Arrangement_visitor: public Kinetic::Sort_visitor_base
{
  Arrangement_visitor(Arrangement *a):p_(a){}
  template <class Vertex_handle>
  void remove_vertex(Vertex_handle a) {
    p_->erase(a);
  }
  template <class Vertex_handle>
  void create_vertex(Vertex_handle a) {
    p_->insert(a);
  }
  template <class Vertex_handle>
  void after_swap(Vertex_handle a, Vertex_handle b) {
    p_->swap(a, b);
  }
  Arrangement *p_;
};
```

Now we define the actual arrangement data structure.

```
template <class TraitsT>
class Planar_arrangement:
  public Kinetic::Sort<TraitsT,
                       Arrangement_visitor<Planar_arrangement<TraitsT> >
   > {
  typedef TraitsT Traits;
  typedef Planar_arrangement<TraitsT> This;
  typedef typename Kinetic::Sort<TraitsT,
                                 Arrangement_visitor<This> > Sort;
  typedef Arrangement_visitor<This> Visitor;
```

```
  typedef typename Traits::Active_objects_table::Key Key;

public:
  typedef CGAL::Exact_predicates_inexact_constructions_kernel::Point_2
    Approximate_point;
  typedef std::pair<int,int> Edge;
  typedef typename Sort::Vertex_handle Vertex_handle;

  // Register this KDS with the MovingObjectTable and the Simulator
  Planar_arrangement(Traits tr): Sort(tr, Visitor(this)) {}

  Approximate_point vertex(int i) const
  {
    return approx_coords_[i];
  }

  size_t vertices_size() const
  {
    return approx_coords_.size();
  }

  typedef std::vector<Edge >::const_iterator Edges_iterator;
  Edges_iterator edges_begin() const
  {
    return edges_.begin();
  }
  Edges_iterator edges_end() const
  {
    return edges_.end();
  }

  void insert(Vertex_handle k) {
    last_points_[*k]=new_point(*k);
  }

  void swap(Vertex_handle a, Vertex_handle b) {
    int swap_point= new_point(*a);
    edges_.push_back(Edge(swap_point, last_points_[*a]));
    edges_.push_back(Edge(swap_point, last_points_[*b]));
    last_points_[*a]= swap_point;
    last_points_[*b]= swap_point;
  }

  void erase(Vertex_handle a) {
    edges_.push_back(Edge(last_points_[*a], new_point(*a)));
  }

  int new_point(typename Traits::Active_objects_table::Key k) {
    double tv=
   CGAL::to_double(Sort::traits().simulator_handle()->current_time());
    double dv=
   CGAL::to_double(Sort::traits().active_objects_table_handle()->at(k).x()(tv));
    approx_coords_.push_back(Approximate_point(tv, dv));
    return approx_coords_.size()-1;
```

```
  }

  std::vector<Approximate_point > approx_coords_;
  std::map<Key, int> last_points_;
  std::vector<Edge> edges_;

};
```

Finally, we have to set everything up. To do this we use some special event classes: *Kinetic::Insert_event<ActiveObjectsTable>* and *Kinetic::Erase_event<ActiveObjectsTable>*. These are events which can be put in the event queue which either insert a primitive into the set of active objects or remove it. Using these, we can allow curves in the arrangement to begin or end in arbitrary places.

```
typedef CGAL::Kinetic::Insert_event<Traits::Active_points_1_table>
   Insert_event;
typedef CGAL::Kinetic::Erase_event<Traits::Active_points_1_table>
   Erase_event;
do {
  NT begin, end;
  Point function;
  // initialize the function and the beginning and end somewhere
  tr.simulator_handle()->new_event(Time(begin),
                                   Insert_event(function,
   tr.active_points_1_table_handle()));
  tr.simulator_handle()->new_event(Time(end),

   Erase_event(Traits::Active_points_1_table::Key(num),

   tr.active_points_1_table_handle()));
  ++num;
} while (true);
```

Kinetic Data Structures Reference Manual

Daniel Russel

71.5 Classified Reference Pages

Kinetic data structures are a way of adding motion to classical geometric data structures. CGAL provides several prepackaged kinetic data structures. Here we present those kinetic data structures and the helper classes that allow their activity to be monitored.

CGAL::Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation>

Definition

The class *Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation>* maintains a Delaunay triangulation on top of the points contained in a *Kinetic::ActiveObjectsTable*. It has one main method of interest, *triangulation()*, which returns the triangulation it is maintaining.

Note that the Delaunay triangulation is fully dynamic as it tracks points added to and removed from the *Kinetic::ActiveObjectsTable*.

The class *Kinetic::Qt_triangulation_2<KineticTriangulation_2, QtWidget_2, QtMovingPoints_2>* displays a kinetic Delaunay triangulation using the Qt widget.

This class is a good example of a simple, but non-trivial, kinetic data structure.

The *Triangulation* template parameter must be a model of *CGAL::Delaunay_triangulation_2<Traits, Tds>* which uses *Traits::Default_instantaneous_kernel* as its geometric traits and a *Tds* whose face inherits from *Kinetic::Delaunay_triangulation_face_base_2<Traits, Base>*.

The optional *Visitor* parameter takes a model of *Kinetic::DelaunayTriangulationVisitor_2*. Methods on this object will be called whenever the triangulation changes.

#include <CGAL/Kinetic/Delaunay_triangulation_2.h>

Is Model for the Concepts

Ref_counted<T>

Types

Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation>:: Triangulation

The template argument triangulation.

Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation>:: Visitor

The template argument for the visitor.

Creation

Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation> dt(Traits tr);

Maintain the Delaunay triangulation of the points in *tr.active_points_2_handle()*.

Operations

Triangulation *dt.triangulation() const*

Access the triangulation that is maintained.

Visitor& *dt.visitor()* Access the visitor.

Vertex_handle *dt.insert(Point_key k)*

Insert the point.

void *dt.erase(Vertex_handle h)*

Erase the vertex.

See Also

Kinetic::DelaunayTriangulationVisitor_2, *Kinetic::Delaunay_triangulation_default_visitor_2*, *Kinetic::Delaunay_triangulation_recent_edges_visitor_2<Triangulation>*, *Kinetic::Delaunay_triangulation_event_log_visitor_2*, *Kinetic::Qt_Delaunay_triangulation_2*.

Class

CGAL::Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation>

Definition

The class *Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation>* maintains a Delaunay triangulation on top of the points contained in a *Kinetic::ActiveObjectsTable*. It has one main method of interest. *triangulation()* which returns the triangulation it is maintaining. In addition, as an optimisation, you can turn on and off whether it is currently maintaining its certificates. This allows a large number of changes to the underlying points to be made at one time without recomputing the certificates each time a single point changes.

Note that the Delaunay triangulation is fully dynamic as it tracks points added to and removed from the *Kinetic::ActiveObjectsTable*.

The class *Kinetic::Qt_triangulation_3<Traits>*, included as part of the demo code, displays a kinetic Delaunay triangulation in three dimensions using the Coin library.

The optional *Visitor* template argument is a model of *Kinetic::DelaunayTriangulationVisitor_3* and can be used to monitor changes in the kinetic data structure.

The optional *Triangulation* template argument must be a model of a *CGAL::DelaunayTriangulation_3* which uses *Traits::Default_instantaneous_kernel* as its geometric traits and has *Kinetic::Delaunay_triangulation_cell_base_3<Traits, Base>* a the cell type.

#include <CGAL/Kinetic/Delaunay_triangulation_3.h>

Types

Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation>:: Triangulation

The template argument.

Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation>:: Visitor

The template argument.

Creation

Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation> dt(Traits tr);

Maintain the Delaunay triangulation of the points in *tr.active_points_3_handle()*.

Operations

*const Triangulation**	*dt.triangulation()*	Access the triangulation that is maintained.

bool	*dt.has_certificates()*	This method returns true if the *Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation>* is currently maintaining certificates for a Delaunay triangulation.
void	*dt.set_has_certificates(bool tf)*	This method allows you to control whether the triangulation is maintaining certificates.
Visitor&	*dt.visitor()*	Access the visitor.

Kinetic:Delaunay_triangulation_2<Traits, Triangulation, Visitor>

Class

CGAL::Kinetic::Delaunay_triangulation_recent_edges_visitor_2< Triangulation>

Definition

The concept *Kinetic::Delaunay_triangulation_recent_edges_visitor_2<Triangulation>* provides a model of *Kinetic::DelaunayTriangulationVisitor_2* which tracks which edges were created in the most recent change.

Is Model for the Concepts

Kinetic::DelaunayTriangulationVisitor_2

Creation

Kinetic::Delaunay_triangulation_recent_edges_visitor_2<Triangulation> a;

default constructor.

Kinetic::Delaunay_triangulation_recent_edges_visitor_2<Triangulation>:: iterator

The iterator through the recently created edges.

Operations

iterator	*a.begin() const*	Begin iteration through the recent edges.
iterator	*a.end() const*	End iteration through the recent edges.
bool	*a.contains(Triangulation::Edge) const*	Returns true if this edge exists in the set.

Kinetic::DelaunayTriangulationVisitor_2

Definition

This concept is for proxy objects which get notified when a kinetic Delaunay triangulation changes.

Operations

void	*v.pre_remove_vertex(Vertex_handle)*	
		The vertex is about to be deleted.
void	*v.post_remove_vertex(Point_key)*	
		The vertex was just removed.
void	*v.pre_insert_vertex(Point_key)*	
		The vertex is about to be inserted into the cell (although the *Cell_handle* might be *NULL*).
void	*v.post_insert_vertex(Vertex_handle)*	
		The vertex was just inserted.
void	*v.change_vertex(Vertex_handle)*	
		The trajectory of the point at the vertex changed.
void	*v.create_face(Face_handle f)*	
		The face has just been made.
void	*v.destroy_face(Face_handle f)*	
		The face is about to be destroyed.
void	*v.pre_flip(Edge)*	The edge is about to be flipped.
void	*v.post_flip(Edge)*	The edge was just created with a flip.

Has Models

Kinetic::Delaunay_triangulation_visitor_base_2, *Kinetic::Delaunay_triangulation_recent_edges_visitor_2< Triangulation>*, *Kinetic::Delaunay_triangulation_event_log_visitor_2*

Kinetic::DelaunayTriangulationVisitor_3

Definition

This concept is for proxy objects which get notified when a kinetic Delaunay triangulation changes.

Operations

void *v.pre_remove_vertex(Vertex_handle)*

The vertex is about to be deleted.

void *v.post_remove_vertex(Point_key, Cell_handle)*

The vertex was just removed.

void *v.pre_insert_vertex(Point_key, Cell_handle)*

The vertex is about to be inserted into the cell (although the *Cell_handle* might be *NULL*).

void *v.post_insert_vertex(Vertex_handle)*

The vertex was just inserted.

void *v.change_vertex(Vertex_handle)*

The trajectory of the point at the vertex changed.

void *v.create_cell(Cell_handle)*

The cell was just created and initialized.

void *v.destroy_cell(Cell_handle)*

The cell is about to be removed.

void *v.pre_edge_flip(Edge)*

The edge is about to be flipped.

void *v.post_edge_flip(Facet)*

The facet was just created with a flip.

void *v.pre_facet_flip(Facet)*

The facet is about to be flipped.

void *v.post_facet_flip(Edge)*

The edge was just created with a flip.

Has Models

Kinetic::Delaunay_triangulation_3<Traits, Triangulation, Visitor>

CGAL::Kinetic::Enclosing_box_2<Traits>

Definition

The class *Kinetic::Enclosing_box_2<Traits>* keeps the points in the simulation inside of a box. Whenever the points come close to the wall of the box they bounce off of the wall.

Note that, in general, points hit the wall of the box at times which are not easily represented by standard (rational) number types. The resulting trajectories would also have non-rational coefficients, complicating and slowing the simulation. In order to handle this, the *Kinetic::Enclosing_box_2<Traits>* bounces the points at the nearest easily representable time before the point would leave the box.

#include <CGAL/Kinetic/Enclosing_box_2.h>

Types

Kinetic::Enclosing_box_2<Traits>:: NT	The number type used to represent the walls of the box and perform calculations. Generally this is *Traits::NT*.

Creation

Kinetic::Enclosing_box_2<Traits> eb(Traits, NT xmin, NT xmax, NT ymin, NT ymax);

This constructs a bounding box with the dimensions specified by the last 4 arguments. They are optional and will take the values ± 10 if omitted.

CGAL::Kinetic::Enclosing_box_3<Traits>

Definition

The class *Kinetic::Enclosing_box_3<Traits>* keeps the points in the simulation inside of a box. Whenever the points come close to the wall of the box they bounce off of the wall.

Note that, in general, points hit the wall of the box at times which are not easily represented by standard (rational) number types. The resulting trajectories would also have non-rational coefficients, complicating and slowing the simulation. In order to handle this, the *Kinetic::Enclosing_box_3<Traits>* bounces the points at the nearest easily representable time before the point would leave the box.

#include <CGAL/Kinetic/Enclosing_box_3.h>

Types

Kinetic::Enclosing_box_3<Traits>:: NT	The number type used to represent the walls of the box and perform calculations. Generally this is *Traits::NT*.

Creation

Kinetic::Enclosing_box_3<Traits> eb(Traits, NT xmin, NT xmax, NT ymin, NT ymax, NT zmin, NT zmax);

This constructs a bounding box with the dimensions specified by the last 6 arguments. They are optional and will take the values ± 10 if omitted.

Class

CGAL::Kinetic::Erase_event<ActiveObjectsTable>

Definition

This event erases a point from the *ActiveObjectsTable* when it is processed.

#include <CGAL/Kinetic/Erase_event.h>

Is Model for the Concepts

Kinetic::Simulator::Event

Creation

Kinetic::Erase_event<ActiveObjectsTable> i(ActiveObjectsTable::Key k, ActiveObjectsTable::Handle t);

Erase the object k from the table t when processed.

See Also

Kinetic::ActiveObjectsTable, *Kinetic::Active_objects_vector<MovingObject>*.

Example

```
typedef CGAL::Kinetic::Exact_simulation_traits Simulation_traits;
typedef Simulation_traits::Kinetic_kernel::Point_2 Moving_point_2;
typedef
   CGAL::Kinetic::Insert_event<Simulation_traits::Active_points_2_table>
   Insert_event;
typedef CGAL::Kinetic::Delaunay_triangulation_2<Simulation_traits> KDel;

Simulation_traits tr;

KDel kdel(tr);

Moving_point_2 mp(Moving_point_2::NT(0),
                  Moving_point_2::NT(0));
tr.simulator_handle()->new_event(Simulation_traits::Simulator::Time(3),

   Erase_event(*tr.active_objects_table_handle()->keys_begin(),

   tr.active_points_2_table_handle()));
```

Kinetic::EventLogVisitor

Definition

This concept is for visitors which maintain a text log of events.

Types

Kinetic::EventLogVisitor:: Event_iterator	An iterator through strings defining the events that occurred. Each event is represented by a *std::string*.

Operations

Event_iterator	*v.events_begin()*	Begin iterating through the events.
Event_iterator	*v.events_end()*	

Has Models

Kinetic::Delaunay_triangulation_event_log_visitor_3, *Kinetic::Delaunay_triangulation_event_log_visitor_2*, *Kinetic::Regular_trianglation_event_log_visitor_3*, *Kinetic::Sort_event_log_visitor*

Class

CGAL::Kinetic::Insert_event<ActiveObjectsTable>

Definition

This event inserts a point into the *ActiveObjectsTable* when it is processed.

#include <CGAL/Kinetic/Insert_event.h>

Is Model for the Concepts

Kinetic::Simulator::Event

Creation

Kinetic::Insert_event<ActiveObjectsTable> i(ActiveObjectsTable::Data o, ActiveObjectsTable::Handle t);

Insert the object o, into the table t when processed.

See Also

Kinetic::ActiveObjectsTable, *Kinetic::Active_objects_vector<MovingObject>*.

Example

```
typedef CGAL::Kinetic::Exact_simulation_traits Simulation_traits;
typedef Simulation_traits::Kinetic_kernel::Point_2 Moving_point_2;
typedef
   CGAL::Kinetic::Insert_event<Simulation_traits::Active_points_2_table>
   Insert_event;
typedef CGAL::Kinetic::Delaunay_triangulation_2<Simulation_traits> KDel;

Simulation_traits tr;

KDel kdel(tr);

Moving_point_2 mp(Moving_point_2::Coordinate(0),
                  Moving_point_2::Coordinate(0));
tr.simulator_handle()->new_event(Simulation_traits::Simulator::Time(3),
                                 Insert_event(mp,

   tr.active_points_2_table_handle()));
```

CGAL::Kinetic::Qt_moving_points_2<Traits, QtWidget_2>

Class

Definition

The class *Kinetic::Qt_moving_points_2<Traits, QtWidget_2>* displays a set of moving points in 2D.

See Section 71.4.3 for an example using this class.

#include <CGAL/Kinetic/IO/Qt_moving_points_2.h>

Creation

Kinetic::Qt_moving_points_2<Traits, QtWidget_2> a(QtGui::Handle, Traits::Active_points_2_table::Handle)

default constructor.

See Also

Kinetic::Qt_widget_2<Simulator>.

Class

CGAL::Kinetic::Qt_triangulation_2<KineticTriangulation_2, QtWidget_2, QtMovingPoints_2>

Definition

The class draws a triangulation into a *CGAL::Qt_widget_2*. This class is very simple and a good one to look at if you want to see how to draw your own two dimensional kinetic data structure.

See Section 71.4.3 for an example using this class.

#include <CGAL/Kinetic/IO/Qt_triangulation_2.h>

Creation

Kinetic::Qt_triangulation_2<KineticTriangulation_2, QtWidget_2, QtMovingPoints_2> a(KineticTriangulation_2::Handle, QtWidget_2::Handle, QtMovingPoints_2::Handle)

Construct the object and make all the connections with the appropriate other objects.

See Also

Kinetic::Qt_widget_2<Simulator>

CGAL::Kinetic::Qt_widget_2<Simulator>

Definition

The class *Kinetic::Qt_widget_2<Simulator>* implements a graphical interface for 2D kinetic data structures.

#include <CGAL/Kinetic/IO/Qt_widget_2.h>

Types

Kinetic::Qt_widget_2<Simulator>:: Listener	The listener base to listen for when to update the picture. This class includes an extra method *Qt_widget widget()* which returns the *Qt_widget* object which can be used for drawing.

Creation

*Kinetic::Qt_widget_2<Simulator> a(int argc, char *argv[], Simulator::Handle);*

default constructor.

```
#include <CGAL/basic.h>
#include <CGAL/Kinetic/Exact_simulation_traits.h>
#include <CGAL/Kinetic/Delaunay_triangulation_2.h>
#include <CGAL/Kinetic/Delaunay_triangulation_vertex_base_2.h>
#include <CGAL/Kinetic/Delaunay_triangulation_recent_edges_visitor_2.h>
#include <CGAL/Kinetic/Enclosing_box_2.h>
#include <CGAL/Kinetic/IO/Qt_moving_points_2.h>
#include <CGAL/Kinetic/IO/Qt_triangulation_2.h>
#include <CGAL/Kinetic/IO/Qt_widget_2.h>
#include <CGAL/Kinetic/Insert_event.h>

int main(int argc, char *argv[])
{
  typedef CGAL::Kinetic::Exact_simulation_traits Traits;

 typedef CGAL::Triangulation_data_structure_2<

    CGAL::Kinetic::Delaunay_triangulation_vertex_base_2<Traits::Instantaneous_kernel>,
     CGAL::Kinetic::Delaunay_triangulation_face_base_2<Traits> > TDS;
  typedef CGAL::Delaunay_triangulation_2<Traits::Instantaneous_kernel,
    TDS > Del;
  // Color edges based on how recently they were created
  typedef
    CGAL::Kinetic::Delaunay_triangulation_recent_edges_visitor_2<Del>
    Visitor;
  typedef CGAL::Kinetic::Delaunay_triangulation_2<Traits, Visitor, Del>
    KDel;
  typedef CGAL::Kinetic::Qt_widget_2<Traits::Simulator> Qt_gui;
```

```
  typedef CGAL::Kinetic::Qt_moving_points_2<Traits, Qt_gui> Qt_mps;
  typedef CGAL::Kinetic::Qt_triangulation_2<KDel,
   Traits::Instantaneous_kernel, Qt_gui> Qt_triangulation;
  // Keeps the points confined
  typedef CGAL::Kinetic::Enclosing_box_2<Traits> Box;

  CGAL_SET_LOG_LEVEL(CGAL::Log::LOTS);

  // Run from time 0 until a really large value of time
  Traits tr(0, 10000000);
  Box::Handle box= new Box(tr);
  KDel::Handle kdel= new KDel(tr);

  Qt_gui::Handle qtsim= new Qt_gui(argc, argv, tr.simulator_handle());

  Qt_mps::Handle qtmps= new Qt_mps(qtsim, tr);
  Qt_triangulation::Handle qtdel= new Qt_triangulation(kdel,
   tr.instantaneous_kernel_object(), qtsim);
  Traits::Kinetic_kernel::Point_2 p;
  std::cin >> p;
  tr.active_points_2_table_handle()->insert(p);
  return qtsim->begin_event_loop();
}
```

CGAL::Kinetic::Regular_triangulation_3<Traits, Visitor, Triangulation>

Class

Definition

The class *Kinetic::Regular_triangulation_3<Traits, Visitor, Triangulation>* maintains a triangulation of set of moving weighted points. Its interface is the same as *Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation>*.

Note that the regular triangulation tracks as points are added to the *Kinetic::ActiveObjectsTable*, but not removed from it.

The optional *Triangulation* template argument must be a model of *CGAL::RegularTriangulation_3* which has *Kinetic::Regular_triangulation_cell_base_3<Traits, Base>* as a cell base and *Kinetic::Regular_triangulation_vertex_base_3<Traits, Base>* as a vertex base.

#include <CGAL/Kinetic/Regular_triangulation_3.h>

See Also

Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation>. *Kinetic::RegularTriangulationVisitor_3*.

Example

```
#define CGAL_CHECK_EXACTNESS
#define CGAL_CHECK_EXPENSIVE

#include <CGAL/Kinetic/Regular_triangulation_exact_simulation_traits.h>
#include <CGAL/Kinetic/Regular_triangulation_3.h>

int main()
{
    typedef CGAL::Kinetic::Regular_triangulation_exact_simulation_traits
   Traits;
    typedef CGAL::Kinetic::Regular_triangulation_3<Traits> KDel;

    Traits tr(0,100000.0);

CGAL::Kinetic::Regular_triangulation_cell_base_3<Traits, Base>

Definition

This is the base class for faces used by *Kinetic::Regular_triangulation_3<Traits, Triangulation, Visitor>*.

#include <CGAL/Kinetic/Regular_triangulation_cell_base_3.h>

Class

CGAL::Kinetic::Regular_triangulation_event_log_visitor_3

Definition

The concept *Kinetic::Regular_triangulation_event_log_visitor_3* provides a model of *Kinetic::RegularTriangulationVisitor_3* and *EventLogVisitor* which logs edge flip events.

Is Model for the Concepts

Kinetic::RegularTriangulationVisitor_3, *Kinetic::EventLogVisitor*

See Also

Kinetic::Regular_triangulation_3<Traits, Triangulation, Visitor>

CGAL::Kinetic::Regular_triangulation_instantaneous_kernel< ActiveObjectsTable, StaticKernel>

Class

Definition

The class *Kinetic::Regular_triangulation_instantaneous_kernel<ActiveObjectsTable, StaticKernel>* is an instantaneous kernel for use with a regular triangulation data structure. There is not currently a reason for the user to call this directly unless the user wants created their own simulation traits as it is included as part of the *Kinetic::Regular_triangulation_exact_simulation_traits*.

#include <CGAL/Kinetic/Regular_triangulation_instantaneous_kernel.h>

Is Model for the Concepts

CGAL::RegularTriangulationTraits_3, *Kinetic::InstantaneousKernel*

See Also

Kinetic::Regular_triangulation_3<Traits, Visitor, Triangulation>.

Class

CGAL::Kinetic::Regular_triangulation_vertex_base_3<Traits, Base>

Definition

This is the base class for the vertices of the triangulation class used by *Kinetic::Regular_triangulation_3<Traits, Triangulation, Visitor>*.

#include <CGAL/Kinetic/Regular_triangulation_vertex_base_3.h>

Kinetic::RegularTriangulationVisitor_3

Concept

Definition

This concept is for proxy objects which get notified when a kinetic regular triangulation changes. It inherits all the methods of *DelaunayTriangulationVisitor_3*.

Is Model for the Concepts

Kinetic::DelaunayTriangulationVisitor_3

Operations

void *v.pre_move(Key, Cell)*

The point defined by *Key* is about to move from the cell.

void *v.post_move(Key, Cell)*

The point defined by *Key* just moved to the cell.

Has Models

Kinetic::Regular_triangulation_visitor_base_3, *Kinetic::Regular_triangulation_event_log_visitor_3*

Class

CGAL::Kinetic::Regular_triangulation_visitor_base_3

Definition

The concept *Kinetic::Regular_triangulation_visitor_base_3* provides a model of *Kinetic::RegularTriangulationVisitor_3*. You can extend this class if you only want to implement a few methods from *Kinetic::RegularTriangulationVisitor_3*.

Is Model for the Concepts

Kinetic::RegularTriangulationVisitor_3

Creation

Kinetic::Regular_triangulation_visitor_base_3 a;

default constructor.

CGAL::Kinetic::Sort_event_log_visitor

Class

Definition

The concept *Kinetic::Sort_event_log_visitor* provides a model of *SortVisitor* and *EventLogVisitor* which logs changes to the structure.

Is Model for the Concepts

Kinetic::SortVisitor, *Kinetic::EventLogVisitor*

See Also

Kinetic::Sort<Traits, Visitor>

CGAL::Kinetic::Sort<Traits, Visitor>

Definition

The class *Kinetic::Sort<Traits, Visitor>* maintains a sorted list of objects. It is the simplest kinetic data structure provided and is a good place to start when looking at the basics of implementing a kinetic data structure.

The *Kinetic::SortVisitor* can be used to monitor what is happening.

#include <CGAL/Kinetic/Sort.h>

Creation

Kinetic::Sort<Traits, Visitor> s(Traits tr);	The basic constructor.

Types

Kinetic::Sort<Traits, Visitor>:: Visitor	The type of the visitor.
Kinetic::Sort<Traits, Visitor>:: Traits	The traits type.
Kinetic::Sort<Traits, Visitor>:: Vertex_handle	The handle used to refer to vertex in the sorted list. Dereferencing this returns a *Key* into the *ActiveObjectsTable*.
Kinetic::Sort<Traits, Visitor>:: Handle	A reference counted pointer to be used for storing references to the object.
Kinetic::Sort<Traits, Visitor>:: Const_handle	A reference counted pointer to be used for storing references to the object.

Operations

Visitor&	*s.visitor()*	Access the visitor.
Traits&	*s.traits()*	Access the traits.
Vertex_handle	*s.insert(Point_key k)*	Insert the point.
void	*s.erase(Vertex_handle k)*	Erase the point.
Iterator	*s.begin()*	Begin iterating through the ordered *Vertex_handle*s (the iterator is convertible to *Vertex_handle*.
Iterator	*s.end()*	End iterating through the ordered *Vertex_handle*s (the iterator is convertible to *Vertex_handle*.

Chapter 72

Kinetic Framework

Daniel Russel

Contents

This chapter describes a framework for implementing kinetic data structures and sweepline algorithms. If you just would like to use existing kinetic data structures, please read Chapter 71 instead. Readers wishing to brush up on their familiarity with kinetic data structures or better understand the terminology we use should read Section 71.2 of that chapter. A brief overview of the framework can be found in Section 71.3 (also of that chapter) and it too is recommended reading. Here we dive right in to discussing to discussing the architecture of the framework in Section 72.1 and finally we give several examples of using the framework to implement a kinetic data structure in Section 72.3. The framework makes heavy use of our *Polynomial_kernel* package to provide models of the *Kinetic::FunctionKernel* concept.

The framework was first presented at ALENEX [GKR04].

72.1 Architecture

This package provides a framework to allow exact implementation of kinetic data structures and sweepline algorithms. Below we discuss in detail each one of the first four major concepts which help in implementing

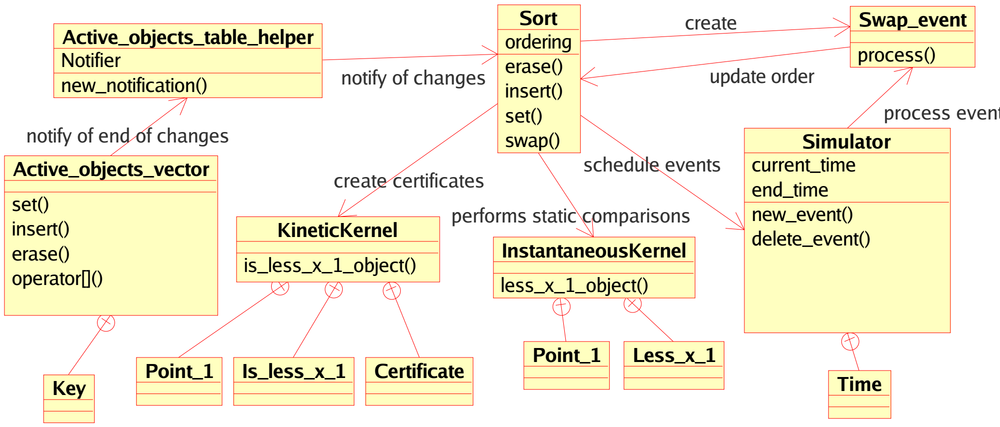

Figure 72.1: The figure, identical to the one in the overview of the previous chapter, shows the interaction between the *Kinetic::Sort<Traits, Visitor>* kinetic data structure and the various pieces of our framework. Other, more complicated, kinetic data structures will also use the *Kinetic::InstantaneousKernel* in order to insert/remove geometric primitives and audit themselves. *Kinetic::Sort<Traits, Visitor>* uses the sorting functionality in STL instead.

kinetic data structures: the *Kinetic::Simulator*, the *Kinetic::Kernel*, the *Kinetic::ActiveObjectsTable* and the *Kinetic::InstantaneousKernel*. The *Kinetic::FunctionKernel* concept is discussed separately in Section 72.2.

72.1.1 The Kinetic::Simulator

The *Kinetic::Simulator* is the central repository of all active events. It maintains the event queue and can use its knowledge of the events in the queue to find times for the kinetic data structures to easily check their own correctness (this will be discussed in more detail later in this section). Kinetic data structures call methods of the *Kinetic::Simulator* to schedule new events, deschedule old ones and access and change data contained in already scheduled events (the operations on existing events are performed using a key which was returned when the event was scheduled). For controlling the simulation, methods in the *Kinetic::Simulator* allow stepping through events, advancing time and even running the simulation backwards (that is we run the simulation with the time running in the opposite direction).

The kinetic sorting example in Figure 71.4.1 shows the basic usage of the *Kinetic::Simulator*. First, the *Simulator* is created by the *Kinetic::SimulationTraits*. The kinetic data structure gets a handle to the simulator from the traits class and uses the handle to add its events to the simulation. The *Kinetic::Simulator* is then told to advance time up until the end of the simulation, processing all events along the way.

Each event is represented by a *Kinetic::Simulator::Time* and an instance of a model of the *Kinetic::Simulator::Event* concept. Models of the *Kinetic::Simulator::Event* concept are responsible for taking the appropriate action in order to handle the kinetic event they represent. Specifically, the *Kinetic::Simulator::Event* concept specifies one method, *Kinetic::Simulator::Event::process()*, that is called when the event occurs. The body of the *Kinetic::Simulator::Event::process()* method typically simply calls a method of the kinetic data structure that created the event; for example in our kinetic sorting example, processing an event means calling the *Kinetic::Sort<Traits, Visitor>::swap(Iterator)* method of the kinetic sorting data structure.

In the model of the *Kinetic::Simulator* concept that we provide, *Kinetic:Default_simulator<FunctionKernel, EventQueue>*, any model of the *Kinetic::Simulator::Event* concept can be inserted as an event. This ability implies that events can be mixed at run time, which is essential when we want to support multiple kinetic data structures operating on the same set of moving geometric primitives.

The *Kinetic::Simulator::Time* concept is defined by the simulator, typically to be some representation of a root of a polynomial, taken from the *Kinetic::FunctionKernel* (details of the algebraic side of the package will be discussed in Section 72.2). For most kinetic data structures *Kinetic::Simulator::Time* only needs to support comparisons (we need to compare events, in order to process them in the correct order) and a few other non-arithmetic operations.

When the failure times of certificates are sorted exactly (as opposed to when we numerically approximate the roots of the certificate polynomials) the correctness of kinetic data structures can be easily verified. Let I be an open interval between the last event processed and the next event to be processed. As was mentioned in the introduction kinetic data structures do not change combinatorially in I. In addition, although the static data structures can be degenerate at the roots defining the two ends of the interval, they are not, in general, degenerate in the interior. An independent check of the integrity of kinetic data structures can be provided by, for example, using an *Kinetic::InstantaneousKernel* (cf. Subsection 72.1.4) to rebuild the static version of the structure from scratch at some time interior to I and compare it to the kinetic version. This auditing can typically catch algorithmic or programming errors much closer to the time they arise in the simulation than, for example, using visual inspection. Such easy auditing is one of the powerful advantages of having an exact computational framework since, as with static data structures, when using inexact computations differentiating between errors of implementation and numeric errors is quite tricky.

Kinetic data structures receive alerts of appropriate times to audit themselves using a notification framework. The same framework is also used by the *Kinetic::ActiveObjectsTable* to alert kinetic data structures when the set of primitives changes (see Subsection 72.1.3). To use the notification framework, the kinetic data structure creates a proxy object which implements a standard *Listener* interface. It then registers this proxy with the *Kinetic::Simulator*. When the *Kinetic::Simulator* finds an appropriate time for the kinetic data structures to audit themselves it calls the function *Listener::new_notification(Type)* on each of the registered proxy objects. A helper for creating such proxy objects, called *Kinetic::Simulator_kds_listener<Listener, KDS>*, is provided by the framework. It translates the notification into a function call (*audit()*) on the kinetic data structure. Pointers in the notification framework are reference counted appropriately to avoid issues caused by the creation and destruction order of kinetic data structures and the simulator. See Section 72.1.5 for a more complete discussion of this part of the framework.

Internally the *Kinetic::Simulator* maintains a priority queue containing the scheduled events. The type of the priority queue is a template argument to our *Kinetic::Simulator* model and, as such, it can be replaced by the user. In our package, we provide two different types of priority queues, a heap and a two-list priority queue. A two-list queue is a queue in which there is a sorted front list, containing all events before some time and an unsorted back list. The queue tries to maintain a small number of elements in the front list, leaving most of them in the unsorted main pool. The two-list queue, although an unconventional choice, is our default queue when using exact computation because it minimizes comparisons involving events that are far in the future. These events are likely to be deleted before they are processed, so extra work done structuring them is wasted. Our experiments have shown that, for example, the two-list queue causes a 20% reduction in running time relative to a binary heap for Delaunay triangulations with degree 3 polynomial motions and 20 points.

72.1.2 The Kinetic::Kernel

The *Kinetic::Kernel* is structured very much like static CGAL kernels. It defines a number of primitives, which in the model provided are *Kinetic::Kernel::Point_1*, *Kinetic::Kernel::Point_2*, *Kinetic::Kernel::Point_3* and *Kinetic::Kernel::Weighted_point_3*. The primitives are defined by a set of Cartesian coordinates each of which is a function of time, a *Kernel::MotionFunction*. In addition it defines constructions and certificate generators which act on the primitives. The certificate generators are the direct analog of the non-kinetic predicates. Each certificate generator take a number of primitives as arguments, but instead of producing an element from a discrete set they produce a set of discrete failure times for the certificate. These failure times are wrapped in a model of *Kinetic::Certificate*.

A *Kinetic::Certificate* is a simple object whose primary function is to produce a *Kinetic::Simulator::Time* object representing the failure time of the certificate. Since, the handling of most certificate failures involves creating a new certificate whose certificate function is the negation of the old certificate function, a *Kinetic::Certificate* object caches any work that could be useful to isolate future roots of the certificate function (such as the Sturm sequence of the certificate function). To illustrate this further, if you have two one-dimensional points with coordinate functions $p_0(t)$ and $p_1(t)$, the certificate that the first moving point is after the second corresponds to the inequality $p_0(t) - p_1(t) > 0$. When the certificate fails and the two points cross, the new certificate is $p_1(t) - p_0(t) > 0$, which is the negated version of the certificate just processed and which has the same roots.

The model of *Kinetic::Kernel* provided includes the certificate generators necessary for Delaunay triangulations (in one, two and three dimensions) and regular triangulations (in 3D). New certificates can be fairly easily added. An example is included in the distributed code.

72.1.3 The Kinetic::ActiveObjectsTable

The *Kinetic::ActiveObjectsTable* stores a set of kinetic primitives. Its purpose is to notify kinetic data structures when new primitives are added, when primitives are removed or when a trajectories change. Each primitive is uniquely identified by a Key, assigned by the table when the primitive is added, that can be used to change or remove it. We provide one model of the *Kinetic::ActiveObjectsTable* concept, called *Kinetic::Active_objects_vector<MovingObject>* which stores all the moving primitives in an *std::vector<D>*.

Notifications of changes to the set of active objects are handled using a setup similar to the *Kinetic::Simulator* audit time notification. We provide a helper class, *Kinetic::Active_objects_listener_helper<ActiveObjectsTable, KDS>*, which translates the notifications into *insert(Key)*, *erase(Key)* or *set(Key)* function calls on the kinetic data structure.

72.1.4 The Kinetic::InstantaneousKernel

The *Kinetic::InstantaneousKernel* allows existing CGAL data structures to be used on moving data as it appears at some instant of time. Models of this concept are, by definition, models of a CGAL Kernel or a traits class, and, therefore, can then be used as the traits class of CGAL's algorithms and data structures.

Consider for example the kinetic Delaunay data structure in either two or three dimensions. Internally, it uses a *Delaunay_triangulation_2<Traits, Tds>* or *Delaunay_triangulation_3<Traits, Tds>* to represent the triangulation, instantiated with a model of the *Kinetic::InstantaneousKernel* concept as its traits class. At initialization, as well as at times during the simulation when we want to insert a point to the kinetic Delaunay triangulation, a static version of the Delaunay triangulation is conceptually instantiated. More precisely, the time for the copy of the model of the *Kinetic::InstantaneousKernel* stored in the CGAL triangulation is set to be the current time (or rather, as discussed in the introduction, a more convenient time determined by the *Kinetic::Simulator* combinatorially equivalent to the current time). The kinetic data structure then calls the *Delaunay_triangulation_3<Traits, Tds>::insert(Point)* insert method to insert the point. The static insert method called uses various predicate functors on the moving points which evaluate to the values that the predicates have at that instant in time. Removal is handled in an analogous manner. Auditing of the geometric structure is easily handled in a similar manner (in the case of Delaunay triangulations by simply calling the *verify()* method after setting the time).

72.1.5 Miscellaneous: notification and reference management

We describe some coding conventions used, graphical display, notification and reference management support in the framework in the following sections.

Reference management

A number of objects need to maintain pointers to other independent objects. For example, each kinetic data structure must have access to the *Kinetic::Simulator* so that it can schedule and deschedule events. These pointers are all reference counted in order to guarantee that they are always valid. We provide a standard reference counting pointer and object base to facilitate this, namely *Ref_counted<Object>*.

Each shared object in the framework defines a type *Handle* which is the type for a reference counter pointer pointing to it. These should be used for storing pointers to the objects in order to avoid dangling pointers. In addition, many of the objects expect such pointers as arguments.

Runtime event passing

Runtime events must be passed from *notifiers*, namely the *Kinetic::ActiveObjectsTable* and the *Kinetic::Simulator* to *listeners*, typically the kinetic data structures. For example, kinetic data structures are notified when new primitives are added to the *Kinetic::ActiveObjectsTable*. On reciving the notification, it will add the new primitive to the combinatorial structure it is maintaining. The events are passed using a simple, standardized notification interface. To receive notifications, the listener first defines a small proxy class which inherits from a *Listener* base type provided by the notifier. On creation, the *Listener* base class registers itself with the notifier on construction (and unregisters itself on destruction).

When the some state of the notifier changes, it calls the *new_notification* method on the listener proxy object provided and passes it a label corresponding to the name of the field that changed. The proxy object can then call an appropriate method on the kinetic data structure or whetever the listening class is.

In order to unregister on destruction, the *Listener* must store a (reference counted) pointer to the object providing notifications. This pointer can be accessed through the *notifier()* field. The *Listener* object stores a reference counted pointer to the notifying object, while the notifying object stores a plain pointer to the *Listener*. It can do this since the *Listener* is guaranteed to unregister itself when it is destroyed. This avoids circular reference counted pointers as well as dangling pointers.

72.2 Algebraic Kernel

The interface between the algebraic kernel and the kinetic data structures package was kept quite minimal in order to ease the implementation of various underlying computation models. The interface is detailed in the reference page (*Kinetic::FunctionKernel*).

We provide models of the algebraic kernel that handle polynomial *Kinetic::Function* objects. The provided models perform

- exact computations using Sturm sequences to isolate roots
- exact computations using Descartes rule of sign in order to isolate roots (Sturm sequences are also used in order to properly handle even multiplicity roots)

- filtered exact computations using Descartes rule of sign
- numeric (inexact) root approximations
- numeric root approximations which take advantage of certain assumptions that can be made about the types of polynomials solved in the process of evaluating kinetic data structures
- a wrapper for CORE::Expr which implements the required concepts.

The exact models, which we implement the numerics for, handle non-square-free polynomials and polynomials with arbitrary field number type coefficients and are quite robust.

72.2.1 Kinetic::FunctionKernel customized for kinetic data structures

There are several modifications we can make to how the roots are handled to optimize for the case of kinetic data structures. The first are motivated by the question of how to handle degeneracies (certificate functions which have roots at the same time). Naively, there is no way to differentiate between a certificate which fails immediately when it is created and one whose function is momentarily 0, but will be valid immediately in the future. In order to handle such degeneracies we ensure that all the certificate function generators produce certificate functions which are positive when the corresponding certificates are valid. Then, if we have a degeneracy we can differentiate between a certificate which fails immediately and one which is simply degenerate by looking at the sign of the certificate function immediately following the root (equivalently, by looking at the derivative). In addition, this allows us, under the assumption that computations are performed exactly, to check that all certificates are not invalid upon creation.

The assumption that certificates are positive when valid is particular useful when using numeric solvers. Without it there is no reliable way to tell whether a root near the current time is the certificate having become valid just before the current time, or failing shortly in the future. Testing the sign of the function immediately after the root reliably disambiguates the two cases.

In addition, we have to specially handle even roots of functions. For the most part these can just be discarded as dropping an even root is equivalent to perturbing the simulation to remove the degeneracy. However, when we are using the *Kinetic::Simulator* to audit the kinetic data structures, they most be broken up in to two, equal, roots to avoid auditing at the degeneracy.

72.3 Examples

We provide a number of examples of different levels of usage of the kinetic data structures framework, both for kinetic data structures as well as sweepline algorithms.

To see how to use existing kinetic data structures, look at the examples in the previous chapter such as Section 71.4.1.

The here we cover implementing kinetic data structures. The examples explained are

- A trivial kinetic data structure which has all the parts of a full kinetic data structure but doesn't do much in Section 72.3.2.
- Adding a new type of certificate to a kernel in Section 72.3.3.

In order to see more detail about how to implement a kinetic data structure, the best place to start is the source code for the kinetic sorting data structure, *Kinetic::Sort<Traits, Visitor>*. Once you are familiar with that, *Kinetic::Delaunay_2<Traits, Triangulation, Visitor>* is the next step in complexity.

We will first explain in detail how a typical kinetic data structure uses the various pieces of the framework, then move on to showing the actual code for a simpler data structure.

72.3.1 Using the Pieces of the Package

Here we will explain how the kinetic sorting data structure uses the various pieces of the package. A schematic of its relationship to the various components is shown in the UML diagram in Figure 72.1. In this subsection we abuse, for reasons of simplicity of presentation, the concept/model semantics: when we refer to concepts we actually refer to an instance of a model of them.

As with most kinetic data structures, *Kinetic::Sort<Traits, Visitor>* maintains some sort of combinatorial structure (in this case a sorted doubly linked list), each element of which has a corresponding certificate in the event queue maintained by the simulator. In the case of sorting, there is one certificate maintained for each "edge" between two consecutive elements in the list.

On creation, the data structure is passed a copy of the *Kinetic::SimulationTraits* for this simulation, which it saves for future use. It gets a handle to to the *Kinetic::ActiveObjectsTable* by calling the *Kinetic::SimulationTraits::active_points_1_table_handle()* method and registers a proxy with the table in order to receive notifications of changes to the point set. The *Kinetic::SimulationTraits* method returns a handle to, rather than a copy of, the *Kinetic::ActiveObjectsTable*, since the table must be shared between all the kinetic data structures using these points. The handles are reference counted pointers, thus saving the user from worrying about cleaning things up properly.

When new points are added to the model of the *Kinetic::ActiveObjectsTable*, the table calls the *new_notification()* method on the proxy of the kinetic data structure, which in turn calls the *insert(Point_key)* method of the kinetic data structure. The *Point_key* here is the key which uniquely identifies the newly inserted point in the table. The data structure then requests an instance of a model of the *Kinetic::InstantaneousKernel* from the *Kinetic::SimulationTraits*. It sets the time on the instantaneous kernel to the time value gotten from the *Kinetic::Simulator::current_time_nt()* method. This method returns a field number type that is between the previous and next event, as discussed in the introduction. An instance of the *Kinetic::InstantaneousKernel::Compare_x_1* predicate (wrapped in order to make it return *less*) and the STL function *std::upper_bound()* are then used to insert the new point in the sorted list. For each inserted object, the kinetic data structure removes the no longer relevant certificate from the event queue by calling the *Kinetic::Simulator::delete_event(Key)* function and creates two new certificates using a *Kinetic::Kernel::Compare_x_1* certificate functor. The new certificates are inserted in the event queue by calling the *Kinetic::Simulator::new_event(Time, Event)* method where *Kinetic::Simulator::Event* is a proxy object which instructs the sort kinetic data structure to swap two points when its *process()* method is called.

Now that the kinetic data structure has been initialized, the simulator is instructed to process all events. Each time an event occurs, the simulator calls the *process()* method on the corresponding proxy object. The proxy, in turn, tells the sort kinetic data structure to swap the two points whose order has changed.

The *Kinetic::Simulator* can periodically instruct the kinetic data structures to audit themselves. As is explained in Section 72.1.1, a proxy object maps the notification on to an *audit()* function call in the kinetic data structure. To audit itself the kinetic data structure builds a list of all the current points and uses *std::sort* to sort this list using a comparison function gotten from the *Kinetic::InstantaneousKernel*. This sorted list is compared to the maintained one to verify correctness. This auditing could also have been done by evaluating the *Kinetic::InstantaneousKernel* predicate for each sorted pair. Since auditing a kinetic data structure typically requires at least linear time in the size of the combinatorial structure, the auditing procedure in between events is deactivated by default. The user can however easily switch it on by defining the *CGAL_CHECK_EXACTNESS* and *CGAL_CHECK_EXPENSIVE* CGAL macros.

This general structure of the interaction between the kinetic data structure and the framework is shared by all of the provided kinetic data structures and has proved itself to go quite far.

72.3.2 The Trivial Kinetic Data Structure

To show how to implement such things, instead of presenting a full kinetic data structure, we present a trivial one which maintains one event in the queue which maintains one event in the queue, scheduled to occur one time unit after the last change was made to the set of active primitives. Two classes are defined, the *Trivial_event*, and the *Trivial_kds*. The event classes must be declared outside of the kinetic data structure so that the *operator<<* can be defined for them.

The kinetic data structure maintains the invariant that it was one event in the queue at all times. This event ccurs one time unit after the last event or change in the set of objects occurs. As a result, the kinetic data structure has the main parts of a real one–it responds to changes in trajectories of the objects and certificate failures (when the event expires).

The public methods can be grouped into three sets which are shared with almost all other kinetic data structures:

- *has_certificates* and *set_has_certificates* which checks/sets whether the kinetic data structure is currently maintaining certificates.
- *insert*, *set*, *erase* which are called by the *Kinetic::Active_objects_listener_helper* in response to the addition, modification, or deletion of an object to, in or from the simulation.
- *audit* which is called periodically by the *Kinetic::Simulator_kds_listener* when kinetic data structures can easily audit themselves.

In addition, it has one method which is called when a certificate fails. The name/existence of such methods depend on the nature of the kinetic data structure in question.

Like many kinetic data structures, it takes a *Kinetic::SimulationTraits* as a template argument. This traits class defines the types needed for the simulation and is responsible for instantiating them.

```
#include <CGAL/Kinetic/Ref_counted.h>
#include <CGAL/Kinetic/Exact_simulation_traits.h>
#include <CGAL/Kinetic/Active_objects_listener_helper.h>
#include <CGAL/Kinetic/Simulator_kds_listener.h>
...

// This must be external since operator<< has to be defined
template <class KDS>
struct Trivial_event
{
  Trivial_event(){}
  Trivial_event(KDS* kds): kds_(kds) {
  }
  void process() const
  {
    kds_->process();
  }
```

```
  KDS* kds_;
};

template <class KDS>
std::ostream &operator<<(std::ostream &out,
                         const Trivial_event<KDS> &) {
  out << "\"An event\"";
  return out;
}

template <class Traits>
struct Trivial_kds: CGAL::Kinetic::Ref_counted<Trivial_kds<Traits> >
{
  typedef Trivial_kds<Traits> This;
  typedef typename Traits::Active_points_1_table::Data Point;
  typedef typename Traits::Simulator::Time Time;
  typedef typename Traits::Active_objects_table::Key Point_key;
  typedef typename Traits::Simulator::Event_key Event_key;
  typedef CGAL::Kinetic::Active_objects_listener_helper<
    typename Traits::Active_points_1_table::Listener, This>
   Active_objects_helper;
  typedef CGAL::Kinetic::Simulator_kds_listener<
    typename Traits::Simulator::Listener, This> Simulator_helper;

  typedef Trivial_event<This> Event;

  Trivial_kds(Traits tr): has_certificates_(true),
                          tr_(tr),
                          nth_(tr.active_points_1_table_handle(), this),
                          sh_(tr.simulator_handle(), this){}

  // this method is called with the value true when the event is
   processed
  void process(bool tf) {
     event_= Event_key();
     set_has_certificates(false);
     set_has_certificates(true);
  }

  void audit() const
  {
     ...
  }

  void set_has_certificates(bool tf) {
    typename Traits::Simulator::Handle sp= tr_.simulator_handle();
    if (has_certificates_ != tf) {
      has_certificates_=tf;
      if (has_certificates_) {
        bool ev= event_;
        CGAL_assertion(!ev);
        Time t= CGAL::to_interval(sp->current_time()).second+1;
        event_= sp->new_event(t, Event(this));
```

```
      } else if (event_) {
        sp->delete_event(event_);
        event_=Event_key();
      }
    }
  }

  bool has_certificates() const {
    return has_certificates_;
  }

  void insert(Point_key k) {
    if (has_certificates_) {
      set_has_certificates(false);
      set_has_certificates(true);
    }
  }

  void set(Point_key k) {
    if (has_certificates_) {
      set_has_certificates(false);
      set_has_certificates(true);
    }
  }

  void erase(Point_key k) {
    if (has_certificates_) {
      set_has_certificates(false);
      set_has_certificates(true);
    }
  }

  ~Trivial_kds(){
     set_has_certificates(false);
  }

protected:
  bool has_certificates_;
  Event_key event_;
  Traits tr_;
  Active_objects_helper nth_;
  Simulator_helper sh_;
};
```

72.3.3 Adding a New Certificate Type

The following example shows how to add a new type of certificate to a simulation.

First we code the actual certificate function generator. It must take some sort (or sorts) of kinetic primitives, compute some function from their coordinates.

```
template <class KineticKernel>
```

```
struct Positive_x_f_2 {
  typedef typename KineticKernel::Certificate_function result_type;
  typedef typename KineticKernel::Point_2 argument_type;
  result_type operator()(const argument_type &p){
    return result_type(p.x()- result_type(0));
  }
};
```

Then we define a kinetic kernel which includes this predicate. To do this we wrap the function generator generator in a *Kinetic::Certificate_generator<Kernel, Generator>*. This wrapper uses the generator to create the certificate function and then the *Kinetic::FunctionKernel* to solve the certificate function. The result is wrapped in a *Kinetic::Certificate* object.

```
template <class FunctionKernel>
class My_kinetic_kernel:
  public CGAL::Kinetic::Cartesian<FunctionKernel> {
  typedef CGAL::Kinetic::Cartesian<FunctionKernel> P;
  typedef My_kinetic_kernel<FunctionKernel> This;
public:
  typedef CGAL::Kinetic::internal::Certificate_generator<This,
   Positive_x_f_2<This> > Positive_x_2;
  Positive_x_2 positive_x_2_object() const
  {
    return Positive_x_2(P::function_kernel_object());
  }
};
```

Now we have the unfortunately rather messy part of assembling a new *Kinetic::SimulationTraits* model. This is done in two steps for convenience.

```
struct My_simulation_traits {
  typedef My_simulation_traits This;

  typedef CGAL::Exact_predicates_exact_constructions_kernel
   Static_kernel;
  //typedef
   CGAL::Regular_triangulation_euclidean_traits_3<Static_kernel_base>
   Static_kernel;
  typedef CGAL::POLYNOMIAL::Polynomial<Static_kernel::FT> Function;
  typedef CGAL::POLYNOMIAL::Sturm_root_stack_traits<Function>
   Root_stack_traits;
  typedef CGAL::POLYNOMIAL::Sturm_root_stack<Root_stack_traits>
   Root_stack;
  typedef CGAL::POLYNOMIAL::Kernel<Function, Root_stack> Function_kernel;

  typedef
   CGAL::Kinetic::Handle_degeneracy_function_kernel<Function_kernel,
   false>  Simulator_function_kernel_base;
  struct Simulator_function_kernel: public
   Simulator_function_kernel_base{};

  typedef My_kinetic_kernel<Simulator_function_kernel> Kinetic_kernel;
  typedef CGAL::Kinetic::Two_list_pointer_event_queue<Function_kernel>
   Event_queue;
```

```
  typedef CGAL::Kinetic::Default_simulator<Simulator_function_kernel,
    Event_queue > Simulator;

  typedef CGAL::Kinetic::Active_objects_vector<Kinetic_kernel::Point_1>
    Active_points_1_table;
  typedef CGAL::Kinetic::Active_objects_vector<Kinetic_kernel::Point_2>
    Active_points_2_table;
  typedef CGAL::Kinetic::Active_objects_vector<Kinetic_kernel::Point_3>
    Active_points_3_table;
  // typedef Active_objects_vector<Kinetic_kernel::Weighted_point_3>
    Active_weighted_points_3_table;

  typedef CGAL::Kinetic::Default_instantaneous_kernel<This>
    Instantaneous_kernel;

  Active_points_1_table* active_points_1_table_handle() const { return
    ap1_.get();}
  Active_points_2_table* active_points_2_table_handle() const {return
    ap2_.get();}
  Active_points_3_table* active_points_3_table_handle() const {return
    ap3_.get();}
  //Active_weighted_points_3_table*
    active_weighted_points_3_table_handle() const {return awp3_.get();}

  Simulator* simulator_handle() const { return sim_.get();}
  const Static_kernel& static_kernel_object() const {return k_;}
  const Kinetic_kernel& kinetic_kernel_object() const {return kk_;}

  Instantaneous_kernel instantaneous_kernel_object() const {
    return Instantaneous_kernel(*this);
  }

  My_simulation_traits(const Simulator::Time &lb,
                       const Simulator::Time &ub): sim_(new Simulator(lb,
     ub)),
                                                   ap1_(new
    Active_points_1_table()),
                                                   ap2_(new
    Active_points_2_table()),
                                                   ap3_(new
    Active_points_3_table())
  {}

  bool is_exact() const {
    return true;
  }
protected:
  Simulator::Handle sim_;
  Active_points_1_table::Handle ap1_;
  Active_points_2_table::Handle ap2_;
  Active_points_3_table::Handle ap3_;
  //Active_weighted_points_3_table::Handle awp3_;
  Static_kernel k_;
```

```
  Kinetic_kernel kk_;
  Function_kernel fk_;
};
```

Now the simulation traits can be used by a kinetic data structure. Note that we define active point table for all dimensions. This is needed by the *Kinetic::InstantaneousKernel*, even if they are not used.

Kinetic Framework Reference Manual

Daniel Russel

72.4 Classified Reference Pages

Definition

Kinetic data structures are a way of adding motion to classical geometric data structures. CGAL provides a number of classes to aid implementation of kinetic data structures.

There are three levels at which the user can interact with the package. The user can use an existing kinetic data structure, write a new kinetic data structure, or replace parts of the framework.The first level is covered in the Chapter 72.

Main Support Classes and Concepts

Here we list the main classes and concepts provided by the framework to support implementing kinetic data structures

Other Concepts

Other Classes

72.5 Alphabetical List of Reference Pages

CGAL::Kinetic::Active_objects_listener<ActiveObjectsTable, KDS>

Class

Definition

The class *Kinetic::Active_objects_listener<ActiveObjectsTable, KDS>* acts as an intermediate between a moving object table and a KDS. It translates the *ActiveObjectsTable::Listener::IS_EDITING* notification events into appropriate calls to *KDS::insert(Key)*, *KDS::set(Key)*, *KDS::erase(Key)*.

Kinetic data structures can still take advantage of the batch editing if they are careful. The methods (such as *KDS::set(Key)* are called in lexicographical order in the *Key*s. So, when a KDS is preparing to update some certificate involving a recently set object, it can first check if the certificate involves another changed object which is lexicographically prior. If so, then the certificate has already been updated and can be skipped.

#include <CGAL/Kinetic/listeners.h>

See Also

Kinetic::Active_objects_vector<MovingObject>, *Kinetic::ActiveObjectsTable*.

Concept

Kinetic::ActiveObjectsTable

Definition

This container holds a set of objects of a particular type. It creates notifications using the standard *Multi_listener<Interface>* interface when a primitive changes or is added or deleted. Objects which are listening for events can then ask which primitives changed.

For speed, modifications to the Kinetic::ActiveObjectsTable can be grouped into editing sessions. A session is begun by calling *set_is_editing(true)* and ended by calling *set_is_editing(false)*. There is one type of notification, namely, *Listener::IS_EDITING* which occurs when the editing mode is set to false, signaling that a batch of changes is completed.

As an convenience, the change methods can be called without setting the editing state to true, this acts as if it were set to true for that one function call.

Types

Kinetic::ActiveObjectsTable:: Key A key identifying an object in the table.

Kinetic::ActiveObjectsTable:: Data The type being stored in the table.

Kinetic::ActiveObjectsTable:: Listener The base class to derive from for listening for runtime events.

The following types are iterators. Each type, *Foo_iterator* has two corresponding methods *foo_begin* and *foo_end* which allow you to iterate through the objects in the set *Foo*.

Kinetic::ActiveObjectsTable:: Key_iterator An iterator through all the valid keys in the table.

Kinetic::ActiveObjectsTable:: Changed_iterator

An iterator through all the objects which have been changed in the last editing session. The iterator iterates through the objects in lexicographical order.

Kinetic::ActiveObjectsTable:: Inserted_iterator

An iterator through all the objects which were added in the last editing session.

Kinetic::ActiveObjectsTable:: Erased_iterator An iterator through all the objects which were deleted in the last editing session.

Creation

Operations

Data	*mot*[*Key key*]	Access the object referenced by the key.
Data	*mot.at(Key key) const*	Access the object referenced by the key.
void	*mot.set_is_editing(bool is_editing)*	Set the editing state of the object. A notification is sent when the editing state is set to false after it has been true, i.e. the editing session is finished. This allows changes to be batched together.
bool	*mot.is_editing() const*	Access the editing state.
void	*mot.set(Key key, Data object)*	This method changes the motion of one moving object. The position at the current time should not be different from the previous current position. However, at the moment I do not check this as there is no reference to time in the Kinetic::ActiveObjectsTable. If *is_editing()* is not true, then it is as if the calls *set_is_editing(true)*, *set(key, value)* and finally *set_is_editing(false)* were made. If it is true, then no notifications are created.
Key	*mot.insert_object(Data ob)*	Insert a new object into the table and return a *Key* which can be used to refer to it. See *set(Key, Data)* for a description of editing modes.
void	*mot.erase(Key key)*	Delete an object from the table. The object with Key key must already be in the table. This does not necessarily decrease the amount of storage used at all. In fact, it is unlikely to do so. See *set(Key,Data)* for an explainating of how the editing modes are used.
void	*mot.clear()*	Remove all objects from the table and free all storage.
void	*mot.is_set(Key) const*	Returns true if the object has been set in the currently notified editing session. Note that this method can only be saftely called when processing an *IS_EDITING* notification.
void	*mot.is_new(Key) const*	Returns true if the object has been set in the currently notified editing session.

void	*mot.clear(Key) const*	Returns true if the object has been set in the currently notified editing session.

Has Models

Kinetic::Active_objects_vector<MovingObject>

See Also

Multi_listener<Interface>, *Kinetic::Active_objects_listener_helper<ActiveObjectsTable, KDS>*

CGAL::Kinetic::Active_objects_vector<MovingObject>

Class

Definition

MovingObjects are stored in a vector. This means that access is constant time, but storage is not generally freed. The only way to be sure is to remove all reference counts for the table or to call *clear()*.

#include <CGAL/Kinetic/Active_objects_vector.h>

Is Model for the Concepts

Kinetic::ActiveObjectsTable

Class

CGAL::Kinetic::Cartesian<FunctionKernel>

Definition

This class provides a model of *Kinetic::Kernel* for use with general Cartesian geometry.

The IO format for points is currently p_0, p_1, ... w. p_i and w are instances of Function. There IO format is typically $c_0 + c_1 t + c_2 t^2 + \ldots$. Beware of issues with CGAL IO of the coeffients as exact number typles often require that the coefficents be expressed as a/b even when b is 1.

#include <CGAL/Kinetic/Cartesian.h>

Types

Kinetic::Cartesian<FunctionKernel>:: Certificate

This is a model of *Kinetic::Certificate*.

Kinetic::Cartesian<FunctionKernel>:: Point_1

Kinetic::Cartesian<FunctionKernel>:: Point_2

Kinetic::Cartesian<FunctionKernel>:: Point_3

Kinetic::Cartesian<FunctionKernel>:: Weighted_point_3

The following are functors which generate *Certificate* objects. Each has a corresponding *_object* method which creates the functor. They are models of *Kinetic::CertificateGenerator*.

Kinetic::Cartesian<FunctionKernel>:: Orientation_2

Kinetic::Cartesian<FunctionKernel>:: Orientation_3

Kinetic::Cartesian<FunctionKernel>:: Side_of_oriented_circle_2

Kinetic::Cartesian<FunctionKernel>:: Side_of_oriented_sphere_3

Kinetic::Cartesian<FunctionKernel>:: Power_test_3

Kinetic::Cartesian<FunctionKernel>:: Weighted_orientation_3

Kinetic::Cartesian<FunctionKernel>:: Compare_x_1

Kinetic::Cartesian<FunctionKernel>:: Compare_x_2

Kinetic::Cartesian<FunctionKernel>:: Compare_y_2

Kinetic::Cartesian<FunctionKernel>:: Compare_x_3

Kinetic::Cartesian<FunctionKernel>:: Compare_y_3

Kinetic::Cartesian<FunctionKernel>:: Compare_z_3

Kinetic::Cartesian<FunctionKernel>:: Compare_distance_2

Kinetic::Cartesian<FunctionKernel>:: Compare_distance_3

Is Model for the Concepts

Kinetic::Kernel.

Concept

Kinetic::Certificate

Definition

The concept represents certificate. Its main purpose is to provide a way of creating *Time* objects corresponding to when the certificate fails and to cache any useful work done in find the *Time* for later.

Operations

Time	*c.failure_time()*	Returns the next failure time.
bool	*c.will_fail()*	Returns true if the certificate will ever fail.
void	*c.pop_failure_time()*	Advances to the next failure time (the next root of the certificate functions).

See Also

Kinetic::Kernel.

Kinetic::CertificateGenerator

Concept

Definition

This functor allows you to create certificate objects of some type. The models of this “concept” take some set of arguments which depend on the certificate being computed (for example three points for a two dimensional orientation) followed by either one or two instances of the *Kinetic::Simulator::Time* concept. The functions either return a *Certificate* or the corresponding value at the current time (if only a time value rather than an interval is passed).

Operations

Certificate *a(Args, Time begin, Time end)*

Return a *Certifate* object for the corresponding certificate.

CGAL::Sign *a(Args, Time t)* Compute the sign of the function at $\lim_{\delta \to 0} t + \delta$. This can be used to evaluate predicates at the current moment.

Has Models

All over the place.

See Also

Kinetic::KineticKernel

Example

Here you see how to use both functions on an orientation predicate.

```
KineticKernel::Point_2 a,b,c;
Simulator::Handle sh;
KineticKernek kk;

KineticKernel::Orientation_2 o2= kk.orientation_2_object();

KineticKernel::Certificate c= o2(a,b,c, sh->current_time(),
    sh->end_time());
if (c.will_fail()) {
  std::cout << "Certificate will fail" << std::endl;
}
// Compute the sign immediately following the current time
CGAL::Sign sn= o2(a,c,b, sh->current_time());
CGAL_postcondition(sn==CGAL::NEGATIVE);
```

Concept

Kinetic::FunctionKernel::ConstructFunction

Definition

The concept is used to construct functions.

Operations

Function	*a(NT a, ...)*	This family of methods takes a list of coefficients and returns a function. There can be any number of coeffients passed as arguments (up to about 25 in the current implementations).

See Also

FunctionKernel

Example

```
Function_kernel fk;
Function_kernel::Construct_function cf= fk.construct_function_object();
Function_kernel::Function f= cf(0,1,2,3,4,5);
```

Kinetic::EventQueue

Concept

Definition

The for priority queues used by the *Simulator*. The concept basically defines a priority queue which supports deletions and changes of items in the queue (but not their priorities). Items in the queue must implement the *Event* concept.

Types

Kinetic::EventQueue:: Key	The type used to access items in the queue in order to change or delete them.
Kinetic::EventQueue:: Priority	The priority type for items in the queue. This is typically the same as *Kinetic::Simulator::Time*

.

Creation

Kinetic::EventQueue q(Priority start, Priority end, int size_hint);

Construct a queue which will start at time start and run until time end.

Operations

template <class Event>
Key *q.insert(Priority, Event)*

Insert an event into the event queue. A *Key* which can be used to manipulated the event is returned.

void	*q.erase(Key)*	Erase an event from the queue.
template <class Event> *void*	*q.set(Key, Event)*	Change the data in the event referred to by the key.
template <class Event> *Event&*	*q.get(Key) const*	Access the event referred to by the passed key.
Priority	*q.priority(Key) const*	Return the priority of the event.
bool	*q.empty()*	Return true if the queue is empty.

Priority	*q.next_priority() const*	
		Return the priority of the next event in the queue.
void	*q.process_next()*	Process the next *Event* by calling its process method with its *Priority*.
void	*q.set_end_priority()*	Set the priority beyond which to ignore events.
bool	*q.contains(Key) const*	
		Return true if the queue contains the event and false if it does not. This is used for auditing events and can be slow if needed.

Has Models

Kinetic::Two_list_pointer_event_queue<FunctionKernel>, *Kinetic::Heap_pointer_event_queue< FunctionKernel>*.

Kinetic::Simulator::Event

Concept

Definition

The concept represents a single event. Models of should be passed to the *Kinetic::Simulator* when scheduling events which will in turn pass them to the *EventQueue*.

Operations

void	*a.process()*	This method is called when the event occurs. This method will only be called once per time this event is scheduled and the event will be removed from the queue immediately afterwards.
*void**	*a.kds()*	Return a *void* * which represents the KDS which this event belongs to. The pointer is used solely to tell if two events come from the same KDS for the purposes of handling degeneracy.
CGAL::Comparison_result	*a.compare_concurrent(Key a, Key b) const*	The two events *a* and *b* occur at the same time (*this* has key *a*). This method returns a *CGAL::Comparison_result* which is used to order the two equal events. If *CGAL::EQUAL* is returned then *merge* will be called.
bool	*a.merge_concurrent(Key a, Key b)*	The two events *a* and *b* occur at the same time (*this* has key *a*) and cannot be perturbed to be unequal. This event allows the KDS to merge event *b* with *a*. If it returns *true* then *b* is dropped from the event queue.
void	*a.audit(Key this_key)*	Audit that this is a valid event. To use this, kinetic data structure can check that this event is indeed pointed to by the correct part of the combinatorial structure.
std::ostream&	*a.write(std::ostream&) const*	Write the event to a stream.

Has Models

All over the place. *Kinetic::Event_base*.

See Also

Kinetic::EventQueue

Example

All of the kinetic data structures provided have models of Event. Here is the code implementing a swap event from the sorting kinetic data structure. Events occuring at equal times are perturbed so that the one that occurs first in the list is processed first (just to illustrate the idea).

```
template <class Certificate, class Id, class Root_enumerator>
class Swap_event {
  typedef Swap_event<class Certificate, class Id, class Root_enumerator>
   This;
public:
  Swap_event(Id o, Sort* sorter,
             const Certificate &s): left_object_(o),
                                    sorter_(sorter),
                                    s_(s){}
  void process(){
    sorter_->swap(left_object_, s_);
  }
  void *kds() const {return sorter_;}
  CGAL::Comparison_result perturb_comparison(typename Sort::Event_key a,
   typename Sort::Event_key b) const {
    return CGAL::compare(std::distance(sorter_->objects_begin(),
   left_object_),
                         std::distance(sorter_->objects_begin(),

   sorter_->simulator_handle()->get_event<This>(b).left_object_));
  }
  bool merge(typename Sort::Event_key a, typename Sort::Event_key b) {
    return false;
  }
  Id left_object_;
  Sort* sorter_;
  Certificate s_;
};
```

Kinetic::FunctionKernel

Definition

The concept Kinetic::FunctionKernel encapsulates all the methods for representing and handing functions. The set is kept deliberately small to easy use of new Kinetic::FunctionKernels, but together these operations are sufficient to allow the correct processing of events, handling of degeneracies, usage of static data structures, run-time error checking as well as run-time verification of the correctness of kinetic data structures. The computation of a polynomial with the variable negated is used for reversing time in kinetic data structures and can be omitted if that capability is not needed.

Types

Kinetic::FunctionKernel:: Function — The type of function being handled.

Kinetic::FunctionKernel:: NT — The basic representational number type.

Kinetic::FunctionKernel:: Root — A type representing the roots of a *Function*.

Kinetic::FunctionKernel:: Root_stack — A model of *RootStack*. These objects can be created by calling the *root_stack_object* method with a *Function* and two (optional) *Root* objects. The enumerator then enumerates all roots of the function in the open inverval defined by the two root arguments. They optional arguments default to positive and negative infinity.

Kinetic::FunctionKernel:: Root_enumerator_traits

The traits for the *Root_enumerator* class.

Each of the following types has a corresponding *type_object* method (not explicitly documented) which takes a *Function* as an argument.

Kinetic::FunctionKernel:: Sign_at — A functor which returns the sign of a *Function* at a *NT* or *Root*.

Kinetic::FunctionKernel:: Sign_after — A functor which returns sign of a function immediately after a root.

The following type is used to construct functions from a list of coefficients. To get an instance use the *construct_function_object()* method.

Kinetic::FunctionKernel:: Construct_function — This functor can be used create instances of *Function*. See its reference page *FunctionKernel::ConstructFunction* for more details.

The following functor likewise have a *type_object* method, but these take arguments other than a *Function*. The arguments are given below.

Kinetic::FunctionKernel:: Sign_between_roots — This functor, creation of which requires two *Root*s, returns the sign of a passed function between the pair of roots.

Kinetic::FunctionKernel:: Differentiate — This functor computes the derivitive of a *Function*. Construction takes no arguments.

The following methods do not require any arguments to get the functor and take one *Function* as a functor argument.

Kinetic::FunctionKernel:: Negate_variable — Map $f(x)$ to $f(-x)$.

Has Models

POLYNOMIAL::Kernel<RootStack>, *POLYNOMIAL::Filtered_kernel<RootStack>*.

See Also

Kinetic::RootEnumerator.

Example

We provide several models of the concept, which are not documented separately. The models of *Kinetic::SimulationTraits* all choose appropriate models. However, if more control is desired, we here provide examples of how to create the various supported *Kinetic::FunctionKernel*.

A Sturm sequence based kernel which supports exact comparisons of roots of polynomials (certificate failure times):

```
typedef CGAL::POLYNOMIAL::Polynomial<CGAL::Gmpq> Function;
typedef CGAL::POLYNOMIAL::Sturm_root_stack_traits<Function>
   Root_stack_traits;
typedef CGAL::POLYNOMIAL::Sturm_root_stack<Root_stack_traits> Root_stack;
typedef CGAL::POLYNOMIAL::Kernel<Function, Root_stack> Function_kernel;
```

A wrapper for *CORE::Expr* which implements the necessary operations:

```
typedef CGAL::POLYNOMIAL::CORE_kernel Function_kernel;
```

A function kernel which computes approximations to the roots of the polynomials:

```
typedef CGAL::POLYNOMIAL::Polynomial<double> Function;
typedef CGAL::POLYNOMIAL::Root_stack_default_traits<Function>
   Root_stack_traits;
typedef CGAL::POLYNOMIAL::Numeric_root_stack<Root_stack_traits>
   Root_stack;
typedef CGAL::POLYNOMIAL::Kernel<Function, Root_stack> Function_kernel;
```

When using the function kernel in kinetic data structures, especially one that is in exact, it is useful to wrap the root stack. The wrapper checks the sign of the certificate function being solved and uses that to handle degeneracies. This is done by, for the inexact solvers

```
typedef Kinetic::Derivitive_filter_function_kernel<Function_kernel>
   KDS_function_kernel;
```

and for exact solvers

```
typedef Kinetic::Handle_degeneracy_function_kernel<Function_kernel>
   KDS_function_kernel;
```

For exact computations, the primary representation for roots is the now standard choice of a polynomial with an associated isolating interval (and interval containing exactly one distinct root of a polynomial) along with whether the root has odd or even multiplicity and, if needed, the Sturm sequence of the polynomial. Two intervals can be compared by first seeing if the isolating intervals are disjoint. If they are, then we know the ordering of the respective roots. If not we can subdivide each of the intervals (using the endpoints of the other interval) and repeat. In order to avoid subdividing endlessly when comparing equal roots, once we subdivide a constant number of times, we use the Sturm sequence of p and $p'q$ (where p and q are the two polynomials and p' is the derivative of p) to evaluate the sign of the second at the root of the first one directly (note that this Sturm sequence is applied to a common isolating interval of the roots of interest of both polynomials).

Concept

Kinetic::FunctionKernel::Function

Definition

The concept represents a function.

Types

Function:: NT	The number type used in describing the function.
Function a(NT);	Construct a constant function from a number.

Operations

NT	*a(NT)*	Evaluate the function at an *NT*.

See Also

FunctionKernel, *FunctionKernel::ConstructFunction*

Example

Several ways to create functions:

Using *Kinetic::ConstructFunction*:

```
Traits::Function_kernel::Construct_function cf=
   traits.function_kernel_object().construct_function_object();
Traits::Kinetic_kernel::Motion_function x= cf(0.0,1.0,2.0);
Traits::Kinetic_kernel::Motion_function y= cf(0.0,1.0,2.0);
Traits::Kinetic_kernel::Point_2 pt(x,y);
```

Using the constructor:

```
double coefs[]={1.0, 2.0, 3.0};
Traits::Kinetic_kernel::Motion_function z(coefs, coefs+3);
```

Using ring operations:

```
Traits::Kinetic_kernel::Motion_function z= x*z+y;
```

CGAL::Kinetic::Default_instantaneous_kernel<SimulationTraits>

Class

Definition

This class provides a model of the *Kinetic::InstantaneousKernel* for use with general Cartesian Geometry. It provides all the predicates needed for Delaunay triangulations and regular triangulations.

#include <CGAL/Kinetic/Default_instantaneous_kernel.h>

Types

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Orientation_2

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Orientation_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Side_of_oriented_circle_2

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Side_of_oriented_sphere_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Power_test_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Weighted_orientation_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_x_1

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_x_2

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_y_2

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_x_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_y_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_z_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_distance_2

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_distance_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Coplanar_orientation_3

Note that this one does not work if the current time is not a *NT*.

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Coplanar_side_of_bounded_circle_3

Note that this one does not work if the current time is not a *NT*.

Is Model for the Concepts

Kinetic::InstantaneousKernel

Kinetic::InstantaneousKernel

Definition

The concept Kinetic::InstantaneousKernel covers models that act as adaptors allowing CGAL static data structures to act on snapshots of kinetic data. Different methods for evaluating predicates are used depending on whether time is set using an *NT* or a *Time* object. Evaluating predicates when time is the former is much cheaper.

Types

Kinetic::InstantaneousKernel:: NT	A number type which can be used to represent the current time. This must be a ring or field type.
Kinetic::InstantaneousKernel:: Time	The type used to represent the current time. This type must be comparable.

Operations

Time	*a.time()*	Return the current time.
NT	*a.time_as_nt()*	Return the current time as an *NT*. As a precondition, *time_is_nt* must be true.
bool	*a.time_is_nt()*	Return true if the last time time was set, it was using an object of type *NT*.
void	*a.set_time(Time)*	Set the current time to have a certain value. All existing predicates are updated automatically.
void	*a.set_time(NT)*	The the current time to be an instance of *NT*. With this more efficient techniques can be used. *time_is_nt()* must be true.
Static_object	*a.static_object(Key)*	Return a static object corresponding to the kinetic object at this instant in time. *time_is_nt()* must be true.

Has Models

Kinetic::Default_instantaneous_kernel

Key

Definition

The concept Key is a unique identifier for something in some sort of table. In general, they can be only created by the table and are returned when a appropriate *new_foo()* method is called on the table. There are two classes of values for a Key, valid and invalid. The latter cannot refer to something in a table. Use the method *is_valid()* to differentiate.

Key a;	The default constructor is guaranteed to construct an invalid key (i.e. one which is false when cast to a bool.

Operations

bool	*a.is_valid() const*	This method returns false if the key was created using the default constructor or was otherwise created to be invalid.
std::ostream&	*std::ostream& << Event*	

Write a text description of the key to a standard stream.

Has Models

Kinetic::Simulator::Event_key, *Kinetic::Active_objects_vector<Object>::Key*.

Kinetic::Kernel

Concept

Definition

The concept Kinetic::Kernel acts as the kinetic analog of a CGAL kernel. It provides some set of primitives and predicats acting on them. The predicates are instances of *Kinetic::CertificateGenerator* and can be used to either create *Certificate*s or to evaluate instantaneous predicates.

Types

Kinetic::Kernel:: Motion_function	The type which is used to represent coordinates of moving primitives. It is a model of the concept *FunctionKernel::Function*. This is the analog of the CGAL kernel *RT*.
Kinetic::Kernel:: Certificate	The type representing the results of predicates. See *Kinetic::Certificate*.
Kinetic::Kernel:: Function_kernel	The type of the function kernel used. See *Kinetic::FunctionKernel*.

Operations

Function_kernel *kk.function_kernel_object() const*

Gets a copy of the function kernel.

Has Models

Kinetic::Cartesian<FunctionKernel>.

Class

CGAL::Listener<Interface>

Definition

The *Listener<Interface>* class provides the core of the run time notification system used by the kinetic data structures package. In short, notifications are handled through proxy objects called listeners. In order to listen for notifications from an object, called the notifier, you make define a small class called a listener proxy, which inherits from the Listener interface defined by the notifier. When constructing your listner poxy, you pass a reference counted pointer to the notifier, which is used to register the proxy for notifications. When a notification occurs, the notifier calls the *new_notification* method on the proxy, passing the type of the notification. The proxy stores a reference counted pointer to the notifier, ensuring that there are never any dangling pointers in the system.

The class *Listener<Interface>* provides base class for listener proxy objects. A notifier should provide a class which inherits from this base. To use this base class, implement a class, here called *Interface*, which defines a type *Interface::Notification_type* and a type *Interface::Notifier_handle*.

The *Notification_type* is generally an enum with one value for each type of notification which can be used.

The *Notifier_handle* is the type of a (ref counted) pointer to the object providing the notifications. The ref counter pointer must provide a nested type *Pointer* which is the type of a raw pointer.

The *Listener<Interface>* maintains a ref counted pointer to the object performing notifications. It is registered for notifications on construction and unregistered on destruction using the function *set_listener(Listener< Interface>*)* on the object providing the notifications. The use of ref counted pointers means that as long as the notification object exists, the object providing the notifications must exist, ensuring that the object providing the notifications is not prematurely destroyed.

These objects cannot be copied since the notifier only support one listener. If copying and more than one listener are desired, the *Multi_listener<Interface>* base class should be used instead.

As a side note, Boost provides a similar functionality in the Boost.Signal package. However, it is quite a bit more complex (and flexible). This complexity add significantly to compile time and (although I did not test this directly), I suspect it is much slower at runtime due to the overhead of worrying about signal orders and not supporting single signals. In addition, it does not get on well with Qt due to collisions with the Qt moc keywords.

There is also the TinyTL library which implements signals. As of writing it did not have any easy support for making sure all pointers are valid, so it did not seem to offer significant code saving over writing my own.

#include <CGAL/Kinetic/Listener.h>

Types

Listener<Interface>:: Notifier_handle	This type is inherited from the *Interface* template argument. It is a reference counted pointer type for the object providing notifications.
Listener<Interface>:: Notification_type	The type (usually an enum) used to distinguish different types of notifications. This is inherited from the *Interface* template argument.

Creation

Listener<Interface> l(Notifier_handle np);

The *Listener<Interface>* subscribes to events coming from the notifier and stores a pointer to the notifier.

Operations

Notifier_handle *l.notifier()*

Return a pointer to the notifier.

virtual void *l.new_notification(Notification_type)*

This method is pure virtual. A class which wishes to receive events must inherit from this class and implement this method. The method will then be called whenever there is a notification.

See Also

Multi_listener<Interface>.

Example

Here is a simplier class that provides notifications:

```
struct Notifier: public CGAL::Kinetic::Ref_counted<Notifier>
{
public:
  Notifier(): data_(0), listener_(NULL){}

  struct Listener_interface
  {
  public:
    typedef enum Notification_type {DATA_CHANGED} Notification_type;
    typedef Notifier::Handle Notifier_handle;
  };

  typedef CGAL::Kinetic::Listener<Listener_interface> Listener;
  friend class CGAL::Kinetic::Listener<Listener_interface>;

  void set_data(int d) {
    data_=d;
    if (listener_ != NULL)
   listener_->new_notification(Listener_interface::DATA_CHANGED);
  }

protected:
  void set_listener(Listener *l) {
    listener_= l;
  }
  Listener* listener() const {return listener_;}
```

```
  int data_;
  Listener *listener_;
};
```

Now the listener:

```
struct My_listener: public Notifier::Listener, public
    CGAL::Kinetic::Ref_counted<My_listener>
{
  typedef Notifier::Listener::Notifier_handle PP;
  My_listener(PP p): P(p){}

  void new_notification(P::Notification_type nt) {
    ...
  }
};
```

CGAL::Multi_listener<Interface>

Class

Definition

The class *Multi_listener<Interface>* implements a base class for listeners where more than one listener is allowed to subscribe to a notifier. See *Listener* for full documentation. This uses the function calls *new_listener()* and *delete_listener()* to register and unrester the listener (instead of *set_listener()*).

#include <CGAL/Kinetic/Multi_listener.h>

See Also

Listener<Interface>.

Class

CGAL::Ref_counted<T>

Definition

The class *Ref_counted<T>* implements a base class for objects which are reference counted. To use it simply inherit from *Ref_counted<T>* (passing the type to be reference counted as the template argument) and then access the object through *Handle* objects rather than bare C++ pointers.

#include <CGAL/Kinetic/Ref_counted.h>

Types

Ref_counted<T>:: Handle	A reference counted pointer to an Object.
Ref_counted<T>:: Const_handle	A const reference counted pointer to an Object.

Creation

Ref_counted<T> rc;	default constructor.

Operations

There are no methods which should be called by users of this class.

Kinetic::RootStack

Concept

Definition

The concept Kinetic::RootStack enumerates through roots of a function contained in a half open interval [lb. . . ub).

Types

Kinetic::RootStack:: Root	The root of a function.
Kinetic::RootStack:: Traits	The traits class for this concept.

Creation

Kinetic::RootStack re; — default constructor.

Kinetic::RootStack re(Function f, Root lb, Root ub, Traits tr);

Construct a Kinetic::RootStack over the roots of *f* in the half open interval [*lb* to *ub*).

Operations

void	*re.pop()*	Advance to the next root. As a precondition, empty() must be false.
Root	*re.top()*	Return the current root. As a precondition, empty() must be false. Note that the *Root* returned might not actually be in the interval (since the solver has not yet proved that there are no more roots).
bool	*re.empty()*	Return true if there are known to be no more roots left. There might not actually be any roots of the polynomial left in the interval, but the work necessary to prove this has been delayed.

See Also

Kinetic::FunctionKernel, *Kinetic::Certificate*.

Concept

Kinetic::SimulationTraits

Definition

This concept ties together the parts needed in order to run a kinetic data structure. We provide several models of this concept:

- *Kinetic::Exact_simulation_traits*
- *Kinetic::Inexact_simulation_traits*
- *Kinetic::Regular_triangulation_exact_simulation_traits*
- *Kinetic::Regular_triangulation_inexact_simulation_traits*

All support trajectories defined by polynomial coordinates. The *Exact* vs *Inexect* picks whether the roots of the certificate functions are compared exactly or approximated numerically. The regular triangulation models have weighted points of the appropriate dimension as the primitive used in the *Kinetic::InstantaneousKernel* and the *Kinetic::ActiveObjectsTable*.

Types

Kinetic::SimulationTraits:: NT — The number type used for representation.

Kinetic::SimulationTraits:: Instantaneous_kernel

A model of *Kinetic::InstantaneousKernel* which can be used to apply static CGAL data structures to snapshots of moving data.

Kinetic::SimulationTraits:: Kinetic_kernel — A model of *Kinetic::Kernel*.

Kinetic::SimulationTraits:: Function_kernel — A model of *Kinetic::FunctionKernel*.

Kinetic::SimulationTraits:: Active_points_[123]_table

A model of *Kinetic::ActiveObjectsTable* which holds the relevant kinetic primitives.

Kinetic::SimulationTraits:: Simulator — A model of *Kinetic::Simulator* which will be used by all the kinetic data structures.

Operations

Instantaneous_kernel *st.instantaneous_kernel_object()*

Get a new instantaneous kernel.

Kinetic_kernel *st.kinetic_kernel_object()*

Get a new kinetic kernel.

Function_kernel *st.function_kernel_object()*

Get a new function kernel.

Simulator::Handle *st.simulator_handle()* Return a pointer to the *Kinetic::Simulator* which is to be used in the simulation.

Active_points_[123]_table::Handle

st.active_points_[123]_table_handle()

Return a pointer to the *Kinetic::ActiveObjectsTable* which is to be used in the simulation.

Has Models

Kinetic::Exact_simulation_traits, *Kinetic::Inexact_simulation_traits*, *Kinetic::Regular_triangulation_exact_simulation_traits*, *Kinetic::Regular_triangulation_inexact_simulation_traits*

Example

The simulation traits class is simply there for convenience in order to bundle a set of related typedefs and create a few objects. As a resulting, creating your own requires little though, and just copying and changing a few lines. An example is below which sets up to use the CORE Sturm sequences to solve polynomials rather than our own (faster) solvers. It can be found in examples/Kinetic_framework/defining_a_simulation_traits.cpp.

```
#include <CGAL/Polynomial/Sturm_root_stack_traits.h>
#include <CGAL/Polynomial/Sturm_root_stack.h>
#include <CGAL/Kinetic/Active_objects_vector.h>
#include <CGAL/Kinetic/Default_instantaneous_kernel.h>
#include <CGAL/Kinetic/Cartesian.h>
#include <CGAL/Kinetic/Handle_degeneracy_function_kernel.h>
#include <CGAL/Kinetic/Default_simulator.h>
#include <CGAL/Kinetic/Two_list_pointer_event_queue.h>
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>

using namespace CGAL::Kinetic;

struct My_simulation_traits {
  typedef My_simulation_traits This;

  typedef CGAL::Exact_predicates_exact_constructions_kernel
   Static_kernel;
  //typedef
   CGAL::Regular_triangulation_euclidean_traits_3<Static_kernel_base>
   Static_kernel;
  typedef CGAL::POLYNOMIAL::Polynomial<Static_kernel::FT> Function;
  typedef CGAL::POLYNOMIAL::Sturm_root_stack_traits<Function>
   Root_stack_traits;
  typedef CGAL::POLYNOMIAL::Sturm_root_stack<Root_stack_traits>
   Root_stack;
  typedef CGAL::POLYNOMIAL::Kernel<Function, Root_stack> Function_kernel;

  typedef
   CGAL::Kinetic::Handle_degeneracy_function_kernel<Function_kernel,
   false>  Simulator_function_kernel_base;
  struct Simulator_function_kernel: public
   Simulator_function_kernel_base{};

  typedef Cartesian<Simulator_function_kernel> Kinetic_kernel;
  typedef Two_list_pointer_event_queue<Function_kernel> Event_queue;
  typedef Default_simulator<Simulator_function_kernel, Event_queue >
   Simulator;

  typedef Active_objects_vector<Kinetic_kernel::Point_1>
   Active_points_1_table;
  typedef Active_objects_vector<Kinetic_kernel::Point_2>
   Active_points_2_table;
  typedef Active_objects_vector<Kinetic_kernel::Point_3>
   Active_points_3_table;
  // typedef Active_objects_vector<Kinetic_kernel::Weighted_point_3>
   Active_weighted_points_3_table;
```

```
  typedef Default_instantaneous_kernel<This> Instantaneous_kernel;

  Active_points_1_table* active_points_1_table_handle() const { return
    ap1_.get();}
  Active_points_2_table* active_points_2_table_handle() const {return
    ap2_.get();}
  Active_points_3_table* active_points_3_table_handle() const {return
    ap3_.get();}
  //Active_weighted_points_3_table*
    active_weighted_points_3_table_handle() const {return awp3_.get();}

  Simulator* simulator_handle() const { return sim_.get();}
  const Static_kernel& static_kernel_object() const {return k_;}
  const Kinetic_kernel& kinetic_kernel_object() const {return kk_;}

  Instantaneous_kernel instantaneous_kernel_object() const {
    return Instantaneous_kernel(*this);
  }

  My_simulation_traits(const Simulator::Time &lb,
                       const Simulator::Time &ub): sim_(new
    Simulator(lb, ub)),
                                                   ap1_(new
    Active_points_1_table()),
                                                   ap2_(new
    Active_points_2_table()),
                                                   ap3_(new
    Active_points_3_table())
                                                   //awp3_(new
    Active_weighted_points_3_table())
{}

  bool is_exact() const {
    return true;
  }
protected:
  Simulator::Handle sim_;
  Active_points_1_table::Handle ap1_;
  Active_points_2_table::Handle ap2_;
  Active_points_3_table::Handle ap3_;
  //Active_weighted_points_3_table::Handle awp3_;
  Static_kernel k_;
  Kinetic_kernel kk_;
  Function_kernel fk_;
};

#endif
```

Class

CGAL::Kinetic::Default_simulator<FunctionKernel, EventQueue>

Definition

The class *Kinetic::Default_simulator<FunctionKernel, EventQueue>* controls kinetic data structures by maintaining a concept of time and ensuring that events are processed when necessary.

#include <CGAL/Kinetic/Default_simulator.h>

Is Model for the Concepts

Kinetic::Simulator.

Creation

Kinetic::Default_simulator<FunctionKernel, EventQueue> sim(const Time start=Time(0), const Time end= Time::infinity())

Construct a *Kinetic::Default_simulator<FunctionKernel, EventQueue>* which will process events between times start and end (events outside this window will be discarded).

CGAL::Kinetic::Simulator_listener<Listener, KDS>

Class

Definition

The class *Kinetic::Simulator_listener<Listener, KDS>* acts as a helper class for kinetic data structures which want to respond to *Simulator::Listener::HAS_AUDIT_TIME* notifications. When kinetic data structures can audit themselves, the *Kinetic::Simulator_listener<Listener, KDS>* calls the *audit()* method on the kinetic data structure.

#include <CGAL/Kinetic/listeners.h>

Creation

*Kinetic::Simulator_listener<Listener, KDS> a(Simulator::Handle, KDS *kds);*

default constructor.

See Also

Kinetic::Simulator, *Listener<Interface>*.

CGAL::Kinetic::Simulator_objects_listener<Simulator_listener, KDS>

Definition

The class *Kinetic::Simulator_objects_listener<Simulator_listener, KDS>* is a helper for classes which wish to react to *Simulator::Listener::DIRECTION_OF_TIME* notifications. The helper object translates such notifications *reverse_time* function calls on the responder. See *Kinetic::Qt_moving_points_2* for a simple example of using this helper function.

#include <CGAL/Kinetic/Simulator_objects_listener.h>

Creation

Kinetic::Simulator_objects_listener<Simulator_listener, KDS> a(Simulator::Handle, KDS);*

default constructor.

See Also

Kinetic::Listener.

Kinetic::Simulator

Definition

The class Kinetic::Simulator controls kinetic data structures by maintaining a the current time and ensuring that events are processed when necessary.

In addition, the Kinetic::Simulator can call on the kinetic data structures to audit themselves at appropriate times. When the last event processed and the next to be processed have different times, then there is a rational value of time at which all kinetic data structures should be non-degenerate (since there are no events at that time). At such a time, kinetic data structures can easily verify their correctness by checking that all the certificate predicates have the correct value. When exactness checks are enabled, whenever the last event processed and the next event to be processed have different times, a *Kinetic::Simulator::Listener::HAS_AUDIT_TIME* notification is made. Kinetic data structures can listen for that event, and when it is made, they can call *Kinetic::Simulator::audit_time()* to get the time value and then verify that their structure is correct.

In addition, at such a time, the *Event::audit(Key)* is called on each event. This allows kinetic data structures to check that the event should be in the queue.

Typically, the simulator is created by the Kinetic:SimulationTraits class and kinetic data structures request a handle to it from there.

Events that occur at or after *Kinetic::Simulator::end_time()* will may not be processed. The exception are events which are scheduled using the *new_final_event(Event)* call which are guaranteed to occur after all other events (but have no particular order amongst themselves).

Types

Kinetic::Simulator:: Function_kernel	The type of the function kernel used to instantiate this Kinetic::Simulator.
Kinetic::Simulator:: Listener	Extend this base class to listen to notifications from this Kinetic::Simulator. There are two types of notifications: *HAS_AUDIT_TIME* and *DIRECTION_OF_TIME*. The first is made when kinetic data structures can perform an audit. The second is made when the direction of time is changed.
Kinetic::Simulator:: Time	The representation type for times in the simulator. It is *Function_kernel::Root_enumerator::Root*.
Kinetic::Simulator:: Event_key	The key to access scheduled *Event* in order to inspect or delete them.
Kinetic::Simulator:: NT	The basic number type used in computations.
Kinetic::Simulator:: Handle	A reference counted pointer to be used for storing references to the object.
Kinetic::Simulator:: Const_handle	A reference counted pointer to be used for storing references to the object.

Creation

Kinetic::Simulator sim(const Time start=Time(0), const Time end= Time::infinity());

Construct a Kinetic::Simulator which will process events between times start and end (events outside this window will be discarded).

Operations

Function_kernel *sim.function_kernel_object() const*

Access the *Function_kernel* object used by the Kinetic::Simulator.

Time *sim.current_time()* Return the current time.

void *sim.set_current_time(Time t)*

Set the current time to *t*, which cannot be less than *current_time*. Any events in the queue before time *t* are processed.

NT *sim.next_time_reprsentable_as_nt() const*

This function returns a time which can be represented using an instance of type *NT* which is shortly after the current time. You can then advance the current time to this one and act on the data structure using the return nt.

bool *sim.has_current_time_as_nt() const*

Return true if there is a rational number which is equivalent to the current time. Equivalent means that it has the same ordering relation to all previous and scheduled events.

bool *sim.has_audit_time() const*

Returns true if the current time is a rational number and there are no events at the current time. This means that the simulation can be audited at this time.

Time *sim.next_event_time() const*

Return the time of the next event in the queue.

Time *sim.end_time() const* Return the time the simulation will end. If time is running backwards, then this returns *Time::infinity()*.

void *sim.set_interval(Time t_cur, Time t_end)*

Set the current time to t_{cur} and the end time to t_{end}. The event queue must be empty. Use this method if you want to reset or extend the simulation.

template <class Event>
Event_key *sim.new_event(Time t, const Event event)*

Schedule a new event at time *t*. The object *event* must implement the concept *Event*. The *Event_key* returned can be used to access or deschedule the event.

template <class Event>
Event_key *sim.new_final_event(const Event event)*

Schedule a new event that will occur at the end of the simulation. This type of event is useful if, for example, you want to run for a while, change all motions, and then run some more.

Event_key *sim.null_event() const* This method returns an *Event_key* which is guaranteed never to be assigned to any real event. This is a very useful placeholder for events which are known never to occur (and allows data structures to differentiate between uninitialized and never failing).

void *sim.audit_event(Event_key) const*

Performs some checks as to whether the key corresponds to a valid event. Generally, a event is valid if it is not defaultly constructed and either is in the queue or is the *null_event()*.

bool *sim.empty() const* Return true if there are no more events.

void *sim.delete_event(const Event_key k)*

Remove the event referenced by *k* from the event queue.

template <class Ev>
typename Queue::Event_handle<Ev>::Handle

sim.event(const Event_key k, const Ev e) const

This method returns a pointer to an event, which can be used for recoving data, such as cached solvers, from that event. The second argument really shouldn't be there, but gcc seems to sometimes have issues if you try to specify the template value directly.

Time	*sim.event_time(Event_key k) const*	
		Return the time at which the event referenced by *k* occurs.
template <class Ev> *Event_key*	*sim.set_event(Event_key k, const Ev ev)*	
		Set the event referenced by key *k* to *ev*, for example if you want to change what happens when that event occurs. A new event key is returned.
Sign	*sim.direction_of_time() const*	
		Return *POSITIVE* if time is running forwards or *NEGATIVE* if it is running backwards.
void	*sim.set_direction_of_time(Sign dir) const*	
		Set which direction time is running.
unsigned int	*sim.current_event_number() const*	
		Return the number of events which have been processed.
void	*sim.set_current_event_number(unsigned int i) const*	
		Process all events up to the ith event. *i* cannot be less than *current_event_number*.

Kinetic::Simulator_objects_listener<Simulator_listener, KDS>, *Kinetic::Simulator_kds_listener<Simulator_listener, KDS>*.

Has Models

Kinetic::Default_simulator<FunctionKernel, EventQueue>

Kinetic::Simulator::Time

Concept

Definition

The concept represents time in the simulator.

Time a(NT); Construct an instance of time from a number type, where NT is the number type used in the simulation.

Operations

std::ostream& *std::ostream& << Time*

Write it to a stream.

double *to_double(Time)*

Return a double approximation of the time value.

std::pair<double, double>

to_interval(Time)

Return an interval containing the time value.

Comparisons with other *Kinetic::Simulator::Time* objects are supported.

Has Models

double, *Kinetic::FunctionKernel::Root*

Chapter 73

STL Extensions for CGAL

Michael Hoffmann, Lutz Kettner, Sylvain Pion, and Ron Wein

Contents

CGAL is designed in the spirit of the generic programming paradigm to work together with the Standard Template Library (STL) [C++98, Aus98]. This chapter documents non-geometric STL-like components that are not provided in the STL standard but in CGAL: a doubly-connected list managing items in place (where inserted items are not copied), a compact container, a multi-set class that uses three-valued comparisons and offers additional functionality, generic algorithms, iterators, functor adaptors for binding and swapping arguments and for composition, functors for projection and creation and adaptor classes around iterators and circulators. See also circulators in Chapter 76. A class storing polymorphic objects is also provided, as well as a class to manage the uncertainty of some values. Finally, tags and policy classes to specify complexity trade-offs of data-structures, and a class which helps specifying that the default types in template parameter lists are desired is also provided.

73.1 Doubly-Connected List Managing Items in Place

The class *In_place_list<T,bool>* manages a sequence of items in place in a doubly-connected list. Its goals are the flexible handling of memory management and performance optimization. The item type has to provide the two necessary pointers `&`*T::next_link* and `&`*T::prev_link*. One possibility to obtain these pointers is to inherit them from the base class *In_place_list_base<T>*.

The class *In_place_list<T,bool>* is a container quite similar to STL containers, with the advantage that it is able to handle the stored elements by reference instead of copying them. It is possible to delete an element only knowing its address and no iterator to it. This used to simplify mutually pointed data structures like a halfedge data structure for planar maps or polyhedral surfaces (the current design does not need this anymore). The usual iterators are also available.

73.2 Compact Container

The class *Compact_container<T, Allocator>* is an STL like container which provides a very compact storage for its elements. It achieves this goal by requiring *T* to provide access to a pointer in it, which is going to be used by *Compact_container<T, Allocator>* for its internal management. The traits class *Compact_container_traits< T>* specifies the way to access that pointer. The class *Compact_container_base* can be used as a base class to provide the pointer, although in this case you do not get the most compact representation. The values that this pointer can have during valid use of the object are valid pointer values to 4 bytes aligned objects (i.e., the two least significant bits of the pointer need to be zero when the object is constructed). Another interesting property of this container is that iterators are not invalidated during *insert* or *erase* operations.

The main deviation from the STL container concept is that the ++ and -- operators of the iterator do not have a constant time complexity in all cases. The actual complexity is related to the maximum size that the container has had during its life time compared to its current size, because the iterator has to go over the "erased" elements as well, so the bad case is when the container used to contain lots of elements, but now has far less. In this case, we suggest to do a copy of the container in order to "defragment" the internal representation.

This container has been developed in order to efficiently handle large data structures like the triangulation and halfedge data structures. It can probably be useful for other kinds of graphs as well.

73.3 Multiset with Extended Functionality

The class *Multiset<Type,Compare,Allocator>* represents a multi-set of elements of type *Type*, represented as a red-black tree (see [CLRS01, Chapter 13] for an excellent introduction to red-black trees). It differs from the STL's *multiset* class-template mainly due to the fact that it is parameterized by a comparison functor *Compare* that returns the three-valued *Comparison_result* (namely it returns either *SMALLER*, *EQUAL*, or *LARGER*), rather than a *less* functor returning *bool*. Thus, it is possible to maintain the underlying red-black tree with less invocations of the comparison functor, which can considerably decrease running times, especially when comparing elements of type *Type* is an expensive operation.

Multiset<Type,Compare,Allocator> also guarantees that the order of elements sent to the comparison functor is fixed. For example, if we insert a new element *x* into the set (or erase an element from the set), then we always invoke *Compare() (x, y)* (and never *Compare() (y, x)*), where *y* is an element already stored in the set. This behavior, not supported by *std::multiset*, is sometimes crucial for designing more efficient comparison predicates.

The interface of *Multiset<Type,Compare,Allocator>* is in general derived from *std::multiset*. However, it extends the interface by offering some additional operations, such as: inserting of an element into the set given its *exact* position (and not just using an insertion hint); looking up keys whose type may differ from *Type*, as long as users supply a comparison functor *CompareKey*, between the keys and set elements; and catenating and splitting sets.

73.4 Polymorphic Object

The class *Object* can store an object of whatever other type. It can be used by a function to return objects of different types. A mechanism to extract the stored object based on its type is also provided. This class is similar to *boost::any*.

73.5 Uncertainty Management

The class *Uncertain*<*T*> represents a range of values of type *T*. *T* is allowed to stand for *bool*, or CGAL's enumeration types *Sign*, *Comparison_result*, *Orientation*, *Oriented_side*, *Bounded_side* and *Angle*.

The idea is that sometimes you are not sure of the result of a function, and you would like to communicate that to the caller. *Uncertain*<*T*> allows just that. It also provides functions to naturally extend the Boolean operations for *Uncertain*<*bool*> for example.

Uncertain<*T*> is used in CGAL as the return type of geometric predicates when the number type used is interval arithmetic like *Interval_nt*. End users typically do not see it as it is hidden in the implementation of the filtered predicates provided by the various filtered kernels, but it is important that providers of predicates that are meant to be filtered by *Filtered_predicate*, know about it.

It can also be used in other contexts as well, as it is a general tool.

73.6 Complexity tags and policies

Some data structures and algorithms can be implemented with different complexity trade-offs between memory usage and time complexity. CGAL provides the tags *Fast* and *Compact* which can be used to select between those variants. For example, the *Location_policy* class is parameterized by these tags and allows to specify the complexity of point location (currently in *Delaunay_triangulation_3* only). Convenient typedefs *Fast_location* and *Compact_location* are also provided.

73.7 Default Arguments in Template Parameter Lists

In C++, it is possible to specify defaults at the end of a template parameter list. Specifying that one wishes to use the default is simply done by omitting it. This is however possible only at the end of the list. *CGAL::Default* provides a simple mechanism that performs something equivalent anywhere in the sequence.

73.8 C++ 11 wrappers

Wrappers for the classes *array* and *tuple* which, based on availability, either use the version of *Boost* or the one provided by the standard library are provided in the namespace *CGAL::cpp11*. The namespace alias *CGAL::cpp0x* is provided for backward compatibility. Those are documented for completeness and implementers. They are not intended to be used by users of the library.

Class

CGAL::In_place_list_base<T>

Definition

The node base classes provides pointers to build linked lists. The class *In_place_sl_list_base<T>* provides a pointer *next_link* for a single linked list. The class *In_place_list_base<T>* provides an additional pointer *prev_link* for doubly linked lists. These names conform to the default parameters used in the template argument lists of the container classes. The pointers are public members.

#include <CGAL/In_place_list.h>

Variables

*T**	*next_link;*	forward pointer
*T**	*prev_link;*	backward pointer

Class

CGAL::In_place_list<T,bool>

Definition

An object of the class *In_place_list<T,bool>* represents a sequence of items of type *T* that supports bidirectional iterators and allows constant time insert and erase operations anywhere within the sequence. The functionality is similar to the *list<T>* in the STL.

The *In_place_list<T,bool>* manages the items in place, i.e., inserted items are not copied. Two pointers of type *T** are expected to be reserved in *T* for the list management. The base class *In_place_list_base<T>* can be used to obtain such pointers.

The *In_place_list<T,bool>* does not copy element items during insertion (unless otherwise stated for a function). On removal of an item or destruction of the list the items are not deleted by default. The second template parameter *bool* is set to *false* in this case. If the *In_place_list<T,bool>* should take the responsibility for the stored objects the *bool* parameter could be set to *true*, in which case the list will delete removed items and will delete all remaining items on destruction. In any case, the *destroy()* member function deletes all items. Note that these two possible versions of *In_place_list<T,bool>* are not assignable to each other to avoid confusions between the different storage responsibilities.

#include <CGAL/In_place_list.h>

Parameters

The full class name is *In_place_list<T, bool managed = false, class Alloc = CGAL_ALLOCATOR(T)>*.

The parameter *T* is supposed to have a default constructor, a copy constructor and an assignment operator. The copy constructor and the assignment may copy the pointers in *T* for the list management, but they do not have to. The equality test and the relational order require the operators == and < for *T* respectively. These operators must not compare the pointers in *T*.

Types

In_place_list<T,bool>:: iterator
In_place_list<T,bool>:: const_iterator

In_place_list<T,bool>:: value_type
In_place_list<T,bool>:: reference
In_place_list<T,bool>:: const_reference
In_place_list<T,bool>:: size_type
In_place_list<T,bool>:: difference_type

In_place_list<T,bool>:: reverse_iterator
In_place_list<T,bool>:: const_reverse_iterator

In_place_list<T,bool>:: allocator_type

Creation

In_place_list<T,bool> l; — introduces an empty list.

In_place_list<T,bool> l(list<T> l1); — copy constructor. Each item in *l1* is copied.

In_place_list<T,bool> l(size_type n, T t = T());

introduces a list with n items, all initialized with copies of t.

template <class InputIterator>
In_place_list<T,bool> l(InputIterator first, InputIterator last);

a list with copies from the range [*first,last*).

In_place_list<T,bool> l(const T first, const T* last);*

non-member-template version.

In_place_list<T,bool> &	$l = l1$	assignment. Each item in *l1* is copied. Each item in *l* is deleted if the *bool* parameter is *true*.
void	*l.swap(l1)*	swaps the contents of *l* with *l1*.
void	*l.destroy()*	all items in *l* are deleted regardless of the *bool* parameter.

Comparison Operations

bool	$l == l1$	test for equality: Two lists are equal, iff they have the same size and if their corresponding elements are equal.
bool	$l < l1$	compares in lexicographical order.

Access Member Functions

iterator	*l.begin()*	returns a mutable iterator referring to the first element in *l*.
const_iterator	*l.begin() const*	returns a constant iterator referring to the first element in *l*.
iterator	*l.end()*	returns a mutable iterator which is the past-end-value of *l*.
const_iterator	*l.end() const*	returns a constant iterator which is the past-end-value of *l*.
bool	*l.empty()*	returns *true* if *l* is empty.
size_type	*l.size()*	returns the number of items in list *l*.
size_type	*l.max_size()*	returns the maximum possible size of the list *l*.
T&	*l.front()*	returns the first item in list *l*.
T&	*l.back()*	returns the last item in list *l*.

allocator_type

	l.get_allocator()	returns the allocator.

Insertion

void	*l.push_front(T&)*	inserts an item in front of list *l*.
void	*l.push_back(T&)*	inserts an item at the back of list *l*.

iterator	*l.insert(iterator pos, T& t)*	
iterator	*l.insert(T* pos, T& t)*	inserts *t* in front of *pos*. The return value points to the inserted item.

void *l.insert(iterator pos, size_type n, T t = T())*
void *l.insert(T* pos, size_type n, T t = T())*

inserts *n* copies of *t* in front of *pos*.

template <class InputIterator>
void *l.insert(iterator pos, InputIterator first, InputIterator last)*

template <class InputIterator>
void *l.insert(T* pos, InputIterator first, InputIterator last)*

inserts the range [*first, last*) in front of iterator *pos*.

As long as member templates are not supported, member functions using *T** instead of the general *InputIterator* are provided.

Removal

void	*l.pop_front()*	removes the first item from list *l*.
void	*l.pop_back()*	removes the last item from list *l*.
void	*l.erase(iterator pos)*	removes the item from list *l*, where *pos* refers to.
void	*l.erase(T* pos)*	removes the item from list *l*, where *pos* refers to.

void *l.erase(iterator first, iterator last)*
void *l.erase(T* first, T* last)*

removes the items in the range [*first, last*) from *l*.

Special List Operations

void	*l.splice(iterator pos, & x)*	
void	*l.splice(T* pos, & x)*	inserts the list *x* before position *pos* and *x* becomes empty. It takes constant time. *Precondition*: & *l*!= &*x*.

void *l.splice(iterator pos, & x, iterator i)* *void* *l.splice(T* pos, & x, T* i)*

inserts an element pointed to by i from list x before position *pos* and removes the element from x. It takes constant time. i is a valid dereferenceable iterator of x. The result is unchanged if $pos == i$ or $pos == ++i$.

void *l.splice(iterator pos, & x, iterator first, iterator last)*
void *l.splice(T* pos, & x, T* first, T* last)*

inserts elements in the range [*first, last*) before position *pos* and removes the elements from x. It takes constant time if $\&x == \&l$; otherwise, it takes linear time. [*first, last*) is a valid range in x.
Precondition: *pos* is not in the range [*first, last*).

void *l.remove(T value)* erases all elements e in the list l for which $e == value$. It is stable.
Precondition: a suitable *operator*== for the type T.

void *l.unique()* erases all but the first element from every consecutive group of equal elements in the list l.
Precondition: a suitable *operator*== for the type T.

void *l.merge(& x)* merges the list x into the list l and x becomes empty. It is stable.
Precondition: Both lists are increasingly sorted. A suitable *operator*< for the type T.

void *l.reverse()* reverses the order of the elements in l in linear time.

void *l.sort()* sorts the list l according to the *operator*< in time $O(n \log n)$ where n = *size()*. It is stable.
Precondition: a suitable *operator*< for the type T.

Example

```
#include <cassert>
#include <algorithm>
#include <CGAL/In_place_list.h>

using CGAL::In_place_list_base;

struct item : public In_place_list_base<item> {
    int key;
    item() {}
    item( const item& i) : In_place_list_base<item>(i), key(i.key) {}
    item( int i) : key(i) {}
    bool operator== (const item& i) const { return key == i.key;}
    bool operator!= (const item& i) const { return ! (*this == i);}
    bool operator== (int i) const         { return key == i;}
    bool operator!= (int i) const         { return ! (*this == i);}
    bool operator<  (const item& i) const { return key < i.key;}
};

int main() {
    typedef CGAL::In_place_list<item,true> List;
    List l;
    item* p = new item(1);
    l.push_back(*p);
    l.push_back(*new item(2));
    l.push_front(*new item(3));
    l.push_front(*new item(4));
    l.push_front(*new item(2));
    List::iterator i = l.begin();
    ++i;
    l.insert(i, *new item(5));
    l.insert(p, *new item(5));
    int a[7] = {2,5,4,3,5,1,2};
    bool ok = std::equal(l.begin(), l.end(), a);
    assert(ok);
    l.sort();
    l.unique();
    assert(l.size() == 5);
    int b[5] = {1,2,3,4,5};
    ok = std::equal(l.begin(), l.end(), b);
    assert(ok);
    return 0;
}
```

CGAL::Compact_container_base

Class

Definition

The class *Compact_container_base* can be used as a base class for your own type *T*, so that *T* can be used directly within *Compact_container<T, Allocator>*. This class stores a *void* * pointer only for this purpose, so it may not be the most memory efficient way to achieve this goal. The other ways are to provide in *T* the necessary member functions so that the template *Compact_container_traits<T>* works, or to specialize it for the particular type *T* that you want to use.

#include <CGAL/Compact_container.h>

Operations

*void**	*ccb.for_compact_container() const*	Returns the pointer necessary for *Compact_container_traits<T>*.
*void**&	*ccb.for_compact_container()*	Returns a reference to the pointer necessary for *Compact_container_traits<T>*.

Class

CGAL::Compact_container_traits<T>

Definition

The traits class *Compact_container_traits<T>* provides the way to access the internal pointer required for *T* to be used in a *Compact_container<T, Allocator>*. Note that this pointer needs to be accessible even when the object is not constructed, which means it has to reside in the same memory place as *T*.

You can specialize this class for your own type *T* if the default template is not suitable.

You can also use *Compact_container_base* as base class for your own types *T* to make them usable with the default *Compact_container_traits<T>*.

#include <CGAL/Compact_container.h>

Parameters

T is any type providing the following member functions:
*void * t.for_compact_container() const;*
*void *& t.for_compact_container();*.

Operations

*static void**	*cct.pointer(const T &t)*	Returns the pointer hold by *t*. The template version defines this function as: *return t.for_compact_container();*
static void&*	*cct.pointer(T &t)*	Returns a reference to the pointer hold by *t*. The template version defines this function as: *return t.for_compact_container();*

CGAL::Compact_container<T, Allocator>

Class

Definition

An object of the class *Compact_container<T, Allocator>* is a container of objects of type T. It matches all the standard requirements for reversible containers, except that the complexity of its iterator increment and decrement operations is not always guaranteed to be amortized constant time.

This container is not a standard *sequence* nor *associative* container, which means the elements are stored in no particular order, and it is not possible to specify a particular place in the iterator sequence where to insert new objects. However, all dereferenceable iterators are still valid after calls to *insert()* and *erase()*, except those that have been erased (it behaves similarly to *std::list*).

The main feature of this container is that it is very memory efficient : its memory size is *N*sizeof(T)+o(N)*, where N is the maximum size that the container has had in its past history, its *capacity()* (the memory of erased elements is not deallocated until destruction of the container or a call to *clear()*). This container has been developed in order to store large graph-like data structures like the triangulation and the halfedge data structures.

It supports bidirectional iterators and allows a constant time amortized *insert()* operation. You cannot specify where to insert new objects (i.e. you don't know where they will end up in the iterator sequence, although *insert()* returns an iterator pointing to the newly inserted object). You can erase any element with a constant time complexity.

Summary of the differences with *std::list* : it is more compact in memory since it doesn't store two additional pointers for the iterator needs. It doesn't deallocate elements until the destruction or *clear()* of the container. The iterator does not have constant amortized time complexity for the increment and decrement operations in all cases, only when not too many elements have not been freed (i.e. when the *size()* is close to the *capacity()*). Iterating from *begin()* to *end()* takes *O(capacity())* time, not *size()*. In the case where the container has a small *size()* compared to its *capacity()*, we advise to "defragment the memory" by copying the container if the iterator performance is needed.

The iterators themselves can be used as T, they provide the necessary functions to be used by *Compact_container_traits<T>*. Moreover, they also provide a default constructor value which is not singular : it is copyable, comparable, and guaranteed to be unique under comparison (like *NULL* for pointers). This makes them suitable for use in geometric graphs like handles to vertices in triangulations.

In addition, in a way inspired from the Boost.Intrusive containers, it is possible to construct iterators from references to values in containers using the *iterator_to* and *s_iterator_to* functions.

#include <CGAL/Compact_container.h>

Parameters

The parameter T is required to have a copy constructor and an assignment operator. It also needs to provide access to an internal pointer via *Compact_container_traits<T>*.

The equality test and the relational order require the operators == and < for T respectively.

The parameter *Allocator* has to match the standard allocator requirements, with value type T. This parameter has the default value *CGAL_ALLOCATOR(T)*.

Types

Compact_container<T, Allocator>:: value_type
Compact_container<T, Allocator>:: reference
Compact_container<T, Allocator>:: const_reference
Compact_container<T, Allocator>:: pointer
Compact_container<T, Allocator>:: const_pointer
Compact_container<T, Allocator>:: size_type
Compact_container<T, Allocator>:: difference_type

Compact_container<T, Allocator>:: iterator
Compact_container<T, Allocator>:: const_iterator
Compact_container<T, Allocator>:: reverse_iterator
Compact_container<T, Allocator>:: const_reverse_iterator

Compact_container<T, Allocator>:: allocator_type

Creation

Compact_container<T, Allocator> c(Allocator a = Allocator());

introduces an empty container, eventually specifying a particular allocator *a* as well.

template <class InputIterator>
Compact_container<T, Allocator> c(InputIterator first, InputIterator last, Allocator a = Allocator());

a container with copies from the range [*first,last*), eventually specifying a particular allocator.

Compact_container<T, Allocator> c(cc);

copy constructor. Each item in *cc* is copied. The allocator is copied. The iterator order is preserved.

Compact_container<T, Allocator> & $c = cc$

assignment. Each item in *cc* is copied. The allocator is copied. Each item in *c* is deleted. The iterator order is preserved.

void *c.swap(&cc)*

swaps the contents of *c* and *cc* in constant time complexity. No exception is thrown.

void *c.reserve(size_type value)*

if *value* is less than or equal to *capacity()*, this call has no effect. Otherwise, it is a request for allocation of additional memory so that then *capacity()* is greater than or equal to value. *size()* is unchanged.

Access Member Functions

iterator	*c.begin()*	returns a mutable iterator referring to the first element in *c*.
const_iterator	*c.begin() const*	returns a constant iterator referring to the first element in *c*.
iterator	*c.end()*	returns a mutable iterator which is the past-end-value of *c*.
const_iterator	*c.end() const*	returns a constant iterator which is the past-end-value of *c*.
reverse_iterator	*c.rbegin()*	
const_reverse_iterator	*c.rbegin() const*	
reverse_iterator	*c.rend()*	
const_reverse_iterator	*c.rend() const*	
iterator	*c.iterator_to(reference value) const*	returns an iterator which points to *value*;
const_iterator	*c.iterator_to(const_reference value) const*	returns an iterator which points to *value*;
static iterator	*c.s_iterator_to(reference value)*	returns an iterator which points to *value*;
static const_iterator	*c.s_iterator_to(const_reference value)*	returns an iterator which points to *value*;
bool	*c.empty()*	returns *true* iff *c* is empty.
size_type	*c.size()*	returns the number of items in *c*.
size_type	*c.max_size()*	returns the maximum possible size of the container *c*.
size_type	*c.capacity()*	returns the total number of elements that *c* can hold without requiring reallocation.
Allocator	*c.get_allocator()*	returns the allocator.

Insertion

iterator *c.insert(T t)*

inserts a copy of *t* in *c* and returns the iterator pointing to it.

template <class InputIterator>
void *c.insert(InputIterator first, InputIterator last)*

inserts the range [*first, last*) in *c*.

template <class InputIterator>
void *c.assign(InputIterator first, InputIterator last)*

erases all the elements of *c*, then inserts the range [*first, last*) in *c*.

template < class T1 >
iterator *c.emplace(T1 t1)*

constructs an object of type *T* with the constructor that takes *t1* as argument, inserts it in *c*, and returns the iterator pointing to it. Overloads of this member function are defined that take additional arguments, up to 9.

Removal

void *c.erase(iterator pos)*

removes the item pointed by *pos* from *c*.

void *c.erase(iterator first, iterator last)*

removes the items from the range [*first, last*) from *c*.

void *c.clear()* all items in *c* are deleted, and the memory is deallocated. After this call, *c* is in the same state as if just default constructed.

Ownership testing

The following functions are mostly helpful for efficient debugging, since their complexity is $O(\sqrt{c.capacity()})$.

bool *c.owns(const_iterator pos)*

returns whether *pos* is in the range [*c.begin()*, *c.end()*] (*c.end()* included).

bool *c.owns_dereferencable(const_iterator pos)*

returns whether *pos* is in the range [*c.begin()*, *c.end()*) (*c.end()* excluded).

Merging

void	*c.merge(&cc)*	adds the items of *cc* to the end of *c* and *cc* becomes empty. The time complexity is O(*c.capacity()*-*c.size()*). *Precondition*: *cc* must not be the same as *c*, and the allocators of *c* and *cc* need to be compatible : *c.get_allocator() == cc.get_allocator()*.

Comparison Operations

bool	$c == cc$	test for equality: Two containers are equal, iff they have the same size and if their corresponding elements are equal.
bool	$c\ != cc$	test for inequality: returns !(*c* == *cc*).
bool	$c < cc$	compares in lexicographical order.
bool	$c > cc$	returns *cc* < *c*.
bool	$c <= cc$	returns !(*c* > *cc*).
bool	$c >= cc$	returns !(*c* < *cc*).

Class

CGAL::Multiset<Type,Compare,Allocator>

Definition

An instance *s* of the parametrized data type *Multiset<Type,Compare,Allocator>* is a multi-set of elements of type *Type*, represented as a red-black tree (see [CLRS01, Chapter 13] for an excellent introduction to red-black trees). The main difference between *Multiset<Type,Compare,Allocator>* and STL's *multiset* is that the latter uses a less-than functor with a Boolean return type, while our *Multiset<Type,Compare,Allocator>* class is parameterized by a comparison functor *Compare* that returns the three-valued *Comparison_result* (namely it returns either *SMALLER*, *EQUAL*, or *LARGER*). It is thus possible to maintain the underlying red-black tree with less invocations of the comparison functor. This leads to a speedup of about 5% even if we maintain a set of integers. When each comparison of two elements of type *Type* is an expensive operation (for example, when they are geometric entities represented using exact arithmetic), the usage of a three-valued comparison functor can lead to considerable decrease in the running times.

Moreover, *Multiset<Type,Compare,Allocator>* allows the insertion of an element into the set given its *exact* position, and not just using an insertion hint, as done by *std::multiset*. This can further reduce the running times, as additional comparison operations can be avoided.

In addition, the *Multiset<Type,Compare,Allocator>* guarantees that the order of elements sent to the comparison functor is fixed. For example, if we insert a new element *x* into the set (or erase an element from the set), then we always invoke *Compare() (x, y)* (and never *Compare() (y, x)*), where *y* is an element already stored in the set. This behavior, not supported by *std::multiset*, is sometimes crucial for designing more efficient comparison predicates.

Multiset<Type,Compare,Allocator> also allows for look-up of keys whose type may differ from *Type*, as long as users supply a comparison functor *CompareKey*, where *CompareKey() (key, y)* returns the three-valued *Comparison_result* (*key* is the look-up key and *y* is an element of type *Type*). Indeed, it is very convenient to look-up equivalent objects in the set given just by their key. We note however that it is also possible to use a key of type *Type* and to employ the default *Compare* functor for the look-up, as done when using the *std::multiset* class.

advanced

Finally, *Multiset<Type,Compare,Allocator>* introduces the *catenate()* and *split()* functions. The first function operates on *s* and accepts a second set *s*', such that the maximum element in *s* is not greater than the minimal element in *s*', and concatenates *s*' to *s*. The second function splits *s* into two sets,one containing all the elements that are less than a given key, and the other contains all elements greater than (or equal to) this key.

advanced

Parameters

The *Multiset* class-template has three parameters:

- *Type* — the type of the stored elements.
- *Compare* — the comparison-functor type. This type should provide the following operator for comparing two *Type* elements, namely:
  Comparison_result operator() (const Type& t1, const Type& t2) const;
  The *CGAL::Compare<Type>* functor is used by default. In this case, *Type* must support an equality operator (*operator==*) and a less-than operator (*operator<*).

- *Allocator* — the allocator type.
  CGAL_ALLOCATOR is used by default.

#include <CGAL/Multiset.h>

Assertions

The assertion and precondition flags for the *Multiset* class use *MULTISET* in their names (i.e., *CGAL_MULTISET_NO_ASSERTIONS* and *CGAL_MULTISET_NO_PRECONDITIONS*).

Types

In compliance with STL, the types *value_type* and *key_type* (both equivalent to *Type*), *reference* and *const_reference* (reference to a value-type), *key_compare* and *value_compare* (both equivalent to *Compare*), *size_type* and *difference_type* are defined as well.

Multiset<Type,Compare,Allocator>:: iterator
Multiset<Type,Compare,Allocator>:: const_iterator

bi-directional iterators for the elements stored in the set.

Multiset<Type,Compare,Allocator>:: reverse_iterator
Multiset<Type,Compare,Allocator>:: const_reverse_iterator

reverse bi-directional iterators for the elements stored in the set.

Creation

Multiset<Type,Compare,Allocator> s; creates an an empty set *s* that uses a default comparison functor.

Multiset<Type,Compare,Allocator> s(Compare comp);

creates an an empty set *s* that uses the given comparison functor *comp*.

template <class InputIterator>
Multiset<Type,Compare,Allocator> s(InputIterator first, InputIterator last, Compare comp = Compare());

creates a set *s* containing all elements in the range *[first, last)*, that uses the comparison functor *comp*.

Multiset<Type,Compare,Allocator> s(other); copy constructor.

Multiset<Type,Compare,Allocator>

$s = other$ assignment operator.

void	*s.swap(& other)*	swaps the contents of *s* with those of the other set.

Access Member Functions

Compare	*s.key_comp() const*	the comparison functor used.
Compare	*s.value_comp() const*	the comparison functor used (same as above). Both functions have a non-const version that return a reference to the comparison functor.
bool	*s.empty()*	returns *true* if the set is empty, *false* otherwise.
size_t	*s.size()*	returns the number of elements stored in the set.
size_t	*s.max_size()*	returns the maximal number of elements the set can store (same as *size()*).
iterator	*s.begin()*	returns an iterator pointing to the first element stored in the set (a *const* version is also available).
iterator	*s.end()*	returns an iterator pointing beyond the last element stored in the set (a *const* version is also available).
reverse_iterator	*s.rbegin()*	returns a reverse iterator pointing beyond the last element stored in the set (a *const* version is also available).
reverse_iterator	*s.rend()*	returns a reverse iterator pointing to the first element stored in the set (a *const* version is also available).

Comparison Operations

bool	*s == other*	returns *true* if the sequences of elements in the two sets are pairwise equal (using the comparison functor).
bool	*s < other*	returns *true* if the element sequence in *s* is lexicographically smaller than the element sequence of *other*.

Insertion Methods

iterator	*s.insert(Type x)*	inserts the element *x* into the set and returns an iterator pointing to the newly inserted element.

template <class InputIterator>
void *s.insert(InputIterator first, InputIterator last)*

inserts all elements in the range *[first, last)* into the set.

iterator *s.insert(iterator position, Type x)*

inserts the element x with a given iterator used as a hint for the position of the new element. It Returns an iterator pointing to the newly inserted element.

iterator *s.insert_before(iterator position, Type x)*

inserts the element x as the predecessor of the element at the given position.
Precondition: The operation does not violate the set order — that is, x is not greater than the element pointed by *position* and not less than its current predecessor.

iterator *s.insert_after(iterator position, Type x)*

inserts the element x as the successor of the element at the given position.
Precondition: The operation does not violate the set order — that is, x is not less than the element pointed by *position* and not greater than its current successor.

Removal Methods

size_t *s.erase(Type x)* erases all elements equivalent to x from the set and returns the number of erased elements.

void *s.erase(iterator position)*

erases the element pointed by *position*.

void *s.clear()* clears the set (erases all stored elements).

Look-up Methods

All methods listed in this section can also accept a *Type* element as a look-up key. In this case, it is not necessary to supply a *CompareKey* functor, as the *Compare* functor will be used by default.

template <class Key, class CompareKey>
iterator *s.find(Key key, CompareKey comp_key)*

searches for the an element equivalent to *key* in the set. If the set contains objects equivalent to *key*, it returns an iterator pointing to the first one. Otherwise, *end()* is returned (a *const* version is also available).

template <class Key, class CompareKey>

size_t *s.count(Key key, CompareKey comp_key) const*

returns the number of elements equivalent to *key* in the set.

template <class Key, class CompareKey>
iterator *s.lower_bound(Key key, CompareKey comp_key)*

returns an iterator pointing to the first element in the set that is not less than *key*. If all set elements are less than *key*, *end()* is returned (a *const* version is also available).

template <class Key, class CompareKey>
iterator *s.upper_bound(Key key, CompareKey comp_key)*

returns an iterator pointing to the first element in the set that is greater than *key*. If no set element is greater than *key*, *end()* is returned (a *const* version is also available).

template <class Key, class CompareKey>
std::pair<iterator,iterator>

s.equal_range(Key key, CompareKey comp_key)

returns the range of set elements equivalent to the given key, namely *(lower_bound(key), upper_bound(key))* (a *const* version is also available).

template <class Key, class CompareKey>
std::pair<iterator,bool>

s.find_lower(Key key, CompareKey comp_key)

returns a pair comprised of *lower_bound(key)* and a Boolean flag indicating whether this iterator points to an element equivalent to the given key (a *const* version is also available).

advanced

Special Operations

void *s.replace(iterator position, Type x)*

replaces the element stored at the given position with *x*.
Precondition: The operation does not violate the set order — that is, *x* is not less that *position*'s predecessor and not greater than its successor.

void *s.swap(iterator pos1, iterator pos2)*

swaps places between the two elements given by *pos1* and *pos2*.
Precondition: The operation does not violate the set order — that is, *pos1* and *pos2* store equivalent elements.

void *s.catenate(Self& s_prime)*

concatenates all elements in *s_prime* into *s* and clears *s_prime*. All iterators to *s* and to *s_prime* remain valid.
Precondition: The maximal element in *s* is not greater than the minimal element in *s_prime*.

template <class Key, class CompareKey>
void *s.split(Key key, CompareKey comp_key, Self& s_prime)*

splits *s* such that it contains all elements that are less than the given *key* and such that *s_prime* contains all other elements.
Precondition: *s_prime* is initially empty.

void *s.split(iterator position, Self& s_prime)*

splits *s* such that it contains all set elements in the range *[begin, position)* and such that *s_prime* contains all elements in the range *[position, end())*.
Precondition: *s_prime* is initially empty.

advanced

Implementation

Multiset uses a proprietary implementation of a red-black tree data-structure. The red-black tree invariants guarantee that the height of a tree containing n elements is $O(\log n)$ (more precisely, it is bounded by $2\log_2 n$). As a consequence, all methods that accept an element and need to locate it in the tree (namely *insert(x)*, *erase(x)*, *find(x)*, *count(x)*, *lower_bound(x)* , *upper_bound(x)*, *find_lower(x)* and *equal_range(x)*) take $O(\log n)$ time and perform $O(\log n)$ comparison operations.

On the other hand, the set operations that accept a position iterator (namely *insert_before(pos, x)*, *insert_after(pos, x)* and *erase(pos)*) are much more efficient as they can be performed at a *constant* amortized cost (see [GS78] and [Tar83] for more details). More important, these set operations require *no* comparison operations. Therefore, it is highly recommended to maintain the set via iterators to the stored elements, whenever possible. The function *insert(pos, x)* is safer to use, but it takes amortized $O(\min\{d, \log n\})$ time, where d is the distance between the given position and the true position of x. In addition, it always performs at least two comparison operations.

advanced

The *catenate()* and *split()* functions are also very efficient, and can be performed in $O(\log n)$ time, where n is the total number of elements in the sets, and without performing any comparison operations (see [Tar83] for the details). Note however that the size of two sets resulting from a split operation is initially unknown, as it is impossible to compute it in less than linear time. Thus, the first invocation of *size()* on such a set takes linear time, and *not* constant time.

advanced

The design is derived from the STL *multiset* class-template (see, e.g, [MS96]), where the main differences between the two classes are highlighted in the class definition above.

CGAL::Object

#include <CGAL/Object.h>

Definition

Some functions can return different types of objects. A typical C++ solution to this problem is to derive all possible return types from a common base class, to return a pointer to this class and to perform a dynamic cast on this pointer. The class *Object* provides an abstraction. An object *obj* of the class *Object* can represent an arbitrary class. The only operations it provides is to make copies and assignments, so that you can put them in lists or arrays. Note that *Object* is NOT a common base class for the elementary classes. Therefore, there is no automatic conversion from these classes to *Object*. Rather this is done with the global function *make_object*. This encapsulation mechanism requires the use of *assign* or *object_cast* to use the functionality of the encapsulated class.

This class is similar in spirit to *boost::any*.

Creation

Object obj;	introduces an empty object.
Object obj(o);	Copy constructor.

Objects of type *Object* are normally created using the global function *make_object*.

Operations

Object &	*obj* = *o*	Assignment.
bool	*obj.empty()*	returns true, if *obj* does not contain an object.
template<class T> *bool*	*obj.is()*	returns true, iff *obj* contains an object of type *T*.
std::type_info	*obj.type() const*	returns the type information of the contained type, or *typeid(void)* if empty.

Construction of an *Object* storing an object of type *T* can be performed using the *make_object* global function :

template <class T> *Object*	*make_object(T t)*	Creates an object that contains *t*.

Assignment of an object of type *Object* to an object of type *T* can be done using *assign* :

template <class T> *bool*	*assign(T& c, o)*	assigns *o* to *c* if *o* was constructed from an object of type *T*. Returns *true*, if the assignment was possible. For efficiency reasons, we recommend using *object_cast* instead.

Another possibility to access the encapsulated object is to use *object_cast*, which avoids the default constructor and assignment required by *assign* :

template <class T>
*const T** *object_cast(const * o)*

Returns a pointer to the object of type *T* stored by *o*, if any, otherwise returns *NULL*.

template <class T>
T *object_cast(o)*

Returns a copy of the object of type *T* stored by *o*, if any, otherwise throws an exception of type *Bad_object_cast*.

Example

In the following example, the object class is used as return value for the intersection computation, as there are possibly different return values.

```
{
    typedef Cartesian<double>    K;
    typedef K::Point_2           Point_2;
    typedef K::Segment_2         Segment_2;

    Point_2 point;
    Segment_2 segment, segment_1, segment_2;

    std::cin >> segment_1 >> segment_2;

    Object obj = intersection(segment_1, segment_2);

    if (assign(point, obj)) {
        /* do something with point */
    } else if (assign(segment, obj)) {
        /* do something with segment*/
    }

    /* there was no intersection */
}
```

A more efficient way to access the object is to use *object_cast*, which allows to skip a default construction and assignment :

```
{
    typedef Cartesian<double>    K;
    typedef K::Point_2           Point_2;
    typedef K::Segment_2         Segment_2;

    Segment_2 segment_1, segment_2;

    std::cin >> segment_1 >> segment_2;
```

```
    Object obj = intersection(segment_1, segment_2);

    if (const Point_2 * point = object_cast<Point_2>(&obj)) {
        /* do something with *point */
    } else if (const Segment_2 * segment = object_cast<Segment_2>(&obj)) {
        /* do something with *segment*/
    }

    /* there was no intersection */
}
```

The intersection routine itself looks roughly as follows:

```
template < class Kernel >
Object intersection(Segment_2<Kernel> s1, Segment_2<Kernel> s2)
{

    if (/* intersection is a point */ ) {

      Point_2<Kernel> p = ...  ;
      return make_object(p);

    } else if (/* intersection is a segment */ ) {

      Segment_2<Kernel> s = ...  ;
      return make_object(s);
    }

    /* empty intersection */
    return Object();
}
```

Function

CGAL::cpp0x::next

There is actually no function in namespace *CGAL::cpp0x* with this name, but a using declaration which imports a function from another namespace. By order of priority: the one in namespace *std* is used (provided by C++0x), if not found, then the one in namespace *boost* is used.

Definition

The function returns the result of *operator++* on a ForwardIterator. The exact behaviour is described in §24.4.4 of the C++ standard draft N3242.

#include <CGAL/algorithm.h>

See Also

boost::next
CGAL::cpp0x::prev . . . . page 4171

CGAL::cpp0x::prev

Function

If C++0x is available the function *std::prev* is imported into the namespace *CGAL::cpp0x*, otherwise *CGAL::cpp0x::prev* is declared with the signature as given in §24.4.4 of the ISO C++ Standard and forwarded to *boost::prior*.

Definition

The function returns the result of *operator--* on a BidirectionalIterator. The exact behaviour is described in §24.4.4 of the C++ standard draft N3242.

#include <CGAL/algorithm.h>

See Also

boost::prior
CGAL::cpp0x::next . . . . page 4170

CGAL::predecessor

This function is deprecated. *CGAL::cpp0x::prev* should be used instead.

deprecated

Definition

The function *predecessor* returns the previous iterator, i.e. the result of *operator--* on a bidirectional iterator.

#include <CGAL/algorithm.h>

template <class BidirectionalIterator>
BidirectionalIterator predecessor(BidirectionalIterator it)

returns *--it*.

See Also

CGAL::successor .... page 4173

deprecated

CGAL::successor

This function is deprecated. *CGAL::cpp0x::next* should be used instead.

deprecated

Definition

The function *successor* returns the next iterator, i.e. the result of *operator++* on a forward iterator.

#include <CGAL/algorithm.h>

template <class ForwardIterator>
ForwardIterator successor(ForwardIterator it)

returns $++it$.

See Also

CGAL::predecessor .... page 4172

deprecated

Function

CGAL::cpp0x::copy_n

This provides an implementation of the standard function *copy_n* from the C++0x standard. If *copy_n* is available in the *std::* namespace a using declaration is used, otherwise an alternative implementation from CGAL is used.

Definition

The function *cpp0x::copy_n* copies *n* items from an input iterator to an output iterator. Its exact behaviour is defined in §25.3.1 of the C++ standard draft N3242.

#include <CGAL/algorithm.h>

CGAL::copy_n

Function

This function is deprecated, *CGAL::cpp0x::copy_n* should be used instead.

deprecated

Definition

The function *copy_n* copies *n* items from an input iterator to an output iterator which is useful for possibly infinite sequences of random geometric objects.[1]

#include <CGAL/algorithm.h>

template <class InputIterator, class Size, class OutputIterator>
OutputIterator copy_n(InputIterator first, Size n, OutputIterator result)

copies the first *n* items from *first* to *result*. Returns the value of *result* after inserting the *n* items.

See Also

CGAL::Counting_iterator<Iterator, Value> . . . . page 4185

deprecated

[1]The STL release June 13, 1997, from SGI contains an equivalent function, but it is not part of the ISO standard.

Function

CGAL::min_max_element

Definition

The function *min_max_element* computes the minimal and the maximal element of a range. It is modeled after the STL functions *min_element* and *max_element*. The advantage of *min_max_element* compared to calling both STL functions is that one only iterates once over the sequence. This is more efficient especially for large and/or complex sequences.

#include <CGAL/algorithm.h>

template < class ForwardIterator >
std::pair< ForwardIterator, ForwardIterator >

min_max_element(ForwardIterator first, ForwardIterator last)

returns a pair of iterators where the first component refers to the minimal and the second component refers to the maximal element in the range [*first*, *last*). The ordering is defined by *operator<* on the value type of *ForwardIterator*.

template < class ForwardIterator, class CompareMin, class CompareMax >
std::pair< ForwardIterator, ForwardIterator >

min_max_element(ForwardIterator first,
ForwardIterator last,
CompareMin comp_min,
CompareMax comp_max)

returns a pair of iterators where the first component refers to the minimal and the second component refers to the maximal element in the range [*first*, *last*).
Requirement: *CompareMin* and *CompareMax* are adaptable binary function objects: $VT \times VT \rightarrow bool$ where *VT* is the value type of *ForwardIterator*.

Example

The following example program computes the minimal and maximal element of the sequence $(3, 6, 5)$. Hence the output is *min = 3, max = 6*.

```
#include <CGAL/algorithm.h>
#include <vector>
#include <iostream>

using std::vector;
using std::pair;
using std::cout;
using std::endl;
using CGAL::min_max_element;
```

```
int main()
{
  vector< int > v;
  v.push_back(3);
  v.push_back(6);
  v.push_back(5);
  typedef std::vector< int >::iterator iterator;
  pair< iterator, iterator > p = min_max_element(v.begin(), v.end());
  cout << "min = " << *p.first << ", max = " << *p.second << endl;
  return 0;
}
```

Class

CGAL::Dispatch_output_iterator<V,O>

Definition

The class *Dispatch_output_iterator<V,O>* defines an *OutputIterator* that contains a tuple of output iterators, and dispatches among those based on the type of the value type which is put in it. It also inherits from *O*, which makes it easy to treat like a tuple.

Parameters

V must be a *CGAL::cpp0x::tuple<...>* of the types of values to be accepted and dispatched. *O* must be a *CGAL::cpp0x::tuple<...>* of the types of corresponding output iterators.

#include <CGAL/iterator.h>

Is Model for the Concepts

OutputIterator

Inherits From

O

Types

typedef V	*Value_type_tuple;*
typedef O	*Iterator_tuple;*

Creation

Dispatch_output_iterator<V,O> i(I...o);

Constructor taking all the output iterators.

Iterator_tuple *i.get_iterator_tuple() const*

returns a reference to the tuple of output iterators.

template < typename... V, typename... O>
Dispatch_output_iterator<tuple<V...>, tuple<O...> >

dispatch_output(O... o)

returns a *Dispatch_output_iterator* constructed from the arguments.

See Also

CGAL::Dispatch_or_drop_output_iterator<V,O> . . . . page 4180

Class

CGAL::Dispatch_or_drop_output_iterator<V,O>

Definition

The class *Dispatch_or_drop_output_iterator<V,O>* defines an *OutputIterator* that contains a tuple of output iterators, and dispatches among those based on the type of the value type which is put in it. Other types are also accepted, and the object is simply discarded in this case. It also inherits from *O*, which makes it easy to treat like a tuple.

Parameters

V must be a *CGAL::cpp0x::tuple<...>* of the types of values to be accepted and dispatched. *O* must be a *CGAL::cpp0x::tuple<...>* of the types of corresponding output iterators.

#include <CGAL/iterator.h>

Is Model for the Concepts

OutputIterator

Inherits From

O

Types

typedef V	*Value_type_tuple;*
typedef O	*Iterator_tuple;*

Creation

Dispatch_or_drop_output_iterator<V,O> i(I...o);

Constructor taking all the output iterators.

Iterator_tuple *i.get_iterator_tuple() const*

returns a reference to the tuple of output iterators.

template < typename... V, typename... O>
Dispatch_or_drop_output_iterator<tuple<V...>, tuple<O...> >

dispatch_or_drop_output(O... o)

returns a *Dispatch_or_drop_output_iterator* constructed from the arguments.

See Also

CGAL::Dispatch_output_iterator<V,O> . . . . page 4178

Class

CGAL::Emptyset_iterator

Definition

The class defines an *OutputIterator* that ignores everything written to it. One can think of it as being connected to `/dev/null`.

#include <CGAL/iterator.h>

Is Model for the Concepts

OutputIterator

Creation

Emptyset_iterator i;

default constructor.

See Also

CGAL::Oneset_iterator . . . . page **??**
CGAL::Const_oneset_iterator . . . . page **??**

CGAL::Oneset_iterator<T>

Class

Definition

The class *Oneset_iterator<T>* defines an *BidirectionalIterator* that always refers to one specific object of type *T*. Internally, *Oneset_iterator<T>* stores a pointer to the referred object.

#include <CGAL/iterator.h>

Is Model for the Concepts

BidirectionalIterator

Creation

Oneset_iterator<T> i(T& t);

creates an iterator referring to *t*.

See Also

CGAL::Emptyset_iterator .... page 4182
CGAL::Const_oneset_iterator .... page **??**

Class

CGAL::Const_oneset_iterator<T>

Definition

The class *Const_oneset_iterator<T>* defines an *RandomAccessIterator* that always refers to a copy of a specific object of type T.

#include <CGAL/iterator.h>

Is Model for the Concepts

RandomAccessIterator

Creation

Const_oneset_iterator<T> i(T& t);

creates an iterator that always refers to some copy of t. The copy is constructed by invoking T's copy constructor and remains constant during i's lifetime.

See Also

CGAL::Emptyset_iterator . . . . page 4182
CGAL::Oneset_iterator . . . . page **??**

CGAL::Counting_iterator<Iterator, Value>

Definition

The iterator adaptor *Counting_iterator<Iterator, Value>* adds a counter to the internal iterator of type *Iterator* and defines equality of two instances in terms of this counter. It can be used to create finite sequences of possibly infinite sequences of values from input iterators.

#include <CGAL/iterator.h>

Is Model for the Concepts

InputIterator

Requirements

Iterator is a model for *InputIterator*.

Creation

Counting_iterator<Iterator, Value> i(std::size_t n = 0);

initializes the internal counter to n and i has a singular value.

Counting_iterator<Iterator, Value> i(Iterator j, std::size_t n = 0);

initializes the internal counter to n and i to j.

See Also

CGAL::copy_n . . . . page 4175

Class

CGAL::Insert_iterator<Container>

Definition

The output iterator *Insert_iterator<Container>* is similar to *std::insert_iterator*, but differs in that it calls the *insert()* function of the container without the iterator additional argument.

#include <CGAL/iterator.h>

Is Model for the Concepts

OutputIterator

Requirements

Container provides a member function *insert(const Container::const_reference&)*.

Creation

Insert_iterator<Container> i(Container &c);

initializes the internal container reference to *c*.

There is also a global function similar to *std::inserter*:

template < class Container >
Insert_iterator<Container>

inserter(Container &x)

Constructs *Insert_iterator<Container>(x)*.

CGAL::N_step_adaptor<I,int N>

Class

Definition

The adaptor *N_step_adaptor<I,int N>* changes the step width of the iterator or circulator class I to N. It is itself an iterator or circulator respectively. The behavior is undefined if the adaptor is used on a range $[i, j)$ where $j - i$ is not a multiple of n.

#include <CGAL/iterator.h>

Creation

N_step_adaptor<I,int N> i(I j);	down cast.

Class

CGAL::Filter_iterator<Iterator, Predicate>

Definition

The iterator adaptor *Filter_iterator<Iterator, Predicate>* acts as a filter on a given range. Whenever the iterator is in– or decremented, it ignores all iterators for which the given *Predicate* is true. The iterator category is the same as for *Iterator*.

Note: Boost also provides the same functionality via the *boost::filter_iterator* class. Unfortunately, the semantics chosen for accepting or rejecting elements based on the predicate's result are opposite as the semantic chosen here. What is more, the argument of the predicate is different: the predicate used with *boost::filter_iterator* must take the value type of the iterator, as argument, and not the iterator itself.

#include <CGAL/iterator.h>

Requirements

- *Iterator* is a model for *ForwardIterator*.
- *Predicate* is a functor: *Iterator* $\rightarrow$ *bool*.

Creation

Filter_iterator<Iterator, Predicate> *i*;

Filter_iterator<Iterator, Predicate> *i(Iterator e, Predicate p, Iterator c = e);*

creates an iterator which filters values according to *p*. Initializes by taking the first valid iterator (according to *p*), starting at *c*, and stopping at *e* if none is found.

There is also a global function to help the use of *Filter_iterator<Iterator, Predicate>*:

template < class Iterator, class Predicate >
inline Filter_iterator< Iterator, Predicate >

filter_iterator(Iterator e, Predicate p, Iterator c = e)

Constructs *Filter_iterator<Iterator, Predicate>(e, p, c)*.

CGAL::Join_input_iterator_1<Iterator, Creator>

Class

Definition

The class *Join_input_iterator_1<Iterator, Creator>* joins an iterator and a creator function object. The result is again an iterator (of the same iterator category type as the original iterator) that reads an object from the stream and applies a creator function object to that object.

#include <CGAL/iterator.h>

Is Model for the Concepts

InputIterator

Types

Join_input_iterator_1<Iterator, Creator>:: value_type

typedef to *Creator::result_type*.

Creation

Join_input_iterator_1<Iterator, Creator> join(Iterator i, Creator creator);

creates a join iterator from the given iterator *i* and the functor *creator*. Applies *creator* to each item read from *i*.

Join_input_iterator_1<Iterator, Creator> join(Iterator i);

creates a join iterator from the given iterator *i* and a default constructed instance of *Creator*. The latter instance is applied to each item read from *i*.

See Also

CGAL::Creator_1<Arg, Result> . . . . page 4209

CGAL::Inverse_index<IC>

Definition

The class *Inverse_index<IC>* constructs an inverse index for a given range $[i, j)$ of two iterators or circulators of type *IC*. The first element *I* in the range $[i, j)$ has the index 0. Consecutive elements are numbered incrementally. The inverse index provides a query for a given iterator or circulator k to retrieve its index number. *Precondition:* The iterator or circulator must be either of the random access category or the dereference operator must return stable and distinguishable addresses for the values, e.g. proxies or non-modifiable iterator with opaque values will not work.

#include <CGAL/iterator.h>

Creation

Inverse_index<IC>	*inverse*;	invalid index.
Inverse_index<IC>	*inverse(IC i);*	empty inverse index initialized to start at i.
Inverse_index<IC>	*inverse(IC i, IC j);*	inverse index initialized with range $[i, j)$.

Operations

std::size_t	*inverse*[*IC k*]	returns inverse index of k. *Precondition*: k has been stored in the inverse index.
void	*inverse.push_back(IC k)*	adds k at the end of the indices.

Implementation

For random access iterators or circulators, it is done in constant time by subtracting i. For other iterator categories, an STL *map* is used, which results in a $\log j - i$ query time. The comparisons are done using the operator *operator<* on pointers.

See Also

CGAL::Random_access_adaptor<IC> . . . . page 4191
CGAL::Random_access_value_adaptor<IC,T> . . . . page 4192

CGAL::Random_access_adaptor<IC>

Class

Definition

The class *Random_access_adaptor<IC>* provides a random access for data structures. Either the data structure supports random access iterators or circulators where this class maps function calls to the iterator or circulator, or a STL *std::vector* is used to provide the random access. The iterator or circulator of the data structure are of type *IC*.

#include <CGAL/iterator.h>

Types

Random_access_adaptor<IC>:: size_type	size type of the STL *std::vector*.

Creation

Random_access_adaptor<IC> random_access; invalid index.

Random_access_adaptor<IC> random_access(IC i);

empty random access index initialized to start at *i*.

Random_access_adaptor<IC> random_access(IC i, IC j);

random access index initialized to the range $[i, j)$.

void

random_access.reserve(size_type r)

reserve *r* entries, if a *std::vector* is used internally.

Operations

IC *random_access*[*size_type n*] returns iterator or circulator to the *n*-th item.
Precondition: $n <$ number of items in *random_access*.

void

random_access.push_back(IC k) adds *k* at the end of the indices.

See Also

CGAL::Inverse_index<IC> . . . . page 4190
CGAL::Random_access_value_adaptor<IC,T> . . . . page 4192

Class

CGAL::Random_access_value_adaptor<IC,T>

Definition

The class *Random_access_value_adaptor<IC,T>* provides a random access for data structures. It is derived from *Random_access_adaptor<IC>*. Instead of returning iterators from the *operator[]* methods, it returns the dereferenced value of the iterator. The iterator or circulator of the data structure are of type *IC*. Their value type is T.

#include <CGAL/iterator.h>

Operations

Creation and operations see *Random_access_adaptor<IC>*, with the exception of:

T&	*random_access*[*size_type n*]	returns a reference to the n-th item. *Precondition*: $n <$ number of items in *random_access*.

CGAL::compare_to_less

Definition

The function *compare_to_less* is used to change a functor returning a *Comparison_result* to one which returns a bool. The returned functor will return *true* iff the original one returns *SMALLER*.

#include <CGAL/function_objects.h>

template < class F >
Compare_to_less< F >   *compare_to_less(F f)*

returns a functor equivalent to f, but which returns a bool instead of a *Comparison_result*.

See Also

CGAL::Compare_to_less<F> . . . . page 4194

Class

CGAL::Compare_to_less<F>

Definition

The class *Compare_to_less<F>* is used to convert a functor which returns a *Comparison_result* to a predicate (returning bool) : it will return true iff the return value of *F* is *SMALLER*. The class is used in conjunction with the *compare_to_less* function; see there for an explanation on how exactly the functors are combined.

#include <CGAL/function_objects.h>

Types

Compare_to_less<F>:: Type	type of the composed functor.

CGAL::compare_to_less . . . . page 4193

Projection_object

Functor
Concept

Definition

The concept Projection_object is modeled after the STL concept *UnaryFunction*, but takes also care of (const) references.

Projection_object:: argument_type	argument type.
Projection_object:: result_type	result type.

Creation

Projection_object o;	default constructor.

Operations

result_type`&`	*o.operator()(argument_type* `&`*) const*
const result_type`&`	*o.operator()(const argument_type* `&`*) const*

Has Models

Functor
Class

CGAL::Identity<Value>

Definition

The class *Identity<Value>* represents the identity function on *Value*.

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object . . . . page 4195

Identity<Value>:: argument_type	typedef to *Value*.
Identity<Value>:: result_type	typedef to *Value*.

Creation

Identity<Value> o;	default constructor.

Operations

result_type&	*o.operator()(argument_type& x) const*
	returns *x*.
const result_type&	*o.operator()(const argument_type& x) const*
	returns *x*.

CGAL::Dereference<Value>

Definition

The class *Dereference<Value>* dereferences a pointer (*operator**).

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object . . . . page 4195

Dereference<Value>:: argument_type	typedef to *Value**.
Dereference<Value>:: result_type	typedef to *Value*.

Creation

Dereference<Value> o;	default constructor.

Operations

result_type&   *o.operator()(argument_type& x) const*

returns **x*.

const result_type&   *o.operator()(const argument_type& x) const*

returns **x*.

CGAL::Get_address<Value>

Definition

The class *Get_address<Value>* gets the address of an lvalue (*operator*`&`).

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object . . . . page 4195

Get_address<Value>:: argument_type typedef to *Value*.

Get_address<Value>:: result_type typedef to *Value**.

Creation

Get_address<Value> o; default constructor.

Operations

result_type`&` *o.operator()(argument_type*`&` *x) const*

returns `&`*x*.

const result_type`&` *o.operator()(const argument_type*`&` *x) const*

returns `&`*x*.

CGAL::Cast_function_object<Arg, Result>

Functor
Class

Definition

The class *Cast_function_object<Arg, Result>* applies a C-style type cast to its argument.

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object . . . . page 4195

Cast_function_object<Arg, Result>:: argument_type

typedef to *Arg*.

Cast_function_object<Arg, Result>:: result_type

typedef to *Result*.

Creation

Cast_function_object<Arg, Result> o; default constructor.

Operations

result_type& *o.operator()(argument_type*& *x) const*

returns *(Result)x*.

const result_type& *o.operator()(const argument_type*& *x) const*

returns *(Result)x*.

Functor
Class

CGAL::Project_vertex<Node>

Definition

The class *Project_vertex<Node>* calls the member function *vertex()* on an instance of type *Node*.

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object . . . . page 4195

Project_vertex<Node>:: argument_type	typedef to *Node*.
Project_vertex<Node>:: result_type	typedef to *Node::Vertex*.

Creation

Project_vertex<Node> o;	default constructor.

Operations

result_type& *o.operator()(argument_type& n) const*

returns *n.vertex()*.

const result_type& *o.operator()(const argument_type& n) const*

returns *n.vertex()*.

CGAL::Project_facet<Node>

Definition

The class *Project_facet<Node>* calls the member function *facet()* on an instance of type *Node*.

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object . . . . page 4195

Project_facet<Node>:: argument_type	typedef to *Node*.
Project_facet<Node>:: result_type	typedef to *Node::Facet*.

Creation

Project_facet<Node> o;	default constructor.

Operations

result_type& *o.operator()(argument_type& n) const*

returns *n.facet()*.

const result_type& *o.operator()(const argument_type& n) const*

returns *n.facet()*.

Functor
Class

CGAL::Project_point<Node>

Definition

The class *Project_point<Node>* calls the member function *point()* on an instance of type *Node*.

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object . . . . page 4195

Project_point<Node>:: argument_type	typedef to *Node*.
Project_point<Node>:: result_type	typedef to *Node::Point*.

Creation

Project_point<Node> o;	default constructor.

Operations

result_type& *o.operator()(argument_type& n) const*

returns *n.point()*.

const result_type& *o.operator()(const argument_type& n) const*

returns *n.point()*.

CGAL::Project_normal<Node>

Definition

The class *Project_normal<Node>* calls the member function *normal()* on an instance of type *Node*.

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object . . . . page 4195

Project_normal<Node>:: argument_type	typedef to *Node*.
Project_normal<Node>:: result_type	typedef to *Node::Normal*.

Creation

Project_normal<Node> o;	default constructor.

Operations

result_type& *o.operator()(argument_type& n) const*

returns *n.normal()*.

const result_type& *o.operator()(const argument_type& n) const*

returns *n.normal()*.

CGAL::Project_plane<Node>

Definition

The class *Project_plane<Node>* calls the member function *plane()* on an instance of type *Node*.

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object . . . . page 4195

Project_plane<Node>:: argument_type	typedef to *Node*.
Project_plane<Node>:: result_type	typedef to *Node::Plane*.

Creation

Project_plane<Node> o;	default constructor.

Operations

result_type& *o.operator()(argument_type& n) const*

returns *n.plane()*.

const result_type& *o.operator()(const argument_type& n) const*

returns *n.plane()*.

CGAL::Project_next<Node>

Definition

The class *Project_next<Node>* calls the member function *next()* on an instance of type *Node*.

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object . . . . page 4195

Project_next<Node>:: argument_type	typedef to *Node**.
Project_next<Node>:: result_type	typedef to *Node**.

Creation

Project_next<Node> o;	default constructor.

Operations

result_type&	*o.operator()(argument_type& n) const*
	returns *n->next()*.
const result_type&	*o.operator()(const argument_type& n) const*
	returns *n->next()*.

Functor Class

Functor
Class

CGAL::Project_prev<Node>

Definition

The class *Project_prev<Node>* calls the member function *prev()* on an instance of type *Node*.

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object . . . . page 4195

Project_prev<Node>:: argument_type	typedef to *Node**.
Project_prev<Node>:: result_type	typedef to *Node**.

Creation

Project_prev<Node> o;	default constructor.

Operations

result_type&	*o.operator()(argument_type& n) const*
	returns *n->prev()*.
const result_type&	*o.operator()(const argument_type& n) const*
	returns *n->prev()*.

Functor
Class

CGAL::Project_next_opposite<Node>

Definition

The class *Project_next_opposite<Node>* calls the member functions *next()->opposite()* on an instance of type *Node*.

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object . . . . page 4195

Project_next_opposite<Node>:: argument_type	typedef to *Node**.
Project_next_opposite<Node>:: result_type	typedef to *Node**.

Creation

Project_next_opposite<Node> o;	default constructor.

Operations

result_type& *o.operator()(argument_type& n) const*

returns *n->next()->opposite()*.

const result_type& *o.operator()(const argument_type& n) const*

returns *n->next()->opposite()*.

Functor
Class

CGAL::Project_opposite_prev<Node>

Definition

The class *Project_opposite_prev<Node>* calls the member functions *opposite()->prev()* on an instance of type *Node*.

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object . . . . page 4195

Project_opposite_prev<Node>:: argument_type

typedef to *Node**.

Project_opposite_prev<Node>:: result_type typedef to *Node**.

Creation

Project_opposite_prev<Node> o; default constructor.

Operations

result_type& *o.operator()(argument_type& n) const*

returns *n->opposite()->prev()*.

const result_type& *o.operator()(const argument_type& n) const*

returns *n->opposite()->prev()*.

CGAL::Creator_1<Arg, Result>

Definition

The concept *Creator_1<Arg, Result>* defines types and operations for creating objects from one argument.

#include <CGAL/function_objects.h>

Requirements

Arg is convertible to *Result*.

Creator_1<Arg, Result>:: argument_type	type of argument.
Creator_1<Arg, Result>:: result_type	type of object to create.

result_type *c.operator()(argument_type a) const*

returns *result_type(a)*.

Functor
Class

CGAL::Creator_2<Arg1, Arg2, Result>

Definition

The concept *Creator_2<Arg1, Arg2, Result>* defines types and operations for creating objects from two arguments.

#include <CGAL/function_objects.h>

Requirements

Result defines a corresponding constructor.

Creator_2<Arg1, Arg2, Result>:: argument1_type

type of first argument.

Creator_2<Arg1, Arg2, Result>:: argument2_type

type of second argument.

Creator_2<Arg1, Arg2, Result>:: result_type type of object to create.

result_type *c.operator()(argument_type1 a1, argument_type2 a2) const*

returns *result_type(a1, a2)*.

CGAL::Creator_3<Arg1, Arg2, Arg3, Result>

Functor
Class

Definition

The concept *Creator_3<Arg1, Arg2, Arg3, Result>* defines types and operations for creating objects from three arguments.

#include <CGAL/function_objects.h>

Requirements

Result defines a corresponding constructor.

Creator_3<Arg1, Arg2, Arg3, Result>:: argument1_type

type of first argument.

Creator_3<Arg1, Arg2, Arg3, Result>:: argument2_type

type of second argument.

Creator_3<Arg1, Arg2, Arg3, Result>:: argument3_type

type of third argument.

Creator_3<Arg1, Arg2, Arg3, Result>:: result_type

type of object to create.

result_type *c.operator()(argument_type1 a1, argument_type2 a2, argument_type3 a3) const*

returns *result_type(a1, a2, a3)*.

Functor
Class

CGAL::Creator_4<Arg1, Arg2, Arg3, Arg4, Result>

Definition

The concept *Creator_4<Arg1, Arg2, Arg3, Arg4, Result>* defines types and operations for creating objects from four arguments.

#include <CGAL/function_objects.h>

Requirements

Result defines a corresponding constructor.

Creator_4<Arg1, Arg2, Arg3, Arg4, Result>:: argument1_type

type of first argument.

Creator_4<Arg1, Arg2, Arg3, Arg4, Result>:: argument2_type

type of second argument.

Creator_4<Arg1, Arg2, Arg3, Arg4, Result>:: argument3_type

type of third argument.

Creator_4<Arg1, Arg2, Arg3, Arg4, Result>:: argument4_type

type of 4th argument.

Creator_4<Arg1, Arg2, Arg3, Arg4, Result>:: result_type

type of object to create.

result_type *c.operator()(*
argument_type1 a1,
argument_type2 a2,
argument_type3 a3,
argument_type4 a4) const

returns *result_type(a1, a2, a3, a4)*.

CGAL::Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>

Functor Class

Definition

The concept *Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>* defines types and operations for creating objects from five arguments.

#include <CGAL/function_objects.h>

Requirements

Result defines a corresponding constructor.

Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument1_type

type of first argument.

Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument2_type

type of second argument.

Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument3_type

type of third argument.

Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument4_type

type of 4th argument.

Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument5_type

type of 5th argument.

Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: result_type

type of object to create.

result_type c.operator()(
argument_type1 a1,
argument_type2 a2,
argument_type3 a3,
argument_type4 a4,
argument_type5 a5) const

returns *result_type(a1, a2, a3, a4, a5)*.

Functor
Class

CGAL::Creator_uniform_2<Arg, Result>

Definition

The concept *Creator_uniform_2<Arg, Result>* defines types and operations for creating objects from two arguments of the same type.

#include <CGAL/function_objects.h>

Requirements

Result defines a constructor from two *Arg* arguments.

Creator_uniform_2<Arg, Result>:: argument_type

type of arguments; typedef to *Arg*.

Creator_uniform_2<Arg, Result>:: result_type type of object to create; typedef to *Result*.

result_type *c.operator()(argument_type a1, argument_type a2) const*

returns *result_type(a1, a2)*.

CGAL::Creator_uniform_3<Arg, Result>

Functor
Class

Definition

The concept *Creator_uniform_3<Arg, Result>* defines types and operations for creating objects from three arguments of the same type.

#include <CGAL/function_objects.h>

Requirements

Result defines a constructor from three *Arg* arguments.

Creator_uniform_3<Arg, Result>:: argument_type

type of arguments; typedef to *Arg*.

Creator_uniform_3<Arg, Result>:: result_type type of object to create; typedef to *Result*.

result_type *c.operator()(argument_type a1, argument_type a2, argument_type a3) const*

returns *result_type(a1, a2, a3)*.

Functor
Class

CGAL::Creator_uniform_4<Arg, Result>

Definition

The concept *Creator_uniform_4<Arg, Result>* defines types and operations for creating objects from four arguments of the same type.

#include <CGAL/function_objects.h>

Requirements

Result defines a constructor from four *Arg* arguments.

Creator_uniform_4<Arg, Result>:: argument_type

type of arguments; typedef to *Arg*.

Creator_uniform_4<Arg, Result>:: result_type type of object to create; typedef to *Result*.

result_type *c.operator()(argument_type a1, argument_type a2, argument_type a3, argument_type a4) const*

returns *result_type(a1, a2, a3, a4)*.

CGAL::Creator_uniform_5<Arg, Result>

Definition

The concept *Creator_uniform_5<Arg, Result>* defines types and operations for creating objects from five arguments of the same type.

#include <CGAL/function_objects.h>

Requirements

Result defines a constructor from five *Arg* arguments.

Creator_uniform_5<Arg, Result>:: argument_type

type of arguments; typedef to *Arg*.

Creator_uniform_5<Arg, Result>:: result_type type of object to create; typedef to *Result*.

result_type *c.operator()(argument_type a1, argument_type a2, argument_type a3, argument_type a4, argument_type a5) const*

returns *result_type(a1, a2, a3, a4, a5)*.

Functor
Class

CGAL::Creator_uniform_6<Arg, Result>

Definition

The concept *Creator_uniform_6<Arg, Result>* defines types and operations for creating objects from six arguments of the same type.

#include <CGAL/function_objects.h>

Requirements

Result defines a constructor from six *Arg* arguments.

Creator_uniform_6<Arg, Result>:: argument_type

type of arguments; typedef to *Arg*.

Creator_uniform_6<Arg, Result>:: result_type — type of object to create; typedef to *Result*.

result_type *c.operator()(argument_type a1, argument_type a2, argument_type a3, argument_type a4, argument_type a5, argument_type a6) const*

returns *result_type(a1, a2, a3, a4, a5, a6)*.

CGAL::Creator_uniform_7<Arg, Result>

Functor
Class

Definition

The concept *Creator_uniform_7<Arg, Result>* defines types and operations for creating objects from seven arguments of the same type.

#include <CGAL/function_objects.h>

Requirements

Result defines a constructor from seven *Arg* arguments.

Creator_uniform_7<Arg, Result>:: argument_type

type of arguments; typedef to *Arg*.

Creator_uniform_7<Arg, Result>:: result_type type of object to create; typedef to *Result*.

result_type c.operator()(argument_type a1, argument_type a2, argument_type a3, argument_type a4, argument_type a5, argument_type a6, argument_type a7) const

returns *result_type(a1, a2, a3, a4, a5, a6, a7)*.

CGAL::Creator_uniform_8<Arg, Result>

Definition

The concept *Creator_uniform_8<Arg, Result>* defines types and operations for creating objects from eight arguments of the same type.

#include <CGAL/function_objects.h>

Requirements

Result defines a constructor from eight *Arg* arguments.

Creator_uniform_8<Arg, Result>:: argument_type

type of arguments; typedef to *Arg*.

Creator_uniform_8<Arg, Result>:: result_type — type of object to create; typedef to *Result*.

result_type *c.operator()(*
argument_type a1,
argument_type a2,
argument_type a3,
argument_type a4,
argument_type a5,
argument_type a6,
argument_type a7,
argument_type a8) const

returns *result_type(a1, a2, a3, a4, a5, a6, a7, a8)*.

CGAL::Creator_uniform_9<Arg, Result>

Functor
Class

Definition

The concept *Creator_uniform_9<Arg, Result>* defines types and operations for creating objects from nine arguments of the same type.

#include <CGAL/function_objects.h>

Requirements

Result defines a constructor from nine *Arg* arguments.

Creator_uniform_9<Arg, Result>:: argument_type

type of arguments; typedef to *Arg*.

Creator_uniform_9<Arg, Result>:: result_type — type of object to create; typedef to *Result*.

result_type *c.operator()(*
argument_type a1,
argument_type a2,
argument_type a3,
argument_type a4,
argument_type a5,
argument_type a6,
argument_type a7,
argument_type a8,
argument_type a9) const

returns *result_type(a1, a2, a3, a4, a5, a6, a7, a8, a9)*.

Functor
Class

CGAL::Creator_uniform_d<Arg, Result>

Definition

The concept *Creator_uniform_d<Arg, Result>* defines types and operations for creating objects from two arguments of the same type.

#include <CGAL/function_objects.h>

Requirements

Result defines a constructor from three arguments: one *d* dimension and two *Arg* arguments.

Creator_uniform_d<Arg, Result>:: argument_type

type of arguments; typedef to *Arg*.

Creator_uniform_d<Arg, Result>:: result_type type of object to create; typedef to *Result*.

result_type *c.operator()(argument_type a1, argument_type a2) const*

returns *result_type(d, a1, a2)*.

CGAL::Twotuple<T>

This class is deprecated, and will be removed in some future CGAL release. Please use *CGAL::cpp0x::array* instead.

deprecated

Definition

The *Twotuple<T>* class stores a homogeneous (same type) pair of objects of type T. A *Twotuple<T>* is much like a container, in that it ”owns” its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

#include <CGAL/Twotuple.h>

Requirements

T must be *Assignable*.

Types

typedef T	*value_type;*

Variables

T	*e0;*	first element
T	*e1;*	second element

Creation

Twotuple<T> t;	introduces a *Twotuple<T>* using the default constructor of the elements.
Twotuple<T> t(T x, T y);	constructs a *Twotuple<T>* such that *e0* is constructed from *x* and *e1* is constructed from *y*.

deprecated

Class

CGAL::Threetuple<T>

This class is deprecated, and will be removed in some future CGAL release. Please use *CGAL::cpp0x::array* instead.

deprecated

Definition

The *Threetuple<T>* class stores a homogeneous (same type) triple of objects of type *T*. A *Threetuple<T>* is much like a container, in that it "owns" its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

#include <CGAL/Threetuple.h>

Requirements

T must be *Assignable*.

Types

typedef T *value_type;*

Variables

T	*e0;*	first element
T	*e1;*	second element
T	*e2;*	third element

Creation

Threetuple<T> t;

introduces a *Threetuple<T>* using the default constructor of the elements.

Threetuple<T> t(T x, T y, T z);

constructs a *Threetuple<T>* such that *e0* is constructed from *x*, *e1* is constructed from *y* and *e2* is constructed from *z*.

deprecated

Class

CGAL::Fourtuple<T>

This class is deprecated, and will be removed in some future CGAL release. Please use *CGAL::cpp0x::array* instead.

deprecated

Definition

The *Fourtuple<T>* class stores a homogeneous (same type) fourtuple of objects of type *T*. A *Fourtuple<T>* is much like a container, in that it "owns" its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

#include <CGAL/Fourtuple.h>

Requirements

T must be *Assignable*.

Types

typedef T *value_type;*

Variables

T	*e0;*	first element
T	*e1;*	second element
T	*e2;*	third element
T	*e3;*	fourth element

Creation

Fourtuple<T> t;

introduces a *Fourtuple<T>* using the default constructor of the elements.

Fourtuple<T> t(T x, T y, T z, T t);

constructs a *Fourtuple<T>* such that *e0* is constructed from *x*, *e1* from *y*, *e2* from *z* and *e3* from *t*.

deprecated

Class

CGAL::Sixtuple<T>

This class is deprecated, and will be removed in some future CGAL release. Please use *CGAL::cpp0x::array* instead.

deprecated

Definition

The *Sixtuple<T>* class stores a homogeneous (same type) sixtuple of objects of type *T*. A *Sixtuple<T>* is much like a container, in that it "owns" its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

#include <CGAL/Sixtuple.h>

Requirements

T must be *Assignable*.

Types

typedef T	*value_type;*

Variables

T	*e0;*	first element
T	*e1;*	second element
T	*e2;*	third element
T	*e3;*	fourth element
T	*e4;*	fifth element
T	*e5;*	sixth element

Creation

Sixtuple<T> t;

introduces a *Sixtuple<T>* using the default constructor of the elements.

Sixtuple<T> t(T x, T y, T z, T t, T u, T v);

constructs a *Sixtuple<T>* such that *e0* is constructed from *x*, *e1* from *y*, *e2* from *z*, *e3* from *t*, *e4* from *u* and *e5* from *v*.

deprecated

Class

CGAL::Triple<T1, T2, T3>

Class

Definition

The Triple class is an extension of *std::pair*. *Triple<T1, T2, T3>* is a heterogeneous triple: it holds one object of type *T1*, one of type *T2*, and one of type *T3*. A *Triple<T1, T2, T3>* is much like a container, in that it "owns" its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

This class is NOT RECOMMENDED anymore. We recommend that you use *CGAL::cpp0x::tuple* or *CGAL::cpp0x::array* instead for new uses.

#include <CGAL/utility.h>

Requirements

T1, *T2* and *T3* must be *Assignable*. Additional operations have additional requirements.

Types

typedef T1	*first_type;*
typedef T2	*second_type;*
typedef T3	*third_type;*

Variables

T1	*first;*	first element. Please access it using *get<0>()*.
T2	*second;*	second element. Please access it using *get<1>()*.
T3	*third;*	third element. Please access it using *get<2>()*.

Creation

Triple<T1, T2, T3> t;

introduces a triple using the default constructor of the three elements.

Triple<T1, T2, T3> t(T1 x, T2 y, T3 z);

constructs a triple such that *first* is constructed from *x*, *second* is constructed from *y*, and *third* is constructed from *z*.

template <class U, class V, class W>
Triple<T1, T2, T3> t(U u, V v, W w);

constructs a triple such that *first* is constructed from *u*, *second* is constructed from *v*, and *third* is constructed from *w*. *Requirement*: Proper conversion operators exist from *U* to *T1*, *V* to *T2*, and *W* to *T3*.

template <int i>
T *t.get()*

Gives access to *first*, *second* or *third* whenever *i* is 0, 1 or 2, via a, potentially const, reference. Note: *T* stands for *T1*, *T2* or *T3* depending on *i*.

template <class T1, class T2, class T3>
bool $x < y$

The comparison operator. It uses lexicographic comparison: the return value is true if the first element of *x* is less than the first element of *y*, and false if the first element of *y* is less than the first element of *x*. If neither of these is the case, then it returns true if the second element of *x* is less than the second element of *y*, and false if the second element of *y* is less than the second element of *x*. If neither of these is the case, then it returns the result of comparing the third elements of *x* and *y*. This operator may only be used if *T1*, *T2* and *T3* define the comparison operator.

template <class T1, class T2, class T3>
bool $x == y$

The equality operator. The return value is true if and only the first elements of *x* and *y* are equal, the second elements of *x* and *y* are equal, and the third elements of *x* and *y* are equal. This operator may only be used if *T1*, *T2* and *T3* define the equality operator.

template <class T1, class T2, class T3>
Triple<T1, T2, T3>

make_triple(T1 x, T2 y, T3 z)

Equivalent to *Triple<T1, T2, T3>(x, y, z)*.

template <class T1, class T2, class T3>
Triple<T1, T2, T3>

make_tuple(T1 x, T2 y, T3 z)

Equivalent to *Triple<T1, T2, T3>(x, y, z)*.

CGAL::Quadruple<T1, T2, T3, T4>

Class

Definition

The Quadruple class is an extension of *std::pair*. *Quadruple<T1, T2, T3, T4>* is a heterogeneous quadruple: it holds one object of type *T1*, one of type *T2*, one of type *T3*, and one of type *T4*. A *Quadruple<T1, T2, T3, T4>* is much like a container, in that it “owns” its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

This class is NOT RECOMMENDED anymore. We recommend that you use *CGAL::cpp0x::tuple* or *CGAL::cpp0x::array* instead for new uses.

#include <CGAL/utility.h>

Requirements

T1, *T2*, *T3* and *T4* must be *Assignable*. Additional operations have additional requirements.

Types

typedef T1	*first_type;*
typedef T2	*second_type;*
typedef T3	*third_type;*
typedef T4	*fourth_type;*

Variables

T1	*first;*	first element. Please access it using *get<0>()*.
T2	*second;*	second element. Please access it using *get<1>()*.
T3	*third;*	third element. Please access it using *get<2>()*.
T4	*fourth;*	fourth element. Please access it using *get<3>()*.

Creation

Quadruple<T1, T2, T3, T4> t;

introduces a quadruple using the default constructor of the four elements.

Quadruple<T1, T2, T3, T4> t(T1 x, T2 y, T3 z, T4 w);

constructs a quadruple such that *first* is constructed from *x*, *second* is constructed from *y*, *third* is constructed from *z*, and *fourth* is constructed from *w*.

template <class U, class V, class W, class X>
Quadruple<T1, T2, T3, T4> t(U u, V v, W w, X x);

constructs a quadruple such that *first* is constructed from *u*, *second* is constructed from *v*, *third* is constructed from *w*, and *fourth* is constructed from *x*.
Requirement: Proper conversion operators exist from *U* to *T1*, *V* to *T2*, *W* to *T3*, and *X* to *T4*.

template <int i>
T *t.get()*

Gives access to *first*, *second*, *third* or *fourth* whenever *i* is 0, 1, 2 or 3, via a, potentially const, reference. Note: *T* stands for *T1*, *T2*, *T3* or *T4* depending on *i*.

template <class T1, class T2, class T3, class T4>
bool $x < y$

The comparison operator. It uses lexicographic comparison: the return value is true if the first element of *x* is less than the first element of *y*, and false if the first element of *y* is less than the first element of *x*. If neither of these is the case, then it returns true if the second element of *x* is less than the second element of *y*, and false if the second element of *y* is less than the second element of *x*. If neither of these is the case, then it returns true if the third element of *x* is less than the third element of *y*, and false if the third element of *y* is less than the third element of *x*. If neither of these is the case, then it returns the result of comparing the fourth elements of *x* and *y*. This operator may only be used if *T1*, *T2*, *T3*, and *T4* define the comparison operator.

template <class T1, class T2, class T3, class T4>
bool $x == y$

The equality operator. The return value is true if and only the first elements of *x* and *y* are equal, the second elements of *x* and *y* are equal, the third elements of *x* and *y* are equal, and the fourth elements of *x* and *y* are equal. This operator may only be used if *T1*, *T2*, *T3*, and *T4* define the equality operator.

template <class T1, class T2, class T3, class T4>
Quadruple<T1, T2, T3, T4>

make_quadruple(T1 x, T2 y, T3 z, T4 w)

Equivalent to *Quadruple<T1, T2, T3, T4>(x, y, z, w)*.

template <class T1, class T2, class T3, class T4>
Quadruple<T1, T2, T3, T4>

make_tuple(T1 x, T2 y, T3 z, T4 w)

Equivalent to *Quadruple<T1, T2, T3, T4>(x, y, z, w)*.

CGAL::Boolean_tag<bool value>

Class

Definition

Depending on *bool value* the class *Boolean_tag<bool value>* indicates that something is *true* or *false* respectively.

#include <CGAL/tags.h>

Constants

static const bool *value;*

See Also

Class

CGAL::Uncertain<T>

Definition

An object of the class *Uncertain<T>* represents an uncertainty on the value of type *T*. This uncertainty is represented by a non-empty range of values of type *T*.

The idea is that sometimes you are not sure of the result of a function, and you would like to communicate that to the caller. *Uncertain<T>* allows just that.

Uncertain<T> is also meant to be used as a drop-in replacement for *T* in some template contexts, as much as possible. This is why it provides overloaded operators and functions to naturally extend the Boolean operations for *Uncertain<bool>* for example, or the operations on enumeration types.

Uncertain<T> is used in CGAL as the return type of geometric predicates when the number type used is interval arithmetic like *Interval_nt*. End users typically do not see it, as it is hidden in the implementation of the filtered predicates provided by the various filtered kernels, but it is important that providers of predicates that are meant to be filtered by *Filtered_predicate*, know about it.

Note concerning CGAL assertions: assertions checking an expression of type *Uncertain<bool>* will trigger an assertion failure only if the assertion is certainly *false*. In case of an indeterminate value, the assertion is not triggered. This means that we assume, in case of doubt, that there is no error.

It can also be used in other contexts as well, as it is a general tool. This can be seen as support for non-deterministic programming. Finally, note that this class has some common points with *boost::tribool*.

#include <CGAL/Uncertain.h>

Parameters

The parameter *T* can either be *bool* or one of the three-valued (-1, 0, 1) enumeration types: *Sign*, *Comparison_result*, *Orientation*, *Oriented_side*, *Bounded_side* or *Angle*.

Some functions are defined only when *T* is *bool* or alternatively when it is one of the enumeration types listed previously.

Types

Uncertain<T>:: value_type — The type *T*.

Uncertain<T>:: Uncertain_conversion_exception

The type of the exception thrown for uncertain conversions. It is a typedef to the type *CGAL::Uncertain_conversion_exception* which derives from *std::range_error*.

Creation

Uncertain<T> u; — introduces a certain object with value *T()*.

Uncertain<T> u(T t); introduces a certain object with value t.

Uncertain& $u = T\, t$ assigns the certain value t to u.

Uncertain<T> u(T i, T s); introduces an object representing the range with lower bound i and upper bound s.
Precondition: $i <= s$.

Access Functions

The following functions are meant to be used very rarely, they provide ways to inspect the content of an *Uncertain<T>* object.

T	*u.inf() const*	returns the lower bound of the range represented by u.
T	*u.sup() const*	returns the upper bound of the range represented by u.
bool	*u.is_same(Uncertain u) const*	

returns true whether u and u are the same range (equality as sets).

Uncertainty testing and conversion

There are several ways to extract the content of an *Uncertain* object. The simplest way is to rely on the implicit conversion from *Uncertain<T>* to *T*. In this case, no special code has to be written, apart from an exception handler (anywhere higher in the call stack) to manage the uncertain case. The more involved one is more efficient, but requires manual treatment of the uncertain case, such as:

```
Uncertain<bool> b = ...;
if (is_certain(b))
  bool cert_b = get_certain(b); // Extract the certain bool it contains
  ...
else
  ... // b is indeterminate
```

Another option is :

```
Uncertain<bool> b = ...;
if (certainly(b))
  ... // b is certainly true
else if (certainly_not(b))
  ... // b is certainly false
else
  ... // b is indeterminate
```

There are many other handy functions which can be used for easier usage depending on the context. They are listed in the sequel.

bool *u.is_certain() const* returns *true* iff the value is certain, that is, it is unique, the range is a singleton. That is, *u.inf() == u.sup()*.

T	*u.make_certain() const*	if *u.is_certain()*, then returns the certain value which is represented. Otherwise, throws an exception of type *Uncertain_conversion_exception*. A profile counter of the number of such exceptions thrown during the execution of the program is available with *CGAL_PROFILE*.
T	*T(u)*	conversion operator to *T*. It does and returns the same thing as *u.make_certain()*. Note that relying on the automatic conversion can throw exceptions, which defeats the purpose of propagating uncertainty. Nevertheless, in many cases, it is hard to avoid it, for example for the `&&` and || operators for *bool* (see below).

Static member function

static Uncertain<T> *Uncertain<T>::indeterminate()*

returns an indeterminate range.

Free functions

template <class T> *T*	*inf(Uncertain<T> u)*	returns *u.inf()*.
template <class T> *T*	*sup(Uncertain<T> u)*	returns *u.sup()*.
template <class T> *bool*	*is_certain(T t)*	returns *true*.
template <class T> *bool*	*is_certain(Uncertain<T> u)*	returns *u.is_certain*().
template <class U> *U*	*indeterminate()*	returns *U::indeterminate()* if *U* is *Uncertain<T>*, and *U()* otherwise.
template <class T> *bool*	*is_indeterminate(T u)*	returns *false*.
template <class T> *bool*	*is_indeterminate(Uncertain<T> u)*	returns *!is_certain(u)*.

template <class T>

T *get_certain(T t)* returns *t*.

template <class T>
T *get_certain(Uncertain<T> u)*

returns *u.make_certain*().
Precondition: *u.is_certain*().

template <class T>
T *make_certain(T t)* returns *t*.

template <class T>
T *make_certain(Uncertain<T> u)*

returns *u.make_certain*().

template <class T>
Uncertain<T> *make_uncertain(T t)* returns *Uncertain<T>(u)*.

template <class T>
Uncertain<T> *make_uncertain(Uncertain<T> u)*

returns *u*.

Overloaded operators

The overloaded operators and functions are defined as preserving the set-inclusion property. Similarly to interval arithmetic, the returned range is guaranteed to contain the result of the operation over all values of the input range(s). In the following documentation we express this as the extension of the corresponding function over the type *T*.

template <class T>
Uncertain<bool> *Uncertain<T> u == Uncertain<T> v*

returns the extension of the equality operator over *u* and *v*.

template <class T>
Uncertain<bool> *Uncertain<T> u == T v* returns *u* == *make_uncertain(v)*.

template <class T>
Uncertain<bool> *T u == Uncertain<T> v* returns *v* == *u*.

template <class T>
Uncertain<bool> *Uncertain<T> u != Uncertain<T> v*

returns the extension of the inequality operator over *u* and *v*.

template <class T>

Uncertain<bool> *Uncertain<T> u* $!=$ *T v* returns *u != make_uncertain(v)*.

template <class T>
Uncertain<bool> *T u* $!=$ *Uncertain<T> v* returns *v != u*.

Overloaded operators for *Uncertain<bool>* only

Uncertain<bool> ! *Uncertain<bool> u* returns the range containing the negated values of *u*.

Uncertain<bool> *Uncertain<bool> u* | *Uncertain<bool> v*

returns the range containing the values computed as logical or from *u* and *v*.

Uncertain<bool> *Uncertain<bool> u* | *bool v*

returns *u* — *make_uncertain(v)*.

Uncertain<bool> *bool u* | *Uncertain<bool> v*

returns *v* — *u*.

Uncertain<bool> *Uncertain<bool> u* & *Uncertain<bool> v*

returns the range containing the values computed as logical and from *u* and *v*.

Uncertain<bool> *Uncertain<bool> u* & *bool v*

returns *u* & *make_uncertain(v)*.

Uncertain<bool> *bool u* & *Uncertain<bool> v*

returns *v* & *u*.

Note : the logical operators && and || are not overloaded on purpose. The reason is that, when *f()* && *g()* is evaluated and they return *bool*, then *g()* is only evaluated when *f()* returns *true*. One could have a dependency so that *g()* has an internal precondition that required that *f()* had returned *true*. The overloaded operators for user-defined types can not provide this short-circuiting property, and so, if the overloaded operators where provided, then *g()* would be evaluated, no matter the result of *f()*, which could lead to an unwanted situation, or a performance loss. The & and | operators do not have this short-circuiting property, and are therefore overloaded safely.

When translating normal code to use and propagate uncertainty, such as :

```
// Logical AND
if ( (p.x() == 0) && (p.y() == 0) )
  ...
else
  ...

// Logical OR
if ( (q.x() == 0) || (q.y() == 0) )
  ...
else
  ...
```

One can do, for example :

```
// Logical AND
Uncertain<bool> tmp = (p.x() == 0);
Uncertain<bool> res = certainly_not(tmp) ? make_uncertain(false) : tmp
 & (p.y() == 0);

... // Use res

// Logical OR
Uncertain<bool> tmp = (q.x() == 0);
Uncertain<bool> res = certainly(tmp) ? make_uncertain(true) : tmp |
 (q.y() == 0);

... // Use res
```

This ensures that the first expression is not evaluated twice, and that the second is evaluated only if needed.

This behavior can also be emulated through the use of macros, but only using non-standard features ("statement expressions", such as provided by GCC). The macros *CGAL_AND* and *CGAL_OR* are provided that perform the lazy evaluation of these logical operations. On compilers that do not support statement expressions, the macros simply expand to the && and || operators (which will throw an exception instead of propagating the uncertainty).

```
// Logical AND
Uncertain<bool> res = CGAL_AND( p.x() == 0 , p.y() == 0 );

... // Use res

// Logical OR
Uncertain<bool> res = CGAL_OR( q.x() == 0 , q.y() == 0 );

... // Use res
```

For convenience, the macros *CGAL_AND_3* and *CGAL_OR_3* are also provided to support boolean operations with 3 arguments instead of 2.

Overloaded operators and functions for *Uncertain<enum T>* **only**

template <class T>

Uncertain<bool> *Uncertain<T> u* < *Uncertain<T> v*

returns the extension of the less-than operator over *u* and *v*.

template <class T>
Uncertain<bool> *Uncertain<T> u* < *T v* returns *u* < *make_uncertain(v)*.

template <class T>
Uncertain<bool> *T u* < *Uncertain<T> v* returns *make_uncertain(u)* < *v*.

template <class T>
Uncertain<bool> *Uncertain<T> u* > *Uncertain<T> v*

returns the extension of the greater-than operator over *u* and *v*.

template <class T>
Uncertain<bool> *Uncertain<T> u* > *T v* returns *u* > *make_uncertain(v)*.

template <class T>
Uncertain<bool> *T u* > *Uncertain<T> v* returns *make_uncertain(u)* > *v*.

template <class T>
Uncertain<bool> *Uncertain<T> u* <= *Uncertain<T> v*

returns the extension of the less-than or equal operator over *u* and *v*.

template <class T>
Uncertain<bool> *Uncertain<T> u* <= *T v* returns *u* <= *make_uncertain(v)*.

template <class T>
Uncertain<bool> *T u* <= *Uncertain<T> v* returns *make_uncertain(u)* <= *v*.

template <class T>
Uncertain<bool> *Uncertain<T> u* >= *Uncertain<T> v*

returns the extension of the greater-than or equal operator over *u* and *v*.

template <class T>
Uncertain<bool> *Uncertain<T> u* >= *T v* returns *u* > *make_uncertain(v)*.

template <class T>
Uncertain<bool> *T u* >= *Uncertain<T> v* returns *make_uncertain(u)* >= *v*.

template <class T>

Uncertain<T> *Uncertain<T> u* $*$ *Uncertain<T> v*

returns the extension of the multiplication operator over *u* and *v*. This requires *T* to have a multiplication operator as well.

template <class T>
Uncertain<T> *Uncertain<T> u* $*$ *T v* returns *u* * *make_uncertain(v)*.

template <class T>
Uncertain<T> *T u* $<$ *Uncertain<T> v* returns *make_uncertain(u)* * *v*.

template <class T>
Uncertain<T> $-$*Uncertain<T> u* returns the extension of the unary minus operator over *u*.

template <class T, class U>
Uncertain<T> *enum_cast(Uncertain<U> u)*

returns the extension of the *enum_cast<T>* function over *u*.

Other free functions for *Uncertain<bool>*

bool *certainly(Uncertain<bool> u)*

returns *true* iff *u.is_certain()*, and the *u.make_certain*() returns *true*.

bool *certainly(bool u)* returns *u*.

bool *possibly(Uncertain<bool> u)*

returns *true* iff *u.is_certain()* returns *false*, or if *u.make_certain*() returns *true*.

bool *possibly(bool u)* returns *u*.

bool *certainly_not(Uncertain<bool> u)*

returns *true* iff *u.is_certain()*, and the *u.make_certain*() returns *false*.

bool *certainly_not(bool u)* returns *!u*.

bool *possibly_not(Uncertain<bool> u)*

returns *true* iff *u.is_certain()* returns *false*, or if *u.make_certain*() returns *false*.

bool *possibly_not(bool u)* returns *!u*.

CGAL::Interval_nt<bool>

CGAL::cpp11::array<T, int>

Class

Definition

An object of the class *cpp11::array<T, int>* represents an array of elements of type *T*, the number of which is specified by the second template argument.

There is actually no class in namespace *CGAL::cpp11* with this name, but a using declaration which imports a class from another namespace. By order of priority: the one in namespace *std* is used (provided by C++0x), if not found, then the one in namespace *std::tr1* is used (provided by TR1), and finally, the fallback solution is taken from Boost.

#include <CGAL/array.h>

Parameters

The parameter *T* is the value type. The second parameter is the dimension of the array.

Construction functions

The array class does not provide a constructor which can be used to initialize data members. CGAL therefore provides a *make_array* function for this purpose, up to a certain number of arguments.

template <class T>
array<T, 1> *make_array(T a)* returns an array of dimension 1 whose first element is *a*.

template <class T>
array<T, 2> *make_array(T a1, T a2)*

returns an array of dimension 2 whose first element is *a1* and second element is *a2*.

Class

CGAL::cpp11::tuple<...>

Definition

An object of the class *cpp11::tuple<...>* represents a heterogeneous tuple of elements of the types specified in parameters, which are in variadic number.

There is actually no class in namespace *CGAL::cpp11* with this name, but a using declaration which imports a class from another namespace. By order of priority: the one in namespace *std* is used (provided by C++0x), if not found, then the one in namespace *std::tr1* is used (provided by TR1), and finally, the fallback solution is taken from Boost.

#include <CGAL/tuple.h>

Parameters

The parameters ... are the value types.

Free functions and helper classes

Some free functions part of the standard interface of *tuple* are also brought in namespace *CGAL::cpp11* with using declarations, these are *make_tuple*, *get*, *tie*. Like in C++0x, the *get* function template is specialized so that it can take *std::pair* as argument. Two standard helper classes are also provided for convenience (*tuple_size* and *tuple_element*).

CGAL::Fast

Definition

Fast is a tag class. It can be used to parameterize a complexity policy in order to specify a particularly fast variant of an algorithm. For example, passing *Location_policy<Fast>* as parameter to *Delaunay_triangulation_3* selects a fast point location at the expense of more memory usage.

#include <CGAL/Complexity_tags.h>

Class

CGAL::Default

Definition

Default is a tag class. It can be used to state that one wants to use the default argument of a template parameter of a class template.

This can be useful in several cases: (a) when one needs a non-default value for another template parameter coming next (since C++ only supports defaults at the end of lists), (b) when the default is actually a complex expression, e.g. refering to previous template parameters (in this case, it shortens compiler error messages and mangled symbol names), (c) when defining the default involves circular dependencies of type instantiations (there, it breaks the cycle in a nice way).

Using the mechanism is easy : just plug *Default* as template argument in the place where you would like to use the default. You should refer to the documentation of the template class you are using in order to know whether this functionality is offered.

Also beware that the type of the instantiated template class will not be the same when instantiating it using *Default* instead of the type of the default argument, even though their interfaces will otherwise be the same. This may have consequences in some cases.

Is Model for the Concepts

DefaultConstructible, CopyConstructible

advanced

In order to help the template class writer, *Default* provides a convenient way to extract the desired type for a template parameter which may be defaulted using *Default*. It is enough to fetch the type as *Default::Get< Parameter, Type>::type*, as in the example program below.

Types

Default:: template <typename Parameter, typename Type> struct Get;

A nested template providing a typedef *type* which equals *Type* if *Parameter* is *Default*, and *Parameter* otherwise.

advanced

Example

```
#include <CGAL/Default.h>

// A is a concrete type
struct A {};

// B is the template class which has 2 template parameters
// with default arguments : A and int.
```

```
template < typename A1_ = A, typename A2 = int >
struct B
{
    B()
      : a1()
    {}

    // Note that it is also possible to use CGAL::Default
    // instead of A as the default argument for A1_ above.

    // Extract the desired type for A1 :
    typedef typename CGAL::Default::Get<A1_, A>::type  A1;

    A1 a1;
};

int main ()
{
    B<CGAL::Default, double> b;

    A a = b.a1; //  It is really of type A.
}
```

Chapter 74

CGAL and the Boost Graph Library

Andreas Fabri and Fernando Cacciola and Ron Wein

Contents

Many geometric data structures can be interpreted as graphs, as they consist of vertices, edges and faces. This is the case for the halfedge data structure, for the polyhedron, for arrangements and for triangulations. With means of duality one can also interpret faces as vertices and edges between adjacent faces as edges of the dual graph.

As the scope of CGAL is geometry and not graph algorithms, we provide the necessary classes and functions that allow to use the algorithms of the Boost Graph Library (BGL) [SLL02] for CGAL data structures.

74.1 A Short Introduction to the Boost Graph Library

The algorithms of the BGL operate on models of the various *graph concepts*. The *traits class boost::graph_traits* allows the algorithms to determine the types of vertices and edges. *Free functions* that operator on graphs allow the algorithms to obtain, for example, the source vertex of an edge, or all edges incident to a vertex. The algorithms use *property maps* to associate information to vertices and edges. The algorithms allow *visitors* to register callbacks that will be called during the execution of the algorithms. Finally, the graph algorithms use the *named parameter* mechanism, which allows to pass the arguments in arbitrary order.

Graph Concepts

The BGL introduces several graph concepts, which have different sets of characteristics and requirements, as for example whether one can enumerate all vertices or all edges, whether one only can get the outgoing edges of a vertex, or also the ingoing edges, or whether one can add and remove vertices and edges or not.

Graph concepts in the BGL manual: `http://www.boost.org/libs/graph/doc/graph_concepts.html`

The Graph Traits Class

The algorithms determine types with the help of the traits class *boost::graph_traits*. Such types are the *vertex_descriptor* which is equivalent to a vertex handle in CGAL data structures, the *vertex_iterator* which is similar to the vertex iterators in CGAL data structures, and the *out_edge_iterator* which is similar to edge circulators, which allow to enumerate the edges incident to a vertex. The latter two are similar and not equivalent, because their value type is a *vertex_descriptor*, whereas in CGAL handles, iterators, and cicrulators all have the same value type, namely the vertex type. Given a graph type *G* the declaration of a vertex descriptor looks as follows: *boost::graph_traits<G>::vertex_descriptor vd;*.

The graph traits in the BGL manual: `http://www.boost.org/libs/graph/doc/graph_traits.html`

Free Functions for Exploring a Graph

The algorithms obtain incidence information with the help of global functions like *pair<vertex_iterator,vertex_iterator> vertices(const Graph& g);* for getting an iterator range which allows to enumerate all vertices, or *int num_vertices(const Graph&);* for getting the number of vertices of a graph, or *vertex_descriptor source(edge_descriptor, const Graph&*, for getting the source vertex of an edge. Note, that the way we have written the types is a simplification, that is in reality the signature of the first of the above functions is *pair<boost::graph_traits<Graph>::vertex_iterator,boost::graph_traits<Graph>::vertex_iterator> vertices(const Graph& g);*.

The free functions required for graph concepts: `http://www.boost.org/libs/graph/doc/graph_concepts.html`

Property Maps

Another feature used heavily in the BGL is the *property map* which is offered by the Boost Property Map Library. Property maps are used to attach information to vertices and edges. It is again a traits class and some free functions for obtaining the property map from a graph, and for getting and putting properties.

The free functions are *get* and *put*. The first one is overloaded. One version allows to obtain a property map for a given property tag. For example *m = get(g, boost::vertex_index)* gives us a property map that associates an index in the range *[0, num_vertices(g))* to each vertex descriptor of the graph. The second version of the *get* function allows to read it as follows for a vertex descriptor *vd*: *int vdi = get(m, vd)*. Just as *get* allows to read data, *put* allows to write them. For example, the Dijksta's shortest path algorithm writes the predecessor of each vertex, as well as the distance to the source in such a property map.

The data themselves may be stored in the vertex or edge, or they may be stored in an external data structure, or they may be computed on the fly. This is an “implementation detail” of the particular property map.

Property maps in the Boost manuals: `http://www.boost.org/libs/property_map/doc/property_map.html`

Visitors

Visitors are ojects that provide functions that get called at specified event points by the algorithm they visit. The notion of visitors is a design pattern, and also used in CGAL, e.g., the *Arr_observer<Arrangement>* in the arrangement package.

The functions as well as the event points are library specific. Event points in graph algorithms are, for example, when a vertex is traversed the first time, or when all outgoing edges of a vertex are traversed.

Visitors in the BGL manual: `http://www.boost.org/libs/graph/doc/visitor_concepts.html`

Named Parameters

The algorithms of the BGL often have many parameters. Although the default value is most often appropriate, one has to write them explicitly, if one only wants to deviate from the default for the last one. The solution to this problem is to first write a tag and then the parameter, which for Dijkstra's shortest path algorithm, might look as follows:

```
std::vector<vertex_descriptor> p(num_vertices(g));
std::vector<int> d(num_vertices(g));
vertex_descriptor s = vertex(A, g);
dijkstra_shortest_paths(g, s, predecessor_map(&p[0]).distance_map(&d[0]));
```

The named parameters in the example use the tags *predecessor_map* and *distance_map* and they are concatenated with the dot operator.

Named parameters in the BGL manual: `http://www.boost.org/libs/graph/doc/bgl_named_params.html`

74.2 Extensions of the BGL

CGAL provides the partial specializations and free functions such that several data structures become model of some of the BGL graph concepts. Furthermore, we define the new graph concept *HalfedgeGraph*, a traits class *halfedge_graph_traits*, and free functions for accessing opposite edges as well as the clockwise and counterclockwise neighbor of an edge around a given vertex.

These extensions are used by the surface simplification algorithms which follow the design of the BGL as sketched in the previous section.

74.3 Header Files, Namespaces, and Naming Conventions

As we interface two libraries we have to explain what resides in which namespace, and what naming conventions we apply to what.

Partial specializations of the *boost::graph_traits<Graph>* for the CGAL package *Package* are in the namespace *boost* and in the headerfile *<CGAL/boost/graph/graph_traits_Package.h>*.

The *halfedge_graph_traits* class is in the namespace *CGAL*, but it is not capitalized as the *boost::graph_traits* is not. The same holds for the types and enums for vertex and edge properties.

74.4 Polyhedral Surfaces as Model of the Boost Graph Concept

The class *Polyhedron_3* is model of the graph concept. Furthermore this chapter introduces a new graph concept, the *HalfedgeGraph*.

74.4.1 Example: Minimum Spanning Tree of a Polyhedral Surface

The example code computes the minimum spanning tree on a polyhedral surface. More examples can be found in Chapter 53 on surface mesh simplification.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/boost/graph/graph_traits_Polyhedron_3.h>
#include <CGAL/boost/graph/properties_Polyhedron_3.h>

#include <iostream>
#include <list>

#include <boost/graph/kruskal_min_spanning_tree.hpp>

typedef CGAL::Cartesian<double>                                Kernel;
typedef Kernel::Vector_3                                       Vector;
typedef Kernel::Point_3                                        Point;
typedef CGAL::Polyhedron_3<Kernel>                             Polyhedron;

typedef boost::graph_traits<Polyhedron>::vertex_descriptor
   vertex_descriptor;
typedef boost::graph_traits<Polyhedron>::vertex_iterator
   vertex_iterator;
typedef boost::graph_traits<Polyhedron>::edge_descriptor
   edge_descriptor;

// The BGL makes heavy use of indices associated to the vertices
// We use a std::map to store the index

typedef std::map<vertex_descriptor,int> VertexIndexMap;
VertexIndexMap vertex_id_map;

// A std::map is not a property map, because it is not lightweight
typedef boost::associative_property_map<VertexIndexMap>
   VertexIdPropertyMap;
VertexIdPropertyMap vertex_index_pmap(vertex_id_map);

void
kruskal(const Polyhedron& P)
{
```

```
// associate indices to the vertices
{
  vertex_iterator vb, ve;
  int index = 0;

  // boost::tie assigns the first and second element of the std::pair
  // returned by boost::vertices to the variables vit and ve
  for(boost::tie(vb,ve)=boost::vertices(P); vb!=ve; ++vb ){
    vertex_descriptor  vd = *vb;
    vertex_id_map[vd]= index++;
  }
}

// We use the default edge weight which is the squared length of the
 edge
// This property map is defined in graph_traits_Polyhedron_3.h

// In the function call you can see a named parameter: vertex_index_map
 std::list<edge_descriptor> mst;

 boost::kruskal_minimum_spanning_tree(P,
                                              std::back_inserter(mst),

  boost::vertex_index_map(vertex_index_pmap) );

 std::cout << "#VRML V2.0 utf8\n"
    "Shape {\n"

74.4.2 Example: Using Vertices, and Edges with an ID

The following example program shows a call to the BGL Kruskal's minimum spanning tree algorithm accessing the id() field stored in a Polyhedron vertex.
The main function illustrates the access to the id() field.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/Polyhedron_items_with_id_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/boost/graph/graph_traits_Polyhedron_3.h>
#include <CGAL/boost/graph/properties_Polyhedron_3.h>

#include <iostream>
#include <list>

#include <boost/graph/kruskal_min_spanning_tree.hpp>

typedef CGAL::Cartesian<double>
   Kernel;
typedef Kernel::Point_3
   Point;
typedef CGAL::Polyhedron_3<Kernel,CGAL::Polyhedron_items_with_id_3>
   Polyhedron;

typedef boost::graph_traits<Polyhedron>::vertex_descriptor
   vertex_descriptor;
typedef boost::graph_traits<Polyhedron>::vertex_iterator
   vertex_iterator;
```

```
typedef boost::graph_traits<Polyhedron>::edge_descriptor
    edge_descriptor;

void
kruskal( const Polyhedron& P)
{

  // We use the default edge weight which is the squared length of the
    edge
  // This property map is defined in graph_traits_Polyhedron_3.h

  // This function call requires a vertex_index_map named parameter which
  // when  ommitted defaults to "get(vertex_index,graph)".
  // That default works here because the vertex type supports the "id()"
  // field which is used by the vertex_index internal property.
  std::list<edge_descriptor> mst;
  boost::kruskal_minimum_spanning_tree(P,std::back_inserter(mst));

  std::cout << "#VRML V2.0 utf8\n"
    "Shape {\n"
    "appearance Appearance {\n"
    "material Material { emissiveColor 1 0 0}}\n"
    "geometry\n"
    "IndexedLineSet {\n"
    "coord Coordinate {\n"
    "point [ \n";

  vertex_iterator vb, ve;
  for(boost::tie(vb,ve) = boost::vertices(P); vb!=ve; ++vb){
    std::cout << (*vb)->point() << "\n";
  }

  std::cout << "]\n"
    "}\n"
    "coordIndex [\n";

  for(std::list<edge_descriptor>::iterator it = mst.begin(); it !=
    mst.end(); ++it){
    std::cout << boost::source(*it,P)->id()
              << ", " << boost::target(*it,P)->id() <<  ", -1\n";
  }

  std::cout << "]\n"
    "}#IndexedLineSet\n"
    "}# Shape\n";
}

int main() {

  Polyhedron P;
```

```
  Point a(1,0,0);
  Point b(0,1,0);
  Point c(0,0,1);
  Point d(0,0,0);

  P.make_tetrahedron(a,b,c,d);

  // associate indices to the vertices using the "id()" field of the
     vertex.
  vertex_iterator vb, ve;
  int index = 0;

  // boost::tie assigns the first and second element of the std::pair
  // returned by boost::vertices to the variables vit and ve
  for(boost::tie(vb,ve)=boost::vertices(P); vb!=ve; ++vb ){
    vertex_descriptor  vd = *vb;
    vd->id() = index++;
  }

  kruskal(P);
  return 0;
}
```

74.5 Triangulations as Models of the Boost Graph Concept

Triangulations have vertices and faces. Edges are pairs of a face and the index of the edge. Particular care has to be taken with the infinite vertex, and its incident edges. One can either use a *boost::filtered_graph*, which makes the infinite edges invisible, or one can have a property map that returns an infinite length for these edges.

A classical example for an algorithm that is a combination of computational geometry and graph theory is the *Euclidean Minimum Spanning Tree* for a point set in the plane. It can be computed by running the minimum spanning tree algorithm on a Delaunay triangulation of the point set.

74.5.1 Example: Euclidean Minimum Spanning Tree

In the following example we create a Delaunay triangulation and run Kruskal's minimum spanning tree algorithm on it. Because the vertex handles of the triangulation are not indices in an array, we have to provide a property map that maps vertex handles to int's in the range *[0, t.number_of_vertices())*.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/boost/graph/graph_traits_Delaunay_triangulation_2.h>

#include <boost/graph/kruskal_min_spanning_tree.hpp>
#include <boost/graph/filtered_graph.hpp>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
```

```
typedef K::Point_2 Point;

typedef CGAL::Delaunay_triangulation_2<K> Triangulation;

// As we only consider finite vertices and edges
// we need the following filter

template <typename T>
struct Is_finite {

  const T* t_;

  Is_finite()
    : t_(NULL)
  {}

  Is_finite(const T& t)
    : t_(&t)
  { }

  template <typename VertexOrEdge>
  bool operator()(const VertexOrEdge& voe) const {
    return ! t_->is_infinite(voe);
  }
};

typedef Is_finite<Triangulation> Filter;
typedef boost::filtered_graph<Triangulation,Filter,Filter>
    Finite_triangulation;
typedef boost::graph_traits<Finite_triangulation>::vertex_descriptor
    vertex_descriptor;
typedef boost::graph_traits<Finite_triangulation>::vertex_iterator
    vertex_iterator;
typedef boost::graph_traits<Finite_triangulation>::edge_descriptor
    edge_descriptor;

// The BGL makes use of indices associated to the vertices
// We use a std::map to store the index
typedef std::map<vertex_descriptor,int> VertexIndexMap;
VertexIndexMap vertex_id_map;

// A std::map is not a property map, because it is not lightweight
typedef boost::associative_property_map<VertexIndexMap>
    VertexIdPropertyMap;
VertexIdPropertyMap vertex_index_pmap(vertex_id_map);

int
main(int,char*[])
{
  Triangulation t;
  Filter is_finite(t);
  Finite_triangulation ft(t, is_finite, is_finite);

  Point p ;
```

```
  while(std::cin >> p){
    t.insert(p);
  }

  vertex_iterator vit, ve;
  // Associate indices to the vertices
  int index = 0;
  // boost::tie assigns the first and second element of the std::pair
  // returned by boost::vertices to the variables vit and ve
  for(boost::tie(vit,ve)=boost::vertices(ft); vit!=ve; ++vit ){
    vertex_descriptor  vd = *vit;
    vertex_id_map[vd]= index++;
    }

  // We use the default edge weight which is the squared length of the
     edge
  // This property map is defined in graph_traits_Triangulation_2.h

  // In the function call you can see a named parameter: vertex_index_map
   std::list<edge_descriptor> mst;
   boost::kruskal_minimum_spanning_tree(t,
                                         std::back_inserter(mst),

   vertex_index_map(vertex_index_pmap));

   std::cout << "The edges of the Euclidean mimimum spanning tree:" <<
   std::endl;

   for(std::list<edge_descriptor>::iterator it = mst.begin(); it !=
   mst.end(); ++it){
     edge_descriptor ed = *it;
     vertex_descriptor svd = boost::source(ed,t);
     vertex_descriptor tvd = boost::target(ed,t);
     Triangulation::Vertex_handle sv = svd;
     Triangulation::Vertex_handle tv = tvd;
     std::cout << "[ " << sv->point() << "  |  " << tv->point() << " ] "
   << std::endl;
   }

   return 0;
}
```

File: examples/BGL_triangulation_2/emst.cpp

74.5.2 Example: Storing the Vertex ID in the Vertex

The algorithms of the BGL extensively use of the indices of vertices. In the previous example we stored the index in a *std::map* and turned that map in a property map. This property map was then passed as argument to the shortest path function.

If the user does not pass explicitly a property map, the graph algorithms use the property map returned by the call *boost::get(boost::vertex_index,ft)*. This property map assumes that the vertex has a member function *id()* that returns a reference to an int. Therefore CGAL offers a class *Triangulation_vertex_base_with_id_2*. It is in the users responsibility to set the indices properly.

The example further illustrates that the graph traits also works for the Delaunay triangulation.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_vertex_base_with_id_2.h>
#include <CGAL/boost/graph/graph_traits_Delaunay_triangulation_2.h>

#include <climits>
#include <boost/graph/dijkstra_shortest_paths.hpp>
#include <boost/graph/filtered_graph.hpp>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point;

typedef CGAL::Triangulation_vertex_base_with_id_2<K> Tvb;
typedef CGAL::Triangulation_face_base_2<K> Tfb;
typedef CGAL::Triangulation_data_structure_2<Tvb,Tfb> Tds;
typedef CGAL::Delaunay_triangulation_2<K, Tds> Triangulation;

// consider finite vertices and edges.

template <typename T>
struct Is_finite {

  const T* t_;

  Is_finite()
    : t_(NULL)
  {}

  Is_finite(const T& t)
    : t_(&t)
  { }

  template <typename VertexOrEdge>
  bool operator()(const VertexOrEdge& voe) const {
    return ! t_->is_infinite(voe);
  }
};

typedef Is_finite<Triangulation> Filter;
typedef boost::filtered_graph<Triangulation,Filter,Filter>
    Finite_triangulation;
typedef boost::graph_traits<Finite_triangulation>::vertex_descriptor
    vertex_descriptor;
typedef boost::graph_traits<Finite_triangulation>::vertex_iterator
    vertex_iterator;

int
```

```
main(int,char*[])
{
  Triangulation t;
  Filter is_finite(t);
  Finite_triangulation ft(t, is_finite, is_finite);

  t.insert(Point(0,0));
  t.insert(Point(1,0));
  t.insert(Point(0.2,0.2));
  t.insert(Point(0,1));
  t.insert(Point(0,2));

  vertex_iterator vit, ve;
  // associate indices to the vertices
  int index = 0;
  for(boost::tie(vit,ve)=boost::vertices(ft); vit!=ve; ++vit ){
    vertex_descriptor  vd = *vit;
    vd->id()= index++;
  }

  typedef boost::property_map<Triangulation, boost::vertex_index_t>::type
    VertexIdPropertyMap;
  VertexIdPropertyMap vertex_index_pmap = get(boost::vertex_index, ft);

  // Dijkstra's shortest path needs property maps for the predecessor and
    distance

  std::vector<double> distance(boost::num_vertices(ft));
  boost::iterator_property_map<std::vector<double>::iterator,
   VertexIdPropertyMap>
    distance_pmap(distance.begin(), vertex_index_pmap);

  vertex_descriptor source =  *boost::vertices(ft).first;
  std::cout << "\nStart dijkstra_shortest_paths at " << source->point()
   << std::endl;

  boost::dijkstra_shortest_paths(ft, source ,
                                 distance_map(distance_pmap)
                                 .predecessor_map(predecessor_pmap));

  for(boost::tie(vit,ve)=boost::vertices(ft); vit!=ve; ++vit ){
    vertex_descriptor vd = *vit;
    std::cout << vd->point() << " [" << vd->id() << "] ";
    std::cout << " has distance = "  << get(distance_pmap,vd) << " and
   predecessor ";
    vd = get(predecessor_pmap,vd);
    std::cout << vd->point() << " [" << vd->id() << "]\n";
  }
  return 0;
}
```

File: examples/BGL_triangulation_2/dijkstra_with_internal_properties.cpp

74.6 Arrangements as Models of the Boost Graph Concept

For the arrangements CGAL offers the graph traits for the arrangement itself as well as for its dual graph.

74.6.1 Example for the Arrangement as Graph

Arrangement instances are adapted to *boost* graphs by specializing the *boost:graph_traits* template for *Arrangement_2* instances. The graph-traits states the graph concepts that the arrangement class models (see below) and defines the types required by these concepts.

In this specialization the *Arrangement_2* vertices correspond to the graph vertices, where two vertices are adjacent if there is at least one halfedge connecting them. More precisely, *Arrangement_2::Vertex_handle* is the graph-vertex type, while *Arrangement_2::Halfedge_handle* is the graph-edge type. As halfedges are directed, we consider the graph to be directed as well. Moreover, as several interior-disjoint x-monotone curves (say circular arcs) may share two common endpoints, inducing an arrangement with two vertices that are connected with several edges, we allow parallel edges in our *boost* graph.

Given an *Arrangement_2* instance, we can efficiently traverse its vertices and halfedges. Thus, the arrangement graph is a model of the concepts *VertexListGraph* and *EdgeListGraph* introduced by the BGL. At the same time, we use an iterator adapter of the circulator over the halfedges incident to a vertex (*Halfedge_around_vertex_circulator* — see Section 32.2.2), so it is possible to go over the ingoing and outgoing edges of a vertex in linear time. Thus, our arrangement graph is a model of the concept *BidirectionalGraph* (this concept refines *IncidenceGraph*, which requires only the traversal of outgoing edges).

It is important to notice that the vertex descriptors we use are *Vertex_handle* objects and *not* vertex indices. However, in order to gain more efficiency in most BGL algorithm, it is better to have them indexed $0,1,\ldots,(n-1)$, where n is the number of vertices. We therefore introduce the *Arr_vertex_index_map<Arrangement>* class-template, which maintains a mapping of vertex handles to indices, as required by the BGL. An instance of this class must be attached to a valid arrangement vertex when it is created. It uses the notification mechanism (see Section 32.7) to automatically maintain the mapping of vertices to indices, even when new vertices are inserted into the arrangement or existing vertices are removed.

In most algorithm provided by the BGL, the output is given by *property maps*, such that each map entry corresponds to a vertex. For example, when we compute the shortest paths from a given source vertex s to all other vertices we can obtain a map of distances and a map of predecessors — namely for each v vertex we have its distance from s and a descriptor of the vertex that precedes v in the shortest path from s. If the vertex descriptors are simply indices, one can use vectors to efficiently represent the property maps. As this is not the case with the arrangement graph, we offer the *Arr_vertex_property_map<Arrangement,Type>* template allows for an efficient mapping of *Vertex_handle* objects to properties of type *Type*. Note however that unlike the *Arr_vertex_index_map* class, the vertex property-map class is not kept synchronized with the number of vertices in the arrangement, so it should not be reused in calls to BGL functions in case the arrangement is modified in between these calls.

In the following example we construct an arrangement of 7 line segments, as shown in Figure 74.1, then use Dijkstra's shortest-paths algorithm from the BGL to compute the graph distance of all vertices from the leftmost vertex in the arrangement v_0. Note the usage of the *Arr_vertex_index_map* and the *Arr_vertex_property_map* classes. The latter one, instantiated by the type *double* is used to map vertices to their distances from v_0.

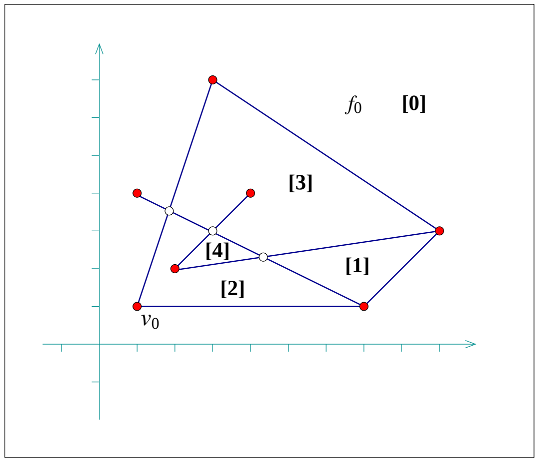

Figure 74.1: An arrangement of 7 line segments, as constructed by *ex_bgl_primal_adapter.cpp* and *ex_bgl_dual_adapter.cpp*. The breadth-first visit times for the arrangement faces, starting from the unbounded face f_0, are shown is brackets.

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

#include <climits>
#include <boost/graph/dijkstra_shortest_paths.hpp>

#include <CGAL/graph_traits_Arrangement_2.h>
#include <CGAL/Arr_vertex_index_map.h>

typedef CGAL::Cartesian<Number_type>                    Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>              Traits_2;
typedef Traits_2::Point_2                               Point_2;
typedef Traits_2::X_monotone_curve_2                    Segment_2;
typedef CGAL::Arrangement_2<Traits_2>                   Arrangement_2;

// A functor used to compute the length of an edge.
class Edge_length_func
{
public:

  // Boost property type definitions:

/* The folowing is a workaround for a bug in the BGL upto and including
    version
 * 103400.
 *
 * Unfortunately some of the calls to the get() function below from the
    BGL
 * code are qualified with the boost namespace, while others are not. For
     The
 * qualified calls the compiler naturally looks for the definition of the
 * function in boost namespace. For the other calls it searches the CGAL
 * namespace according to ADL (Koenig Lookup), as the type of the 1st
 * parameter is in CGAL namespace.
 *
 * One way to get around it is to provide 2 similar functions that do the
 * same thing. One in CGAL namespace provided in CGAL/Arr_vertex_map.h,
    and
 * the other in boost namespace below. The signature of the latter is
    slightly
 * changed to avoid redefinition. The type of its 1st parameter is
    defined in
 * boost namespace, and is a simple derivation of the 1st parameter of
    the
 * CGAL::get() function.

74.6.2 Example for the Dual of an Arrangement as Graph

It is possible to give a dual graph representation for an arrangement instance, such that each arrangement face corresponds to a graph vertex and two vertices are adjacent iff the corresponding faces share a common edge on their boundaries. This is done by specializing the *boost:graph_traits* template for *Dual<Arrangement_2>* instances, where *Dual<Arrangement_2>* is a template specialization that gives a dual interpretation to an arrangement instance.

In dual representation, *Arrangement_2::Face_handle* is the graph-vertex type, while *Arrangement_2::Halfedge_handle* is the graph-edge type. We treat the graph edges as directed, such that a halfedge e is directed from f_1, which is its incident face, to f_2, which is the incident face of its twin halfedge. As two arrangement faces may share more than a single edge on their boundary, we allow parallel edges in our *boost* graph. As is the case in the primal graph, the dual arrangement graph is also a model of the concepts *VertexListGraph*, *EdgeListGraph* and *BidirectionalGraph* (thus also of *IncidenceGraph*).

Since we use *Face_handle* objects as the vertex descriptors, we define the *Arr_face_index_map<Arrangement>* class-template, which maintains an efficient mapping of face handles to indices. We also provide the template *Arr_face_property_map<Arrangement,Type>* for associating arbitrary data with the arrangement faces.

In the following example we construct the same arrangement as in example *ex_bgl_primal_adapter.cpp* (see Figure 74.1), and perform breadth-first search on the graph faces, starting from the unbounded face. We extend the DCEL faces with an unsigned integer, marking the discover time of the face and use a breadth-first-search visitor to obtain these times and update the faces accordingly:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arrangement_2.h>

#include <climits>
#include <boost/graph/dijkstra_shortest_paths.hpp>

#include <CGAL/graph_traits_Dual_Arrangement_2.h>
#include <CGAL/Arr_face_index_map.h>
```

```
#include "arr_print.h"

typedef CGAL::Cartesian<Number_type>                        Kernel;

HalfedgeGraph

Concept

Definition

The concept HalfedgeGraph describes the requirements for a graph that is structurally equivalent to a polyhedral surface represented by a halfedge data structure, and it provides an interface for efficient access to the opposite edge of an edge, and to the successor and predecessor of an edge in the iterator range of the incoming edges of a vertex. Each vertex has a geometric position in space. As in a halfedge data structure we define the face adjacent to a halfedge to be to the *left* of the halfedge.

Requirements

For each *directed edge* $e = (v,w)$ its opposite edge $e' = (w,v)$ must be part of the graph.

The incoming edges of a vertex v have a fixed order, that is all calls of *in_edges(v,g)* must return the same iterator range, modulo a cyclic permutation. The order must be *clockwise*.

As the HalfedgeGraph is equivalent to a polyhedral surface there must exist an embedding for the vertices and edges such that the ordered edges do not intersect.

Refines

BidirectionalGraph
PropertyGraph

A model of HalfedgeGraph must have the *interior properties edge_is_border* attached to its edges, and it must have *vertex_is_border* and *vertex_point* attached to its vertices.

Associated Types

HalfedgeGraph:: halfedge_graph_traits<HalfedgeGraph>::Point

The type of the geometric location of a vertex.

Because (directed) edges must come in pairs, there is the additional notion of an *undirected edge*[1] for a pair of opposite directed edges. The number of undirected edges is exactly half the number of directed edges.

Note that the notion of directed and undirected edges does not imply the existence of two different types. The type *edge_descriptor* is used for both. An undirected edge must be implicitly handled, and there is no requirement on which of the directed edges of the undirected edge must be used to represent it.

HalfedgeGraph:: halfedge_graph_traits<HalfedgeGraph>::undirected_edge_iterator

An iterator that iterates over one and only one of the directed edges in each pair of opposite directed edges. The value type of the iterator is *boost::graph_traits<HalfedgeGraph> ::edge_descriptor*.

[1] The directed edges are not called *halfedges* (as in a *HalfedgeDS*) because from the point of view of this graph, being a refinement of a BGL graph, each directed edge is an edge in itself. In other words, the unqualified term edge refers to one and only one directed edge and not to a pair.

Valid Expressions

Following the BGL design, the following graph operations are defined as free rather than member functions.

template<class Graph>
std::pair<typename halfedge_graph_traits<HalfedgeGraph>::undirected_edge_iterator, typename halfedge_graph_traits<HalfedgeGraph>::undirected_edge_iterator>

undirected_edges(Graph g)

Returns the undirected edges of g.

An edge $e = (v, w)$ is said to be the *opposite edge* of edge $e' = (w, v)$.

template<class Graph>
typename boost::graph_traits<Graph const>::edge_descriptor

opposite_edge(typename boost::graph_traits<Graph const>::edge_descriptor e, Graph g)

Returns the opposite edge of e.

An edge $e' = (v, w)$ is called the *clockwise neighbor* of edge $e = (u, w)$, and e the *counterclockwise neighbor* of e', iff there exist two iterators *it* and it' in the iterator range *in_edges(w,g)* such that ***it* == *e* and ***it' == e'*, and *it' == it*++ or *it* is the last and *it'* the first iterator of the iterator range.

template<class Graph>
typename boost::graph_traits<Graph const>::edge_descriptor

next_edge_cw(typename boost::graph_traits<Graph const>::edge_descriptor e, Graph g)

Returns the clockwise neighbor of e.

template<class Graph>
typename boost::graph_traits<Graph const>::edge_descriptor

next_edge_ccw(typename boost::graph_traits<Graph const>::edge_descriptor e, Graph g)

Returns the counterclockwise neighbor of e.

A composition of these access functions yields an access function for the edge cycle adjacent to the same face. An edge $e' = (v, w)$ is called the *successor* of edge $e = (u, v)$, and e the *predecessor* of e', iff e' is the clockwise neighbor of the opposite edge of e.

template<class Graph>
typename boost::graph_traits<Graph const>::edge_descriptor

next_edge(typename boost::graph_traits<Graph const>::edge_descriptor e, Graph g)

Returns the successor of e.

template<class Graph>
typename boost::graph_traits<Graph const>::edge_descriptor

prev_edge(typename boost::graph_traits<Graph const>::edge_descriptor e, Graph g)

Returns the predecessor of *e*.

Class

boost::graph_traits< CGAL::Arrangement_2<Traits,Dcel> >

Definition

The class *graph_traits< CGAL::Arrangement_2<Traits,Dcel> >* is a partial specialization of *boost::graph_traits* for the class *Arrangement_2*. It provides the types associated to the graph concepts *BidirectionalGraph* and *EdgeAndVertexListGraph*.

#include <CGAL/boost/graph/graph_traits_Arrangement_2.h>

Types

typename CGAL::Arrangement_2::Vertex_handle

vertex_descriptor; The vertex descriptor.

typename CGAL::Arrangement_2::Halfedge_handle

edge_descriptor; The edge descriptor.

graph_traits< CGAL::Arrangement_2<Traits,Dcel> >:: vertex_iterator

An iterator corresponding to *CGAL::Arrangement_2::Vertex_iterator*, with the difference that its value type is a vertex descriptor and not *CGAL::Arrangement_2::Vertex*.

graph_traits< CGAL::Arrangement_2<Traits,Dcel> >:: edge_iterator

An iterator corresponding to *CGAL::Arrangement_2::Halfedge_iterator* with the difference that its value type is an edge descriptor and not *CGAL::Arrangement_2::Halfedge*.

graph_traits< CGAL::Arrangement_2<Traits,Dcel> >:: in_edge_iterator

An edge iterator which only iterates over the incoming edges around a vertex. It corresponds to a *CGAL::Arrangement_2::Halfedge_around_vertex_circulator* with the difference that its value type is an edge descriptor and not *CGAL::Arrangement_2::Halfedge*.

graph_traits< CGAL::Arrangement_2<Traits,Dcel> >:: out_edge_iterator

An edge iterator which only iterates over the outgoing halfedges around a vertex. It corresponds to a *CGAL::Arrangement_2::Halfedge_around_vertex_circulator* with the difference that its value type is an edge descriptor and not *CGAL::Arrangement_2::Halfedge*.

boost::sallow_parallel_edge_tag

edge_parallel_category;

Indicates that this graph does support multiedges.

boost::bidirectional_graph_tag

traversal_category; Indicates that this graph is bidirectional.

typename Arrangement_2::size_type

vertices_size_type; The size type of the vertex list.

typename Arrangement_2::size_type

edges_size_type; The size type of the edge list.

typename Arrangement_2::size_type

degree_size_type; The size type of the adjacency list.

The const specialization, *boost::graph_traits*< *CGAL::Arrangement_2*<*Traits,Dcel*> *const*> is also defined, using the constant handles in the arrangement.

Class

boost::graph_traits< CGAL::Polyhedron_3<Traits> >

Definition

The class *graph_traits< CGAL::Polyhedron_3<Traits> >* is a partial specialization of *boost::graph_traits* for the class *Polyhedron_3*. It provides the types associated to the graph concepts *BidirectionalGraph* and *EdgeAndVertexListGraph*.

#include <CGAL/boost/graph/graph_traits_Polyhedron_3.h>

Types

typename CGAL::Polyhedron_3::Vertex_handle

vertex_descriptor; The vertex descriptor.

typename CGAL::Polyhedron_3::Halfedge_handle

edge_descriptor; The edge descriptor.

graph_traits< CGAL::Polyhedron_3<Traits> >:: vertex_iterator

An iterator corresponding to *CGAL::Polyhedron_3::Vertex_iterator*, with the difference that its value type is a vertex descriptor and not *CGAL::Polyhedron_3::Vertex*.

graph_traits< CGAL::Polyhedron_3<Traits> >:: edge_iterator

An iterator corresponding to *CGAL::Polyhedron_3::Halfedge_iterator* with the difference that its value type is an edge descriptor and not *CGAL::Polyhedron_3::Halfedge*.

graph_traits< CGAL::Polyhedron_3<Traits> >:: in_edge_iterator

An edge iterator which only iterates over the incoming edges around a vertex. It corresponds to a *CGAL::Polyhedron_3::Halfedge_around_vertex_circulator* with the difference that its value type is an edge descriptor and not *CGAL::Polyhedron_3::Halfedge*.

graph_traits< CGAL::Polyhedron_3<Traits> >:: out_edge_iterator

An edge iterator which only iterates over the outgoing halfedges around a vertex. It corresponds to a *CGAL::Polyhedron_3::Halfedge_around_vertex_circulator* with the difference that its value type is an edge descriptor and not *CGAL::Polyhedron_3::Halfedge*.

boost::disallow_parallel_edge_tag

edge_parallel_category;

Indicates that this graph does not support multiedges.

boost::bidirectional_graph_tag

traversal_category; Indicates that this graph is bidirectional.

typename Polyhedron_3::size_type

vertices_size_type; The size type of the vertex list.

typename Polyhedron_3::size_type

edges_size_type; The size type of the edge list.

typename Polyhedron_3::size_type

degree_size_type; The size type of the adjacency list.

The const specialization, *boost::graph_traits*< *CGAL::Polyhedron_3*<*Traits*> *const*> is also defined, using the constant handles in the polyhedron.

Class

boost::graph_traits< CGAL::Triangulation_2<GT, TDS> >

Definition

The triangulations of CGAL are all models of the concepts *BidirectionalGraph* and *VertexAndEdgeListGraph* of the Boost Graph Library [SLL02].

The class *graph_traits< CGAL::Triangulation_2<GT, TDS> >* is a partial specialization of the class *boost::graph_traits<G>*.

The mapping between vertices and edges of the triangulation and the graph is rather straightforward, but there are some subtleties. The value type of the BGL iterators is the vertex or edge descriptor, whereas in CGAL all iterators and circulators are also handles and hence have as value type Vertex or Edge.

The graph traits class for triangulations does not distinguish between finite and infinite vertices and edges. As the edge weight computed with the default property map of BGL algorithms (obtained with *boost::get(t, boost::edge_weight)*) is the length of the edge, the edge weight is not well defined for infinite edges. For algorithms that make use of the edge weight the user must therefore define a *boost::filtered_graph* or pass a property map to the algorithm that returns "infinity" for infinite edges.

Note also that when you derive from the class *CGAL::Triangulation_2* you must upcast the object in order to use this partial specialization.

For the user convenience, CGAL provides the partial specializations for all 2D triangulation classes.

#include <CGAL/boost/graph/graph_traits_Triangulation_2.h>

Types

typedef Triangulation::Vertex_handle

vertex_descriptor; The vertex descriptor.

graph_traits< CGAL::Triangulation_2<GT, TDS> >:: edge_descriptor

The edge descriptor. It is constructible from and convertible to *Triangulation::Edge*. The edge descriptor is not a simple typedef, but a proper class, because in an undirected graph the edges *(u,v)* and *(v,u)* must be equal. This is not the case for the Edge type of the triangulation.

graph_traits< CGAL::Triangulation_2<GT, TDS> >:: vertex_iterator

The vertex iterator type. Its value type is *vertex_descriptor*.

graph_traits< CGAL::Triangulation_2<GT, TDS> >:: edge_iterator

The edge iterator type, Its value type is *edge_descriptor*.

graph_traits< CGAL::Triangulation_2<GT, TDS> >:: out_edge_iterator

An iterator for the outgoing edges incident to a vertex. Its value type is *edge_descriptor*.

graph_traits< CGAL::Triangulation_2<GT, TDS> >:: in_edge_iterator

An iterator for the incoming edges incident to a vertex. Its value type is *edge_descriptor*.

graph_traits< CGAL::Triangulation_2<GT, TDS> >:: adjacency_iterator

An iterator for the vertices adjacent to a vertex. Its value type is *vertex_descriptor*.

typedef boost::undirected_tag

directed_category;

typedef boost::disallow_parallel_edge_tag

edge_parallel_category;

Class

CGAL::halfedge_graph_traits< CGAL::Polyhedron_3<Traits> >

Definition

The class *halfedge_graph_traits< CGAL::Polyhedron_3<Traits> >* is a partial specialization of *CGAL::halfedge_graph_traits* for *Polyhedron_3*. It provides the types associated to the *HalfedgeGraph* concept.

#include <CGAL/boost/graph/halfedge_graph_traits_Polyhedron_3.h>

Types

halfedge_graph_traits< CGAL::Polyhedron_3<Traits> >:: undirected_edge_iterator

An edge iterator that iterates over one of the two opposite edges forming an undirected edge.
The value type is *CGAL::Polyhedron_3::Halfedge_const_handle*.

typename CGAL::Polyhedron_3<Traits>::Point_3

Point;	The point type of the vertex.

CGAL::Triangulation_vertex_base_with_id_2<TriangulationTraits_2, TriangulationVertexBase_2>

Class

Definition

The class *Triangulation_vertex_base_with_id_2* is a model of the concept *TriangulationVertexBase_2*, the base vertex of a 2D-triangulation. It provides an integer field that can be used to index vertices for BGL algorithms.

Note that the user is in charge to set the index correctly before running a graph algorithm.

#include <CGAL/Triangulation_vertex_base_with_id_2.h>

Parameters

The first template argument is the geometric traits class *TriangulationTraits_2* which provides the *Point_2*.

The second template argument is a vertex base class from which *Triangulation_vertex_base_with_id_2* derives. It has the default value *Triangulation_vertex_base_2<TriangulationTraits_2>*.

Is Model for the Concepts

CGAL::HalfedgeDS_halfedge_max_base_with_id<Refs>

Definition

The class *HalfedgeDS_halfedge_max_base_with_id<Refs>* is a model of the *HalfedgeDSHalfedge* concept. *Refs* is an instantiation of a *HalfedgeDS*. It is equivalent to *CGAL::HalfedgeDS_halfedge_base< Refs, CGAL::Tag_true, CGAL::Tag_true, CGAL::Tag_true>* with an added integer field which can be used to index halfedges in BGL algorithms. The class contains support for the previous, next, opposite, vertex and face pointers and the required type definitions. It can be used for deriving own halfedges.

Note that the user is in charge to set the index correctly before running a graph algorithm.

CGAL::HalfedgeDS_face_max_base_with_id<Refs>

Definition

The class *HalfedgeDS_face_max_base_with_id<Refs>* is a model of the *HalfedgeDSFace* concept. *Refs* is an instantiation of a *HalfedgeDS*. It is equivalent to *CGAL::HalfedgeDS_face_base< Refs, CGAL::Tag_true>* with an added integer field which can be used to index faces in BGL algorithms.. The class contains support for the incident halfedge pointer and the required type definitions. It can be used for deriving own faces.

Note that the user is in charge to set the index correctly before running a graph algorithm.

#include <CGAL/HalfedgeDS_face_max_base_with_id.h>

Is Model for the Concepts

HalfedgeDSFace . . . . page 1850

Creation

HalfedgeDS_face_max_base_with_id<Refs> f;		default constructor.
int	*f.id() const*	Returns the index.
int&	*f.id()*	Returns a reference to the index stored in the face.

CGAL::Polyhedron_items_with_id_3

Definition

The class *Polyhedron_items_with_id_3* is a model of the *PolyhedronItems_3* concept. It provides definitions for vertices with points, halfedges, and faces with plane equations, all of them with an additional integer field which can be used to index the items in a BGL algorithm. The polyhedron traits class must provide the respective types for the point and the plane equation. Vertices and facets both contain a halfedge handle to an incident halfedge.

#include <CGAL/Polyhedron_items_with_id_3.h>

Is Model for the Concepts

PolyhedronItems_3 . . . . page 1818

Types in *Polyhedron_items_with_id_3::Vertex_wrapper<Refs,Traits>::Vertex*

typedef Traits::Point_3 *Point;*
typedef CGAL::Tag_true *Supports_vertex_point;*

Types in *Polyhedron_items_with_id_3::Face_wrapper<Refs,Traits>::Face*

typedef Traits::Plane_3 *Plane;*
typedef CGAL::Tag_true *Supports_face_plane;*

Additional methods in all three items.

int *item.id() const*

Returns the index.

int& *item.id()* Returns a reference to the index stored in the item.

Creation

Polyhedron_items_with_id_3 items; default constructor.

Operations

Supported as required by the *PolyhedronItems_3* concept.

boost::edge_index_t

enum edge_index_t { *edge_index*}*;*

The constant *edge_index* is a property tag which identifies the *index* property of an edge of a BGL Graph.

Enum

CGAL::edge_is_border_t

#include <CGAL/boost/graph/properties.h>

enum edge_is_border_t { *edge_is_border* }*;*

The constant *edge_is_border* is a property tag which refers to the property of an edge of being a border edge.

edge_is_border is an interior property. That is, a property map for *edge_is_border* can be extracted from any model of a *HalfedgeGraph* using the BGL PropertyGraph interface:

boost::get(edge_is_border,graph)

The Boolean flag that indicates if the edge is a border can be directly accessed via:

boost::get(edge_is_border,graph,edge).

CGAL::vertex_is_border_t

#include <CGAL/boost/graph/properties.h>

enum vertex_is_border_t { *vertex_is_border*}*;*

The constant *vertex_is_border* is a property tag which refers to the property of a vertex of being a border vertex.

vertex_is_border is an interior property, that is, a property map for *vertex_is_border* can be extracted from any model of a *HalfedgeGraph* using the BGL PropertyGraph interface:

boost::get(vertex_is_border,graph)

The Boolean flag that indicates if the vertex is a border can be directly accessed via:

boost::get(vertex_is_border,graph,edge)

Enum

CGAL::vertex_point_t

#include <CGAL/boost/graph/properties.h>

enum vertex_point_t { *vertex_point*}*;*

The constant *vertex_point* is a property tag which refers to the geometric embedding property of a vertex of a *HalfedgeGraph*.

A *vertex_point* is an interior property, that is, a property map for a *vertex_point* can be extracted from any model of a *HalfedgeGraph* using the BGL PropertyGraph interface:

boost::get(vertex_point,graph)

A point of a vertex can be directly accessed via:

boost::get(vertex_point,graph,vertex)
boost::put(vertex_point,graph,vertex,newpoint)

CGAL and Boost Property Maps

Andreas Fabri and Laurent Saboret

Contents

75.1 A Short Introduction to the Boost Property Maps Library

The Boost Property Map Library consists mainly of interface specifications in the form of concepts. These interface specifications are intended for use by implementors of generic libraries in communicating requirements on template parameters to their users. In particular, the Boost Property Map concepts define a general purpose interface for mapping key objects to corresponding value objects, thereby hiding the details of how the mapping is implemented from algorithms. The implementation of types fulfilling the property map interface is up to the client of the algorithm to provide.

The Boost Property Map Library also contains a few adaptors that convert commonly used data-structures that implement a mapping operation, such as builtin arrays (pointers), iterators, and std::map, to have the property map interface.

Free functions *get* and *put* allow getting and putting information through a property map. The data themselves may be stored in the element, or they may be stored in an external data structure, or they may be computed on the fly. This is an “implementation detail” of the particular property map.

Property maps in the Boost manuals: `http://www.boost.org/libs/property_map/doc/property_map.html`

75.2 CGAL and Boost Property Maps

Some algorithms in CGAL take as input parameters iterator ranges and property maps to access information attached to elements of the sequence.

For example, the algorithms of chapters *Point_set_processing_3* 58 and *Surface_reconstruction_points_3* 49 take as input parameters iterator ranges and property maps to access each point's position and normal. Position and normal might be represented in various ways, e.g., as a class derived from the CGAL point class, or as a *std::pair<Point_3<K>, Vector_3<K> >*, or as a *boost::tuple<..,Point_3<K>, ..., Vector_3<K> >*.

This component provides property maps to support these cases:
CGAL::Dereference_property_map<T>
CGAL::First_of_pair_property_map<Pair> and *CGAL::Second_of_pair_property_map<Pair>*
CGAL::Nth_of_tuple_property_map<N, Tuple>

75.2.1 Example with Dereference_property_map

The following example reads a point set and removes 5% of the points. It uses *CGAL::Dereference_property_map<Point_3>* as position property map.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/property_map.h>
#include <CGAL/remove_outliers.h>
#include <CGAL/IO/read_xyz_points.h>

#include <vector>
#include <fstream>

// types
typedef CGAL::Exact_predicates_inexact_constructions_kernel Kernel;
typedef Kernel::Point_3 Point;

int main(void)
{
  // Reads a .xyz point set file in points[].
  // The Dereference_property_map property map can be omitted here as it
   is the default value.
  std::vector<Point> points;
  std::ifstream stream("data/oni.xyz");
  if (!stream ||
      !CGAL::read_xyz_points(stream, std::back_inserter(points),
                             CGAL::Dereference_property_map<Point>()))
  {
    std::cerr << "Error: cannot read file data/oni.xyz" << std::endl;
    return EXIT_FAILURE;
  }

  // Removes outliers using erase-remove idiom.
  // The Dereference_property_map property map can be omitted here as it
   is the default value.
  const double removed_percentage = 5.0; // percentage of points to
   remove
```

```
  const int nb_neighbors = 24; // considers 24 nearest neighbor points
  points.erase(CGAL::remove_outliers(points.begin(), points.end(),

   CGAL::Dereference_property_map<Point>(),
                                               nb_neighbors, removed_percentage),
                points.end());

  // Optional: after erase(), use Scott Meyer's "swap trick" to trim
    excess capacity
  std::vector<Point>(points).swap(points);

  return EXIT_SUCCESS;
}
```

File: examples/Point_set_processing_3/remove_outliers_example.cpp

75.2.2 Example with Pairs

The following example reads a point set from an input file and writes it to a file, both in the xyz format. Position and normal are stored in pairs and accessed through property maps.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/property_map.h>
#include <CGAL/IO/read_xyz_points.h>
#include <CGAL/IO/write_xyz_points.h>

#include <utility> // defines std::pair
#include <vector>
#include <fstream>

// types
typedef CGAL::Exact_predicates_inexact_constructions_kernel Kernel;
typedef Kernel::Point_3 Point;
typedef Kernel::Vector_3 Vector;

// Point with normal vector stored as a std::pair.
typedef std::pair<Point, Vector> Pwn;

int main(void)
{
    // Reads a .xyz point set file in points[].
    // Note: read_xyz_points_and_normals() requires an output iterator
    // over points and as well as property maps to access each
    // point position and normal.
    std::vector<Pwn> points;
    std::ifstream in("data/oni.xyz");
    if (!in ||
        !CGAL::read_xyz_points_and_normals(
            in,std::back_inserter(points),
            CGAL::First_of_pair_property_map<Pwn>(),
            CGAL::Second_of_pair_property_map<Pwn>()))
    {
```

```
      std::cerr << "Error: cannot read file data/oni.xyz" << std::endl;
      return EXIT_FAILURE;
    }

    // Saves point set.
    // Note: write_xyz_points_and_normals() requires an output iterator
    // over points as well as property maps to access each
    // point position and normal.
    std::ofstream out("oni_copy.xyz");
    if (!out ||
        !CGAL::write_xyz_points_and_normals(
            out, points.begin(), points.end(),
            CGAL::First_of_pair_property_map<Pwn>(),
            CGAL::Second_of_pair_property_map<Pwn>()))
    {
      return EXIT_FAILURE;
    }

    return EXIT_SUCCESS;
}
```

File: examples/Point_set_processing_3/read_write_xyz_point_set_example.cpp

75.2.3 Example with Tuples

The following example reads a point set in the *xyz* format and computes the average spacing. Index, position and color are stored in a tuple and accessed through property maps.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/compute_average_spacing.h>
#include <CGAL/IO/read_xyz_points.h>

#include <vector>
#include <fstream>
#include <boost/tuple/tuple.hpp>

// Types
typedef CGAL::Exact_predicates_inexact_constructions_kernel Kernel;
typedef Kernel::FT FT;
typedef Kernel::Point_3 Point;

// Data type := index, followed by the point, followed by three integers
    that
// define the Red Green Blue color of the point.
typedef boost::tuple<int, Point, int, int, int>
    IndexedPointWithColorTuple;

int main(void)
{
    // Reads a .xyz point set file in points.
    // As the point is the second element of the tuple (that is with
    index 1)
```

```
    // we use a property map that accesses the 1st element of the tuple.
    std::vector<IndexedPointWithColorTuple> points;
    std::ifstream stream("data/sphere_20k.xyz");
    if (!stream ||
        !CGAL::read_xyz_points(
            stream, std::back_inserter(points),

   CGAL::Nth_of_tuple_property_map<1,IndexedPointWithColorTuple>()))
    {
      std::cerr << "Error: cannot read file data/sphere_20k.xyz" <<
   std::endl;
      return EXIT_FAILURE;
    }

    // Initialize index and RGB color fields in tuple.
    // As the index and RGB color are respectively the first and
   third-fifth elements
    // of the tuple we use a get function from the property map that
   accesses the 0
    // and 2-4th elements of the tuple.
    for(unsigned int i = 0; i < points.size(); i++)
    {
      points[i].get<0>() = i;   // set index value of tuple to i

      points[i].get<2>() = 0;   // set RGB color to black
      points[i].get<3>() = 0;
      points[i].get<4>() = 0;
    }

    // Computes average spacing.
    const unsigned int nb_neighbors = 6; // 1 ring
    FT average_spacing = CGAL::compute_average_spacing(
                          points.begin(), points.end(),

   CGAL::Nth_of_tuple_property_map<1,IndexedPointWithColorTuple>(),
                          nb_neighbors);
    std::cout << "Average spacing: " << average_spacing << std::endl;

    return EXIT_SUCCESS;
}
```

File: examples/Point_set_processing_3/average_spacing_example.cpp

CGAL and Boost Property Maps Reference Manual

Andreas Fabri and Laurent Saboret

This package provides a framework for interfacing CGAL data structures with algorithms expecting Boost Property Maps.

75.3 Classified Reference Pages

Classes

75.4 Alphabetical List of Reference Pages

Class

CGAL::Dereference_property_map<T>

Definition

Property map that converts a *T** pointer (or in general an iterator over *T* elements) to the *T* object.

#include <CGAL/property_map.h>

Parameters

template<typename T>
struct *Dereference_property_map*;

Inherits From

boost::put_get_helper< T&, Dereference_property_map<T> >

Is Model for the Concepts

Model of *boost::LvaluePropertyMap* concept.

Types

Dereference_property_map<T>:: key_type	typedef to *T**
Dereference_property_map<T>:: value_type	typedef to *T*
Dereference_property_map<T>:: reference	typedef to *T&*
Dereference_property_map<T>:: category	*boost::lvalue_property_map_tag*

Creation

Dereference_property_map<T> pmap; — Constructor.

Operations

template<class Iter>
reference *pmap*[*Iter it*] — Access a property map element.
Template Parameters:
Iter: Type convertible to *key_type*.

Related Functions

Dereference_property_map<typename value_type_traits<Iter>::type>

make_dereference_property_map(Iter)

Free function to create a *Dereference_property_map* property map.

Example

See *property_map.cpp* example.

CGAL::First_of_pair_property_map<Pair>

Definition

Property map that accesses the first item of a *std::pair*.

#include <CGAL/property_map.h>

Parameters

template<typename Pair>
struct *First_of_pair_property_map*;

Parameters:
Pair: Instance of *std::pair*.

Inherits From

boost::put_get_helper< Pair::first_type& , First_of_pair_property_map<Pair> >

Is Model for the Concepts

Model of *boost::LvaluePropertyMap* concept.

Types

First_of_pair_property_map<Pair>:: key_type	typedef to *Pair**
First_of_pair_property_map<Pair>:: value_type	typedef to *Pair::first_type*
First_of_pair_property_map<Pair>:: reference	typedef to *value_type&*
First_of_pair_property_map<Pair>:: category	*boost::lvalue_property_map_tag*

Creation

First_of_pair_property_map<Pair> pmap;	Constructor.

Operations

template<class Iter> *reference*	*pmap*[*Iter pair*]	Access a property map element. *Template Parameters*: *Iter*: Type convertible to *key_type*.

Related Functions

First_of_pair_property_map<typename value_type_traits<Iter>::type>

make_first_of_pair_property_map(Iter)

Free function to create a *First_of_pair_property_map* property map.

See Also

CGAL::Second_of_pair_property_map<Pair> . . . . page 4309

Example

See *property_map.cpp* example.

CGAL::Nth_of_tuple_property_map<N, Tuple>

Class

Definition

Property map that accesses the Nth item of a *boost::tuple*.

#include <CGAL/property_map.h>

Parameters

template<int N, typename Tuple>
struct *Nth_of_tuple_property_map*;

Parameters:
N: Index of the item to access. *Tuple*: Instance of *boost::tuple*.

Inherits From

boost::put_get_helper< boost::tuples::element<N, Tuple>::type& , *Nth_of_tuple_property_map<N, Tuple> >*

Is Model for the Concepts

Model of *boost::LvaluePropertyMap* concept.

Types

Nth_of_tuple_property_map<N, Tuple>:: key_type

typedef to *Tuple**

Nth_of_tuple_property_map<N, Tuple>:: value_type

typedef to *boost::tuples::element<N, Tuple>::type*

Nth_of_tuple_property_map<N, Tuple>:: reference

typedef to *value_type&*

Nth_of_tuple_property_map<N, Tuple>:: category

boost::lvalue_property_map_tag

Creation

Nth_of_tuple_property_map<N, Tuple> pmap; Constructor.

Operations

template<class Iter>
reference *pmap*[*Iter tuple*]

Access a property map element.
Template Parameters:
Iter: Type convertible to *key_type*.

Related Functions

Nth_of_tuple_property_map<N, typename value_type_traits<Iter>::type>

make_nth_of_tuple_property_map(Iter)

Free function to create a *Nth_of_tuple_property_map* property map.

Example

See *property_map.cpp* example.

CGAL::Second_of_pair_property_map<Pair>

Class

Definition

Property map that accesses the second item of a *std::pair*.

#include <CGAL/property_map.h>

Parameters

template<typename Pair>
struct *Second_of_pair_property_map*;

Parameters:
Pair: Instance of *std::pair*.

Inherits From

boost::put_get_helper< Pair::second_type& , Second_of_pair_property_map<Pair> >

Is Model for the Concepts

Model of *boost::LvaluePropertyMap* concept.

Types

Second_of_pair_property_map<Pair>:: key_type

typedef to *Pair**

Second_of_pair_property_map<Pair>:: value_type

typedef to *Pair::second_type*

Second_of_pair_property_map<Pair>:: reference

typedef to *value_type&*

Second_of_pair_property_map<Pair>:: category

boost::lvalue_property_map_tag

Creation

Second_of_pair_property_map<Pair> pmap; Constructor.

Operations

template<class Iter>
reference *pmap*[*Iter pair*] Access a property map element.
Template Parameters:
Iter: Type convertible to *key_type*.

Related Functions

Second_of_pair_property_map<typename value_type_traits<Iter>::type>

make_second_of_pair_property_map(Iter)

Free function to create a *Second_of_pair_property_map* property map.

See Also

CGAL::First_of_pair_property_map<Pair> . . . . page 4305

Example

See *property_map.cpp* example.

Chapter 76

Handles, Ranges and Circulators

Olivier Devillers, Lutz Kettner, Sylvain Pion, Michael Seel, and Mariette Yvinec

Contents

76.1 Handles

Most data structures in CGAL use the concept of *Handle* in their user interface to refer to the elements they store. This concept describes what is sometimes called a trivial iterator. A *Handle* is akeen to a pointer to an object providing the dereference operator *operator*()* and member access *operator->()* but no increment or decrement operators like iterators. A *Handle* is intended to be used whenever the referenced object is not part of a logical sequence.

Model for a handle A simple pointer *T**, an iterator or a circulator with value type *T*, are also handles.

76.2 Ranges

Most data structures in CGAL use the concept of an iterator range. The *Range* and *ConstRange* concepts encapsulate the access to the first and the past-the-end iterators of an iterator range. STL containers are models of *Range*. The Boost.Range library provides good support around this concept as well.

76.3 Circulators

An introduction to the concept of circulators is given here. A couple of adaptors are presented that convert between iterators and circulators. Some useful functions for circulators follow. This chapter concludes with a discussion of the design decisions taken. For the full description of the circulator requirements, the provided base classes, the circulator tags, and the support for generic algorithms that work for iterators as well as for circulators please refer to the reference pages. Note that circulators are not part of STL, but of CGAL.

76.3.1 Introduction

The concept of iterators in STL is tailored for linear sequences [C++98, MS96]. In contrast, circular sequences occur naturally in many combinatorial and geometric structures. Examples are polyhedral surfaces and planar maps, where the edges emanating from a vertex or the edges around a facet form a circular sequence.

Since circular sequences do not allow for efficient iterators, we have introduced the new concept of *circulators*. They share most of the requirements of iterators, while the main difference is the lack of a past-the-end position in the sequence. Appropriate adaptors are provided between iterators and circulators to integrate circulators smoothly into the framework of STL. An example of a generic `contains` function illustrates the use of circulators. As usual for circular structures, a `do`-`while` loop is preferable, such that for the specific input, `c == d`, all elements in the sequence are reached.

```
template <class Circulator, class T>
bool contains( Circulator c, Circulator d, const T& value) {
    if (c != 0) {
        do {
            if (*c == value)
                return true;
        } while (++c != d);
    }
    return false;
}
```

Three circulator categories are defined: forward, bidirectional and random-access circulators. Given a circulator `c`, the operation `*c` denotes the item the circulator refers to. The operation `++c` advances the circulator by one item and `--c` steps a bidirectional circulator one item backwards. For random-access circulators `c+n` advances the circulator `n` steps. Two circulators can be compared for equality.

Circulators have a different notion of reachability and ranges than iterators. A circulator `d` is called *reachable* from a circulator `c` if `c` can be made equal to `d` with finitely many applications of the operator `++`. Due to the circularity of the sequence this is always true if both circulators refer to items of the same sequence. In particular, `c` is always reachable from `c`. Given two circulators `c` and `d`, the range `[c,d)` denotes all circulators obtained by starting with `c` and advancing `c` until `d` is reached, but does not include `d`, for `d` $\neq$ `c`. So far it is the same range definition as for iterators. The difference lies in the use of `[c,c)` to denote all items in the circular sequence, whereas for an iterator `i` the range `[i,i)` denotes the empty range. As long as `c != d` the range `[c,d)` behaves like an iterator range and could be used in STL algorithms. For circulators however, an additional test `c == NULL` is required that returns true if and only if the circular sequence is empty. As for C++, we recommend the use of 0 instead of `NULL`.

Besides the conceptual cleanness, the main reason for inventing a new concept with a similar intent as iterators is efficiency. An iterator is supposed to be a light-weight object – merely a pointer and a single indirection to advance the iterator. Although iterators could be written for circular sequences, we do not know of an efficient solution. The missing past-the-end situation in circular sequences can be solved with an arbitrary sentinel in the cyclic order, but this would destroy the natural symmetry in the structure (which is in itself a bad idea) and additional bookkeeping in the items and checking in the iterator advance method reduces efficiency. Another solution may use more bookkeeping in the iterator, e.g. with a start item, a current item, and a kind of winding-number that is zero for the `begin()`-iterator and one for the past-the-end situation[1]. We have introduced the concept of circulators that allows light-weight implementations and the CGAL support library provides adaptor classes that convert between iterators and circulators (with the corresponding penalty in efficiency), so as to integrate this new concept into the framework of STL.

A serious design problem is the slight change of the semantic for circulator ranges as compared to iterator ranges. Since this semantic is defined by the intuitive operators `++` and `==`, which we would like to keep for circulators as well, circulator ranges can be used in STL algorithms. This is in itself a useful feature, if there would not be the definition of a full range $[c, c)$ that an STL algorithm will treat as an empty range. However, the likelihood of a mistake may be overestimated, since for a container `C` supporting circulators there is no `end()` member function, and an expression such as `std::sort( C.begin(), C.end())` will fail. It is easy to distinguish iterators and circulators at compile time, which allows for generic algorithms supporting both as arguments. It is also possible to protect algorithms against inappropriate arguments using the same technique, see the reference pages for circulators, specifically the *Assert_iterator* and *is_empty_range* functions.

Warning: Please note that the definition of a range is different from that of iterators. An interface of a data structure must declare whether it works with iterators, circulators, or both. STL algorithms always specify only iterators in their interfaces. A range $[c, d)$ of circulators used in an interface for iterators will work as expected as long as $c \mathrel{!}= d$. A range $[c, c)$ will be interpreted as the empty range like for iterators, which is different than the full range that it should denote for circulators.

76.3.2 Forward Circulator

A class *Circulator* that satisfies the requirements of a forward circulator with the value type T, supports the following operations. See the reference pages for the full set of requirements. Note that the stated return values are not required, only a return value that is convertible to the stated type is required. As for C++, we recommend the use of 0 instead of `NULL`.

Types

Circulator:: value_type	the value type T.
Circulator:: reference	either reference or const reference to T.
Circulator:: pointer	either pointer or const pointer to T.
Circulator:: size_type	unsigned integral type that can hold the size of the sequence.
Circulator:: difference_type	signed integral type that can hold the distance between two circulators.
Circulator:: iterator_category	circulator category *Forward_circulator_tag*.

Creation

Circulator c;	a circulator equal to *NULL* denoting an empty sequence.
Circulator c(d);	a circulator equal to d.

[1] This is currently implemented as the adaptor class which provides a pair of iterators for a given circulator.

Operations

Circulator&	$c = d$	Assignment.
bool	$c == NULL$	Test for emptiness.
bool	$c \mathrel{!}= NULL$	Test for non-emptiness, i.e. *!(c == NULL)*.
bool	$c == d$	*c* is equal to *d* if they refer to the same item.
bool	$c \mathrel{!}= d$	Test for inequality, i.e. *!(c == d)*.
reference	$*c$	Returns the value of the circulator. If *Circulator* is mutable **c = t* is valid. *Precondition*: *c* is dereferenceable.
pointer	$c->$	Returns a pointer to the value of the circulator. *Precondition*: *c* is dereferenceable.
Circulator&	$++c$	Prefix increment operation. *Precondition*: *c* is dereferenceable. *Postcondition*: *c* is dereferenceable.
Circulator	$c++$	Postfix increment operation. The result is the same as that of: *Circulator tmp = c; ++c; return tmp;* .

76.3.3 Bidirectional Circulator

A class *Circulator* that satisfies the requirements of a bidirectional circulator with the value type *T*, supports the following operations in addition to the operations supported by a forward circulator.

Types

Circulator:: iterator_category

circulator category *Bidirectional_circulator_tag*.

Operations

Circulator&	$--c$	Prefix decrement operation. *Precondition*: *c* is dereferenceable. *Postcondition*: *c* is dereferenceable.
Circulator	$c--$	Postfix decrement operation. The result is the same as that of *Circulator tmp = c; --c; return tmp;* .

76.3.4 Random Access Circulator

A class *Circulator* that satisfies the requirements of a random access Circulator for the value type *T*, supports the following operations in addition to the operations supported by a bidirectional Circulator. In contrast to random access iterators, no comparison operators are available for random access circulators.

Types

Circulator:: iterator_category

circulator category *Random_access_circulator_tag*.

Operations

Circulator& $c += difference\_type\ n$

The result is the same as if the prefix increment operation was applied n times, but it is computed in constant time.

Circulator $c + difference\_type\ n$ Same as above, but returns a new circulator.

Circulator $difference\_type\ n + c$ Same as above.

Circulator& $c -= difference\_type\ n$

The result is the same as if the prefix decrement operation was applied n times, but it is computed in constant time.

Circulator $c - difference\_type\ n$ Same as above, but returns a new circulator.

reference $c[\ difference\_type\ n]$ Returns **(c + n)*.

difference_type $c - Circulator\ d$ returns the difference between the two circulators. The value will be in the interval $[1-s, s-1]$ if s is the size of the total sequence. The difference for a fixed circulator c (or d) with all other circulators d (or c) is a consistent ordering of the elements in the data structure. There has to be a minimal circulator $d_{\min}$ for which the difference $c - d_{\min}$ to all other circulators c is non-negative.

Circulator *c.min_circulator() const*

Returns the minimal circulator $c_{\min}$ in constant time.

76.3.5 Adaptors Between Iterators and Circulators

Algorithms working on iterator ranges can not be applied to circulator ranges in full generality, only to subranges (see the warning in Section 76.3.1). The following adaptors convert circulators to iterators and vice versa (with the unavoidable space and time penalty) to reestablish this generality.

#include <CGAL/circulator.h>

Container_from_circulator	container-like class with iterators built from a circulator
Circulator_from_iterator	circulator over a range of two iterators
Circulator_from_container	circulator for a container

The following example applies the generic `std::reverse()` algorithm from STL to a sequence given by a bidirectional circulator `c`. It uses the *Container_from_circulator* adaptor.

```
Circulator c;  // c must be at least bidirectional.
CGAL::Container_from_circulator<Circulator> container(c);
std::reverse( container.begin(), container.end());
```

Another example defines a circulator *c* for a vector of *int*'s. However, since there are no elements in the vector, the circulator denotes an empty sequence. If there were elements in the vector, the circulator would implement a random access modulus the size of the sequence.

```
std::vector<int> v;
typedef  CGAL::Circulator_from_iterator<
             std::vector<int>::iterator > Circulator;
Circulator c( v.begin(), v.end());
```

76.3.6 Functions on Circulators

A few functions deal with circulators and circulator ranges. The type *C* denotes a circulator. The type *IC* denotes either a circulator or an iterator. More on algorithms that work with circulators as well with iterators can be found in the reference pages.

#include <CGAL/circulator.h>

circulator_size(C c)	size of the sequence reachable by *c*
circulator_distance(C c, C d)	number of elements in the range $[c,d)$
iterator_distance(IC ic1, IC ic2)	number of elements in the range $[ic2,ic1)$
is_empty_range(IC ic1, IC ic2)	test the range $[ic2,ic1)$ for emptiness

Handles, Ranges and Circulators Reference Manual

Olivier Devillers, Lutz Kettner, Sylvain Pion, Michael Seel, and Mariette Yvinec

The concept of iterators in the STL is tailored for linear sequences.

CGAL extends this in several directions. First, it supports the notion of *Handle* (also sometimes refered to as the trivial iterator) which is used to document that no traversal operation is needed, only reference to an element. It also uses the *Range* and *ConstRange* concepts which encapsulates the access to both the first and the past-the-end iterators of an iterator range.

Besides linear sequences, circular sequences also occur naturally in many combinatorial and geometric structures. Examples are polyhedral surfaces and planar maps, where the edges emanating from a vertex or the edges around a facet form a circular sequence.

We provide several functions, classes and macros to assist in working with circulators: distance computation, adaptor classes converting between circulators and iterators, base classes to ease the implementation of circulators, and support for generic algorithms that work with circulators as well as with iterators.

Function

CGAL::Assert_circulator

Definition

Each of the following assertions, applicable to an iterator or a circulator or both, checks at compile time if its argument is of the kind stated in the assertions name, i.e. a circulator, an iterator, or a particular category of either an iterator or a circulator. Note that neither input nor output circulators exists.

#include <CGAL/circulator.h>

void	*Assert_circulator(C c)*
void	*Assert_iterator(I i)*
void	*Assert_circulator_or_iterator(IC i)*

void	*Assert_input_category(I i)*
void	*Assert_output_category(I i)*
void	*Assert_forward_category(IC ic)*
void	*Assert_bidirectional_category(IC ic)*
void	*Assert_random_access_category(IC ic)*

See Also

Circulator_tag, *Circulator_traits*, *query_circulator_or_iterator*, *Circulator*.

CGAL::circulator_distance

Function

Definition

The distance of a circulator c to a circulator d is the number of elements in the range $[c,d)$. It is defined to be zero for a circulator on an empty sequence and it returns the size of the data structure when applied to a range of the form $[c,c)$.

#include <CGAL/circulator.h>

template <class C>
C::difference_type *circulator_distance(C c, C d)*

See Also

circulator_size, *iterator_distance*, *is_empty_range*, *Circulator*.

CGAL::circulator_size

Definition

The size of a circulator is the size of the data structure it refers to. It is zero for a circulator on an empty sequence. The size can be computed in linear time for forward and bidirectional circulators, and in constant time for random access circulators using the minimal circulator. The function *circulator_size(c)* returns the circulator size. It uses the *c.min_circulator()* function if *c* is a random access circulator.

#include <CGAL/circulator.h>

template <class C>
C::size_type *circulator_size(C c)*

See Also

circulator_distance, *iterator_distance*, *is_empty_range*, *Circulator*.

Circulator

Definition

Note: This specification is a revised version based on the C++ Standard [C++98], which is available now. In particular, iterator traits are now assumed and required.

Iterators in the STL were tailored for linear sequences. The specialization for circular data structures leads to slightly different requirements which we will summarize in the *circulators* concept. The main difference is that a circular data structure has no natural past-the-end value. As a consequence, a container supporting circulators will not have an `end()`-member function. The semantic of a circulator range differs from the semantic of an iterator range. For a circulator c the range $[c,c)$ denotes the sequence of all elements in the data structure. For iterators, this range defines the empty sequence. A separate test for an empty sequence has been added to the circulator requirements: A comparison $c ==$ `NULL` for a circulator c is true for an empty sequence. As for C++, we recommend the use of 0 instead of `NULL`.

Similar to STL iterators, we distinguish between forward, bidirectional, and random access circulators[2]. Most requirements for circulators are equal to those for iterators. We present the changes, please refer to [MS96, chapter 18] or [C++98] for the iterator requirements.

Past-the-end value: There is no past-the-end value for circulators.

Singular values: There are no singular values for circulators[3]

Empty sequence: The comparison $c ==$ `NULL` (or $c == 0$) for a circulator c is `true` if c denotes an empty sequence, and `false` otherwise.

Dereferenceable values: A circulator that does not denote an empty sequence is dereferenceable.

Reachability: Each dereferenceable circulator can reach itself with a finite and non-empty sequence of applications of *operator++*.

Ranges: For any circulator c the range $[c,c)$ is a valid range. If the circulator refers to an empty sequence, the range $[c,c)$ denotes the empty range. Otherwise the circulator is dereferenceable and the range $[c,c)$ denotes the sequence of all elements in the data structure. *Remark:* When a circulator is used in a place of an iterator, as, for example, with an STL algorithm, it will work as expected with the only exception that, in STL algorithms, the range $[c,c)$ denotes always the empty range. This is not a requirement, but a consequence of the requirements stated here and the fact that the STL requirements for iterator ranges are based on the `operator++` and the `operator==`, which we use for circulators as well. In principle, we face here the difference between a `while` loop and a `do-while` loop.

Types: For a circulator of type C the following local types are required:

`C::value_type`	value type the circulator refers to.
`C::reference`	reference type used for the return type of `C::operator*()`.
`C::pointer`	pointer type used for the return type of `C::operator->()`.
`C::size_type`	unsigned integral type that can hold the size of a sequence
`C::difference_type`	signed integral type that can hold the distance between two circulators.
`C::iterator_category`	circulator category.

[2] Input circulators are a contradiction, since any circulator is supposed to return once to itself. Output circulators are not supported since they would be indistinguishable from output iterators.

[3] Since circulators must be implemented as classes anyway, there is no need to allow singular values for them. An un-initalized circulator does not have a singular value, but is supposed to refer to an empty sequence.

Forward Circulators

In the following, we assume that `a` and `b` are circulators of type `C`, `r` is of type `C&` (is assignable), and `T` denotes the value type of `C`. Let `D` be the distance type of `C`. As for C++, we recommend the use of 0 instead of `NULL`.

`C()`	a circulator equal to *NULL* denoting an empty sequence.
`a == NULL`	Returns `true` if `a` denotes an empty sequence, `false` otherwise. For simplicity, `NULL == a` is not required. The behavior for comparisons with pointer-like values different than `NULL` is undefined. A runtime assertion is recommended.
`a != NULL`	Returns `!(a == NULL)`.
`++r`	Like for forward iterators, but a dereferenceable circulator `r` will always be dereferenceable after `++r` (no past-the-end value). *Precondition:* `r` does not denote an empty sequence.
`r++`	Same as for `++r`.
`C::iterator_category`	circulator category `CBP_Forward_circulator_tag`.

Bidirectional Circulators

The same requirements as for the forward circulators hold for bidirectional iterators with the following change of the iterator category:

`C::iterator_category`	circulator category `CBP_Bidirectional_circulator_tag`.

Random Access Circulators

The same requirements as for the bidirectional circulators hold for random access iterators with the following changes and extensions.

The idea of random access extends naturally to circulators using equivalence classes modulus the length of the sequence. With this in mind, the additional requirements for random access iterators hold also for random access circulators. The only exception is that the random access iterator is required to provide a total order on the sequence, which a circulator cannot provide[4].

The difference of two circulators is not unique as for iterators. A reasonable requirement demands that the result is in a certain range $[1 - \mathit{size}, \mathit{size} - 1]$, where *size* is the size of the sequence, and that whenever a circulator `a` is fixed that the differences with all other circulators of the sequence form a consistent ordering.

For the adaptor to iterators a minimal circulator $d_{\min}$ is required for which the difference $c - d_{\min}$ to all other circulators c is non negative.

`b - a`	limited range and consistent ordering as explained above.
`a.min_circulator()`	returns the minimal circulator from the range $[a, a)$.
`C::iterator_category`	circulator category `CBP_Random_access_circulator_tag`.

[4] One might define an order by splitting the circle at a fixed point, e.g. the start circulator provided from the data structure. This is what the adaptor to iterators will do. Nonetheless, we do not require this for circulators.

Const Circulators

As with iterators, we distinguish between circulators and const circulators. The expression `*a = t` with `t` of type `T` is valid for mutable circulators. It is invalid for const circulators.

Circulators in Container Classes

For a container `x` of type `X` that supports circulators `c` the following naming convention is recommended:

`X::Circulator`	the type of the mutable circulator.
`X::Const_circulator`	the type of the const circulator.
`c = x.begin()`	the start circulator of the sequence. It is of type `X::Circulator` for a mutable container or `X::Const_circulator` for a const container. There must not be an `end()` member function.

If a container will support iterators and circulators, the member function `circulator_begin()` is proposed. However, the support of iterators and circulators simultaneously is not recommended, since it would lead to fat interfaces. The natural choice should be supported, the other concept will be available through adaptors.

Example

A generic `contains` function accepts a range of circulators and a value. It returns *true* if the value is contained in the sequence of items denoted by the range of circulators. As usual for circular structures, a `do-while` loop is preferable, such that for the specific input, `c == d`, all elements in the sequence are reached. Note that the example simplifies if the sequence is known to be non-empty, which is for example the common case in polyhedral surfaces where vertices and facets have at least one incident edge.

```
template <class Circulator, class T>
bool contains( Circulator c, Circulator d, const T& value) {
    if (c != 0) {
        do {
            if (*c == value)
                return true;
        } while (++c != d);
    }
    return false;
}
```

CGAL::Circulator_from_container<C>

Definition

The adaptor *Circulator_from_container<C>* provides a circulator for an STL container *C* of equal category as the iterator provided by the container. The iterator must be at least of the forward iterator category. The corresponding non-mutable circulator is called *Const_circulator_from_container<C>*.

The container type *C* is supposed to conform to the STL requirements for container (i.e. to have a *begin()* and an *end()* iterator as well as the local types *reference*, *const_reference*, *value_type*, *size_type*, and *difference_type*).

#include <CGAL/circulator.h>

Types

All types required for circulators are provided.

Creation

Circulator_from_container<C> c; — a circulator *c* on an empty sequence.

Circulator_from_container<C> c(C container);*

a circulator *c* initialized to refer to the first element in *container*, i.e. *container.begin()*. The circulator *c* refers to an empty sequence if the *container* is empty.

Circulator_from_container<C> c(C container, C::iterator i);*

a circulator *c* initialized to refer to the element **i* in *container*.
Precondition: **i* is dereferenceable and refers to *container*.

Operations

The adaptor conforms to the requirements of the corresponding circulator category. An additional member function *current_iterator()* returns the current iterator pointing to the same position as the circulator does.

See Also

Container_from_circulator, *Circulator_from_iterator*, *Circulator*.

Example

The following program composes two adaptors – from a container to a circulator and back to an iterator. It applies an STL sort algorithm on a STL vector with three elements. The resulting vector will be `[2 5 9]` as it is checked by the assertions. The program is part of the CGAL distribution.

```
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/circulator.h>

typedef CGAL::Circulator_from_container< std::vector<int> >  Circulator;
typedef CGAL::Container_from_circulator<Circulator>          Container;
typedef Container::iterator                                   Iterator;

int main() {
    std::vector<int> v;
    v.push_back(5);
    v.push_back(2);
    v.push_back(9);
    Circulator c( &v);
    Container  container( c);
    std::sort( container.begin(), container.end());
    Iterator i = container.begin();
    assert( *i == 2);
    i++;    assert( *i == 5);
    i++;    assert( *i == 9);
    i++;    assert(  i == container.end());
    return 0;
}
```

File: examples/Circulator/circulator_prog2.cpp

Class

CGAL::Circulator_from_iterator<I>

Definition

The adaptor *Circulator_from_iterator<I>* converts two iterators of type *I*, a begin and a past-the-end value, to a circulator of equal category. The iterator must be at least of the forward iterator category. The circulator will be mutable or non-mutable according to the iterator. Iterators provide no *size_type*. This adapter assumes *std::size_t* instead.

#include <CGAL/circulator.h>

Types

typedef I *iterator;*

In addition all types required for circulators are provided.

Creation

Circulator_from_iterator<I> c;

a circulator *c* on an empty sequence.

Circulator_from_iterator<I> c(I begin, I end, I cur = begin);

a circulator *c* initialized to refer to the element **cur* in a range `[`*begin*`,`*end*`)`. The circulator *c* refers to a empty sequence if *begin==end*.

Circulator_from_iterator<I> c(Circulator_from_iterator<I,T,Size,Dist> d, I cur);

a copy of circulator *d* referring to the element **cur*. The circulator *c* refers to a empty sequence if *d* does so.

Operations

The adaptor conforms to the requirements of the respective circulator category. An additional member function *current_iterator()* returns the current iterator pointing to the same position as the circulator does.

See Also

Container_from_circulator, *Circulator_from_container*, *Circulator*.

Example

The following program composes two adaptors – from an iterator to a circulator and back to an iterator. It applies an STL sort algorithm on a STL vector containing three elements. The resulting vector will be `[2 5 9]` as it is checked by the assertions. The program is part of the CGAL distribution.

```
#include <CGAL/basic.h>
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/circulator.h>

typedef  std::vector<int>::iterator                       I;
typedef  CGAL::Circulator_from_iterator<I>                Circulator;
typedef  CGAL::Container_from_circulator<Circulator> Container;
typedef  Container::iterator                              Iterator;

int main() {
    std::vector<int> v;
    v.push_back(5);
    v.push_back(2);
    v.push_back(9);
    Circulator c( v.begin(), v.end());
    Container  container( c);
    std::sort( container.begin(), container.end());
    Iterator i = container.begin();
    assert( *i == 2);
    i++;    assert( *i == 5);
    i++;    assert( *i == 9);
    i++;    assert(  i == container.end());
    return 0;
}
```

File: examples/Circulator/circulator_prog1.cpp

Another example usage for this adaptor is a random access circulator over the built-in C arrays. Given an array of type `T*` with a begin pointer `b` and a past-the-end pointer `e` the adaptor *Circulator_from_iterator<T*> c(b,e)* is a random access circulator *c* over this array.

Class

CGAL::Circulator_tag

Definition

Iterators and circulators as well as different categories of circulators can be distinguished with the use of discriminating functions and the following circulator tags. A couple of base classes simplify the task of writing own circulators. They declare the appropriate tags and the local types needed for circulators. To use the tags or base classes only it is sufficient to include:

#include <CGAL/circulator_bases.h>
#include <CGAL/circulator.h>

Compile Time Tags

struct Circulator_tag {};	any circulator.
struct Iterator_tag {};	any iterator.
struct Forward_circulator_tag {};	derived from *forward_iterator_tag*.
struct Bidirectional_circulator_tag {};	derived from *bidirectional_iterator_tag*.
struct Random_access_circulator_tag {};	derived from *random_access_iterator_tag*.

Base Classes

template < class Category, class T, class Dist = std::ptrdiff_t, class Size = std::size_t, class Ptr = T, class Ref = T& >*
struct Circulator_base {};

struct Forward_circulator_base {};
struct Bidirectional_circulator_base {};
struct Random_access_circulator_base {};

See Also

query_circulator_or_iterator, *Circulator_traits*, *Assert_circulator*, *CGAL_For_all*, *is_empty_range*, *Circulator*.

Example

The above declarations can be used to distinguish between iterators and circulators and between different circulator categories. The assertions can be used to protect a templatized algorithm against instantiations that do not fulfill the requirements. The following example program illustrates both.

```
#include <cassert>
#include <list>
#include <CGAL/circulator.h>

template <class C> inline  int foo( C c, std::forward_iterator_tag) {
```

```
    CGAL::Assert_circulator( c);
    CGAL::Assert_forward_category( c);
    return 1;
}
template <class C> inline  int foo( C c,
   std::random_access_iterator_tag) {
    CGAL::Assert_circulator( c);
    CGAL::Assert_random_access_category( c);
    return 2;
}
template <class I> inline  int foo( I i, CGAL::Iterator_tag) {
    CGAL::Assert_iterator( i);
    return 3;
}

template <class C> inline  int foo( C c, CGAL::Circulator_tag) {
    CGAL::Assert_circulator( c);
    typedef std::iterator_traits<C> Traits;
    typedef typename Traits::iterator_category iterator_category;
    return foo( c, iterator_category());
}
template <class IC> inline  int foo( IC ic) {
    typedef CGAL::Circulator_traits<IC> Traits;
    typedef typename Traits::category category;
    return foo( ic, category());
}

int main() {
    typedef CGAL::Forward_circulator_base<int>       F;
    typedef CGAL::Random_access_circulator_base<int> R;
    F f = F();
    R r = R();
    std::list<int> l;
    assert( foo( f)         == 1);
    assert( foo( r)         == 2);
    assert( foo( l.begin()) == 3);
    return 0;
}
```

File: examples/Circulator/circulator_prog3.cpp

Implementation

Since not all current compilers can eliminate the space needed for the compile time tags even when deriving from them, we implement a variant for each base class that contains a protected *void** data member called *_ptr*. Here, the allocated space in the derived classes can be reused.

template <class T, class Dist, class Size> *class Forward_circulator_ptrbase {};*	forward circulator.
template <class T, class Dist, class Size> *class Bidirectional_circulator_ptrbase {};*	bidirectional circulator.

template <class T, class Dist, class Size> *class Random_access_circulator_ptrbase* {}*;*	random access circulator.

CGAL::Circulator_traits<C>

Definition

The circulator traits class distinguishes between circulators and iterators. It defines a local type *category* that is identical to the type *Circulator_tag* if the iterator category of the argument *C* is a circulator category. Otherwise it is identical to the type *Iterator_tag*.

The local type *iterator_category* gives the corresponding iterator category for circulators, i.e. one of *forward_iterator_tag*, *bidirectional_iterator_tag*, or *random_access_iterator_tag*.

The local type *circulator_category* gives the corresponding circulator category for iterators, i.e. one of *Forward_circulator_tag*, *Bidirectional_circulator_tag*, or *Random_access_circulator_tag*.

#include <CGAL/circulator.h>

Types

Circulator_traits<C>:: category	either *Iterator_tag* or *Circulator_tag*.
Circulator_traits<C>:: iterator_category	corresponding iterator category for circulators.
Circulator_traits<C>:: circulator_category	corresponding circulator category for iterator

Example

A generic function *bar* that distinguishes between a call with a circulator range and a call with an iterator range:

```
template <class I>
void bar( I i, I j, CGAL::Iterator_tag) {
    CGAL::Assert_iterator(i);
    // This function is called for iterator ranges [i,j).
}
template <class C>
void bar( C c, C d, CGAL::Circulator_tag) {
    CGAL::Assert_circulator(c);
    // This function is called for circulator ranges [c,d).
}
template <class IC>
void bar( IC i, IC j) {  // calls the correct function
    return bar( i, j, typename CGAL::Circulator_traits<IC>::category());
}
```

CGAL::Container_from_circulator<C>

Definition

The adaptor *Container_from_circulator<C>* is a class that converts any circulator type *C* to a kind of container class, i.e. a class that provides an *iterator* and a *const_iterator* type and two member functions – *begin()* and *end()* – that return the appropriate iterators. By analogy to STL container classes these member functions return a const iterator in the case that the container itself is constant and a mutable iterator otherwise.

#include <CGAL/circulator.h>

Types

typedef C   *Circulator;*
Container_from_circulator<C>:: iterator
Container_from_circulator<C>:: const_iterator
Container_from_circulator<C>:: value_type
Container_from_circulator<C>:: reference
Container_from_circulator<C>:: const_reference
Container_from_circulator<C>:: pointer
Container_from_circulator<C>:: const_pointer
Container_from_circulator<C>:: size_type
Container_from_circulator<C>:: difference_type

Creation

Container_from_circulator<C> container;

any iterator of *container* will have a singular value.

Container_from_circulator<C> container(C c);

any iterator of *container* will have a singular value if the circulator *c* corresponds to an empty sequence.

Operations

iterator	*container.begin()*	the start iterator.
const_iterator	*container.begin() const*	the start const iterator.
iterator	*container.end()*	the past-the-end iterator.
const_iterator	*container.end() const*	the past-the-end const iterator.

The *iterator* and *const_iterator* types are of the appropriate iterator category. In addition to the operations required for their category, they have a member function *current_circulator()* that returns a circulator pointing to the same position as the iterator does.

See Also

Circulator_from_iterator, *Circulator_from_container*, *Circulator*.

Example

The generic `reverse()` algorithm from the STL can be used with an adaptor if at least a bidirectional circulator `c` is given.

```
Circulator c;  // c is assumed to be a bidirectional circulator.
CGAL::Container_from_circulator<Circulator> container(c);
reverse( container.begin(), container.end());
```

Implementation

The iterator adaptor keeps track of the number of rounds a circulator has done around the ring-like data structure (a kind of winding number). It is used to distinguish between the start position and the end position which will be denoted by the same circulator internally. This winding number is zero for the *begin()*-iterator and one for the *end()*-iterator. It is incremented whenever the internal circulator passes the *begin()* position. Two iterators are equal if their internally used circulators and winding numbers are equal. This is more general than necessary since an iterator equal to *end()*-iterator is not supposed to be incremented any more, which is here still possible in a defined manner.

The implementation is different for random access iterators. The random access iterator has to be able to compute the size of the data structure in constant time. This is for example needed if the difference of the past-the-end iterator and the begin iterator is taken, which is exactly the size of the data structure. Therefore, if the circulator is of the random-access category, the adapter chooses the minimal circulator for the internal anchor position. The minimal circulator is part of the random access circulator requirements, see Page 4324. For the random access iterator the adaptor implements a total ordering relation that is currently not required for random access circulators.

CGAL_For_all

Definition

In order to write algorithms that work with iterator ranges as well as with circulator ranges we have to consider the difference of representing an empty range. For iterators this is the range $[i,i)$, while for circulators it would be $c == NULL$, the empty sequence test. The function *is_empty_range* provides the necessary generic test which accepts an iterator range or a circulator range and says whether the range is empty or not.

#include <CGAL/circulator.h>

A macro *CGAL_For_all(i, j)* simplifies the writing of such simple loops as the one in the example of the function *is_empty_range*. *i* and *j* can be either iterators or circulators. The macro loops through the range [*i, j*). It increments *i* until it reaches *j*. The implementation looks like:

CGAL_For_all(i,j) ≡
```
for ( bool _circ_loop_flag = ! ::CGAL::is_empty_range(i,j);
        _circ_loop_flag;
        _circ_loop_flag = ((++i) != (j))
    )
```

Note that the macro behaves like a *for*-loop. It can be used with a single statement or with a statement block. For bidirectional iterators or circulators, a backwards loop macro *CGAL_For_all_backwards(i, j)* exists that decrements *j* until it reaches *i*.

Handle

Definition

Most data structures in CGAL use the concept of Handle in their user interface to refer to the elements they store. This concept describes what is sometimes called a trivial iterator. A Handle is akin to a pointer to an object providing the dereference operator *operator*()* and member access *operator->()* but no increment or decrement operators like iterators. A Handle is intended to be used whenever the referenced object is not part of a logical sequence.

Like iterators, the handle can be passed as template argument to *std::iterators_traits* in order to extract its *value_type*, the type of the element pointed to. The *iterator_category* is *void*.

Refines

DefaultConstructible, CopyConstructible, Assignable, EqualityComparable

The default constructed object must be unique as far as the equality operator is concerned (this serves the same purpose as NULL for pointers). (Note that this is not a generally supported feature of iterators of standard containers.)

Dereference

value_type&	$*h$	returns the object pointed to.
*value_type**	h −>	returns a pointer to the object pointed to.

Has Models

pointers
const pointers
iterators
circulators

Concept

Range

Definition

CGAL and the STL heavily use the concepts of iterators and iterator ranges to describe linear sequences of elements, and algorithms operating on these.

The Range concept aims at encapsulating an iterator range, by providing access to the first and past-the-end iterators of a range. The advantage is that the syntax for passing ranges is much more concise than passing two arguments separately.

Ranges come in different categories depending on the category of their iterator : mutable or constant (modifiability of the elements pointed to), and forward, bidirectional or random-access. The category can be queried using *std::iterator_traits* and the corresponding iterator type. Note that the concepts *Range* and *ConstRange* do not require anything on the category or the value type of the iterator. It must be precised in the documentation of any model of these concepts. For example, in the case of a vector of points, one would say: *This type is a model of Range concept, its iterator type is random-access and its value type is Point*.

Boost also offers the Boost.Range library which provides good support for ranges.

Finally, let us note that ranges, in general (especially in template context) need to be passed and returned by (const) reference for efficiency. This is a difference with iterators which are typically passed by value.

Refines

ConstRange

Boost's Range concept

Types

Range:: const_iterator	The constant iterator type.
Range:: iterator	The iterator type. It must be convertible to *const_iterator*.
Range:: size_type	An unsigned integral type that can represent the size of a range.

Member functions

const_iterator	*r.begin() const*	returns the const iterator pointing to the first element.
const_iterator	*r.end() const*	returns the past-the-end const iterator.
iterator	*r.begin()*	returns the iterator pointing to the first element.
iterator	*r.end()*	returns the past-the-end iterator.
size_type	*r.size() const*	returns the size of the range.
bool	*r.empty() const*	returns whether the range is empty.

Has Models

STL containers

ConstRange

Definition

A constant iterator range. Refer to the *Range* concept for more details.

Refines

Boost's Range concept

Types

ConstRange:: const_iterator	The constant iterator type.
ConstRange:: size_type	An unsigned integral type that can represent the size of a range.

Member functions

const_iterator	*r.begin() const*	returns the const iterator pointing to the first element.
const_iterator	*r.end() const*	returns the past-the-end const iterator.
size_type	*r.size() const*	returns the size of the range.
bool	*r.empty() const*	returns whether the range is empty.

Range

CGAL::is_empty_range

Definition

In order to write algorithms that work with iterator ranges as well as with circulator ranges we have to consider the difference of representing an empty range. For iterators this is the range $[i,i)$, while for circulators it would be *c == NULL*, the empty sequence test. The function *is_empty_range* provides the necessary generic test which accepts an iterator range or a circulator range and says whether the range is empty or not.

#include <CGAL/circulator.h>

template< class IC>		
bool	*is_empty_range(IC i, IC j)*	is *true* if the range [*i, j*) is empty, *false* otherwise. *Precondition*: *IC* is either a circulator or an iterator type. The range [*i, j*) is valid.

Example

The following function *process_all* accepts a range $[i, j)$ of an iterator or circulator *IC* and processes each element in this range:

```
template <class IC>
void process_all( IC i, IC j) {
    if (! CGAL::is_empty_range( i, j)) {
        do {
            process(*i);
        } while (++i != j);
    }
}
```

CGAL::query_circulator_or_iterator

Function

Definition

The following function distinguishes between circulators and iterators. It is based on iterator traits [C++98, Mye95] and *Circulator_traits*.

#include <CGAL/circulator.h>

template <class I>
Iterator_tag *query_circulator_or_iterator(I i)*

if the iterator category of *I* belongs to an iterator.

template <class C>
Circulator_tag *query_circulator_or_iterator(C c)*

if the iterator category of *C* belongs to a circulator.

Circulator_tag, *Circulator_traits*, *Assert_circulator*, *Circulator*.

Chapter 77

Geometric Object Generators

Olivier Devillers, Susan Hert, Michael Hoffmann, Lutz Kettner, and Sven Schönherr

Contents

77.1 Introduction

A variety of generators for geometric objects are provided in CGAL. They are useful as synthetic test data sets, e.g. for testing algorithms on degenerate object sets and for performance analysis.

Two kinds of point generators are provided: first, random point generators and second deterministic point generators. Most random point generators and a few deterministic point generators are provided as input iterators. The input iterators model an infinite sequence of points. The function *CGAL::cpp0x::copy_n()* can be used to copy a finite sequence; see Section 73.9. The iterator adaptor *Counting_iterator* can be used to create finite iterator ranges; see Section 73.9. Other generators are provided as functions that write to output iterators. Further functions add degeneracies or random perturbations.

In 2D, we provide input iterators to generate random points in a disc (*Random_points_in_disc_2*), in a square (*Random_points_in_square_2*), on a circle (*Random_points_on_circle_2*), on a segment (*Random_points_on_segment*), and on a square (*Random_points_on_square_2*). For generating grid points we provide three functions, *points_on_segment_2*, *points_on_square_grid_2* that write to output iterators and an input iterator *Points_on_segment_2*.

For 3D points, input iterators are provided for random points uniformly distributed in a sphere (*Random_points_in_sphere_3*) or cube (*Random_points_in_cube_3*) or on the boundary of a sphere (*Random_points_on_sphere_3*). For generating 3D grid points, we provide the function *points_on_cube_grid_3* that writes to an output iterator.

For higher dimensions, input iterators are provided for random points uniformly distributed in a d-dimensional cube (*Random_points_in_cube_d*) or d-dimensional ball (*Random_points_in_ball_d*) or on the boundary of a sphere (*Random_points_on_sphere_d*). For generating grid points, we provide the function *points_on_grid_d* that writes to an output iterator.

We also provide two functions for generating more complex geometric objects. The function *random_convex_set_2* computes a random convex planar point set of a given size where the points are drawn from a specific domain and *random_polygon_2* generates a random simple polygon from points drawn from a specific domain.

77.1.1 Random Perturbations

Degenerate input sets like grid points can be randomly perturbed by a small amount to produce *quasi*-degenerate test sets. This challenges numerical stability of algorithms using inexact arithmetic and exact predicates to compute the sign of expressions slightly off from zero. For this the function *perturb_points_2* is provided.

77.1.2 Adding Degeneracies

For a given point set certain kinds of degeneracies can be produced by adding new points. The *random_selection()* function is useful for generating multiple copies of identical points. The function *random_collinear_points_2()* adds collinearities to a point set.

77.1.3 Support Functions and Classes for Generators

The function *random_selection* chooses n items at random from a random access iterator range which is useful to produce degenerate input data sets with multiple entries of identical items.

77.2 Example Generating Degenerate Point Sets

We want to generate a test set of 1000 points, where 60% are chosen randomly in a small disc, 20% are from a larger grid, 10% are duplicates points, and 10% collinear points. A random shuffle removes the construction order from the test set. See Figure 77.1 for the example output.

```
#include <CGAL/Simple_cartesian.h>
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/point_generators_2.h>
#include <CGAL/algorithm.h>
#include <CGAL/random_selection.h>

using namespace CGAL;

typedef Simple_cartesian<double>          R;
```

```
typedef R::Point_2                          Point;
typedef Creator_uniform_2<double,Point>  Creator;
typedef std::vector<Point>                  Vector;

int main() {
    // Create test point set. Prepare a vector for 1000 points.
    Vector points;
    points.reserve(1000);

    // Create 600 points within a disc of radius 150.
    Random_points_in_disc_2<Point,Creator> g( 150.0);
    CGAL::cpp0x::copy_n( g, 600, std::back_inserter(points));

    // Create 200 points from a 15 x 15 grid.
    points_on_square_grid_2( 250.0, 200,
   std::back_inserter(points),Creator());

    // Select 100 points randomly and append them at the end of
    // the current vector of points.
    random_selection( points.begin(), points.end(), 100,
                      std::back_inserter(points));

    // Create 100 points that are collinear to two randomly chosen
    // points and append them to the current vector of points.
    random_collinear_points_2( points.begin(), points.end(), 100,
                               std::back_inserter( points));

    // Check that we have really created 1000 points.
    assert( points.size() == 1000);

    // Use a random permutation to hide the creation history
    // of the point set.
    std::random_shuffle( points.begin(), points.end(), default_random);

    // Check range of values.
    for ( Vector::iterator i = points.begin(); i != points.end(); i++){
        assert( i->x() <=  251);
        assert( i->x() >= -251);
        assert( i->y() <=  251);
        assert( i->y() >= -251);
    }
    return 0;
}
```

File: examples/Generator/random_degenerate_point_set.cpp

77.3 Example Generating Grid Points

The second example demonstrates the point generators with integer points. Arithmetic with *double*s is sufficient to produce regular integer grids. See Figure 77.2 for the example output.

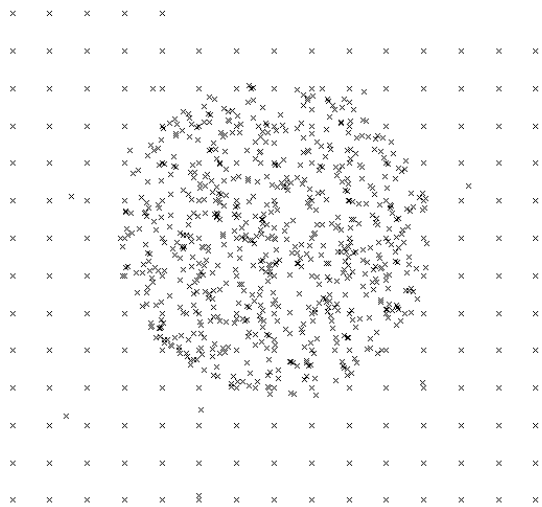

Figure 77.1: Output of example program for point generators.

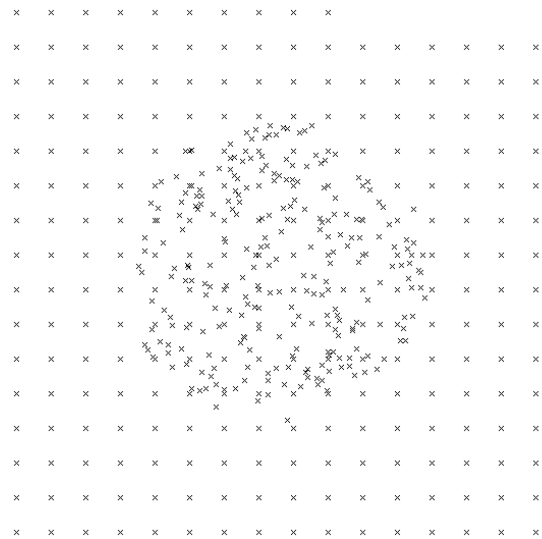

Figure 77.2: Output of example program for point generators working on integer points.

```
#include <CGAL/Simple_cartesian.h>
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/point_generators_2.h>
#include <CGAL/algorithm.h>

using namespace CGAL;

typedef Simple_cartesian<int>          K;
typedef K::Point_2                     Point;
typedef Creator_uniform_2<int,Point>   Creator;

int main() {
    // Create test point set. Prepare a vector for 400 points.
    std::vector<Point> points;
    points.reserve(400);

    // Create 250 points from a 16 x 16 grid. Note that the double
    // arithmetic _is_ sufficient to produce exact integer grid points.
    // The distance between neighbors is 34 pixel = 510 / 15.
    points_on_square_grid_2( 255.0, 250,
   std::back_inserter(points),Creator());

    // Lower, left corner.
    assert( points[0].x() == -255);
    assert( points[0].y() == -255);

    // Upper, right corner. Note that 6 points are missing to fill the
   grid.
    assert( points[249].x() == 255 - 6 * 34);
    assert( points[249].y() == 255);
```

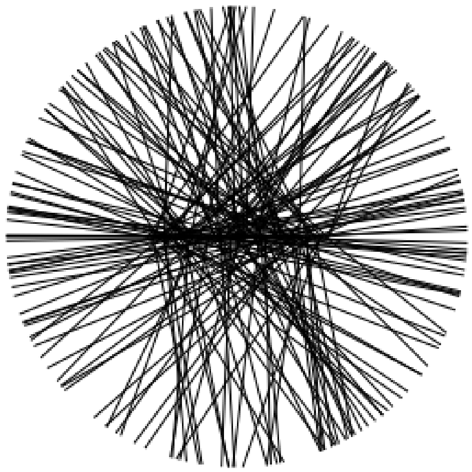

Figure 77.3: Output of the first example program for the generic generator.

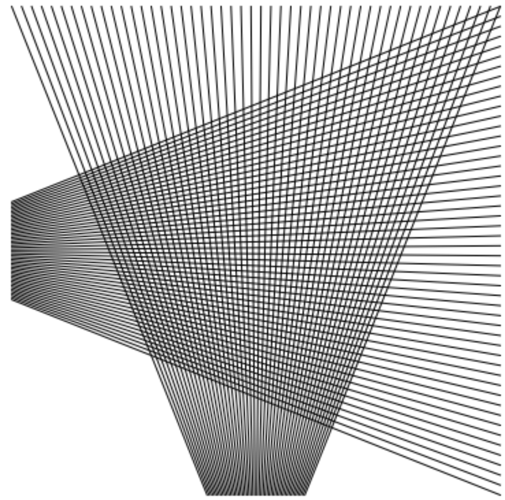

Figure 77.4: Output of the second example program for the generic generator without using intermediate storage.

```
    // Create 250 points within a disc of radius 150.
    Random_points_in_disc_2<Point,Creator> g( 150.0);
    CGAL::cpp0x::copy_n( g, 250, std::back_inserter(points));

    // Check that we have really created 500 points.
    assert( points.size() == 500);
    return 0;
}
```

File: examples/Generator/random_grid.cpp

77.4 Examples Generating Segments

The following two examples illustrate the use of the generic functions from Section 73.9 like *Join_input_iterator_2* to generate composed objects from other generators – here two-dimensional segments from two point generators.

We want to generate a test set of 200 segments, where one endpoint is chosen randomly from a horizontal segment of length 200, and the other endpoint is chosen randomly from a circle of radius 250. See Figure 77.3 for the example output.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/Point_2.h>
#include <CGAL/Segment_2.h>
#include <CGAL/point_generators_2.h>
```

```
#include <CGAL/function_objects.h>
#include <CGAL/Join_input_iterator.h>
#include <CGAL/algorithm.h>

using namespace CGAL;

typedef Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2                               Point;
typedef Creator_uniform_2<double,Point>  Pt_creator;
typedef K::Segment_2                             Segment;
typedef std::vector&lt;Segment&gt;                     Vector;

int main() {
    // Create test segment set. Prepare a vector for 200 segments.
    Vector segs;
    segs.reserve(200);

    // Prepare point generator for the horizontal segment, length 200.
    typedef  Random_points_on_segment_2<Point,Pt_creator>  P1;
    P1 p1( Point(-100,0), Point(100,0));

    // Prepare point generator for random points on circle, radius 250.
    typedef  Random_points_on_circle_2<Point,Pt_creator>  P2;
    P2 p2( 250);

    // Create 200 segments.
    typedef Creator_uniform_2< Point, Segment> Seg_creator;
    typedef Join_input_iterator_2< P1, P2, Seg_creator> Seg_iterator;
    Seg_iterator g( p1, p2);
    CGAL::cpp0x::copy_n( g, 200, std::back_inserter(segs));

    assert( segs.size() == 200);
    for ( Vector::iterator i = segs.begin(); i != segs.end(); i++){
        assert( i->source().x() <=  100);
        assert( i->source().x() >= -100);
        assert( i->source().y() ==    0);
        assert( i->target().x() * i->target().x() +
                i->target().y() * i->target().y() <=  251*251);
        assert( i->target().x() * i->target().x() +
                i->target().y() * i->target().y() >=  249*249);
    }
    return 0;
}
```

File: examples/Generator/random_segments1.cpp

The second example generates a regular structure of 100 segments; see Figure 77.4 for the example output. It uses the *Points_on_segment_2* iterator, *Join_input_iterator_2* and *Counting_iterator* to avoid any intermediate storage of the generated objects until they are used.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
```

```cpp
#include <algorithm>
#include <vector>
#include <CGAL/point_generators_2.h>
#include <CGAL/function_objects.h>
#include <CGAL/Join_input_iterator.h>
#include <CGAL/Counting_iterator.h>

using namespace CGAL;

typedef Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2                                      Point;
typedef K::Segment_2                                    Segment;
typedef Points_on_segment_2<Point>                      PG;
typedef Creator_uniform_2< Point, Segment>              Creator;
typedef Join_input_iterator_2< PG, PG, Creator>         Segm_iterator;
typedef Counting_iterator<Segm_iterator,Segment>        Count_iterator;
typedef std::vector&lt;Segment&gt;                            Vector;

int main() {
    // Create test segment set. Prepare a vector for 100 segments.
    Vector segs;
    segs.reserve(100);

    // A horizontal like fan.
    PG p1( Point(-250, -50), Point(-250, 50),50);   // Point generator.
    PG p2( Point( 250,-250), Point( 250,250),50);
    Segm_iterator  t1( p1, p2);                     // Segment generator.
    Count_iterator t1_begin( t1);                   // Finite range.
    Count_iterator t1_end( t1, 50);
    std::copy( t1_begin, t1_end, std::back_inserter(segs));

    // A vertical like fan.
    PG p3( Point( -50,-250), Point(  50,-250),50);
    PG p4( Point(-250, 250), Point( 250, 250),50);
    Segm_iterator  t2( p3, p4);
    Count_iterator t2_begin( t2);
    Count_iterator t2_end( t2, 50);
    std::copy( t2_begin, t2_end, std::back_inserter(segs));

    CGAL_assertion( segs.size() == 100);
    for ( Vector::iterator i = segs.begin(); i != segs.end(); i++){
        CGAL_assertion( i->source().x() <=  250);
        CGAL_assertion( i->source().x() >= -250);
        CGAL_assertion( i->source().y() <=  250);
        CGAL_assertion( i->source().y() >= -250);
        CGAL_assertion( i->target().x() <=  250);
        CGAL_assertion( i->target().x() >= -250);
        CGAL_assertion( i->target().y() <=  250);
        CGAL_assertion( i->target().y() >= -250);
    }
    return 0;
}
```

File: examples/Generator/random_segments2.cpp

77.5 Example Generating Point Sets in d dimensions

The following example generates points inside a cube in dimension 5 (examples for ball and sphere are available in the example directory) :

```
#include <iostream>
#include <vector>
#include <CGAL/Cartesian_d.h>
#include <CGAL/point_generators_d.h>

typedef CGAL::Cartesian_d<double>                          Kd;
typedef Kd::Point_d                                        Point;

int main ()
{
  int nb_points = 10;
  int dim =5;
  double size = 100.0;
  std::cout << "Generating "<<nb_points<<" random points in a cube in "
        <<dim<<"D, coordinates from "<<-size<<" to "<<size<<std::endl;
  std::vector<Point> v;
  v.reserve (nb_points);
  CGAL::Random_points_in_cube_d<Point> gen (dim, size);
  for (int i = 0; i < nb_points; ++i) v.push_back (*gen++);
  for (int i = 0; i < nb_points; ++i) std::cout<<" "<<v[i]<<std::endl;
  return 0;
}
```

File: examples/Generator/cube_d.cpp

The output of this example looks like:

```
Generating 10 random points in a cube in 5D, coordinates from -100 to 100
 5 32.9521 26.0403 59.3979 -99.2553 15.5102

Next example generates grid points in dimension $dim = 4$. Since the required number of points, 20 is between 2^{dim} and 3^{dim} the supporting grid has $3 \times 3 \times 3 \times 3$ points. Since the size parameter is 5, the coordinates are in $\{-5, 0, 5\}$, but since the number of points verifies $20 \le 3^{dim-1}$, all generated points have the same last coordinate -5.

```
#include <iostream>
#include <vector>
#include <CGAL/Cartesian_d.h>
#include <CGAL/point_generators_d.h>
#include <CGAL/constructions_d.h>

typedef CGAL::Cartesian_d<double>                                 Kd;
typedef Kd::Point_d                                               Point;
typedef CGAL::Creator_uniform_d
          <std::vector<double>::iterator, Point>                  Creator_d;

int main ()
{
  int nb_points = 20;
  int dim = 4;
  double size = 5.0;
  std::cout << "Generating "<<nb_points<<" grid points in "
              <<dim<<"D" << std::endl;
  std::vector<Point> v;
  v.reserve(nb_points);
  CGAL::points_on_cube_grid_d (dim, size, (std::size_t) nb_points,
                               std::back_inserter(v), Creator_d(dim) );
  for (int i = 0; i < nb_points; ++i) std::cout<<"  "<<v[i]<<std::endl;
  return 0;
}
```

File: examples/Generator/grid_d.cpp

The output of previous example corresponds to the points of this figure depicted in red or pink (pink points are "inside" the cube). The output is:

```

77.6 Design and Implementation History

Lutz Kettner coded generators in 2D and 3D For points *in* and *on* sphere, points are generated in a cube up to the moment the point is inside the sphere, then it is normalized to go on the boundary if needed.

Sven Schnherr implemented the Random class.

Michael Hoffmann coded the random convex polygon,

Geert-Jan Giezeman and Susan Hert coded the random simple polygon.

Olivier Devillers coded generators in high dimensions. For points *in ball* and *on sphere*, points are generated on a sphere/ball boundary as a product of normal distributions, then it is normalized. If needed a random radius (with relevant distribution) is used to put the point inside the ball.

Geometric Object Generators Reference Manual

Olivier Devillers, Susan Hert, Michael Hoffmann, Lutz Kettner, and Sven Schönherr

This chapter describes the functions and classes provided in CGAL that are useful for generating synthetic test data sets, *e.g.,* for testing algorithms on degenerate object sets and for performance analysis. These include a class for generating random numbers and function for selecting random items from a set of objects, generators for two-dimensional and three-dimensional points sets, a generator for random convex sets and one for simple polygons. The STL algorithm *std::random_shuffle* is useful with these functions and classes to to achieve random permutations for otherwise regular generators (*e.g.*, points on a grid or segment).

Variable

CGAL::default_random

Definition

The variable *default_random* is the default random numbers generator used for the generator functions and classes.

#*include* <*CGAL/Random.h*>

Random   *default_random;*

CGAL::perturb_points_2

Function

Definition

The function *perturb_points_2* perturbs each point in a given range of points by a random amount.

#include <CGAL/point_generators_2.h>

template <class ForwardIterator>
void perturb_points_2(
ForwardIterator first,
ForwardIterator last,
double xeps,
double yeps = xeps,
Random& rnd = default_random,
Creator creator = Creator_uniform_2<Kernel_traits<P>::Kernel::RT,P>)

perturbs the points in the range $[first, last)$ by replacing each point with a random point from the *xeps* $\times$ *yeps* rectangle centered at the original point. Two random numbers are needed from *rnd* for each point.

Requirements

- *Creator* must be a function object accepting two *double* values *x* and *y* and returning an initialized point *(x,y)* of type *P*.

  Predefined implementations for these creators like the default are described in Section 73.9.
- The *value_type* of the *ForwardIterator* must be assignable to *P*.
- *P* is equal to the *value_type* of the *ForwardIterator* when using the default initializer.
- The expressions *to_double((*first).x())* and *to_double((*first).y())* must result in the respective coordinate values.

Function

CGAL::points_on_segment_2

Definition

The function *points_on_segment_2* generates a set of points equally spaced on a segment given the endpoints of the segment.

#include <CGAL/point_generators_2.h>

template <class P, class OutputIterator>
OutputIterator *points_on_segment_2(P p, P q, std::size_t n, OutputIterator o)*

creates n points equally spaced on the segment from p to q, i.e. $\forall i : 0 \leq i < n : o[i] := \frac{n-i-1}{n-1} p + \frac{i}{n-1} q$. Returns the value of o after inserting the n points.

CGAL::Points_on_segment_2<Point_2>

Class

Definition

The class *Points_on_segment_2<Point_2>* is a generator for points on a segment whose endpoints are specified upon construction. The points are equally spaced

Is Model for the Concepts

PointGenerator . . . . page 4366

Types

typedef std::input_iterator_tag	*iterator_category;*
typedef Point_2	*value_type;*
typedef std::ptrdiff_t	*difference_type;*
*typedef const Point_2**	*pointer;*
typedef Point_2	*reference;*

Creation

Points_on_segment_2<Point_2> g(Point_2 p, Point_2 q, std::size_t n, std::size_t i = 0);

g is an input iterator creating points of type P equally spaced on the segment from p to q. $n-i$ points are placed on the segment defined by p and q. Values of the index parameter i larger than 0 indicate starting points for the sequence further from p. Point p has index value 0 and q has index value $n-1$. *Requirement*: The expressions *to_double(p.x())* and *to_double(p.y())* must result in the respective *double* representation of the coordinates of p, and similarly for q.

Operations

double	*g.range()*	returns the range in which the point coordinates lie, i.e. $\forall x : \|x\| \leq$ *range()* and $\forall y : \|y\| \leq$*range()*

.

Point_2	*g.source()*	returns the source point of the segment.
Point_2	*g.target()*	returns the target point of the segment.

CGAL::points_on_square_grid_2

Function

Definition

The function *points_on_square_grid_2* generates a given number of points on a square grid whose size is determined by the number of points to be generated.

#include <CGAL/point_generators_2.h>

```
template <class OutputIterator, Creator creator>
OutputIterator          points_on_square_grid_2(
                            double a,
                            std::size_t n,
                            OutputIterator o,
                            Creator creator = Creator_uniform_2<Kernel_traits<P>::Kernel::RT,P>)
```

creates the first n points on the regular $\lceil\sqrt{n}\,\rceil \times \lceil\sqrt{n}\,\rceil$ grid within the square $[-a,a] \times [-a,a]$. Returns the value of o after inserting the n points.

Requirements

- *Creator* must be a function object accepting two *double* values x and y and returning an initialized point *(x,y)* of type P. Predefined implementations for these creators like the default can be found in Section 73.9.
- The *OutputIterator* must accept values of type P. If the *OutputIterator* has a *value_type* the default initializer of the *creator* can be used. P is set to the *value_type* in this case.

std::random_shuffle

Function

CGAL::points_on_cube_grid_3

Definition

The function *points_on_cube_grid_3* generates a given number of points on a cubic grid whose size is determined by the number of points to be generated.

#include <CGAL/point_generators_3.h>

template <class OutputIterator, Creator creator>
OutputIterator *points_on_cube_grid_3(*
double a,
std::size_t n,
OutputIterator o,
Creator creator = Creator_uniform_3<Kernel_traits<P>::Kernel::RT,P>)

creates the first n points on the regular $\lceil n^{1/3} \rceil \times \lceil n^{1/3} \rceil \times \lceil n^{1/3} \rceil$ grid within the cube $[-a,a] \times [-a,a] \times [-a,a]$. Returns the value of o after inserting the n points.

Requirements

- *Creator* must be a function object accepting three *double* values x, y, and z and returning an initialized point *(x,y,z)* of type P. Predefined implementations for these creators like the default can be found in Section 73.9.
- The *OutputIterator* must accept values of type P. If the *OutputIterator* has a *value_type* the default initializer of the *creator* can be used. P is set to the *value_type* in this case.

CGAL::points_on_cube_grid_d

Function

Definition

The function *points_on_cube_grid_d* generates a given number of points on a cubic grid in any dimension whose size is determined by the number of points to be generated.

#include <CGAL/point_generators_d.h>

template <class OutputIterator, Creator creator>
OutputIterator *points_on_cube_grid_d(int dim, double a, std::size_t n, OutputIterator o, Creator creator)*

creates the first n points on the regular $\lceil n^{1/dim} \rceil \times \lceil n^{1/dim} \rceil \times \ldots \times \lceil n^{1/dim} \rceil$ grid within the hypercube $[-a,a]^{dim}$. Returns the value of o after inserting the n points.

Requirements

- *Creator* must be a functor accepting an integer (the dimension) and two iterators and returning an initialized point of type P whose coordinates are given by the iterator. For example: *Creator_uniform_d< Kernel_traits<Point_d>::Kernel::RT, Point_d>*. The dimension of *Creator* should be *dim*.
- The *OutputIterator* must accept values of type P.

Concept

PointGenerator

Definition

The concept PointGenerator defines the requirements for a point generator, which can be used in places where input iterators are called for.

Refines

InputIterator

Has Models

Types

PointGenerator:: value_type	the type of point being generated.

Operations

double	*pg.range() const*	return an absolute bound for the coordinates of all generated points.

Function

CGAL::random_collinear_points_2

Definition

#include <CGAL/point_generators_2.h>

template <class RandomAccessIterator, class OutputIterator>
OutputIterator random_collinear_points_2(RandomAccessIterator first, RandomAccessIterator last, std::size_t n, OutputIterator first2, Random& rnd = default_random, Creator creator = Creator_uniform_2<Kernel_traits<P>::Kernel::RT,P>)

randomly chooses two points from the range $[first, last)$, creates a random third point on the segment connecting these two points, writes it to *first2*, and repeats this *n* times, thus writing *n* points to *first2* that are collinear with points in the range $[first, last)$. Three random numbers are needed from *rnd* for each point. Returns the value of *first2* after inserting the *n* points.

Requirements

- *Creator* must be a function object accepting two *double* values *x* and *y* and returning an initialized point *(x,y)* of type *P*. Predefined implementations for these creators like the default can be found in Section 73.9.
- The *value_type* of the *RandomAccessIterator* must be assignable to *P*. *P* is equal to the *value_type* of the *RandomAccessIterator* when using the default initializer.
- The expressions *to_double((*first).x())* and *to_double((*first).y())* must result in the respective coordinate values.

CGAL::random_selection . . . . page 4373
std::random_shuffle

Function

CGAL::random_convex_set_2

Definition

The function *random_convex_set_2* computes a random convex planar point set of given size where the points are drawn from a specific domain.

#include <CGAL/random_convex_set_2.h>

template < class OutputIterator, class PointGenerator, class Traits >
OutputIterator random_convex_set_2(std::size_t n, OutputIterator o, PointGenerator pg, Traits t = Default_traits)

computes a random convex n-gon by writing its vertices (oriented counterclockwise) to o. The resulting polygon is scaled such that it fits into the bounding box as specified by pg. Therefore we cannot easily describe the resulting distribution.
Precondition: $n \geq 3$.

Requirements

1. *PointGenerator* is a model of the concept PointGenerator
2. *Traits* is a model of the concept RandomConvexSetTraits_2
3. *Point_generator::value_type* is equivalent to *Traits::Point_2* and *OutputIterator::value_type*.
4. if *Traits* is not specified, *Point_generator::value_type* must be *Point_2*< *R* > for some representation class *R*,

The default traits class *Default_traits* is *Random_convex_set_traits_2*. .

See Also

CGAL::Random_points_in_square_2<Point_2, Creator> . . . . page 4385
CGAL::Random_points_in_disc_2<Point_2, Creator> . . . . page 4383

Implementation

The implementation uses the centroid method described in [Sch96] and has a worst case running time of $O(r \cdot n + n \cdot \log n)$, where r is the time needed by pg to generate a random point.

Example

The following program displays a random convex 500-gon where the points are drawn uniformly from the unit square centered at the origin.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>

#include <iostream>
#include <iterator>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2                         Point_2;
typedef CGAL::Random_points_in_square_2<
     Point_2,
     CGAL::Creator_uniform_2< double, Point_2 > >
                                           Point_generator;
int main() {
  // create 500-gon and write it into a window:
  CGAL::random_convex_set_2(
            500,
            std::ostream_iterator<Point_2>(std::cout, "\n"),
            Point_generator( 0.5));
  return 0;
}
```

File: examples/Generator/random_convex_set.cpp

Function

CGAL::random_polygon_2

Definition

The function *random_polygon_2* constructs a random simple polygon from points that are drawn from a specific domain. Though each simple polygon defined on this set of points has a non-zero probability of being constructed, some polygons may have higher probabilities than others. The overall distribution of the generated polygons is not known since it depends on the generated points.

#include <CGAL/random_polygon_2.h>

template < class OutputIterator, class PointGenerator, class Traits >
OutputIterator random_polygon_2(std::size_t n, OutputIterator result, PointGenerator pg, Traits t = Default_traits)

computes a random simple polygon by writing its vertices (oriented counterclockwise) to *result*. The polygon generated will have a number of vertices equal to the number of unique points in the first n points generated by *pg*.

Requirements

1. *Traits* is a model of the concept RandomPolygonTraits_2
2. *PointGenerator::value_type* is equivalent to *Traits::Point_2* and *OutputIterator::value_type*.

The default traits class *Default_traits* is the kernel in which *Traits::Point_2* is defined.

See Also

CGAL::Random_points_in_disc_2<Point_2, Creator> . . . . page 4383
CGAL::Random_points_in_square_2<Point_2, Creator> . . . . page 4385

Implementation

The implementation is based on the method of eliminating self-intersections in a polygon by using so-called "2-opt" moves. Such a move eliminates an intersection between two edges by reversing the order of the vertices between the edges. No more than $O(n^3)$ such moves are required to simplify a polygon defined on n points [vLS82]. Intersecting edges are detected using a simple sweep through the vertices and then one intersection is chosen at random to eliminate after each sweep. The worse-case running time is therefore $O(n^4 \log n)$.

Example

The following program displays a random simple polygon with up to 100 vertices, where the vertex coordinates are drawn uniformly from the unit square centered at the origin.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_polygon_2.h>
#include <CGAL/Random.h>
#include <CGAL/algorithm.h>

#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz RT;
#else
// NOTE: the choice of double here for a number type may cause problems
//       for degenerate point sets
#include <CGAL/double.h>
typedef double RT;
#endif

#include <fstream>
#include <list>

typedef CGAL::Simple_cartesian<RT>                        K;
typedef K::Point_2                                        Point_2;
typedef std::list<Point_2>                                Container;
typedef CGAL::Polygon_2<K, Container>                     Polygon_2;
typedef CGAL::Creator_uniform_2<int, Point_2>             Creator;
typedef CGAL::Random_points_in_square_2<Point_2, Creator>
   Point_generator;

const double RADIUS = 100;
const int MAX_POLY_SIZE = 100;

int main( )
{
   Polygon_2            polygon;
   std::list<Point_2>   point_set;
   CGAL::Random         rand;

   int size = rand.get_int(4, MAX_POLY_SIZE);

   // copy size points from the generator, eliminating duplicates, so the
   // polygon will have <= size vertices
   CGAL::copy_n_unique(Point_generator(RADIUS), size,
                       std::back_inserter(point_set));

   std::ostream_iterator< Point_2 >  out( std::cout, " " );
   std::cout << "From the following " << point_set.size() << " points "
             << std::endl;
   std::copy(point_set.begin(), point_set.end(), out);
   std::cout << std::endl;

   CGAL::random_polygon_2(point_set.size(), std::back_inserter(polygon),
                          point_set.begin());
   std::cout << "The following simple polygon was made: " << std::endl;
```

```
    std::cout << polygon << std::endl;
    return 0;
}
```

CGAL::random_selection

Function

Definition

random_selection chooses n items at random from a random access iterator range which is useful to produce degenerate input data sets with multiple entries of identical items.

#include <CGAL/random_selection.h>

template <class RandomAccessIterator, class Size, class OutputIterator, class Random>
OutputIterator random_selection(RandomAccessIterator first, RandomAccessIterator last, Size n, OutputIterator result, Random& rnd = default_random)

chooses a random item from the range $[first, last)$ and writes it to *result*, each item from the range with equal probability, and repeats this n times, thus writing n items to *result*. A single random number is needed from *rnd* for each item. Returns the value of *result* after inserting the n items.
Precondition: *Random* is a random number generator type as provided by the STL or by *Random*.

See Also

CGAL::perturb_points_2 . . . . page 4359

Class

CGAL::Random

Definition

The class *Random* is a random numbers generator. It generates uniformly distributed random *bool*s, *int*s and *double*s. It can be used as the random number generating function object in the STL algorithm *random_shuffle*.

Instances of can be seen as input streams. Different streams are *independent* of each other, i.e. the sequence of numbers from one stream does *not* depend upon how many numbers were extracted from the other streams. At each time, an instance has a *state* that uniquely determines the subsequent numbers being produced.

It can be very useful, e.g. for debugging, to reproduce a sequence of random numbers. This can be done by either initialising with a fixed seed, or by using the state functions as described below.

#include <CGAL/Random.h>

Types

Random:: State	The State type.

Creation

Random random;	introduces a variable *random* of type *Random*. The seed is chosen “randomly”, depending on the system time.
Random random(unsigned int seed);	introduces a variable *random* of type *Random* and initializes its internal state using *seed*. Equal values for *seed* result in equal sequences of random numbers.

Operations

bool	*random.get_bool()*	returns a random *bool*.
template <int b> *int*	*random.get_bits()*	returns a random *int* value from the interval $[0,2\hat{}b)$. This is supposed to be efficient.
int	*random.get_int(int lower, int upper)*	returns a random *int* from the interval $[lower,upper)$.
double	*random.get_double(double lower = 0.0, double upper = 1.0)*	returns a random *double* from the interval $[lower,upper)$.

Distributions

The following member functions are a 1-to-1 correspondence to some distributions from the boost random library.

template <typename IntType>
IntType *random.uniform_smallint(IntType lower=0, IntType upper=9)*

returns a random *IntType* from the interval [*lower*,*upper*]. *IntType* can be an integral type as *int*, *std::ptrdiff_t*, *std::size_t*,etc. **Warning: In contrast to** *get_int* **this function may return** *upper***.**

template <typename IntType>
IntType *random.uniform_int(IntType lower=0, IntType upper=9)*

returns a random *IntType* from the interval [*lower*,*upper*]. *IntType* can be an integral type as *int*, *std::ptrdiff_t*, *std::size_t*,etc. **Warning: In contrast to** *get_int* **this function may return** *upper***.**

template <typename RealType>
Realtype *random.uniform_real(RealType lower = 0.0, RealType upper = 1.0)*

returns a random *RealType* from the interval [*lower*,*upper*). *RealType* can be *float*, *double*, etc.

template <typename RealType>
RealType *random.uniform_01()* returns a random *RealType* from the interval $[0,1)$. *RealType* can be *float*, *double*, etc.

template <typename IntType>
IntType *random(IntType upper)*

returns *randomuniform_int<IntType>(0, upper-1)*.

Seed and State Functions

unsigned int *random.get_seed() const*

returns the seed used for initialization.

void *random.save_state(State& state) const*

saves the current internal state in *state*.

void *random.restore_state(State state)*

restores the internal state from *state*.

Equality Test

bool	*random* == *random2*	returns *true*, iff *random* and *random2* have equal internal states.

Implementation

We use the boost random library function *boost::rand48* to generate the random numbers.

RandomConvexSetTraits_2

Definition

The concept RandomConvexSetTraits_2describes the requirements of the traits class for the function *random_convex_set_2*.

Has Models

Types

RandomConvexSetTraits_2:: Point_2	point class.
RandomConvexSetTraits_2:: FT	class used for doing computations on point and vector coordinates (has to fulfill field type requirements).
RandomConvexSetTraits_2:: Sum	AdaptableBinaryFunction class: *Point_2* $\times$ *Point_2* $\rightarrow$ *Point_2*. It returns the point that results from adding the vectors corresponding to both arguments.
RandomConvexSetTraits_2:: Scale	AdaptableBinaryFunction class: *Point_2* $\times$ *FT* $\rightarrow$ *Point_2*. *Scale(p,k)* returns the point that results from scaling the vector corresponding to p by a factor of k.
RandomConvexSetTraits_2:: Max_coordinate	AdaptableUnaryFunction class: *Point_2* $\rightarrow$ *FT*. *Max_coordinate(p)* returns the coordinate of p with largest absolute value.
RandomConvexSetTraits_2:: Angle_less	AdaptableBinaryFunction class: *Point_2* $\times$ *Point_2* $\rightarrow$ *bool*. It returns *true*, iff the angle of the direction corresponding to the first argument with respect to the positive x-axis is less than the angle of the direction corresponding to the second argument.

Operations

Point_2	*t.origin() const*	return origin (neutral element for the *Sum* operation).

advanced

Concept

RandomPolygonTraits_2

Definition

The concept RandomPolygonTraits_2 describes the requirements for the traits class used by the function *random_polygon_2*.

Has Models

The CGAL kernels.

Types

RandomPolygonTraits_2:: FT	The coordinate type of the points of the polygon (*i.e.*, a field type)
RandomPolygonTraits_2:: Point_2	The point type of the polygon.
RandomPolygonTraits_2:: Orientation_2	Predicate object type that determines the orientation of three points. It must provide *Orientation operator()(Point_2 p, Point_2 q, Point_2 r)* that returns *LEFT_TURN*, if r lies to the left of the oriented line l defined by p and q, returns *RIGHT_TURN* if r lies to the right of l, and returns *COLLINEAR* if r lies on l.
RandomPolygonTraits_2:: Less_xy_2	Binary predicate object type comparing *Point_2*s lexicographically. It must provide *bool operator()(Point_2 p, Point_2 q)* that returns *true* iff $p <_{xy} q$. We have $p <_{xy} q$, iff $p_x < q_x$ or $p_x = q_x$ and $p_y < q_y$, where p_x and p_y denote the x and y coordinates of point p, resp.

Operations

The following two member functions returning instances of the above predicate object types are required.

Less_xy_2	*t.less_xy_2_object()*
Orienation_2	*t.orientation_2_object()*

CGAL::Random_convex_set_traits_2<Kernel>

Definition

The class *Random_convex_set_traits_2<Kernel>*serves as a traits class for the function *random_convex_set_2*.

#include <CGAL/Random_convex_set_traits_2.h>

Is Model for the Concepts

RandomConvexSetTraits_2 . . . . page 4377

Types

typedef Kernel::Point_2

	Point_2;	
typedef Kernel::FT	*FT;*	
Random_convex_set_traits_2<Kernel>:: Sum		function object class derived from *std::binary_function< Point_2, Point_2, Point_2>*
Random_convex_set_traits_2<Kernel>:: Scale		function object class derived from *std::binary_function< Point_2, Point_2, Point_2>*

Random_convex_set_traits_2<Kernel>:: Max_coordinate

function object class derived from *std::unary_function< Point_2, FT>*

Random_convex_set_traits_2<Kernel>:: Angle_less

function object class derived from *std::binary_function< Point_2, Point_2, bool>*

Creation

Random_convex_set_traits_2<Kernel> t;	default constructor

Operations

Point_2	*t.origin() const*	returns CGAL::ORIGIN.

advanced

Class

CGAL::Random_points_in_ball_d<Point_d>

Definition

The class *Random_points_in_ball_d<Point_d>* is an input iterator creating points uniformly distributed in an open ball in any dimension.

Is Model for the Concepts

InputIterator
PointGenerator . . . . page 4366

#include <CGAL/point_generators_d.h>

Types

typedef std::input_iterator_tag	*iterator_category;*
typedef Point_d	*value_type;*
typedef std::ptrdiff_t	*difference_type;*
*typedef const Point_d**	*pointer;*
typedef Point_d	*reference;*

Operations

Random_points_in_ball_d<Point_d> *g(int dim, double r);*

g is an input iterator creating points of type *Point_d* uniformly distributed in the open ball in dimension *dim* with radius r, i.e. $|*g| < r$. $2 \cdot dim + 1$ random numbers are needed from *rnd* for each point.

Chapter 78

Profiling tools, Hash Map, Union-find, Modifiers

Lutz Kettner, Sylvain Pion, and Michael Seel

Contents

78.1 Timers

CGAL provides classes for measuring the user process time and the real time. The class *CGAL::Timer* is the version for the user process time and the class *CGAL::Real_timer* is the version for the real time.

Instantiations of both classes are objects with a state. The state is either *running* or it is *stopped*. The state of an object *t* is controlled with *t.start()* and *t.stop()* . The timer counts the time elapsed since its creation or last reset. It counts only the time where it is in the running state. The time information is given in seconds. The timer counts also the number of intervals it was running, i.e. it counts the number of calls of the *start()* member function since the last reset. If the reset occurs while the timer is running it counts as the first interval.

78.2 Memory Size

CGAL provides access to the memory size used by the program with the *CGAL::Memory_sizer* class. Both the virtual memory size and the resident size are available (the resident size does not account for swapped out memory nor for the memory which is not yet paged-in).

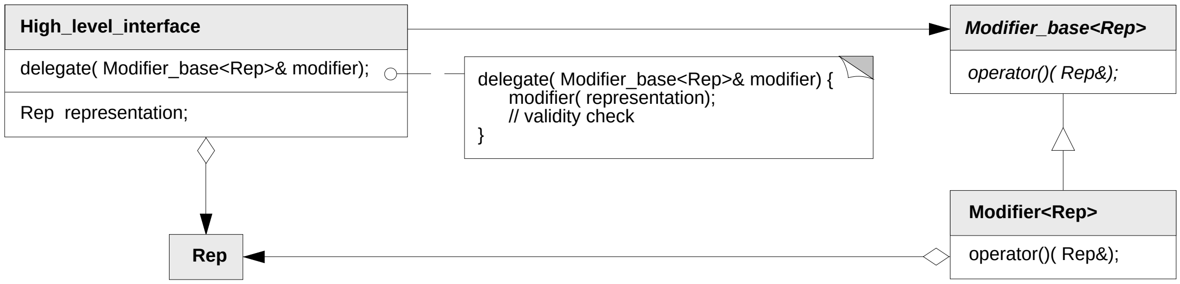

Figure 78.1: Class diagram for the modifier. It illustrates the safe access to an internal representation through an high-level interface.

78.3 Profiling

CGAL provides a way to count the number of times a given line of code is executed during the execution of a program. Such *CGAL::Profile_counter* counters can be added at critical place in the code, and at the end of the execution of a program, the count is printed on *std::cerr*. A macro *CGAL_PROFILER* can be used to conveniently place these counters anywhere. They are disabled by default and activated by the global macro *CGAL_PROFILE*.

78.4 Unique Hash Map

The class *Unique_hash_map* implements an injective mapping between a set of unique keys and a set of data values. This is implemented using a chained hashing scheme and access operations take $O(1)$ expected time. Such a mapping is useful, for example, when keys are pointers, handles, iterators or circulators that refer to unique memory locations. In this case, the default hash function is *Handle_hash_function*.

78.5 Union-find

CGAL also provides a class *Union_find* that implements a partition of values into disjoint sets. This is implemented with union by rank and path compression. The running time for m set operations on n elements is $O(n\alpha(m,n))$ where $\alpha(m,n)$ is the extremely slowly growing inverse of Ackermann's function.

78.6 Protected Access to Internal Representations

High level data structures typically maintain integrity of an internal data representation, which they protect from the user. A minimal while complete interface of the data structure allows manipulations in the domain of valid representations. Additional operations might benefit from being allowed to access the internal data representation directly. An example are intermediate steps within an algorithm where the internal representation would be invalid. We present a general method to accomplish access in a safe manner, such that the high level data structures can guarantee validity after the possibly compromising algorithm has finished its work. An example are polyhedral surfaces in the Basic Library, where a construction process like for a file scanner could be performed more efficiently on the internal halfedge data structure than by using the high-level Euler operators of the polyhedron.

The solution provided here is inspired by the strategy pattern [GHJV95], though it serves a different intent, see Figure 78.1. The abstract base class *Modifier_base<R>* declares a pure virtual member function *operator()* that accepts a single reference parameter of the internal representation type. The member function *delegate()* of the high-level interface calls this *operator()* with its internal representation. An actual modifier implements this virtual function, thus gaining access to the internal representation. Once, the modifier has finished its work, the member function *delegate()* is back in control and can check the validity of the internal representation. Summarizing, a user can implement and apply arbitrary functions based on the internal representation and keeps the benefit if a protected high-level interface. User provided modifiers must in any case return a valid internal representation or the checker in the high-level interface is allowed (and supposed) to abort the program. The indirection via the virtual function invocation is negligible for operations that consists of more than a pointer update or integer addition.

Profiling tools, Hash Map, Union-find, Modifiers Reference Manual

Lutz Kettner, Sylvain Pion, and Michael Seel

This chapter decribes classes for measuring user process time and real time as well as the memory size. It also provides a profile counter tool.

A hash map *CGAL::Unique_hash_map* is offered that is specialized on unique hash values of type *std::size_t*, i.e., it is particularly useful for pointers, handles, iterators, and circulators as key values.

Furthermore, a union-find data structure and the modifier base class is documented.

Concepts

Classes

78.8 Alphabetical List of Reference Pages

CGAL::Handle_hash_function

Class

Definition

The class *Handle_hash_function* is a model for the *UniqueHasFunction* concept. It is applicable for all key types with pointer-like functionality, such as handles, iterators, and circulators. Specifically, for a *key* value the expression `&`**key* must return a unique address.

#include <CGAL/Handle_hash_function.h>

Is Model for the Concepts

UniqueHashFunction . . . . page 4407

Creation

Handle_hash_function hash;	default constructor.

Operations

template <class Handle>		
std::size_t	*hash(Handle key)*	returns unique hash value for any *Handle* type for which `&`**key* gives a unique address. *Requirement*: The type *std::iterator_traits<Handle>::value_type* has to be defined (which it is already for pointers, handles, iterators, and circulators).

See Also

CGAL::Unique_hash_map<Key,Data,UniqueHashFunction> . . . . page 4405

Implementation

Plain type cast of `&`**key* to *std::size_t* and devided by the size of the *std::iterator_traits<Handle>::value_type* to avoid correlations with the internal table size, which is a power of two.

Class

CGAL::Memory_sizer

Definition

The class *Memory_sizer* allows to measure the memory size used by the process. Both the virtual memory size and the resident size are available (the resident size does not account for swapped out memory nor for the memory which is not yet paged-in).

#include <CGAL/Memory_sizer.h>

Types

typedef std::size_t *size_type;*

Creation

Memory_sizer m; Default constructor.

Operations

size_type

m.virtual_size() const

Returns the virtual memory size in bytes.

size_type

m.resident_size() const

Returns the resident memory size in bytes.

Implementation

Accessing this information requires the use of non-portable code. Currently, there is support for Linux platforms, the Microsoft and Intel compiler on Windows, as well as Mac OS X. If a platform is not supported, the two member functions return 0.

CGAL::Modifier_base<R>

Class

Definition

Modifier_base<R> is an abstract base class providing the interface for any modifier. A modifier is a function object derived from *Modifier_base<R>* that implements the pure virtual member function *operator()*, which accepts a single reference parameter *R*`&` on which the modifier is allowed to work. *R* is the type of the internal representation that is to be modified.

#include <CGAL/Modifier_base.h>

Types

typedef R	*Representation;*	the internal representation type.

Operations

virtual void	*modifier.operator()(R*`&` *rep)*	*Postcondition*: *rep* is a valid representation.

Example

The following fragment defines a class `A` with an internal representation `i` of type `int`. It provides a member function `delegate()`, which gives a modifier access to the internal variable and checks validity thereafter. The example modifier sets the internal variable to 42. The example function applies the modifier to an instance of class `A`.

```
class A {
    int i;  // protected internal representation
public:
    void delegate( CGAL::Modifier_base<int>& modifier) {
        modifier(i);
        CGAL_postcondition( i > 0);  // check validity
    }
};

struct Modifier : public CGAL::Modifier_base<int> {
    void operator()( int& rep) { rep = 42;}
};

void use_it() {
    A a;
    Modifier m;
    a.delegate(m);  // a.i == 42 and A has checked that A::i > 0.
}
```

Class

CGAL::Profile_counter

Definition

#include <CGAL/Profile_counter.h>

The class *Profile_counter* provides a way to count the number of times a given line of code is executed during the execution of a program, and print this number at the end of the execution of the program. Such counters can be added at critical places in the code, and at the end of the execution of a program, the count is printed on *std::cerr*, together with an identification string passed to the constructor. The macro *CGAL_PROFILER* can be used to conveniently place these counters anywhere. They are disabled by default and activated by the global macro *CGAL_PROFILE*.

Creation

Profile_counter pc(std::string s); The internal counter is initialized to 0, and the string *s* is stored for further printing by the destructor.

Profile_counter pc; The value of the counter is printed to *std::cerr* together with the string.

Operations

void $++pc$ Increments the internal counter.

#define CGAL_PROFILER(MSG) If *CGAL_PROFILE* is not defined, then *CGAL_PROFILER* is defined to an empty statement. Otherwise, it is defined to *static CGAL::Profile_counter tmp(MSG); ++tmp;*.

```
#define CGAL_PROFILE

#include <CGAL/Profile_counter.h>

int main()
{
  for (int i=0; i<10; ++i)
  {
    CGAL_PROFILER("iterations of the for-loop");
  }
  return 0;
}
```

File: `examples/Profiling_tools/Profile_counter.cpp`

will print at exit:

```
[CGAL::Profile_counter]     10 iterations of the for-loop
```

CGAL::Real_timer

Definition

#include <CGAL/Real_timer.h>

The class *Real_timer* is a timer class for measuring real time. A timer *t* of type *Real_timer* is an object with a state. It is either *running* or it is *stopped*. The state is controlled with *t.start()* and *t.stop()*. The timer counts the time elapsed since its creation or last reset. It counts only the time where it is in the running state. The time information is given in seconds. The timer counts also the number of intervals it was running, i.e. it counts the number of calls of the *start()* member function since the last reset. If the reset occures while the timer is running it counts as the first interval.

Creation

Real_timer t;	state is *stopped.*

Operations

void	*t.start()*	*Precondition*: state is *stopped*.
void	*t.stop()*	*Precondition*: state is *running*.
void	*t.reset()*	reset timer to zero. The state is unaffected.
bool	*t.is_running()*	*true* if the current state is running.
double	*t.time()*	real time in seconds, or 0 if the underlying system call failed.
int	*t.intervals()*	number of start/stop-intervals since the last reset.
double	*t.precision()*	smallest possible time step in seconds, or -1 if the system call failed.
double	*t.max()*	maximal representable time in seconds.

Implementation

The timer class is based in the C function *gettimeofday()* on POSIX systems and the C function *_ftime()* on MS Visual C++. The system calls to these timers might fail, in which case a warning message will be issued through the CGAL error handler and the functions return with the error codes indicated above. The *precision* method computes the precision dynamically at runtime at its first invocation.

CGAL::Timer

Definition

The class *Timer* is a timer class for measuring user process time. A timer *t* of type *Timer* is an object with a state. It is either *running* or it is *stopped*. The state is controlled with *t.start()* and *t.stop()*. The timer counts the time elapsed since its creation or last reset. It counts only the time where it is in the running state. The time information is given in seconds. The timer counts also the number of intervals it was running, i.e. it counts the number of calls of the *start()* member function since the last reset. If the reset occures while the timer is running it counts as the first interval.

#include <CGAL/Timer.h>

Creation

Timer t;	state is *stopped.*

Operations

void	*t.start()*	*Precondition*: state is *stopped*.
void	*t.stop()*	*Precondition*: state is *running*.
void	*t.reset()*	reset timer to zero. The state is unaffected.
bool	*t.is_running()*	*true* if the current state is running.
double	*t.time()*	user process time in seconds, or 0 if the underlying system call failed.
int	*t.intervals()*	number of start/stop-intervals since the last reset.
double	*t.precision()*	smallest possible time step in seconds, or -1 if the system call failed.
double	*t.max()*	maximal representable time in seconds.

Implementation

The timer class is based in the C function *std::clock()* on PC systems and the C function *getrusage()* on standard POSIX systems. The counter for the *std::clock()* based solution might wrap around (overflow) after only about 36 minutes. This won't happen on POSIX systems. The system calls to these timers might fail, in which case a warning message will be issued through the CGAL error handler and the functions return with the error codes indicated above. The *precision* method computes the precision dynamically at runtime at its first invocation.

CGAL::Union_find<T,A>

Class

Definition

An instance *P* of the data type *Union_find<T,A>* is a partition of values of type *T* into disjoint sets. The template parameter *A* has to be a model of the allocator concept as defined in the C++ standard. It has a default argument *CGAL_ALLOCATOR(T)*.

#include <CGAL/Union_find.h>

Types

Union_find<T,A>:: value_type	values stored in items (equal to *T*).
Union_find<T,A>:: handle	handle to values.
Union_find<T,A>:: iterator	iterator over values.

There are also constant versions *const_handle* and *const_iterator*.

Union_find<T,A>:: allocator	allocator.

Creation

Union_find<T,A> P;	creates an instance *P* of type *Union_find<T,A>* and initializes it to the empty partition.

Operations

allocator	*P.get_allocator()*	the allocator of *P*.
std::size_t	*P.number_of_sets()*	returns the number of disjoint sets of *P*.
std::size_t	*P.size()*	returns the number of values of *P*.
std::size_t	*P.bytes()*	returns the memory consumed by *P*.
std::size_t	*P.size(const_handle p)*	returns the size of the set containing *p*.
void	*P.clear()*	reinitializes *P* to an empty partition.
handle	*P.make_set(T x)*	creates a new singleton set containing *x* and returns a handle to it.
handle	*P.push_back(T x)*	same as *make_set(x)*.

template <class Forward_iterator>

void	*P.insert(Forward_iterator first, Forward_iterator beyond)*	
		insert the range of values referenced by *[first,beyond)*. *Requirement*: value type of *Forward_iterator* is T.
handle	*P.find(handle p)*	
const_handle	*P.find(const_handle p)*	returns a canonical handle of the set that contains p, i.e., *P.same_set(p,q)* iff *P.find(p)* and *P.find(q)* return the same handle. *Precondition*: p is a handle in P.
void	*P.unify_sets(handle p, handle q)*	
		unites the sets of partition P containing p and q. *Precondition*: p and q are in P.
bool	*P.same_set(const_handle p, const_handle q)*	
		returns true iff p and q belong to the same set of P. *Precondition*: p and q are in P.
iterator	*P.begin()*	returns an iterator pointing to the first value of P.
iterator	*P.end()*	returns an iterator pointing beyond the last value of P.

Implementation

Union_find<T,A> is implemented with union by rank and path compression. The running time for m set operations on n elements is $O(n\alpha(m,n))$ where $\alpha(m,n)$ is the extremely slow growing inverse of Ackermann's function.

CGAL::Unique_hash_map<Key,Data,UniqueHashFunction>

Definition

An instance *map* of the parameterized data type *Unique_hash_map<Key,Data,UniqueHashFunction>* is an injective mapping from the set of keys of type *Key* to the set of variables of type *Data*. New keys can be inserted at any time, however keys cannot be individually deleted.

An object *hash* of the type *UniqueHashFunction* returns a unique integer index *hash(key)* of type *std::size_t* for all objects *key* stored in *map*. The template parameter has as default the *Handle_hash_function* that hashes all types of pointers, handles, iterators, and circulators.

All variables are initialized to *default_data*, a value of type *Data* specified in the definition of *map*.

#include <CGAL/Unique_hash_map.h>

Types

Unique_hash_map<Key,Data,UniqueHashFunction>:: Key	the *Key* type.
Unique_hash_map<Key,Data,UniqueHashFunction>:: Data	the *Data* type.
Unique_hash_map<Key,Data,UniqueHashFunction>:: Hash_function	the unique hash function type.

In compliance with STL, the types *key_type*, *data_type*, and *hasher* are defined as well.

Creation

Unique_hash_map<Key,Data,UniqueHashFunction> map(Data default = Data(),
std::size_t table_size = 1,
Hash_function fct = Hash_function())

creates an injective function *map* from *Key* to the set of unused variables of type *Data*, sets *default_data* to *default*, passes the *table_size* as argument to the internal implementation, and initializes the hash function with *fct*.

Unique_hash_map<Key,Data,UniqueHashFunction> map(Key first1,
Key beyond1,
Data first2,
Data default = Data(),
std::size_t table_size = 1,
Hash_function fct = Hash_function())

creates an injective function *map* from *Key* to the set of unused variables of type *Data*, sets *default_data* to *default*, passes the *table_size* as argument to the internal implementation, initializes the hash function with *fct*, and inserts all keys from the range *[first1,beyond1)*. The data variable for each inserted *key* is initialized with the corresponding value from the range *[first2, first2 + (beyond1-first1))*.
Precondition: The increment operator must be defined for values of type *Key* and for values of type *Data*. *beyond1* must be reachable from *first1* using increments.

Operations

Data	*map.default_value() const*	the current *default_value*.
Hash_function	*map.hash_function() const*	the current hash function.
bool	*map.is_defined(Key key)*	returns true if *key* is defined in *map*. Note that there can be keys defined that have not been inserted explicitly. Their variables are initialized to *default_value*.
void	*map.clear()*	resets *map* to the injective function *map* from *Key* to the set of unused variables of type *Data*. The *default_data* remains unchanged.
void	*map.clear(Data default)*	resets *map* to the injective function *map* from *Key* to the set of unused variables of type *Data* and sets *default_data* to *default*.
Data&	*map.operator[](const Key& key)*	returns a reference to the variable *map(key)*. If *key* has not been inserted into *map* before, *key* is inserted and initialized with *default_value*.
const Data&	*map.operator[](const Key& key) const*	returns a const reference to the variable *map(key)*. If *key* has not been inserted into *map* before, a const reference to the *default_value* is returned. However, *key* is not inserted into *map*.
Data	*map.insert(Key first1, Key beyond1, Data first2)*	inserts all keys from the range *[first1,beyond1)*. The data variable for each inserted *key* is initilized with the corresponding value from the range *[first2, first2 + (beyond1-first1))*. Returns *first2 + (beyond1-first1)*. *Precondition*: The increment operator must be defined for values of type *Key* and for values of type *Data*. *beyond1* must be reachable from *first1* using increments.

See Also

UniqueHashFunction . . . . page 4407
CGAL::Handle_hash_function . . . . page 4397

Implementation

Unique_hash_map is implemented via a chained hashing scheme. Access operations *map[i]* take expected time $O(1)$. The *table_size* parameter passed to chained hashing can be used to avoid unnecessary rehashing when set to the number of expected elements in the map. The design is derived from the STL *hash_map* and the LEDA type *map*. Its specialization on insertion only and unique hash values allow for a more time- and space-efficient implementation, see also [MN00, Chapter 5]. This implementation makes also use of sentinels that lead to defined keys that have not been inserted.

UniqueHashFunction

Concept

Definition

UniqueHashFunction is a concept for a hash function with unique hash values. An instance *hash* for a model of the UniqueHashFunction concept is a function object. It maps objects of its domain type *Key* to the integral image type *std::size_t*. The image values have to be unique for all keys in the domain type *Key*.

Refines

STL concept HashFunction.

Types

typedef std::size_t	*result_type;*	type of the hash value.

Creation

UniqueHashFunction hash(hash2);		copy constructor.
UniqueHashFunction&	*hash = hash2*	assignment.

Operations

std::size_t	*hash(Key key)*	returns unique hash value for the *key* value.

Chapter 79

IO Streams

Andreas Fabri, Geert-Jan Giezeman, and Lutz Kettner

Contents

All classes in the CGAL kernel provide input and output operators for IO streams. Classes external to CGAL are also supported, by means of *oformat* (Section 79.3). The basic task of such an operator is to produce a representation of an object that can be written as a sequence of characters on devices as a console, a file, or a pipe. In CGAL we distinguish between a raw ascii, a raw binary and a pretty printing format.

enum Mode { *ASCII = 0, BINARY, PRETTY* }*;*

In *ASCII* mode, objects are written as a set of numbers, e.g. the coordinates of a point or the coefficients of a line, in a machine independent format. In *BINARY* mode, data are written in a binary format, e.g. a double is represented as a sequence of four byte. The format depends on the machine. The mode *PRETTY* serves mainly for debugging as the type of the geometric object is written, as well as the data defining the object. For example for a point at the origin with Cartesian double coordinates, the output would be *PointC2(0.0, 0.0)*. At the moment CGAL does not provide input operations for pretty printed data. By default a stream is in ASCII mode.

CGAL provides the following functions to modify the mode of an IO stream.

IO::Mode *set_mode(std::ios& s, IO::Mode m)*

IO::Mode *set_ascii_mode(std::ios& s)*
IO::Mode *set_binary_mode(std::ios& s)*

IO::Mode *set_pretty_mode(std::ios& s)*

The following functions allow to test whether a stream is in a certain mode.

IO::Mode *get_mode(std::ios& s)*

bool *is_ascii(std::ios& s)*
bool *is_binary(std::ios& s)*
bool *is_pretty(std::ios& s)*

79.1 Output Operator

CGAL defines output operators for classes that are derived from the class *ostream*. This allows to write to ostreams as *cout* or *cerr*, as well as to strstreams and fstreams. The output operator is defined for all classes in the CGAL kernel and for the class *Color* as well. Let *os* be an output stream.

ostream& *ostream& os << Class c* Inserts object *c* in the stream *os*. Returns *os*.

Example

```
#include <CGAL/basic.h>
#include <iostream>
#include <fstream>

#include <CGAL/Cartesian.h>
#include <CGAL/Segment_2.h>

typedef CGAL::Point_2< CGAL::Cartesian<double> >     Point;
typedef CGAL::Segment_2< CGAL::Cartesian<double> >   Segment;

int main()
{
    Point p(0,1), q(2,2);
    Segment s(p,q);

    CGAL::set_pretty_mode(std::cout);
    std::cout << p << std::endl << q  << std::endl;

    std::ofstream f("data.txt");
    CGAL::set_binary_mode(f);
    f << s << p ;

    return 1;
}
```

79.2 Input Operator

CGAL defines input operators for classes that are derived from the class *istream*. This allows to read from istreams as *cin*, as well as from strstreams and fstreams. The input operator is defined for all classes in the CGAL kernel. Let *is* be an input stream.

istream&	*istream& is >> Class c*	Extracts object *c* from the stream *is*. Returns *is*.

Example

```
#include <CGAL/basic.h>
#include <iostream>
#include <fstream>

#include <CGAL/Cartesian.h>
#include <CGAL/Segment_2.h>

typedef CGAL::Point_2< CGAL::Cartesian<double> >     Point;
typedef CGAL::Segment_2< CGAL::Cartesian<double> >   Segment;

int
main()
{
    Point p, q;
    Segment s;

    CGAL::set_ascii_mode(std::cin);
    std::cin >> p >> q;

    std::ifstream f("data.txt");
    CGAL::set_binary_mode(f);
    f >> s >> p;

    return 1;
}
```

79.3 IO for non-CGAL types

79.3.1 Using Output Formatting

To ensure that non-CGAL types are formatted correctly (i.e., respecting *IO::Mode*), *oformat* can be used. For types with a *Output_rep* specialization, the respective output routine of *Output_rep* will be called by *oformat*. Otherwise, the stream output operator will be called.

Example

```
std::cout << CGAL::oformat( myobject );
```

Optional, you can provide a second template parameter `F` as a formatting tag:

Example

```
std::cout << CGAL::oformat( myobject, My_formatting_tag() );
```

For a list of formatting tags supported by the type `T`, please refer to the documentation of the respective type.

79.3.2 Customizing Output Formatting

In some situations, you want to control the output formatting for a type `T`. For external types (third party libraries etc.), there might be problems if their stream output operator does not respect *IO::Mode*. The purpose of *Output_rep* is to provide a way to control output formatting that works independently of the object's stream output operator.

Instead of putting `T` directly into an output stream, `T` is wrapped into an output representation *Output_rep*. For convenience, a function *oformat* exists which constructs an instance of *Output_rep*.

If you do not specialize *Output_rep* for `T`, `T`'s stream output operator is called from within *Output_rep*, by default. If you want another behaviour for your type `T`, you have to provide a specialization for that type. Furthermore, you can provide specializations with a second template parameter (a formatting tag). The second template parameter defaults to *Null_tag* and means *default behaviour*.

For example, specializing *Output_rep* for *CORE::BigRat* (without a formatting tag parameter) could look like this:

Example

```
template <class F>
class Output_rep< ::CORE::BigRat, F> {
    const ::CORE::BigRat& t;
public:
    Output_rep( const ::CORE::BigRat& tt) : t(tt) {}

    std::ostream& operator()( std::ostream& out) const {
        switch (get_mode(out)) {
        case IO::PRETTY:{
            if(CGAL_CORE_DENOMINATOR(t) == ::CORE::BigRat(1))
                return out <<CGAL_CORE_NUMERATOR(t);
            else
                return out << CGAL_CORE_NUMERATOR(t)
                           << "/"
                           << CGAL_CORE_DENOMINATOR(t);
            break;
        }

        default:
            return out << CGAL_CORE_NUMERATOR(t)
                       << "/"
                       << CGAL_CORE_DENOMINATOR(t);
        }
    }
};
```

79.4 Colors

An object of the class *CGAL::Color* is a color available for drawing operations in many CGAL output streams.

Each color is defined by a triple of integers (r,g,b) with $0 \leq r,g,b \leq 255$, the so-called *rgb-value* of the color. There are a 11 predefined *Color* constants available: *BLACK*, *WHITE*, *GRAY*, *RED*, *GREEN*, *DEEPBLUE*, *BLUE*, *PURPLE*, *VIOLET*, *ORANGE*, and *YELLOW*.

79.5 Stream Support

Three classes are provided by CGAL as adaptors to input and output stream iterators. The class *Istream_iterator* is an input iterator adaptor and is particularly useful for classes that are similar but not compatible to *std::istream*. Similarly, the class *Ostream_iterator* is an output iterator adaptor. The class *Verbose_ostream* can be used as an output stream. The stream output operator << is defined for any type. The class stores in an internal state a stream and whether the output is active or not. If the state is active, the stream output operator << uses the internal stream to output its argument. If the state is inactive, nothing happens.

IO Streams
Reference Manual

Andreas Fabri, Geert-Jan Giezeman, and Lutz Kettner

All classes in the CGAL kernel provide input and output operators for IO streams. CGAL provides three different printing mode, defined in the enum *Mode*, as well as different functions to set and get the printing mode.

CGAL::Color

Class

Definition

An object of the class *Color* is a color available for drawing operations in many CGAL output streams. Each color is defined by a triple of unsigned chars (r,g,b) with $0 \leq r,g,b \leq 255$, the so-called *rgb-value* of the color.

#include <CGAL/IO/Color.h>

Creation

Color c;	creates a color with rgb-value $(0,0,0)$, i.e. black.
Color c(unsigned char red, unsigned char green, unsigned char blue);	creates a color with rgb-value *(red,green,blue)*.

Operations

bool	$c == q$	Test for equality: Two colors are equal, iff their rgb-values are equal.
bool	$c\ != q$	Test for inequality.
unsigned char	*c.red() const*	returns the red component of c.
unsigned char	*c.green() const*	returns the green component of c.
unsigned char	*c.blue() const*	returns the blue component of c.

Constants

The following constants are predefined:

const Color	*BLACK = Color(0, 0, 0);*	Black.
const Color	*WHITE = Color(255, 255, 255);*	White.
const Color	*RED = Color(255, 0, 0);*	Red.
const Color	*GREEN = Color(0, 255, 0);*	Green.
const Color	*BLUE = Color(0, 0, 255);*	Blue.
const Color	*VIOLET = Color(255, 0, 255);*	Violet.
const Color	*ORANGE = Color(255, 170, 0);*	Orange.

CGAL::Istream_iterator<T,Stream>

Class

Definition

The class *Istream_iterator<T,Stream>* is an input iterator adaptor for the input stream class *Stream* and value type T. It is particularly useful for classes that are similar but not compatible to *std::istream*.

#include <CGAL/IO/Istream_iterator.h>

Creation

Istream_iterator<T,Stream> i;	creates an end-of-stream iterator *i*. This is a past-the-end iterator, and it is useful when constructing a range.
Istream_iterator<T,Stream> i(Stream& s);	creates an input iterator *i* reading from *s*. When *s* reaches end of stream, this iterator will compare equal to an end-of-stream iterator created using the default constructor.

Operations

i fulfills the requirements for an input iterator.

CGAL::Mode

Definition

All classes in the CGAL kernel provide input and output operators for IOStreams. The basic task of such an operator is to produce a representation of an object that can be written as a sequence of characters on devices as a console, a file, or a pipe. The enum *Mode* distinguish between three different printing formats.

In *ASCII* mode, numbers e.g. the coordinates of a point or the coefficients of a line, are written in a machine independent format. In BINARY mode, data are written in a binary format, e.g. a double is represented as a sequence of four byte. The format depends on the machine. The mode PRETTY serves mainly for debugging as the type of the geometric object is written, as well as the data defining the object. For example for a point at the origin with Cartesian double coordinates, the output would be *PointC2(0.0, 0.0)*. At the moment CGAL does not provide input operations for pretty printed data. By default a stream is in ASCII mode.

enum Mode { *ASCII = 0, BINARY, PRETTY* }*;*

CGAL::Ostream_iterator<T,Stream>

Definition

The class *Ostream_iterator<T,Stream>* is an output iterator adaptor for the output stream class *Stream* and value type *T*.

#include <CGAL/IO/Ostream_iterator.h>

Creation

Ostream_iterator<T,Stream> o(Stream& s);	creates an output iterator *o* writing to *s*.

Operations

o fulfills the requirements for an output iterator.

Implementation

The *operator*()* in class *Ostream_iterator<T,Stream>* uses a proxy class.

Function

CGAL::operator<<

Definition

CGAL defines output operators for classes that are derived from the class *ostream*. This allows to write to ostreams as *cout* or *cerr*, as well as to strstreams and fstreams. The output operator is defined for all classes in the CGAL kernel and for the class *Color* as well. Let *os* be an output stream.

ostream& *ostream& os >> Class c*

Inserts object *c* in the stream *os*. Returns *os*.

Example

```
#include <CGAL/basic.h>
#include <iostream>
#include <fstream>

#include <CGAL/Cartesian.h>
#include <CGAL/Segment_2.h>

typedef CGAL::Point_2< CGAL::Cartesian<double> >     Point;
typedef CGAL::Segment_2< CGAL::Cartesian<double> >   Segment;

int main()
{
    Point p(0,1), q(2,2);
    Segment s(p,q);

    CGAL::set_pretty_mode(std::cout);
    std::cout << p << std::endl << q  << std::endl;

    std::ofstream f("data.txt");
    CGAL::set_binary_mode(f);
    f << s << p ;

    return 1;
}
```

CGAL::Input_rep<T,F>

Definition

The definition of *Input_rep* is completely symmetric to *Output_rep*.

Class

Class

CGAL::Output_rep<T,F>

Definition

The purpose of *Output_rep* is to provide a way to control output formatting that works independently of the object's stream output operator.

If you dont specialize *Output_rep* for `T`, `T`'s stream output operator is called from within *Output_rep*, by default. If you want another behaviour for your type `T`, you have to provide a specialization for that type. Furthermore, you can provide specializations with a second template parameter (a formatting tag). The second template parameter defaults to *Null_tag* and means DEFAULT BEHAVIOUR.

Specializations of *Output_rep* should provide the following features:

```
template< class F >
struct Output_rep< Some_type, F > {
    Output_rep( const Some_type& t );
    std::ostream& operator()( std::ostream& out ) const;
};
```

You can also specialize for a formatting tag `F`.

CGAL::iformat

The definition of the function *iformat* is completely symmetric to *oformat*.

Function

CGAL::oformat

Definition

Convenience function to construct an output representation (*Output_rep*) for type `T`.

template <class T>
Output_rep<T>

oformat(T t)

Generic IO for type *T*.

template <class T, typename F>
Output_rep<T,F>

oformat(T t, F)

Generic IO for type *T* with formatting tag.

CGAL::set_ascii_mode

Mode *set_ascii_mode(std::ios& s)*

sets the mode of the IO stream *s* to be the *ASCII* mode. Returns the previous mode of *s*.

Function

CGAL::Verbose_ostream

Class

Definition

The class *Verbose_ostream* can be used as an output stream. The stream output operator << is defined for any type. The class *Verbose_ostream* stores in an internal state a stream and whether the output is active or not. If the state is active, the stream output operator << uses the internal stream to output its argument. If the state is inactive, nothing happens.

#include <*CGAL/IO/Verbose_ostream.h*>

Creation

Verbose_ostream verr(bool active = false, std::ostream& out = std::cerr);

creates an output stream with state set to *active* that writes to the stream *out*.

Operations

template < class T >
Verbose_ostream& *verr << T t*

Example

The class *Verbose_ostream* can be conveniently used to implement for example the *is_valid()* member function for triangulations or other complex data structures.

```
bool is_valid( bool verbose = false, int level = 0) {
    Verbose_ostream verr( verbose);
    verr << "Triangulation::is_valid( level = " << level << ')' << endl;
    verr << "    Number of vertices = " << size_of_vertices() << endl;
    // ...
}
```

Chapter 80

Geomview

Andreas Fabri and Sylvain Pion

Contents

80.1 Definition

This chapter presents the CGAL interface to Geomview[1], which is a viewer for three-dimensional objects, originally developed at the Geometry Center in Minneapolis[2].

Note: The functionality described in this chapter is not available on Windows.

An object of the class *Geomview_stream* is a stream in which geometric objects can be inserted and where geometric objects can be extracted from. The constructor starts Geomview either on the local either on a remote machine.

Not all but most classes of the CGAL kernel have output operators for the *Geomview_stream*. 2D objects are embedded in the *xy*-plane. Input is only provided for points. Polyhedron and 2D and 3D triangulations have output operators for the *Geomview_stream*.

80.2 Implementation

The constructor forks a process and establishes two pipes between the processes. The forked process is then overlaid with Geomview. The file descriptors *stdin* and *stdout* of Geomview are hooked on the two pipes.

[1] `http://www.geomview.org/`
[2] `http://www.geom.umn.edu/`

All insert operators construct expressions in *gcl*, the Geomview command language, which is a subset of LISP. These expressions are sent to Geomview via the pipe. The extract operators notify *interest* for a certain kind of events. When such an event happens Geomview sends a description of the event in *gcl* and the extract operator has to parse this expression.

In order to implement further insert and extract operators you should take a look at the implementation and at the Geomview manual.

80.3 Example

The following program ouputs successively a 2D Delaunay triangulation (projected), a 3D Delaunay, and a terrain from the set of points.

```
#include <CGAL/Cartesian.h>
#include <iostream>

#ifndef CGAL_USE_GEOMVIEW
int main()
{
  std::cout << "Geomview doesn't work on Windows, so..." << std::endl;
  return 0;
}
#else

#include <fstream>
#include <unistd.h> // for sleep()

#include <CGAL/Projection_traits_xy_3.h>

#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Delaunay_triangulation_3.h>

#include <CGAL/IO/Geomview_stream.h>
#include <CGAL/IO/Triangulation_geomview_ostream_2.h>
#include <CGAL/IO/Triangulation_geomview_ostream_3.h>

#include <CGAL/intersections.h>

typedef CGAL::Cartesian<double>  K;

typedef K::Point_2 Point2;
typedef CGAL::Projection_traits_xy_3<K> Gt3;
typedef Gt3::Point Point3;

typedef CGAL::Delaunay_triangulation_2<K>   Delaunay;
typedef CGAL::Delaunay_triangulation_2<Gt3> Terrain;

typedef CGAL::Delaunay_triangulation_3<K>   Delaunay3d;

int main()
{
```

```
  CGAL::Geomview_stream gv(CGAL::Bbox_3(-100, -100, -100, 600, 600,
    600));
  gv.set_line_width(4);
  // gv.set_trace(true);
  gv.set_bg_color(CGAL::Color(0, 200, 200));
  // gv.clear();

  Delaunay D;
  Delaunay3d D3d;
  Terrain T;
  std::ifstream iFile("data/points3", std::ios::in);
  Point3 p;

  while ( iFile >> p )
  {
      D.insert( Point2(p.x(), p.y()) );
      D3d.insert( p );
      T.insert( p );
  }

  // use different colors, and put a few sleeps/clear.

  gv << CGAL::BLUE;
  std::cout << "Drawing 2D Delaunay triangulation in wired mode.\n";
  gv.set_wired(true);
  gv << D;

#if 1 // It's too slow !  Needs to use OFF for that.
  gv << CGAL::RED;
  std::cout << "Drawing its Voronoi diagram.\n";
  gv.set_wired(true);
  D.draw_dual(gv);
#endif

  sleep(5);
  gv.clear();

  std::cout << "Drawing 2D Delaunay triangulation in non-wired mode.\n";
  gv.set_wired(false);
  gv << D;
  sleep(5);
  gv.clear();

  std::cout << "Drawing 3D Delaunay triangulation in wired mode.\n";
  gv.set_wired(true);
  gv << D3d;
  sleep(5);
  gv.clear();
  std::cout << "Drawing 3D Delaunay triangulation in non-wired mode.\n";
  gv.set_wired(false);
  gv << D3d;
  sleep(5);
  gv.clear();
```

```
  std::cout << "Drawing Terrain in wired mode.\n";
  gv.set_wired(true);
  gv << T;
  sleep(5);
  gv.clear();
  std::cout << "Drawing Terrain in non-wired mode.\n";
  gv.set_wired(false);
  gv << T;

  std::cout << "Enter a key to finish" << std::endl;
  char ch;
  std::cin >> ch;

  return 0;
}
#endif
```

Geomview
Reference Manual

Andreas Fabri and Sylvain Pion

This chapter presents the CGAL interface to Geomview[3], which is a viewer for three-dimensional objects, originally developed at the Geometry Center in Minneapolis[4].

Geomview 1.8.1 is required.

Classes

80.4 Alphabetical List of Reference Pages

[3]`http://www.geomview.org/`
[4]`http://www.geom.umn.edu/`

Class

CGAL::Geomview_stream

Definition

An object of the class *Geomview_stream* is a stream in which geometric objects can be inserted and where geometric objects can be extracted from. The constructor starts Geomview either on the local either on a remote machine.

#include <CGAL/IO/Geomview_stream.h>

Creation

Geomview_stream gs(Bbox_3 bbox = Bbox_3(0,0,0, 1,1,1),
*const char *machine = NULL,*
*const char *login = NULL)*

Introduces a Geomview stream *gs* with a camera that sees the bounding box. The command *geomview* must be in the user's *PATH*. If *machine* and *login* are not *NULL*, Geomview is started on the remote machine using *rsh*.

Operations

Output Operators for CGAL Kernel Classes

At the moment not all classes of the CGAL kernel have output operators. 2D objects are embedded in the *xy*-plane.

template <class R>
Geomview_stream& *Geomview_stream& G << Point_2<R> p*

Inserts the point *p* into the stream *gs*.

template <class R>
Geomview_stream& *Geomview_stream& G << Point_3<R> p*

Inserts the point *p* into the stream *gs*.

template <class R>
Geomview_stream& *Geomview_stream& G << Segment_2<R> s*

Inserts the segment *s* into the stream *gs*.

template <class R>
Geomview_stream& *Geomview_stream& G << Segment_3<R> s*

Inserts the segment *s* into the stream *gs*.

template <class R>
Geomview_stream& *Geomview_stream& G << Ray_2<R> r*

Inserts the ray *r* into the stream *gs*.

template <class R>
Geomview_stream& *Geomview_stream& G << Ray_3<R> r*

Inserts the ray *r* into the stream *gs*.

template <class R>
Geomview_stream& *Geomview_stream& G << Line_2<R> l*

Inserts the line *l* into the stream *gs*.

template <class R>
Geomview_stream& *Geomview_stream& G << Line_3<R> l*

Inserts the line *l* into the stream *gs*.

template <class R>
Geomview_stream& *Geomview_stream& G << Triangle_2<R> t*

Inserts the triangle *t* into the stream *gs*.

template <class R>
Geomview_stream& *Geomview_stream& G << Triangle_3<R> t*

Inserts the triangle *t* into the stream *gs*.

template <class R>

Geomview_stream& *Geomview_stream& G << Tetrahedron_3<R> t*

Inserts the tetrahedron *t* into the stream *gs*.

template <class R>
Geomview_stream& *Geomview_stream& G << Sphere_3<R> s*

Inserts the sphere *s* into the stream *gs*.

Geomview_stream& *Geomview_stream& G << Bbox_2 b*

Inserts the bounding box *b* into the stream *gs*.

Geomview_stream& *Geomview_stream& G << Bbox_3 b*

Inserts the bounding box *b* into the stream *gs*.

template < class InputIterator >
void *gs.draw_triangles(InputIterator begin, InputIterator end)*

[*begin*;*end*) is an iterator range with value type *Triangle_3< R>*. This method uses the OFF format to draw several triangles at once, which is much faster than drawing them one by one.

Input Operators for CGAL Kernel Classes

At the moment input is only provided for points. The user has to select a point on the *pick plane* with the right mouse button. The pick plane can be moved anywhere with the left mouse button, before a point is entered.

template <class R>
Geomview_stream& *Geomview_stream& G >> Point_3<R>& p*

Extracts the point *p* from the stream *gs*. The point is echoed by default, and it depends on the stream echo mode status.

Output Operators for CGAL Basic Library Classes

#include <CGAL/IO/Polyhedron_geomview_ostream.h>

template <class Traits, class HDS>
Geomview_stream& *Geomview_stream &G << Polyhedron_3<Traits,HDS> P*

Inserts the polyhedron *P* into the stream *gs*.

#include <CGAL/IO/Triangulation_geomview_ostream_2.h>

template <class GT, class TDS>

Geomview_stream&	*Geomview_stream &G << Triangulation_2<GT,TDS> T*	
		Inserts the 2D triangulation *T* into the stream *gs*. The actual output depends on whether the stream is in wired mode or not. Also note that in the case of terrains (when *GT::Point_2* is *Point_3<R>*), then the 3D terrain is displayed.

#include <CGAL/IO/Triangulation_geomview_ostream_3.h>

template <class GT, class TDS>

Geomview_stream&	*Geomview_stream &G << Triangulation_3<GT,TDS> T*	
		Inserts the 3D triangulation *T* into the stream *gs*. The actual output depends on whether the stream is in wired mode or not.

Colors

Geomview distinguishes between edge and face colors. The edge color is at the same time the color of vertices.

Geomview_stream&	*gs << Color c*	Makes *c* the color of vertices, edges and faces in subsequent IO operations.
Color	*gs.set_bg_color(Color c)*	
		Changes the background color. Returns the old value.
Color	*gs.set_vertex_color(Color c)*	
		Changes the vertex color. Returns the old value.
Color	*gs.set_edge_color(Color c)*	
		Changes the edge color. Returns the old value.
Color	*gs.set_face_color(Color c)*	
		Changes the face color. Returns the old value.

Miscellaneous

void	*gs.clear()*	Deletes all objects.
void	*gs.pickplane()*	Creates a pickplane (useful after a clear).
void	*gs.look_recenter()*	Positions the camera in a way that all objects can be seen.

int	*gs.get_line_width() const*	
		Returns the line width.
int	*gs.set_line_width(int w)*	
		Sets the line width to w. Returns the previous value.
double	*gs.get_vertex_radius() const*	
		Returns the radius of vertices.
double	*gs.set_vertex_radius(double r) const*	
		Sets the radius of vertices to d. Returns the previous value.
string	*gs.get_new_id(string s)*	
		Used to obtain unique identifier names passed to Geomview. On successive calls with the same s value, it will return a string which is s appended with the numbers 0, then 1, then 2... Note that all counters are reset when *clear*() is called.
bool	*gs.set_wired(bool b)*	Sets wired mode. In wired mode, some structures output only there edges, not there surfaces. Returns the previous value. By default, wired mode is off.
bool	*gs.get_wired()*	Returns *true* iff wired mode is on.

advanced

Advanced and Developers Features

The following functions are helpful if you develop your own insert and extract functions. The following functions allow to pass a string from Geomview and to read data sent back by Geomview.

Geomview_stream&	*gs << string s*	Inserts string s into the stream.
Geomview_stream&	*gs >> char* s*	Extracts a string s from the stream. *Precondition*: You have to allocate enough memory.
Geomview_stream&	*gs << int i*	Inserts i into the stream. Puts whitespace around if the stream is in ascii mode.
Geomview_stream&	*gs << unsigned int i*	Inserts i into the stream. Puts whitespace around if the stream is in ascii mode.

Geomview_stream&	*gs << long i*	Inserts *i* into the stream. Puts whitespace around if the stream is in ascii mode. Currently implemented by converting to int, so it can be truncated on 64 bit platforms.
Geomview_stream&	*gs << unsigned long i*	Inserts *i* into the stream. Puts whitespace around if the stream is in ascii mode. Currently implemented by converting to unsigned int, so it can be truncated on 64 bit platforms.
Geomview_stream&	*gs << double d*	Inserts double *d* into the stream. Puts whitespace around if the stream is in ascii mode.
bool	*gs.set_trace(bool b)*	Sets tracing on. The data that are sent to *Geomview* are also sent to *cerr*. Returns the previous value. By default tracing is off.
bool	*gs.get_trace()*	Returns *true* iff tracing is on.
bool	*gs.set_raw(bool b)*	Sets raw mode. In raw mode, kernel points are output without headers and footers, just the coordinates (in binary or ascii mode). This allows the implementation of the stream functions for other objects to re-use the code for points internally, by temporary saving the raw mode to true, and restoring it after. Returns the previous value. By default, raw mode is off.
bool	*gs.get_raw()*	Returns *true* iff raw mode is on.
bool	*gs.set_echo(bool b)*	Sets echo mode. In echo mode, when you select a point in Geomview, the point is actually sent back to Geomview. Returns the previous value. By default, echo mode is on.
bool	*gs.get_echo()*	Returns *true* iff echo mode is on.
bool	*gs.set_binary_mode(bool b = true)*	Sets whether we are in binary mode.
bool	*gs.set_ascii_mode(bool b = true)*	Sets whether we are in ascii mode.
bool	*gs.get_binary_mode()*	Returns *true* iff *gs* is in binary mode.
bool	*gs.get_ascii_mode()*	Returns *true* iff *gs* is in ascii mode.

advanced

Implementation

The constructor forks a process and establishes two pipes between the processes. The forked process is then overlaid with Geomview. The file descriptors *stdin* and *stdout* of Geomview are hooked on the two pipes.

All insert operators construct expressions in *gcl*, the Geomview command language, which is a subset of LISP. These expressions are sent to Geomview via the pipe. The extract operators notify *interest* for a certain kind of events. When such an event happens Geomview sends a description of the event in *gcl* and the extract operator has to parse this expression.

In order to implement further insert and extract operators you should take a look at the implementation and at the Geomview manual.

Chapter 81

CGAL and the Qt Graphics View Framework

Andreas Fabri and Laurent Rineau

Qt is a GUI toolkit for cross-platform application development.

81.1 Introduction

This chapter describes classes that help to visualize two dimensional CGAL objects with the Qt Graphics View Framework.

This framework uses the model view paradigm. *QGraphicsItem*s are stored in a *QGraphicsScene* and are displayed in a *QGraphicsView*. The items have a paint method which is called when an item is in the visible area of a view. The framework is also responsible for dispatching events from the view via the scene to the items. The framework is extensible in the sense that users can add classes derived from *QGraphicsItem*.

Besides visualizing *QGraphicsItem*s users want to enter geometric objects. We provide the input generators for all 2D CGAL kernel objects.

The package includes also a class for providing zooming, panning, and scrolling to the graphics view.

The following sections describe the interaction between all these classes, We finally describe the internals of a *QGraphicsItem*.

81.1.1 Naming Conventions

As Qt and CGAL have different naming conventions, and as this package brings them together we adopted the following, hybrid naming conventions.

- All header files are in the directory *CGAL/Qt/*.
- Class names are concatenated capitalized words, and function names are concatenated capitalized word with the first word in lowercase. The rationale is that these classes are related to Qt, and that they sometimes are derived classes that have to override member functions adhering to this naming scheme.

- All classes are in the nested namespace *CGAL::Qt*.

81.2 Overall Design

In Figure 81.1 you see four classes depicted in grey, that come from the Qt Graphics View Framework. The *QGraphicsScene* contains *QGraphicsItem*s, which get displayed in any number of *QGraphicsView*s. The views are widgets, that is they take screen space in an application.

The fourth class is the *QObject*. It plays an important role in Qt for event handling and memory management. First, it allows to add signals and slots, and to connect them. Second, it allows to install event filters.

81.2.1 Visualizing CGAL Datastructures

In order to visualize for example a *CGAL::Delaunay_triangulation_2<K>*, we provide the graphics item class *CGAL::Qt::TriangulationGraphicsItem<T>*. It provides a *paint* method that draws the edges and vertices of a triangulation using the drawing primitives of the *QPainter*. The color of vertices and edges, can be chosen by setting a user defined *QPen*.

As this graphics item only stores a pointer to a triangulation, it must be notified about changes like the insertion of points coming from a file, a process or as input generated with the mouse. We use the signal/slot mechanism of Qt for that purpose, that is when the triangulation changes the application emits a signal that can get connected to the *modelChanged()* slot of the graphics item.

81.2.2 Navigation

We provide a class *CGAL::Qt::GraphicsViewNavigation* that can be installed as an event filter of a graphics view and its viewport. As for all Qt widgets, the *QGraphicsView* is derived from *QObject*. Events like the mouse buttons pressed or released, the mouse movemed, keys pressed, are passed to the view which first hands them over to the event filter. The *CGAL::Qt::GraphicsViewNavigation* event filter allows to zoom, scroll, and recenter. Finally, the class emits a signal with the mouse coordinates. This can be used to display the current mouse position in the status bar of an application.

81.2.3 Generation of Input

Input of CGAL kernel objects, polylines, etc. is generated by classes derived from *CGAL::Qt::GraphicsViewInput*. As the navigation class, they are event handler of the graphics view, because they have to know where the mouse is, when the user clicks in order to enter a point.

Once the input generator has assembled the object, which can involve several mouse clicks, it emits a *CGAL::Object* wrapping the input. The emitted input can be connected by the application developer to a slot. In the 2D demos of CGAL, which use the Graphics View Framework we connect it to the slot *MainWindow::processInput(CGAL::Object)*. This method unwraps from the *CGAL::Object* and inserts it in the data structure. It then typically emits a signal *modelChanged()* which can be connected to the graphics item representing the data structure.

All input generators we provide use the left mouse button for entering points. The right click terminates a sequence of entered points. 'Delete' and 'backspace' remove the last entered point. 'Esc' resets the input generator. As the 'Ctrl' key is used by the *CGAL::Qt::GraphicsViewNavigation* this modifier is not used.

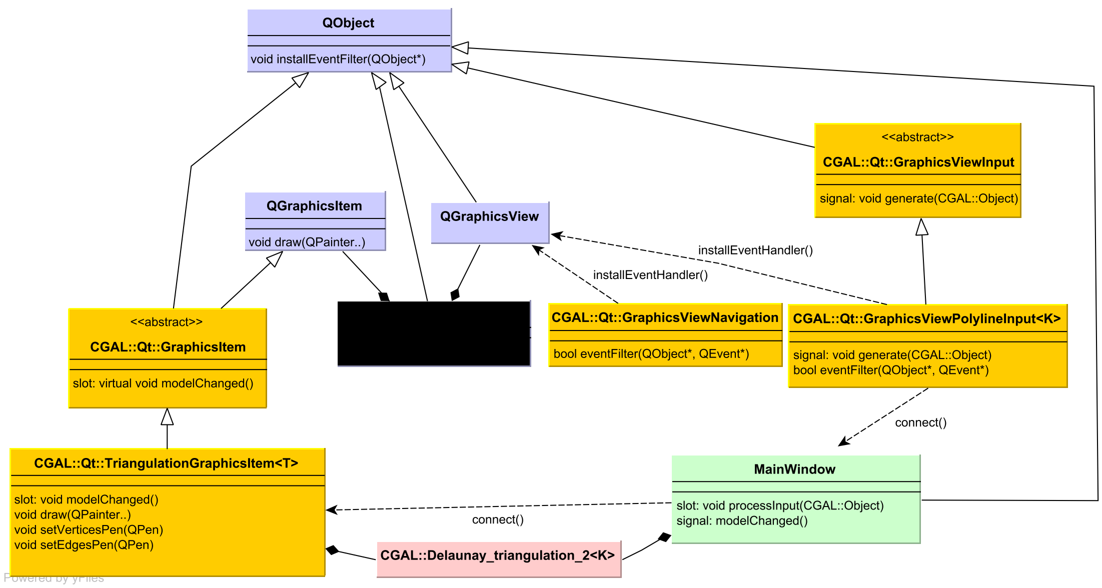

Figure 81.1: UML Class Diagram with the Qt classes (blue), CGAL classes for using the framework (yellow), CGAL data structures (red), and application classes (green).

CGAL::Qt::Converter<K>

Definition

An object of type *Converter<K>* converts 2D CGAL kernel objects to their equivalent objects in *Qt*, and the other way round. Note that some objects have no equivalent. For example the *CGAL::Circle_2<K>* cannot be converted to something in Qt, and the unbounded objects *CGAL::Ray_2<K>* and *CGAL::Line_2<K>* are clipped. Note also that CGAL and *Qt* sometimes also use the same word for different things. For example *line* denotes an unbounded line in CGAL, wheras it denotes a bounded segment in *Qt*.

#include <CGAL/Qt/Converter.h>

Creation

Converter<K> c(QRectF clippingRect);	The clipping rect is used for unbounded CGAL objects.

From CGAL to Qt

QRectF	*c(Bbox_2)*	Converts a bounding box.
QPointF	*c(K::Point_2)*	Converts a point.
QLineF	*c(K::Segment_2)*	Converts a segment.
QLineF	*c(K::Ray_2)*	Clips the ray and converts the resulting segment.
QLineF	*c(K::Line_2)*	Clips the line and converts the resulting segment.
QPolygonF	*c(K::Triangle_2)*	Converts a triangle.
QRectF	*c(K::Iso_rectangle_2)*	Converts an iso rectangle.
QPolygonF	*c(std::list<K::Point_2>)*	Converts a list of points to a polygon.

From Qt to CGAL

K::Point_2	*c(QPointF)*	Converts a point.
K::Segment_2	*c(QLineF)*	Converts a segment.
K::Iso_rectangle_2	*c(QRectF)*	Converts an iso rectangle.
std::list<K::Point_2>	*c(QPolygonF)*	Converts a polygon to a list of points.

Class

CGAL::Qt::PainterOstream<K>

Definition

An object of type *PainterOstream<K>* provides output operators for CGAL kernel objects. As CGAL has unbounded objects the *PainterOstream<K>* must be constructed with a clipping rectangle. This is typically the visible area of the widget where the unbounded object is displayed.

#include <CGAL/Qt/PainterOstream.h>

Creation

PainterOstream<K> os(QPainter qp, QRectF clippingRect);*

The clipping rect is used for unbounded CGAL objects.

Operations

PainterOstream<K>	*os << K::Point_2*	Draws a point.
PainterOstream<K>	*os << K::Segment_2*	Draws a segment.
PainterOstream<K>	*os << K::Ray_2*	Draws a clipped ray.
PainterOstream<K>	*os << K::Line_2*	Draws a clipped line.
PainterOstream<K>	*os << K::Triangle_2*	Draws a triangle.
PainterOstream<K>	*os << K::Iso_rectangle_2*	Draws an iso rectangle.
PainterOstream<K>	*os << K::Circle_2*	Draws a circle.
PainterOstream<K>	*os << K::Circular_arc_2*	Draws a circular arc.
PainterOstream<K>	*os << std::list<K::Point_2>*	Draws a polyline. In order to close it the first and last point must be equal.

PainterOstream<K>	*os << Bbox_2*	Draws an iso rectangle.
PainterOstream<K>	*os << QPen*	Sets the pen used in the next paint operations.
PainterOstream<K>	*os << QBrush*	Sets the brush used in the next paint operations.

Class

CGAL::Qt::GraphicsViewInput

Definition

An object of type *GraphicsViewInput* can emit a signal with *CGAL::Object* as argument.

#include <CGAL/Qt/GraphicsViewInput.h>

Signals

void	*in.generate(Object)*	A signal that emits a *CGAL::Object*.

CGAL::Qt::GraphicsViewPolylineInput<K>

Class

Definition

An object of type *GraphicsViewPolylineInput<K>* creates a list of points. A new vertex is inserted every time the left mouse button is pressed. The list of points is emitted on a right click or when the number of points specified in the constructor is reached. You can use the 'Del' or 'Backspace' key if you want to remove your last entered point in the polygon, and the 'Esc' key if you want to remove all points.

The tool can serve at the same time for entering a single point, a polyline with a given number of points, and for open as well as closed polylines.

For polylines the segment between the last entered point and the current mouse position is only drawn correctly when mouse tracking is enabled in the graphics view. The same holds for closed polygons.

#include <CGAL/Qt/GraphicsViewPolylineInput.h>

Parameters

The template parameter of *GraphicsViewPolylineInput<K>* must be a CGAL *Kernel*.

Inherits From

Qt::GraphicsViewInput

Creation

*GraphicsViewPolylineInput<K> in(QObject *p, QGraphicsScene* s, int n = 0, bool closed = true);*

p is a parent object. s is the scene where the polyline is generated. n is the number of points of the polyline to be generated. If c is equal to 0, the default value, the number of points of the polyline is not limited. When *closed* is *true* the function displays a polygon.

Signals

void *in.generate(CGAL::Object o)*

The object o contains a *std:list<K::Point_2>*.

Class

CGAL::Qt::GraphicsViewIsoRectangleInput<K>

Definition

An object of type *GraphicsViewIsoRectangleInput<K>* creates an axis parallel rectangle.

#include <CGAL/Qt/GraphicsViewIsoRectangleInput.h>

Parameters

The template parameter of *GraphicsViewIsoRectangleInput<K>* must be a CGAL *Kernel*.

Inherits From

GraphicsViewInput

Creation

*GraphicsViewIsoRectangleInput<K> in(QObject *p, QGraphicsScene* s);*

p is a parent object. s is the scene where the iso rectangle is generated.

Signals

void *in.generate(Object o)*

The object o contains a *K::Iso_rectangle_2*.

CGAL::Qt::GraphicsViewCircleInput<K>

Class

Definition

An object of type *GraphicsViewCircleInput<K>* creates a circle, defined by either center and radius, or two or three points on the circle. A new vertex is inserted every time the left mouse button is released. The *Del* key removes the last entered point. The *Esc* key removes all entered points.

#include <CGAL/Qt/GraphicsViewCircleInput.h>

Parameters

The template parameter of *GraphicsViewCircleInput<K>* must be a CGAL *Kernel*.

Inherits From

Qt::GraphicsViewInput

Creation

*GraphicsViewCircleInput<K> in(QObject *p, QGraphicsScene* s, int pointsOnCircle = 1);*

p is a parent object. *s* is the scene where the circle is generated. *pointsOnCircle* is the number of points on the circle to be generated, that is the default value *1* corresponds to the case center/radius.

Signals

void *in.generate(Object o)*

The object *o* contains a *std::pair<K::Point_2, K::FT>* for center and radius, or a *std::pair<K::Point_2, K::Point_2>* for two points defining the circle, or *CGAL::array<K::Point_2, 3>* for three points defining the circle.

Class

CGAL::Qt::GraphicsViewCircularArcInput<K>

Definition

An object of type *GraphicsViewCircularArcInput<K>* creates a circular arc, defined by three points on a circle. A new vertex is inserted every time the left mouse button is released. The *Del* key removes the last entered point. The *Esc* key removes all entered points.

#include <CGAL/Qt/GraphicsViewCircularArcInput.h>

Parameters

The template parameter of *GraphicsViewCircularArcInput<K>* must be a CGAL *CircularKernel*.

Inherits From

Qt::GraphicsViewInput

Creation

*GraphicsViewCircularArcInput<K> in(QObject *p, QGraphicsScene* s);*

p is a parent object. s is the scene where the circular arc is generated.

Signals

void *in.generate(Object o)*

The object o contains a *Circular_arc_2<K>*.

CGAL::Qt::GraphicsItem

Class

Definition

The CGAL graphics items hold pointers to CGAL datastructures. When a datastructure changes, a signal is emitted. An object derived from type *GraphicsItem* must provide an implementation of the virtual slot *modelChanged()*. This typically triggers redrawing, as well as recomputation of the bounding box which in turn may trigger redrawing of overlapping graphics items.

#include <CGAL/Qt/GraphicsItem.h>

Inherits From

QGraphicsItem

Slots

virtual void	*gi.modelChanged()*	This slot must be provided by derived classes.

Class

CGAL::Qt::CircularArcGraphicsItem<CK>

Definition

An object of type *CircularArcGraphicsItem<CK>* is a graphics item that encapsulates a circular arc.

#include <CGAL/Qt/CircularArcGraphicsItem.h>

Parameters

The template parameter of *CircularArcGraphicsItem<CK>* must be a CGAL *CircularKernel*.

Inherits From

Qt::GraphicsItem

Creation

CircularArcGraphicsItem<CK> cagi;

Constructs a graphics item for a circular arc.

Operations

QPen *cagi.edgesPen() const*

Returns the pen used to draw edges.

void *cagi.setEdgesPen()* Sets the pen used to draw edges.

void *cagi.setArc(Circular_arc_2<CK> ca2)*

Sets the circular arc.

CGAL::Qt::TriangulationGraphicsItem<T>

Class

Definition

An object of type *TriangulationGraphicsItem<T>* is a graphics item that encapsulates a 2D triangulation.

#include <CGAL/Qt/TriangulationGraphicsItem.h>

Parameters

The template parameter of *TriangulationGraphicsItem<T>* must be a CGAL 2D triangulation class.

Inherits From

Qt::GraphicsItem

Creation

TriangulationGraphicsItem<T> tgi(T t);*

Constructs a graphics item for a triangulation pointed by *t*.

Operations

QPen	*tgi.verticesPen() const*	Returns the pen used to draw vertices.
void	*tgi.setVerticesPen()*	Sets the pen used to draw vertices.
QPen	*tgi.edgesPen() const*	Returns the pen used to draw edges.
void	*tgi.setEdgesPen()*	Sets the pen used to draw edges.
bool	*tgi.visibleVertices()*	Returns *true*, iff vertices are drawn.
void	*tgi.setVisibleVertices(bool b)*	Sets the property.
bool	*tgi.visibleEdges()*	Returns *true*, iff edges are drawn.
void	*tgi.setVisibleEdges(bool b)*	Sets the property.

Class

CGAL::Qt::ConstrainedTriangulationGraphicsItem<CT>

Definition

An object of type *ConstrainedTriangulationGraphicsItem<CT>* is a graphics item that encapsulates a constrained triangulation.

#include <CGAL/Qt/ConstrainedTriangulationGraphicsItem.h>

Parameters

The template parameter of *ConstrainedTriangulationGraphicsItem<CT>* must be a CGAL 2D constrained triangulation class.

Inherits From

Qt::TriangulationGraphicsItem

Creation

ConstrainedTriangulationGraphicsItem<CT> ctgi(CT ct);*

Constructs a graphics item for triangulation *ct*.

Operations

QPen *ctgi.constraintsPen() const*

Returns the pen used to draw constraints.

void *ctgi.setConstraintsPen()*

Sets the pen used to draw constraints.

CGAL::Qt::VoronoiGraphicsItem<DT>

Class

Definition

An object of type *VoronoiGraphicsItem<DT>* is a graphics item that encapsulates a Delaunay triangulation in order to draw its dual, the Voronoi diagram.

#include <CGAL/Qt/VoronoiGraphicsItem.h>

Parameters

The template parameter *DT* of *VoronoiGraphicsItem<DT>* must be a CGAL 2D Delaunay triangulation class.

Inherits From

Qt::GraphicsItem

Creation

VoronoiGraphicsItem<DT> vgi(DT dt);*

Constructs a graphics item for the dual of the Delaunay triangulation *dt*.

Operations

QPen	*vgi.edgesPen() const*	Returns the pen used to draw edges.
void	*vgi.setEdgesPen()*	Set the pen used to draw edges.
bool	*vgi.visibleEdges()*	Returns *true*, iff edges are drawn.
bool	*vgi.setVisibleEdges(bool b)*	Set the property.

Class

CGAL::Qt::GraphicsViewNavigation

Definition

An object of type *GraphicsViewNavigation* can be added as event filter to a *Qt::QGraphicsView* and its viewport.

Dragging the left mouse button while holding the 'Ctrl' key defines a zoom rectangle. Dragging the right mouse button while holding the 'Ctrl' key translates the scene. 'Ctrl-Shift' and a click of the right mouse button translates what is under the mouse to the center.

#include <CGAL/Qt/GraphicsViewNavigation.h>

Operations

bool	*nav.eventFilter(QObject *obj, QEvent *event)*
	The event filter.

Signals

void	*nav.mouseCoordinates(QPointF p)*
	Emits the real world mouse coordinates.

Chapter 82

CGAL Ipelets

Sébastien Loriot and Sylvain Pion

Contents

82.1 Introduction

The Ipe extensible drawing editor (http://tclab.kaist.ac.kr/ipe/) [Sch95, Che09] is a tool used by computational geometry researchers to produce 2D figures for inclusion in articles or presentations. The extensible adjective sheds a light on an important feature: the possibility for users to write small extensions (called *ipelets*) to interface any algorithm with Ipe. This feature is especially interesting to produce illustrations in a paper describing a new algorithm. This package provides one class that eases the writing of ipelets based on CGAL, reducing the needed knowledge of the API of Ipe. This class is designed to fulfill most of the needs to implement an ipelet for a 2D CGAL algorithm. In addition, this package comes with more than ten complete examples of ipelets: alpha-shape, arrangements, Voronoi diagrams, convex hulls, Hilbert curve, k-order Delaunay, 2D mesh, Minkowski sum, polygon partition, random generators, triangulations . . .

82.2 CGAL Ipelets

The class *CGAL::Ipelet_base* derives from the class *Ipelets* from Ipe and has one template parameter indicating which kernel must be used within the ipelet. In practice, we recommend to use either *CGAL::Exact_predicate_exact_constructions_kernel* or *CGAL::Exact_predicate_inexact_construction_kernel*.

Two main methods are provided by the *CGAL::Ipelet_base* class. The first one, *read_active_objects* retrieves all primitives selected in Ipe when calling an ipelet, and converts them into equivalent CGAL objects. The second method, *draw_in_ipe* draws CGAL objects in the Ipe window. These functions handle basic objects such as points, segments, polygons, circles and circular arcs.

The registration of an ipelet into Ipe can be done using the macro *CGAL_IPELET*. *CGAL_IPELET(ipelet_class_name)* must follow the definition of the ipelet class, in the same file source file.

82.3 Example

The following example shows how the class *CGAL::Ipelet_base* can be used to easily interface the CGAL 2D Delaunay triangulation with Ipe.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/CGAL_Ipelet_base.h>

namespace my_triangulation{

typedef CGAL::Exact_predicates_inexact_constructions_kernel
     Kernel;
typedef CGAL::Delaunay_triangulation_2<Kernel>
     Delaunay;

//Function names of the ipelet
const std::string labels[] = {  "Delaunay","Help" };
//Help message associated to the first function
const std::string hmsg[] = {
  "Draw a Delaunay triangulation of a set of points"
};

class Triangulation_ipelet
  : public CGAL::Ipelet_base<Kernel,2>{
public:
  //declare an ipelet called CGAL Delaunay, with 2 functions (including
   help message).
  Triangulation_ipelet()
    :CGAL::Ipelet_base<Kernel,2>("CGAL Delaunay",labels,hmsg){}
  void protected_run(int);
};

//function called when using the ipelet.
void Triangulation_ipelet::protected_run(int fn)
{
  switch (fn){
    case 1:
      show_help();//print an help message
      return;
    default:
    std::list<Point_2> pt_lst;

    //Recovering points using output iterator of type
    //Dispatch_or_drop_output_iterator
    read_active_objects(
      CGAL::dispatch_or_drop_output<Point_2>(std::back_inserter(pt_lst))
```

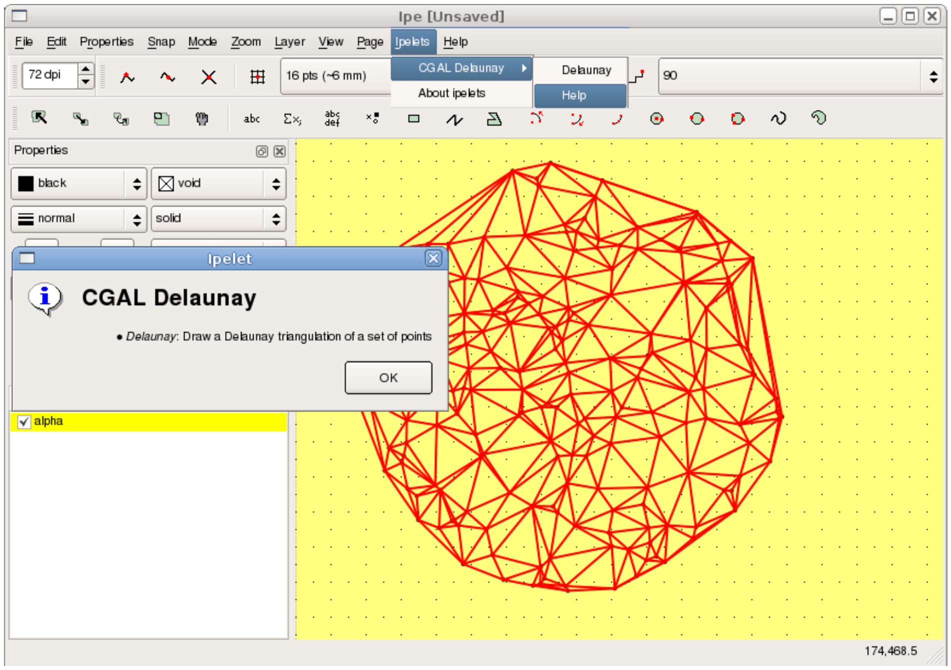

Figure 82.1: The ipelet of the example in action.

```
    );

    if (pt_lst.empty()) {
      print_error_message("No mark selected");
      return;
    }

    Delaunay dt;
    dt.insert(pt_lst.begin(),pt_lst.end());

    //draw the triangulation.
    draw_in_ipe(dt);
  };
}

}//namespace my_triangulation

//register the ipelet in Ipe
CGAL_IPELET(my_triangulation::Triangulation_ipelet)
```

File: demo/CGAL_ipelets/simple_triangulation.cpp

82.4 Installation of the Demo Ipelets

Some working ipelets can be found within the demo directory of this package. To install them you need to go to the demo directory of the package and run cmake. The compilation of these demo requires the source tree and the library of Ipe. If your Ipe installation is not detected you need to set the cmake variables *IPE_INCLUDE_DIR* and *IPE_LIBRARIES*. If you want to install ipelets automatically (using *make install* for example) you also need to set the cmake variable *IPELET_INSTALL_DIR*, if the ipelet installation path has not already been detected. These ipelets have been tested with the versions 6.0pre28 to 6.0pre32 of Ipe, as well as with the version 7 (at least up to version 7.10). These ipelets are a good starting point to design your own ipelet. For more details on how to compile an ipelet, please refer to the Ipe manual.

82.5 Design and Implementation History

A first draft of the CGAL ipelets has been implemented during the internship of Nicolas Carrez, in 2005, supervised by Olivier Devillers. Since then, the ipelets have been rewritten and extended by Sebastien Loriot as a stand-alone software with the help of Laurent Rineau. Finally, an enhanced version has been formally contributed to CGAL in 2009 by Sebastien Loriot. Sylvain Pion has participated in the discussion of the overall design, and contributed the Hilbert sort ipelet demo.

Classes

82.6 Alphabetical List of Reference Pages

CGAL::Ipelet_base<Kernel,int nbf>

Definition

Ipelet_base<Kernel,int nbf> is an abstract base class for defining an ipelet. The only function that needs to be defined in a derived class is *protected_run(int i)* that contains the code of an ipelet. Note that the name of the function suggests that the ipelet may throw exceptions that will be caught by a function of the class *Ipelet_base<Kernel,int nbf>* avoiding Ipe to crash.

Parameters

The *Kernel* template parameter determines the kernel that will be used in the ipelet. This parameter must be set according to the algorithm to be used. The integer *nbf* indicates the number of functions defined by the ipelet.

Types

typedef Kernel	*Kernel;*	The kernel used to define internal types.
typedef Kernel::FT	*FT;*	The number type of the coordinates.
typedef Kernel::Point_2		
	Point_2;	The point type.
typedef Kernel::Circle_2		
	Circle_2;	The circle type.
typedef CGAL::tuple<Circle_2,Point_2,Point_2,CGAL::Sign>		
	Circular_arc_2;	The circular arc type. The *CGAL::Sign*, equals either to *CGAL::COUNTERCLOCKWISE* or *CGAL::CLOCKWISE*, indicates if the arc is the set of points on the circle from the first point to the second point turning clockwise or counterclockwise.
typedef CGAL::Weighted_point<Point,FT>		
	Weighted_point_2;	The weighted point type.
typedef Kernel::Segment_2		
	Segment_2;	The segment type.
typedef Kernel::Line_2		
	Line_2;	The line type.

typedef Kernel::Ray_2

Ray_2; The ray type.

typedef Kernel::Triangle_2

Triangle_2; The triangle type.

typedef CGAL::Polygon_2<Kernel>

Polygon_2; The polygon type.

typedef Kernel::Iso_rectangle_2

Iso_rectangle_2; A type to represent bounding boxes.

The set of *read objects* is defined as the set of objects of type *Point_2*, *Segment_2*, *Polygon_2*, *Circular_arc_2* or *Circle_2*. The set of *drawable objects* is defined as the super set of the set of *read objects* also including objects of type *Line_2*, *Ray_2*, *Triangle_2* and *Iso_rectangle_2*.

template<class output_iterator>

Point_grabber; Class type providing operators to extract points from segments and polygons.

template<class output_iterator>

Segment_grabber; Class type providing operators to extract segments from polygons.

Creation

Ipelet_base<Kernel,int nbf> iplt(const std::string fct_names[], const std::string help_msg[], const std::string name)

initializes an ipelet. The string *name* is the name given to the ipelet in the Ipe menu. The string array *fct_names* contains the names of these functions as they will appear in the submenu of the ipelet. The string array *help_msg* of size one or *nbf-1* contains a help message for each function of the ipelet. These help messages can be printed using the member function *show_help()*. This function expects that the last function defined in the ipelet is dedicated to print the help message. It is advised that the last function defined is dedicated to show a help message.

Access Functions

advanced

*IpePage** *iplt.get_ipe_page()* returns a pointer to an Ipe object representing the drawing page. Refer to the Ipe library documentation for more details.

*IpeletHelper** *iplt.get_ipelet_helper()*

returns a pointer to an Ipe object providing services to Ipelets. Refer to the Ipe library documentation for more details.

advanced

Operations

void *iplt.show_help(bool one_per_func=true)*

Prints in Ipe a pop-up help message constructed from the string array of the constructor. This function expects that the last function defined in the ipelet is dedicated to print the help message. When the boolean *one_per_func* is *true*, one help message per function is printed (except for the help function itself) using the *nbf-1* strings in the array given to the constructor. Otherwise, only one help message is printed using the first string in the array given to the constructor.

void *iplt.print_error_message(std::string msg)*

Prints the string *msg* as a message in Ipe.

void *iplt.protected_run(int i) =0*

function called when the user selects the CGAL ipelet.

template< class V, class O >
Iso_rectangle_2 *iplt.read_active_objects(Dispatch_or_drop_output_iterator<V, O> out, bool deselect_all=true, bool delete_selected_objects=false)*

This function assigns to output iterator *out* all handled objects selected in Ipe. Objects read belong to the set of *read objects* (even within groups). The output iterator *out* must be able to handle all *read objects* (see *CGAL::Dispatch_or_drop_output_iterator<V,O>*). In addition, a bounding box (*Iso_rectangle_2*) of the active objects selected is returned. The two Boolean arguments indicate whether the retrieved objects must be deselected and/or removed. Note that non-retrieved objects (primitives of Ipe not handled or objects dropped by *out*) are automatically deselected, and not deleted. If a non-retrieved object is a sub-path or is inside a group, the whole path or group will not be deleted.

template<class Output_iterator>

boost::function_output_iterator<Point_grabber<Output_iterator> >

iplt.point_grabber(Output_iterator it)

returns an output iterator which wraps *it*. *Output_iterator* must be a model of the output iterator concept accepting assignments from *Point_2*. The returned output iterator will accept assignments from objects of types *Polygon_2* or *Segment_2* or *Point_2*, it decomposes them in objects of type *Point_2* and assigns them to *it*. For more details on the returned output iterator refer to the Boost library documentation.

template<class Output_iterator>
boost::function_output_iterator<Segment_grabber<Output_iterator> >

iplt.segment_grabber(Output_iterator it)

returns an output iterator which wraps *it*. *Output_iterator* must be a model of the output iterator concept accepting assignments from *Segment_2*. The returned output iterator will accept assignments from objects of types *Polygon_2* or *Segment_2*, it decomposes them in objects of type *Segment_2* and assigns them to *it*. For more details on the returned output iterator refer to the Boost library documentation.

template<class T>
void *iplt.draw_in_ipe(T object, bool deselect=false)*

This function draws in the page of Ipe a given object. *T* must be a type inside the set of *drawable objects*. When *object* is of type *Line_2* or *Ray_2*, only the part of the object that is inside the page of Ipe (if not empty) is drawn. This function is also able to draw a 2D CGAL triangulation as a group of segments. If the boolean *deselect* is set to *true*, object drawn is deselected.

template<class T>
void *iplt.draw_in_ipe(T object, Iso_rectangle_2 bbox, bool deselect=false)*

Same as above, except that objects are clipped to *bbox* before been drawn.

template<class Iterator>
void *iplt.draw_in_ipe(Iterator begin,*
Iterator end,
bool makegrp=true,
bool deselectall=false)

This function draws in the page of Ipe a set of objects given by an iterator range. These objects must be of a type inside the set of *drawable objects*. If the boolean *makegrp* is set to *true*, objects drawn define a group in Ipe. If the boolean *deselectall* is set to *true*, objects drawn are deselected.

template<class Iterator>
void *iplt.draw_in_ipe(Iterator begin, Iterator end, Iso_rectangle_2 bbox, bool makegrp=true, bool deselectall=false)*

Same as above, except that objects are clipped to *bbox* before been drawn.

template<class iterator>
void *iplt.draw_polyline_in_ipe(iterator first, iterator last, bool setclose=false, bool deselect=false)*

This function draws in the page of Ipe a polyline defined by an iterator range of points. If the boolean *setclose* is *true*, the polyline drawn is closed. If the boolean *deselect* is set to *true*, polyline drawn is deselected.

template<class Triangulation>
void *iplt.draw_dual_in_ipe(Triangulation T, Iso_rectangle_2 bbox, bool makegrp=true, bool deselect=false)*

This function draws in the page of Ipe the dual of a 2D CGAL triangulation. The edges of the dual are restricted to the interior of *bbox*. If the boolean *makegrp* is set to *true*, segments drawn define a group in Ipe. If the boolean *deselect* is set to *true*, segments drawn are deselected.

template<class Triangulation>
void *iplt.draw_skeleton_in_ipe(Triangulation T, Iso_rectangle_2 bbox, bool makegrp=true, bool deselect=false)*

This function draws in the page of Ipe the Voronoi segment skeleton from a triangulation of segments. The edges are restricted to the interior of *bbox*. If the boolean *makegrp* is set to *true*, segments drawn define a group in Ipe. If the boolean *deselect* is set to *true*, segments drawn are deselected.

template <class T>

std::pair<int,T> *iplt.request_value_from_user(std::string msg)*

This function induces the creation of a dialog box requesting a value from the user. The string *msg* is printed in this dialog box. Ipe lexer tries to convert the user input into an object of type *T* (a simple type such as *int*, *float*, etc). If the conversion is possible, the value is returned within a *std::pair*. The integer of the pair returned is -1 if the user input is not correct, 0 if user input is empty and 1, otherwise. otherwise.

CGAL_IPELET

The registration of a new ipelet can be done using the macro command *CGAL_IPELET*. Taking as a parameter the name of the class defining the new ipelet, that macro must be placed in the source file after the class definition.
